NC STATE UNIVERSITY

2003 Hominy Swamp Creek Monitoring Abstract

Hominy Swamp Creek was restored through the North Carolina Wetlands Restoration Program (NCWRP). The objectives of the project are to:

1.) Establish an stable dimension, pattern and profile on 2230 feet of Hominy Swamp Creek
2.) Improve habitat within Hominy Swamp Creek
3.) Establish an riparian buffer along Hominy Swamp Creek
4.) Incorporate this project into a watershed wide management plan

This is the 2nd year of the 5-year monitoring plan for Hominy Swamp Creek.

Table 1A. Background Information

Project Name	Hominy Swamp Creek
Designer's Name	KCI Associates of North Carolina, P.A. Landmark Center II, Suite 200 4601 Six Forks Road Raleigh, NC 27609
Contractor's Name	Unknown
Project County	Wilson County, North Carolina
Directions to Project Site	From Interstate I-264 take business 264 through the City of Wilson. Business 264 is also Raleigh Road continue on raleigh road until you reach Ripley Road. Head North on Ripley Road the site is on the right side (east) as soon as you turn of Raleigh Road.
Drainage Area	5.4 sq. mi.
USGS Hydro Unit	3020203020040
NCDWQ Subbasin	03-04-07 Neuse River Basin
Project Length	2,232 Linear feet
Restoration Approach	2,232 ft of priority 1 Natural Channel Design (dimension, pattern, and profile) with urban constraints
Date of Completion	September, 2001
Monitoring Dates	May, 2002; November, 2003

Results and Discussion

Overall, while the majority of the stream is functioning well and holding grade, the stream has areas of concern and areas of immediate need. Table 2 shows a summary of monitoring measurement results. Overall the project is performing well. Channel dimension, pattern, and profile are similar to as-built conditions with the exceptions of some limited areas of bank slumping. Vegetation is not succeeding to levels required for mitigation credit. Placed structures are holding grade and functioning well.

Table 2. Summary of Channel Conditions

* Planted value represents number of stems observed alive that were planted.

The following areas of concern should be monitored closely and considered for repair as suggested:

Hominy Swamp Creek

- Easement Limits
  - NCWRP should work with landowners to ensure easement limits are maintained by the park maintenance workers
- Areas with bank slumping
  - Bank slumping has been noted at two locations on the stream on the right bank at STA. 6+50 for approximately 15 ft and on the left bank at STA. 1+10 for approximately 25 ft
  - Overland flow may need to be routed away from areas that show signs of bank erosion and slumping
- Areas lacking stream feature
  - The entire length of restored stream has on four existing riffle features, but as it can be observed from the as-build longitudinal profile there were not may riffles that showed up in the as-build survey
- Vegetation
  - Planting select trees in critical areas where there is localized erosion.
  - The site could benefit from larger containerized trees both for bank stability and aesthetics, although mitigation requirements are currently being met.
  - It is recommended to stake in areas where erosion is problematic, particularly on outside meander bends.
  - Although invasive vegetation has not consumed this project site, there are several species that should be controlled now, most importantly Chinese wisteria and Chinese privet.
  - Mowing should be halted within the specified limits of the riparian buffer.

1.0 BACKGROUND INFORMATION

The background information for this report is referenced from previous monitoring reports conducted by KCI, Inc. The following was excerpted from 2002 KCI monitoring report:

> Project planning was initiated in 1999 for the implementation of an urban stream restoration project in Wilson, North Carolina (Figure 1).
>
> Phase I of the project consisted of the detailed analysis of the 5.4 square mile portion of the Hominy Swamp Creek watershed (located within USGS 14-digit Hydrologic Unit Code 03020203020040, NCDWQ Subbasin 03-04-07 of the Neuse River Basin) that contributes drainage to the project site. The watershed analysis, including the assessment of over 7 miles of stream channel, was conducted for the purpose of developing a clear understanding of existing system characteristics. The resulting Watershed Management Plan identified opportunities to improve water quality and overall system functions including targeted strategies such as wetland/riparian buffer preservation, stormwater BMP development/retrofitting, stream restoration, and community education.
>
> Following coordination with local leaders and citizens groups, Phase II of the project was initiated and focused on the restoration of approximately 2,000 linear feet of degraded stream within the Wilson Recreation Park. Detailed environmental assessments and engineering studies were conducted and design plans and documents were prepared to facilitate the stream and riparian buffer restoration. Implementation of the project was completed in September 2001.
>
> The restoration of this portion of Hominy Swamp Creek, located within the Wilson City Recreational Park, was conducted to correct identified system deficiencies including severe bank erosion, channel widening, and the loss of aquatic habitat resulting from stream channelization, the loss of riparian vegetation, and watershed development. The goal of the project was to develop a stable stream channel with reduced bank erosion, efficient sediment transport, enhanced warm water fisheries, and improved overall stream habitat and site aesthetics. Implementation of the project was completed in September 2001.

1.1 Goals and Objective

The goals and objectives of this project are as follows:

1.) Restore 2,232-linear feet of Hominy Swamp Creek through a priority 1 natural channel design approach.
2.) Establish a riparian zone surrounding restored section of Hominy Swamp Creek.
3.) Improve the habitat within the channel and the riparian zone.
4.) Incorporate this project into a watershed wide management plan.

1.2 Project Location

This project is located within the city limits of Wilson, North Carolina. From Raleigh, follow Interstate I-264 east take business 264 through the City of Wilson. Business 264 is also Raleigh Road continue on Raleigh road until you reach Ripley Road. Head North on Ripley Road the site is on the right side (east) as soon as you turn of Raleigh Road.

1.4 Project Description

A previously straight through the Wilson City Recreational Park, Hominy Swamp Creek was restored using channel dimension, pattern, and profile modifications and the establishment of riparian zone adjacent to the creek. Channel profile is maintained through the use of log and rock cross vanes. Channel pattern is maintained through the use of log single vanes and vegetation along the channel banks. Due to multiple urban constraints, pattern modifications were limited throughout the project.

2.0 YEAR 2003 RESULTS AND DISCUSSION

Year 2003 monitoring results are shown for Hominy Swamp Creek Monitoring.

2.1 Vegetation

Using the Draft Vegetation Monitoring Plan for NCWRP Riparian Buffer and Wetland Restoration Projects, 4 vegetation monitoring plots were randomly located within the riparian buffer of the Hominy Swamp project. No reference area was studied; therefore no comparisons could be made to reference conditions.

2.1.1 Results and Discussion

Vegetation within the riparian buffer of Hominy Swamp Creek is overall considered successful. Because the buffer is so narrow on this project, plots were modified linearly. The upper portion of the restoration site was well vegetated with live stakes and naturally regenerating native species. Native herbaceous plants were growing well, although fescue and honeysuckle were prevalent in these areas. Shrubs, especially those from live stakes, were diverse and healthy. Planted bare root trees averaged 460 stems per acre for the upper two plots. Some of the larger planted trees had apparently been j-rooted during initial planting. Several of these trees had fallen over and inspection of the roots revealed that they had been poorly installed. This appeared to have led to root instability and susceptibility to wind throw. Vegetation in the lower portion of the project was healthy, although numbers of planted bare root trees were lower; average was 200 stems per acre. It appeared that much of the buffer in this region had been mowed and the tree mortality was high as a result. Natural regeneration was also a main vegetation component of this area. Shrubs from stakes again were thriving along the streambanks. Herbaceous plants were less diverse but still dense. Extrapolation from the four plots resulted in an overall average of approximately 330 planted trees per acre for this restoration site. If natural regeneration is included with planted trees, the number is increased to an average of approximately 3230 trees per acre. Both of these estimates are based on a diverse mix of species as well. Natural regeneration obviously plays an important role in the restoration of this site.

Invasive plant species on the site included *Lonicera japonica* (Japanese honeysuckle), *Wisteria sinensis* (Chinese wisteria), *Ligustrum sinense* (Chinese privet) and *Microstegium vimineum*. Chinese wisteria is choking much of the adjacent forest in the upper portion of the project. Several vines were noted within the riparian corridor. Because this plant spreads extensively by rhizomes, it is only a matter of time before it infests the riparian area. Chinese privet was sporadically spread throughout the area, no where abundant. Japanese honeysuckle and microstegium were prevalent throughout.

Recommendations include planting select trees in critical areas where there is localized erosion. The site could benefit from larger containerized trees both for bank stability and aesthetics, although mitigation requirements are currently being met. It is recommended to stake in areas where erosion is problematic, particularly on outside meander bends. Although invasive vegetation has not consumed this project site, there are several species that should be controlled now, most importantly Chinese wisteria and Chinese privet. Mowing should be halted within the specified limits of the riparian buffer.

2.2 Morphology

Restored channel dimension, pattern, profile and substrate were examined during the 2003 monitoring.

2.2.1 Results and Discussion

Hominy Swamp Creek is sand bed channel and therefore the dune and anti-dune characteristics of sand-bed sediment transport should be considered. The channel profile along Hominy Swamp Creek has not shown any significant changes in between monitoring periods. The channel profile along Hominy Swamp Creek has also not shown any significant changes in between the as-build profile and this year's monitoring. The stream profile of by the monitoring and as-build show very few riffle features in the stream. The Mitigation report mentions that the design was to build a riffle/pool sequence plan form, but this intent was not displayed on the as-build survey. The number of defined riffles in the bedform has decreased from 6 in the 2001 as-build, to 4 in 2003. The average riffle slope has not change and many of the riffles have been transformed into runs which are more defined in low gradient systems.

KCI cross section results were recalculated using NCSU techniques for consistency purposes. Data was examined but field identified features were retained. The same datum was used for bankfull for each year's monitoring results. Cross-sections 1 was not field located; they have been re-established and will be monitored in the re-established location and the original location if it can be field located during future monitoring periods. Channel cross-sections 1 and 2 along Hominy Swamp Creek have not shown any significant change in cross-sectional area, this is partly due to cross-section 1 being relocated. Cross-section 3, a pool, has partially filled in with sediment the cross-sectional area has decreased from 76 to 65 square feet. Cross-section 4, a pool has enlarged from 88 to 107 square feet since construction.

Channel substrate in the riffle sections continue have very little change. The D50 decreased on a average from 0.28mm to 0.23mm over the four cross sections. In riffle 1, the D50 decreased from 0.54mm to 0.29mm, and in riffle 2 the D50 decreased from 0.20mm to 0.17mm. The riffles are maintaining a medium sand substrate. The pool cross-section D50 has increased slightly, from 0.20mm to 0.23mm, but not a significantly. A possible cause of decrease in particle size is measurement technique. It is not know if previous surveyors used similar sampling technique. Future monitoring should better evaluate channel substrate.

Channel pattern appears to have been maintained since construction. A few of the outside meander bends are experiencing slight migration through bank slumping but no excessive migration is evident and no shoot cut-offs are apparent. The pattern aligns closely with the as-build pattern (Figure 4). Channel banks throughout Hominy Swamp Creek remains fairly stable, with the exception of two spot areas of bank slumping. Slumping is likely the result of the lack of deep rooting vegetation, steep stream banks, high stream velocities near the channel toe, and possible overland flow into the channel.
