OVERVIEW OF THE MAP OF KNOWN AND POTENTIAL DEBRIS FLOW PATHWAYS

Background and Purpose

The North Carolina General Assembly authorized the North Carolina Geological Survey (NCGS) to produce landslide hazard maps for 19 western counties in response to the number of slope movements (landslides) and destruction caused by the remnants of Hurricanes Frances and Ivan in western North Carolina (N.C.) in September 2004. The intent of the Landslide Hazard Mapping program is to provide the public, local government, and local and state emergency agencies with a planning tool that describes and locates areas where slope movements have occurred, or are likely to occur, and the general areas at risk from these slope movements. The locations of previous slope movements and their deposits are important because slope movements often reoccur in the same general areas, and they typically deposit material in areas where there are pre-

existing slope movement deposits. The slope movement hazard map series for Henderson County, N.C. consists of three maps (Geologic Hazards Map Series 5 (GHMS-5, Sheets 1, 2, and 3)) that are designed to be used in conjunction with each other. Brief descriptions of this map (Sheet 3) and accompanying maps follow.

- 1. Sheet 1, Slope Movement and Slope Movement Deposits Map, shows the extent and distribution of known historical slope movements (all types) and pre-existing slope
- 2. Sheet 2, Stability Index Map, shows where naturally occurring, shallow,
- translational slope movements (e.g., debris flows) may begin on slopes without prior ground disturbing activity in response to a major rainfall event. 3. Sheet 3 (this map), Map of Known and Potential Debris Flow Pathways, shows

where debris flows may travel if they occur.

explanations that correspond to the map unit designations.

These printed maps are smaller scale representations of the digital spatial data that have been created for use in a Geographic Information System (GIS) (Wooten et al., 2011). The NCGS's landslide hazard map products are not intended to be a substitute for a

detailed, site-specific analysis by a qualified geologist or engineer. Map of Known and Potential Debris Flow Pathways (Geologic Hazards Map Series

This color-coded map portrays areas that potentially could be affected by debris flows or other shallow, translational slope movements. The Stability Index Map (Sheet 2) shows areas where shallow translational slope movements are more likely to originate in response to a rain event producing recharge to the shallow groundwater system of at least 5in (~125mm) in a 24-hour period. The Map of Known and Potential Debris Flow Pathways show areas likely to be in the path of these slope movements if they do occur. The pathways include areas significantly further downslope from where the slope movements may initiate. Designated units on this map are: known debris flow pathways, potential debris flow pathways, areas of past debris flow activity, and areas of no known or potential debris flow activity. Table 1 shows the color codes used on the map with

The Map of Known and Potential Debris Flow Pathways indicates the distribution of areas that could potentially be affected by debris flows or other shallow, translational slope movements given the conditions on the ground at the time the map was made. Changes in the landscape as a result of human activity and future debris flows and other types of landslides can alter the potential pathways of subsequent debris flows; therefore, the map represents the general areas that could potentially be affected by debris flows and other shallow translational slope movements. In these locations of known, potential, and past debris flow activity, further slope stability analysis, including onsite field investigation, is recommended prior to siting facilities or undertaking ground-disturbing

The Map of Known and Potential Debris Flow Pathways is derived from two sources: 1. Outlines of debris flow tracks and slope movement deposits from the Slope Movements and Slope Movement Deposits Map

Countywide area broken into public and private lands

2. High hazard areas of the Stability Index Map The following sequential steps outline the method used to produce the areas of potential debris flow pathways using a 20ft (6m) LiDAR-derived digital elevation model (DEM).

1. High hazard zones from the Stability Index Map with areas >0.25 acres (~10,900ft²) or ~1,000m²) were assumed to be the probable source areas for slope movements that could affect areas downslope (i.e., high hazard areas ≤0.25 acres were eliminated as source areas).

2. Hydrologic flow paths, based on topographic gradients and streams mapped by the N.C. Stream Mapping Project, were created in ArcGIS ^{IM} to begin from the center of each 20ft (6m) high hazard cell that met the above criteria.

3. Flow paths were automatically terminated in ArcGISTM when they met one of the following criteria. a. Once they encountered slope gradients of <3 degrees for contiguous areas ≥ 0.25

acres. A nominal slope gradient of 3 degrees was selected because it is consistent with the lowermost downslope extent of most slope movement deposits and debris flow tracks delineated in Western N.C. Note: Flow paths were extended to the downstream extent of debris deposits where these deposits are mapped downstream of slope gradients <3 degrees.

b. When they encountered the 500-year floodplain boundary, as mapped by the N.C. Floodplain Mapping Program.

c. When they encountered water bodies ≥ 0.25 acres, such as ponds or lakes, as mapped by the N.C. Stream Mapping Program. 4. Flow paths were buffered to 33ft (10m) on all sides to delineate the potential debris flow pathways. This buffer approximates the average track width of mapped debris flows in Western N.C. Note: In some cases the automated 33ft (10m) buffering

routine may extend the potential debris flow pathways slightly upslope and over ridge tops above debris flow source areas. Manual editing of the digital map was required to adjust the downstream extents of the

potential debris flow pathways to terminate flow paths deemed to be unrealistic in most

1. Ending flow paths that originated on man-made cut slopes near the base of the cut. 2. Removing flow paths that originated on dams or aggregate stockpiles. 3. Removing flow paths from areas of high hazard on natural slopes that are <0.25

acres after disregarding high hazard areas associated with road cuts within the same high hazard polygon. If the remaining high hazard area associated with the road cut is also <0.25 acres, flow paths were removed from that area as well.

ACKNOWLEDGEMENTS

GHMS-5 (DDS-GHMS-5).

The North Carolina Geological Survey would like to thank Henderson County Government for their assistance and cooperation. Special thanks go to the residents of Henderson County for their willingness to provide information and property access. The North Carolina Department of Transportation - Geotechnical Engineering and Materials and Tests Units, the U.S.D.A. Forest Service and Natural Resources Conservation Service provided much useful data and assistance. Field and map reviews and comments by Francis Ashland, Nick Bozdog, Matt Cable, Bart Cattanach, Jack Drost, Brad Johnson, Brett Laverty, Carl Merschat, Kate Scharer, James Simons, Chip Smith, Kenneth Taylor, Cheryl Waters-Tormey, and Leonard Wiener are greatly appreciated.
