Uranium Mining Impact Study
City of Virginia Beach

Roanoke River Basin Bi-State Commission
North Carolina Delegation
12 March 2012
Concerns about Uranium Mining at Coles Hill

• Proposed mining location is upstream of Lake Gaston, a water source for Virginia Beach
• Refining activities will yield large amounts of radioactive and toxic waste material (tailings) that have to be stored on-site
• A catastrophic failure of a tailings confinement cell can result in contamination of the City of Virginia Beach’s water supply

Uranium Mining & Milling

1. Removal of Overburden and Ore
2. Ore Crushing and Milling
3. Uranium Extraction, Precipitation & Drying

- Liquid and Solid Wastes “Mill Tailings”
- Yellowcake
Current Mining Plan

• Foresees mining approximately 30 million tons of ore to yield 63 million pounds of $\text{U}_3\text{O}_8$
• Proposes deep shaft mining
• Calls for underground storage roughly half of the 22 million cubic yards of tailings
• Up to eight surface impoundments would hold the remainder of the tailings (up to 1.6 million pounds per cell, 40 acre maximum)
Causes of Tailing Cell Failures

![Bar chart showing causes of tailing cell failures with categories such as Foundation, Slope Instability, Overtopping/Overflow, Mine Subsidence, Unusual Rain, Snow melt, Piping/Seepage, Seismic Liquefaction, Structural, Unknown, and Management/Operation. The chart compares incidents worldwide and in Europe. The peak cause is Unusual Rain with significantly higher incidents worldwide.]
Weather Hazards

• Precipitation in Virginia is 5 to 10 times greater than in traditional uranium mining areas in the arid West.

• Topography and climate in the region supports extreme rain events and flooding

• Region is highly susceptible to landslides
Hazard Scenario

• Containment failure due to extreme weather and flooding
• Discharge of mill tailings into the Roanoke watershed
• Transport of contaminated sediment and bulk water downstream to Kerr Lake and Lake Gaston
City of Virginia Beach Study

• Goal: Determine the impact of a discharge of mill tailings into Roanoke or Banister River on water quality downstream
• Provided the results of the Phase 1 Study to the National Academy of Sciences Committee on Uranium Mining.
• Phase 2 expanded the study area to Lake Gaston and focused on Coles Hill site.
Study Qualifiers

• The study simulated a rare event that regulations are supposed to prevent
• The model does not address the issue of whether there will be a catastrophe – it only simulates the outcome if one did occur
Modeling Approach

• 1-D and 2-D hydrodynamic river model
  – Simulate flow of water (1-D: Banister, Dan, Roanoke; 2-D: Kerr and Gaston)

• Sediment transport/morphological model
  – Simulate suspended and bed load transport of sediment and changes in bed elevation/cross-sections as a result of erosion/deposition

• Water quality model
  – Transport and fate of contaminants (U, Th, Ra)
Other Model Characteristics

• Most recent river cross sections available from FEMA, VDOT, USACE were used

• Hydrology was simulated based on historical stream flow data. Tailings release to Banister River is followed by either
  – Wet period (Sep 1996 – Aug 1998)
  – Dry period (Jun 2001 – May 2003)
Other Model Characteristics

• Estimated tailings release volume based on current mining proposal and historical tailings dam failure data
  – Release of 720,000 yd$^3$ of tailings

• Assumed that the City’s Lake Gaston pump station would not operate after tailings release
Scenarios in the Phase 2 Study

- Tailings Release to Banister River
- Hydrology:
  - Wet
  - Dry
- Radionuclide Solubility:
  - High (S1)
  - Low (S2)
Contaminant Fate and Transport

**Water Column:**
Contains dissolved contaminants and contaminants attached to suspended particles.

**Sediments:**
Contains dissolved contaminants in pore water and contaminants attached to settled particles.

General Conclusions

• The impact of a tailings release into the Banister River is highly dependent on the stream flows in the watershed.

• Under any scenario, the partial release of the contents from only one containment cell, will likely result in contaminant concentrations above the SDWA levels.

• The impact is most significant upstream and in the main channels of the reservoirs
General Conclusions (2)

• Contaminant concentrations in the water column of the reservoirs will decrease below SDWA levels within 2 years, but they will likely remain elevated for several years in Banister River.
• Most of the contaminated particulate matter will remain in the Banister River bed sediments for the foreseeable future.
• The contaminated sediments can be re-mobilized during flood events and flushed downstream.
Lake Gaston near Pea Hill Creek

• Radioactivity (radium and thorium) would remain above the MCL
  – For 1 to 21 days during wet years
  – For 7 to 10 months during dry years
• Radium Levels would remain above the MCL
  – For 2 to 8 weeks during wet years
  – For 6 to 16 months during dry years
• Uranium would be elevated but not exceed the MCL
City of Virginia Beach Intake

• If the pump station remained offline, no contamination would migrate into Pea Hill Creek

• However, the inability to withdraw water from Lake Gaston for up to 1.5 years would result in severe water shortages for the Cities of Virginia Beach, Chesapeake and Norfolk
