I. EXECUTIVE SUMMARY/PROJECT ABSTRACT

The Rockwell Pastures Stream and Wetland Restoration Site includes the restoration and enhancement of 17,786 linear feet of stream on ten unnamed tributaries and 1.7 acres of wetland restoration within the parcels owned by Charles R. Dennis and his wife, Dennis Farms Inc., Deese Family LP, and Reece Vane Deese and his wife. The site is located six miles southeast of Albemarle in Stanly County. The project Site lies within the USGS hydrologic unit (HUC) 03040104010020 in the Yadkin River Basin.

This Annual Monitoring Report presents the data from two hydrology monitoring stations, 27 vegetation monitoring plots, three manual crest gauges, three auto crest gauges, a manual rain gauge, an auto-logging rain gauge, 24 stream cross sections, and photo reference locations, as required by the approved Restoration Plan for the site.

Planted stem survival for Monitoring Year 2 for all 27 Vegetation Plots (VP) at Rockwell Pastures was above the interim success criteria of 320 trees per acre at the end of Monitoring Year 3. The plot density ranged from 364 stems per acre for VP #8 to 809 stems per acre in VP #26. The average stem density (excluding livestakes) across all vegetation plots was 626 stems per acre. No volunteer tree species were noted during Monitoring Year 2.

The 2010 vegetation monitoring for Rockwell Pastures utilized the Ecosystem Enhancement Program's (EEP) Carolina Vegetation Survey (CVS) protocol for recording vegetation. This report summarizes the vegetation observations.

Throughout the Year 2 monitoring season, the restored stream channel remained stable and continued to provide the intended habitat and hydrologic functions. All monitored cross sections show little adjustment in stream dimension, and the site remains on track to achieve the stream stability success criteria specified in the Restoration Plan. Four areas along the restoration stream channel are exhibiting minor erosion that presents no major concern to stream stability.

In 2010, AW1 and AW2 hydrology monitoring gauges recorded hydroperiods of 9 and 12 percent of the growing season, well above the success criteria of 7 percent of the growing season specified in the Restoration Plan for the site. The two monitoring gauges at the reference site recorded hydroperiods from 5 to 13 percent of the growing season. Overall, the site was within the range of hydrologic conditions expected in undisturbed non-riparian wetland seeps.

II. PROJECT BACKGROUND

A. Project Goals and Objectives

The goal of this project is to provide functional uplift to the watershed by restoring or enhancing stream, wetland, and riparian areas within the watershed. The mitigation actions improve water quality, ecological function, and habitat, and include:

- Removing excess nutrients and sediment through the use of vegetative buffers,
- Increasing dissolved oxygen concentrations through the use of in-stream structures and the turbulence they produce in pools,
- Stabilizing the stream bank using natural channel design techniques,
- Improving substrate through the use of structures and the elimination of major sediment

- sources from the stream,
- Creating habitat diversity by introducing woody structures such as log vanes and/or root wads,
- Reducing temperature by restoring canopy in the buffer areas,
- Reconnecting streams to their adjacent floodplains and wetlands,
- Raising groundwater levels in adjacent streams by raising adjacent channel bed elevation,
- Removing/plugging ditches used to drain historic wetlands,
- Enhancing infiltration by re-grading and ripping wetlands,
- Breaking up soils historically compacted by cattle to allow the groundwater to come to the surface and wetland vegetation to flourish,
- Improving crossings by replacing pipes and/or stabilizing outfalls,
- Controlling the invasive exotics by removing them during construction,
- Preserving stable on-site streams, wetlands, and riparian buffers draining into the enhancement/restoration reaches,
- Excluding livestock with fencing, and
- Re-vegetating the stream banks, wetlands, and riparian areas to improve bio-diversity and Ecology.

B. Project Restoration Components

All ten stream reaches are located within the parcels owned by Charles R. Dennis and his wife, Dennis Farms Inc., Deese Family LP, and Reece Vane Deese and his wife six miles southeast of Albemarle in Stanly County. The existing stream channels had low sinuosity and varying levels of incision due to historic channelization.

UT 1 – Unnamed Tributary 1 is a second order stream that is located centrally within the project site. This channel had failing banks, and was moderately to severely incised for most of its length. Just below its confluence with UT 4, the area was primarily open with active pastures and a short stretch (375 feet) of sparse woody vegetation at the bottom of the project. The portion of UT 1 above the confluence with UT 4 was located within active agricultural fields. Almost the entire UT 1 stream reach was historically straightened and channelized.

In order to provide functional uplift to UT 1, it was divided into four types of treatment. The uppermost portion (Sta. 100+00 – 102+92) was treated using Enhancement Level II to establish stability. Most of the remaining length of UT 1 was treated using Priority I restoration since the stream was incised and was historically straightened. The priority 1 restoration technique was used to re-connect the stream with its historical floodplain, and to restore the functions of the riparian buffer. An exception was taken with the approach of the lowest portion (approximately 375 feet) that was not incised and had a thin wooded buffer. This area was treated using Enhancement Level II, which included some minor bank grading. The other exception was the reach along the upper portion just above the main farm road where property constraints will only allow the use of buffer planting, benches and grade control structures to provide an improved cross section and bedform (profile) step/pool features. This concession to the landowners was necessary to secure the entire stream corridor. Enhancement Level I credit was proposed in this section. The UT1 sections with buffer widths less than 50 feet do not contribute to the stream mitigation unit yield and are included in the project only for continuity between restored sections.

UT 2 – UT 2 is a small first order perennial stream based on the USGS Topographic Map. This unnamed tributary had similar existing conditions as UT 1. This stream reach is fed by an existing farm pond and is a Bc channel. This stream does not appear to have been relocated, and has a fairly stable and natural morphology with a boulder substrate. UT 2 had a great amount of sedimentation and was heavily impacted by livestock. Aquatic life characteristics of a perennial stream exist within UT 2. Right-hand (gilled) snails, mayflies, bullfrog tadpoles, and minnows were found within this stream reach. Due to livestock access, the herbaceous stream buffer was severely degraded.

To provide functional uplift to UT 2, the Enhancement Level II approach was taken (Sta. 200+ 00 – 206 + 35). A fenced buffer has been provided to exclude livestock from the stream. The 50-foot stream buffer was planted with native forest vegetation.

UT 3 – UT 3 is a first order stream that has both perennial and intermittent portions. This stream reach was heavily impacted by livestock, and the buffer was primarily herbaceous vegetation. The short, upper portion of the stream is intermittent, and was an incised Rosgen E type channel. The lower portion of UT 3 was alternately incised and sedimented, and had failing banks. The entire perennial section of UT 3 appeared to be historically straightened.

The priority 1 restoration technique was used on UT 3 to provide functional uplift. UT 3 was re-connected with its historical floodplain, and a functional riparian buffer was planted. Additionally, livestock was excluded from the stream by fencing the easement.

UT 4 – UT 4 is a first order stream based on the 1:24,000 USGS Topographic Map. The upper portion of the stream is impounded by three small ponds that are fed by a perennial spring. Below the ponds, the upper portion of the stream is relatively stable; however, it is overgrown with invasive species such as Chinese privet (*Ligustrum sinense*) and multiflora rose (*Rosa multiflora*). This portion of the stream has an appropriate riffle-pool sequence. The middle portion of UT4 has been impacted by silviculture. Except for a section of approximately 200 feet, the stream is extremely over-wide (width-to-depth ratio of approximately 79) and braided in most areas. This has resulted in unstable banks, as the stream appears to frequently “wander” across the valley floor. It appeared to have been heavily altered, and the buffer had recently been removed. The area where a power line crosses the stream was excluded from the project site. Above this area is a small riparian wetland with mostly herbaceous vegetation. The lower portion of the stream had been straightened and altered based on topographic and visual observation. Most of the banks were severely unstable as a result of the redirection of the channel. A strong and unstable head-cut separated the lower portion and middle portions of UT4. It appeared to have been historically straightened. The buffers also had been cleared recently, leaving mostly sparse, new-growth vegetation. The geomorphic assessment of the lower portion of UT4 revealed that the stream was incised, and was unstable because of the straightening and other alterations.

The uppermost portion of UT 4 includes three small spring-fed ponds. The stream was restored through these ponds by partially removing the dam structure, and allowing the stream channel to be re-established in the pond bottom. The approach was to establish the lowest, presumably flat, portions of the existing pond bottoms as the flood plain, and to create a channel with the appropriate dimension, pattern, and profile. This approach minimized sediment loss and rapidly re-established the stream and riparian corridor. Immediately below the ponds and for a short

section just above and below the existing road, the stream channel was stable with undercut banks and an appropriate riffle/pool sequence. However, there were invasive species that were removed and replanted with native tree species. As such, this treatment was considered to be Enhancement Level II. Between the above reaches, there was a reach that had been impacted by the farmer on numerous occasions using earth-moving equipment. This reach has multiple threads in some locations and the main part of the stream switches channels, or forms new channels from time to time (i.e. the streams are laterally unstable). The reaches also had excessively wide width to depth ratios, and were overly shallow in areas with bedrock. This area received a combination of Restoration and Enhancement Level I treatment by blocking the multi-threaded areas, building benches using single or double wing deflectors, and adding appropriate bed-form features using log and rock vanes. The goal of this approach was to recreate a single thread channel with an appropriate width to depth ratio that is laterally stable and has better formed riffle-pool complexes. This will greatly improve habitat and reduce sedimentation. From station 436+37 to 449+26, the stream was incised and highly eroded; therefore, it was restored using Priority 1 stream restoration techniques. UT4 was also placed back into its natural valley as it enters the Reese property.

UT 5 and UT 6 – These small, intermittent streams are located in agricultural fields. Since these systems are relatively small, it was anticipated that they could be stabilized by re-establishing a woody riparian buffer. As such, Enhancement Level II was performed on these streams. Providing a riparian buffer to the intermittent portions of the above streams will protect the downstream areas by removing sedimentation sources, and by providing shading to reduce temperature. The stream banks along UT5 and UT6 were unstable due to agriculture and mowing down to the stream edges. A forested buffer will provide filtering for sediments, and shading to reduce temperatures.

UT 7 – This stream reach is bounded by an agricultural field and cutover forest along most of its upper portion above the confluence with UT6. The banks were unstable due to the lack of vegetation, resulting in heavy sedimentation. UT 7 is also bounded by agricultural fields and open pasture to just below its confluence with UT6. Below the confluence, the stream becomes perennial based on a NCDWQ score of 33. The entire length of the stream appeared to have been straightened. The upper portion was incised with failing banks. The lower portion was heavily sedimented just before it entered the valley bottom. UT 7 was heavily impacted by livestock access and hoof shear.

Priority 1 restoration and Enhancement Level II were performed on UT 7 to provide biological uplift. Proper dimensions, pattern, and profile were restored on UT 7 because it had been historically straightened. A riparian buffer was planted to protect the downstream areas by removing sedimentation sources, and to provide shading to reduce temperature. The UT 7 stream reach was also fenced to exclude livestock.

UT 8 – This stream was determined to be an intermittent channel with a stream rating score of 29.75, and a drainage area of 0.02 square miles (13.9 acres). Approximately 83 feet of restoration were added to tie the existing tributary into UT 1, and additional easement was added above the restoration to add approximately 402 feet of Enhancement Level II treatment.

UT 9 – This stream was determined to be a perennial channel with a stream rating score of 50.5, and a drainage area of 0.06 square miles (38.3 acres). The existing stream does not lie within the

protective conservation easement; however, a restoration section of stream approximately 152 feet in length was added within the easement to tie UT 9 into the relocated UT 1.

UT 10 – This stream was determined to be a perennial channel with a stream rating score of 48.25, and a drainage area of 0.11 square miles (69.5 acres). This channel discharges directly from an existing farm pond. Approximately 24 feet of existing stream was located within the protective conservation easement, and a total of 103 feet of stream restoration was added within the easement to tie UT 10 into the relocated UT 1.

Additional details regarding the restoration components of the project are provided in **Table I**.

C. Location and Setting

The Rockwell Pastures Stream and Wetland Restoration Site is located six miles southeast of Albemarle in Stanly County (**Figure 1**). Rockwell Pastures lies within the Yadkin Basin, North Carolina Division of Water Quality (DWQ) sub-basin 03-07-08, and local HUC 03040104010020. The project area is located in the Carolina Slate Belt sub-ecoregion of the Piedmont ecoregion. The site contains ten unnamed tributaries (UT1, UT2, UT3, UT4, UT5, UT6, UT7, UT8, UT9, and UT10) to David’s Creek/Lake Tillery. Lake Tillery is listed as DWQ class Water Supply (WS-IV, CA) waters. The ten unnamed tributaries are considered to be WS-IV streams.

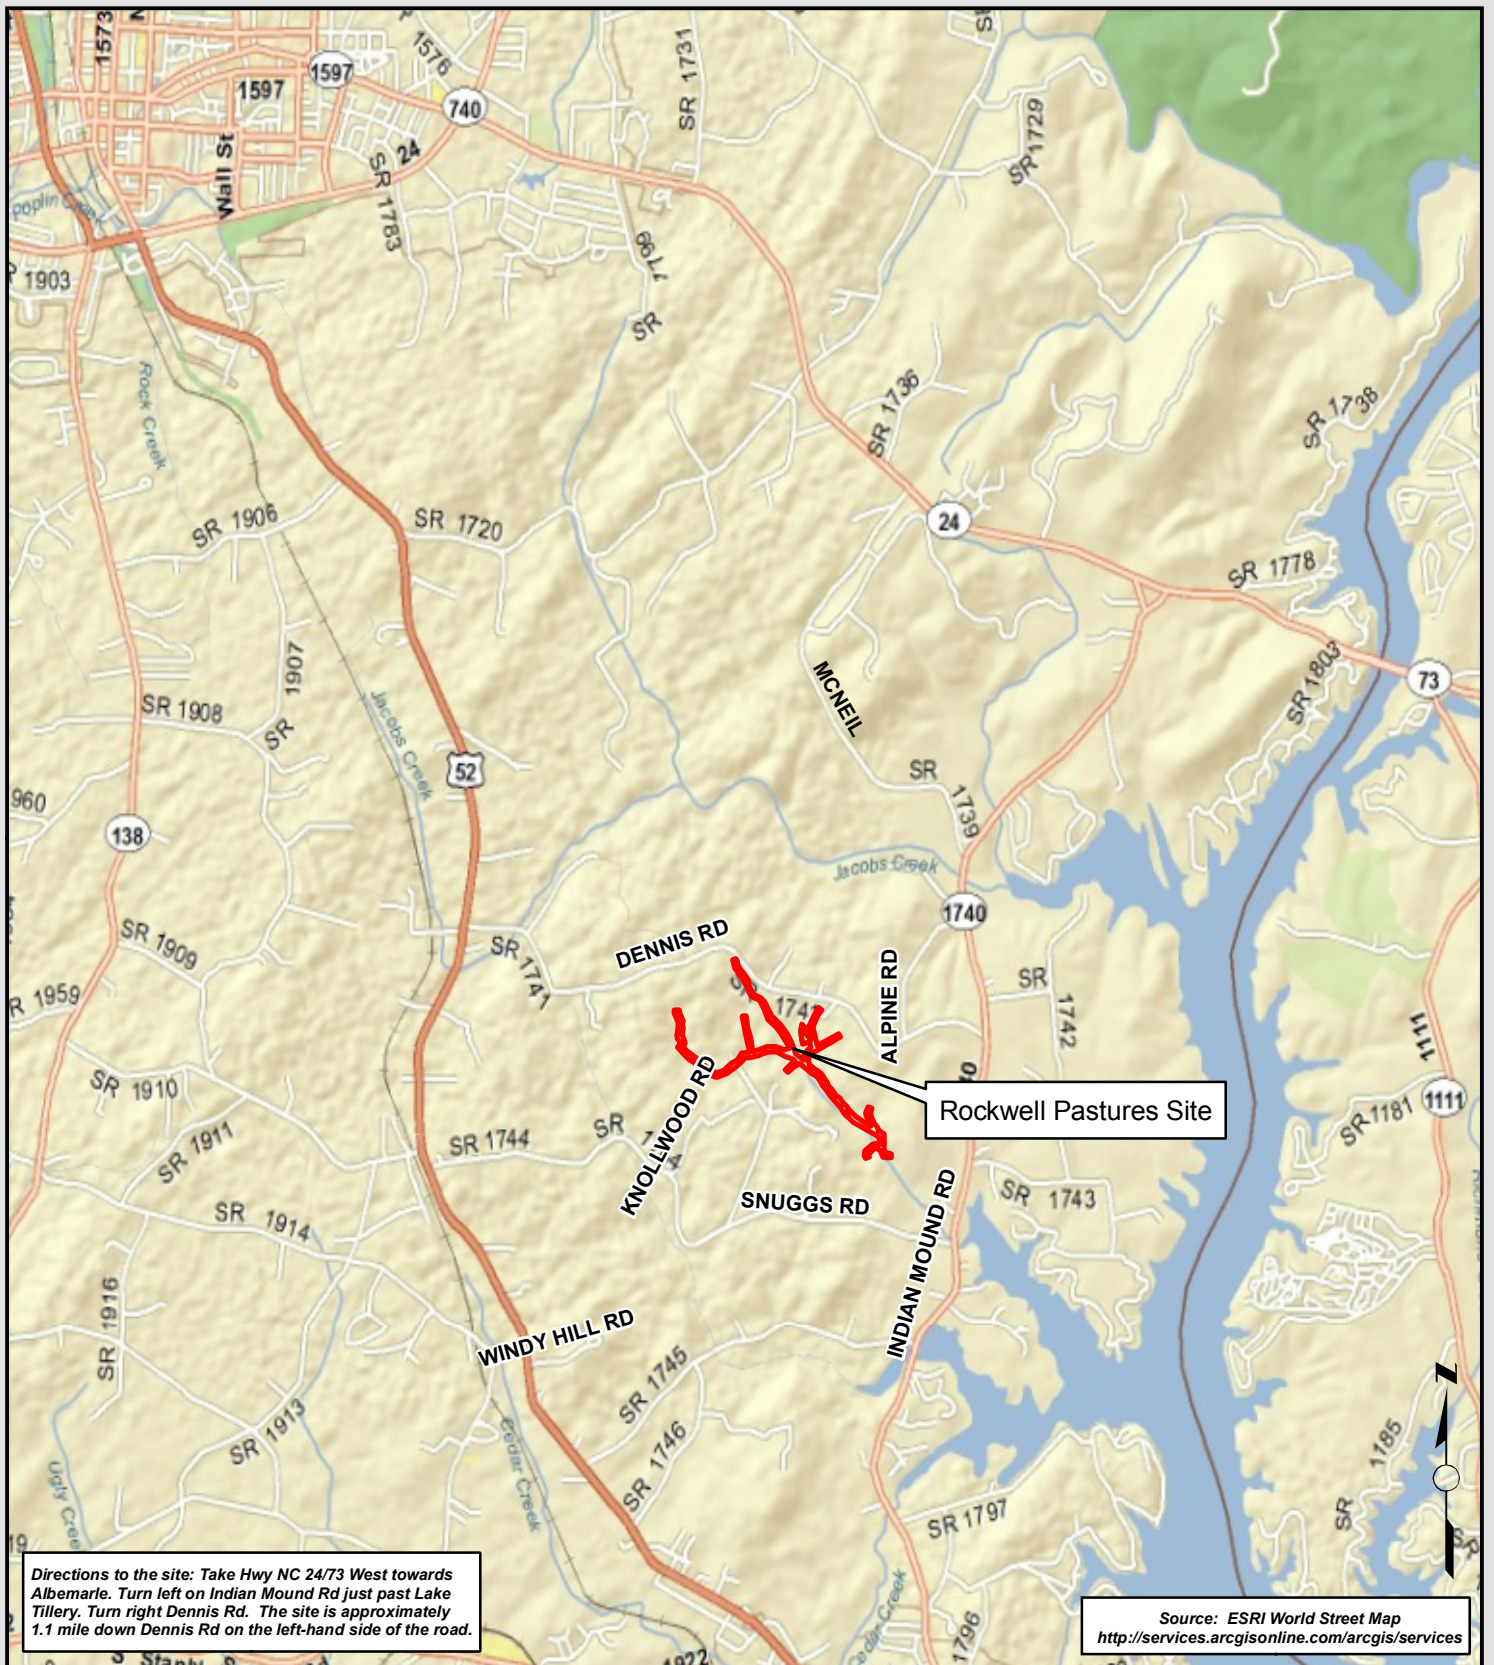

Figure 1.
 Rockwell Pastures Site
 Vicinity Map
 Stanly County, NC

D. Project History and Background

Construction of the Rockwell Pastures Site was completed in May 2009. Following the completion of construction, the As-Built cross sections were installed and surveyed the same month. Year 1 monitoring took place in November 2009. Additional details regarding the timeline of the project are provided in **Table II** below.

The project was designed by Kimley-Horn and Associates, Inc. Construction was performed by RFG Construction, Inc. Monitoring activities for Years 1 and 2 were performed by WK Dickson and Co., Inc. Additional information regarding contractors is shown in **Table III**.

The site is bound by agricultural fields and pastureland. Additional information regarding this stream is included in **Table IVa** and **b**.

E. Monitoring Plan View

A series of monitoring devices have been installed on-site. Twenty-four individual cross-sections were located. Cross-sections were plotted from left to right facing downstream. Each cross-section is also a designated photographic point that is photographed annually. Twenty-seven vegetation-monitoring plots were randomly located within the riparian buffer of the Rockwell Pastures Stream Site. Two automatic HOBO groundwater gauges and two reference HOBO automatic groundwater gauges were installed to measure hydrology success of the wetland restoration area. One manual and one automatic rain gauge were installed to record rainfall onsite. Three manual crest gauges and three automatic crest gauges were installed to record bankfull events on stream reaches UT 1 and UT 4. The locations of all monitoring devices are shown on Figures 3a through 3m (Current Conditions Map).

III. PROJECT CONDITION AND MONITORING RESULTS

Monitoring results are discussed below. Rockwell Pastures Site annual vegetation monitoring was conducted during the week of July 12, 2010 by WK Dickson and Co., Inc personnel.

A. VEGETATION ASSESSMENT

Planted zones related to the stream restoration consist of the riparian buffer zone and the stream banks. The riparian buffer zone initiates at the top of the bank, and continues out perpendicular to the immediate channel following the general pattern of the meandering channel. The planted stream bank initiates at the normal base flow elevation, and extends to the top of bank or interface with the floodplain.

The success of riparian and vegetation planting will be gauged by stem counts of planted species. Stem counts of more than 320 trees per acre after three years, and 260 trees per acre after five years will be considered successful. Photos that are taken at established photos points should indicate maturation of the riparian vegetation community.

The “CVS-EEP Protocol for Recording Vegetation” was utilized during the As-Built (Baseline) and Year 1 vegetation monitoring. A qualitative visual assessment of vegetation was performed throughout the entire project area. Twenty-seven vegetation plots measuring 100 square meters were accessed. Vegetation observations were recorded at cross sections, problem areas, and representative locations. Representative photographs of vegetation conditions were recorded throughout the project area (**Appendix A-3**).

1. Soil Data

The project area is located in the Carolina Slate Belt sub-ecoregion of the Piedmont ecoregion. This sub-region extends from southern Virginia, across the Carolinas, and into a small part of eastern Georgia. The mineral-rich metavolcanic and metasedimentary rocks with slaty cleavage tend to be finer-grained and less metamorphosed than other parts of the Piedmont, and are somewhat less resistant to erosion. In North Carolina, some parts of the region are more rugged and hilly. Trellised drainage patterns also occur in parts of the region. The volcanic-sedimentary rock formations include volcanic slates, basic and acid tuffs, breccias, and interbedded flows. The volcanic slates are deeply weathered in places, forming clay and shale, and the soils generally have high silt contents. Georgeville and Herndon soils (fine, kaolinitic, thermic Typic Hapludults) are common.

The NRCS soil survey for Stanly County maps the following soils within the site: Badin channery silt loam, Ewon very strong loam, Kirksey silt loam, Oakboro silt loam, Tatum gravelly loam, and Tatum channery silt clay.

2. Vegetative Problem Areas

Overall, the site appears to have good vegetation along the stream channel and floodplains. Few areas of bare banks and floodplains were observed during Monitoring Year 2; however, as the site matures, vegetation will become denser, and bare areas will begin to fill in. Three vegetation problem areas were noted during Monitoring Year 2 activities. These areas consist of sparse

vegetation along stream banks and floodplain and one area of the easement, which was accidentally sprayed with an agricultural herbicide.

The vegetation problem areas are shown on the Current Conditions Plan View Maps, which are provided in **Appendix B, B-1**.

3. Stem Counts

Planted stem survival for Monitoring Year 2 for all twenty-seven Vegetation Plots (VP) at Rockwell Pastures was above the interim success criteria of 320 trees per acre at the end of Monitoring Year 3. The plot density ranged from 364 stems per acre for VP #8 to 809 stems per acre in VP #26. The average stem density (excluding livestakes) across all vegetation plots was 626 stems per acre. No volunteer species were noted during Monitoring Year 2. These plots are on track to meet the interim and final success criteria specified in the Restoration Plan.

4. Vegetation Plot Photos

Appendix A contains a vegetation photo log.

B. STREAM ASSESSMENT

WK Dickson and Co., Inc personnel performed annual monitoring activities at the Rockwell Pastures Site during July 2010. During the field visit, qualitative observations were recorded regarding the condition of the stream restoration project. Cross section and longitudinal surveys were also performed at the time of this visit. Twenty-four cross sections and approximately 4,400 linear feet of stream profile was surveyed. Profile on UT 1 was surveyed from station 121+02 to 144+75. Approximately 350 linear feet were surveyed on UT 3 from station 303+05 to 306+50. UT 4 profile survey was performed from station 433+00 to 447+00, and UT 7 was surveyed from 711+48 to 714+39. Photographs were taken at all permanent photo points. Banks were stable with no severe bank erosion. Stream problem areas are described in Appendix B, Table B.1. Problem areas should be monitored, and if they worsen over time, the reason for the problem should be assessed and potential repair options should be presented.

Hydrologic Assessment

The occurrence of bankfull events within the monitoring period is documented by the use of manual crest gauges and auto-recording crest gauges. The three crest gauges will record the highest watermark between site visits. Two crest gauges were installed on stream reach UT1 at the upper portion (Sta. 131+00) and on the lower portion (Sta. 164+20). The third crest gauge was installed on UT4 near station 438+20. The gauges were checked and downloaded every three months to document high flows. The auto-recording crest gauges are used to determine the date and time of each bankfull event. Digital images are used to document the occurrence of debris lines and sediment deposition on the floodplain during monitoring site visits.

During the 2010 monitoring season, three crest gauges were monitored to determine if there were any out-of-bank flow events on the Rockwell Pastures Site (**Table V**). Eight bankfull events were documented during the 2010 monitoring season on Crest Gauge 1. All three crest gauges experienced bankfull events during the months of January, March, May, and June. The largest stream flow documented for Year 2 by the onsite crest gauges was recorded by Crest Gauge 2,

which occurred on June 1 and was 2.34 feet above the bankfull stage. Crest Gauge 3 experienced its largest bankfull event during the same rain event, which was recorded at 2.16 feet above bankfull stage. During the June 1 rain event, manual crest gauges 1 and 2 were washed over by high flows and debris washing downstream. Manual crest gauges 1 and 2 have been repaired. Crest gauge data are presented in **Appendix C** along with the precipitation data.

Table V. Verification of Bankfull Events Rockwell Pastures Site/Project No. D-000624						
Month Recorded	Crest Gauge 1		Crest Gauge 2		Crest Gauge 3	
	Max Height (ft)	Number of Occurrences	Max Height (ft)	Number of Occurrences	Max Height (ft)	Number of Occurrences

1. Problem Areas Plan View

An assessment of the stability of the channel was performed in July 2010 by WK Dickson and Co., Inc. Four areas of concern were observed and documented. SPA1 (Stream Problem Area 1) consists of a riffle head cutting at station 112+00. SPA1 is located in a stream segment where no stream mitigation credits are being generated. The head cut is minor and is not threatening overall channel stability. SPA2, SPA3, and SPA4 are all areas with sparse vegetation and minor erosion. These problem areas are shown in **Appendix B, Section B-1**.

2. Problem Areas Summary Table

The Problem Areas Table Summary is located in **Appendix B as Table B.1**.

3. Representative Stream Problem Areas Photos Section

Representative photos of each category of stream problem areas were taken and are shown in **Appendix B, Section B-3**.

4. Fixed Photo Station Photos

Photos from various photo stations were collected on July 13, 2010 during the stream survey. These photos are included in **Appendix B, Section B-4.**

5. Stability Assessment

A visual qualitative assessment was performed to inspect channel facets, meanders, bed, banks, and installed structures. This visual assessment was confirmed and enhanced with a quantitative assessment of the physical stream survey. The goal of this assessment is to provide a percentage of the features listed in **Table VI** that are stable.

6. Quantitative Morphology

The following tables (**Table VII** and **Table VIII**) summarize the quantitative data collected from the cross-sectional and longitudinal stream survey. These data were analyzed and summarized, and then compared with as-built data. The Quantitative Morphology Tables illustrate the degree of departure, if any, of the current channel from the baseline data. **Tables VII** and **VIII** were

compiled from the cross-section and profile raw data and plots located in **Appendix B** of this report.

C. WETLAND ASSESSMENT

The non-riparian wetland restoration consists of 1.7 acres of non-riparian wetlands. The plan will target the restoration of a non-riparian low elevation seep. Based on the location of the restoration site, the main source of hydrology is from seepage and overland flow. The wetland restoration area at this site was designed to be a combination of piedmont/mountain bottomland forest, piedmont/mountain levee forest, and piedmont/low mountain alluvial forest communities.

As stated in the Restoration Plan, the hydrology success criterion for the site is to restore wetland hydrology at the site so that the water table will remain within 12 inches of the soil surface for at least 7 percent of the growing season continuously (approximately 16 days). The growing season is from March 27 to November 5. Based on a daily minimum temperature greater than 28 degrees Fahrenheit occurring in five of ten years, the growing season for Stanly County is 222 days long. On-site gauge data will be compared to gauge data from a reference wetland in growing seasons with less than normal rainfall. In periods of low rainfall, if a restoration gauge hydroperiod exceeds the reference gauge hydroperiods, and both exceed 5 percent of the growing season, then the gauge will be deemed successful.

Two automated HOBO groundwater gauges, one tipping bucket rain gauge, and one funnel rain gauge were installed prior to the beginning of the first growing season. Two additional automated groundwater gauges were installed in a reference wetland. Groundwater gauges are installed to a minimum depth of 40 inches below the ground surface. The monitoring protocol for the site specifies that automated monitoring stations will be downloaded and checked for malfunctions on a quarterly basis. During quarterly site visits, manual groundwater gauges are read, crest gauge readings are taken, and cumulative rainfall totals are collected from the on-site rain gauges.

Both automated HOBO groundwater gauges have met the success criteria for the 2010 growing season (**Table IX**). AW1 and AW2 exceeded the 7 percent hydrology success criteria by recording hydroperiods of 9 and 14 percent of the growing season respectfully. Precipitation data for Albemarle, North Carolina and the on-site rain gauge are provided in the groundwater gauge data tables in Appendix C. Albemarle precipitation data was provided by the State Climate Office.

IV. METHODOLOGY

A. VEGETATION METHODOLOGY

The following methodology was used for stem count and vegetation monitoring. Twenty-seven vegetation plots were marked out with a meter tape to measure ten meters by ten meters or five meters by twenty meters (100 square meters), depending on the buffer width. Each planted stem in the plots are marked with flagging tape and a PVC marker pole. Photo documentation of each

plot was recorded. All vegetation plot data and inventories were conducted per the 2006 CVS-EEP Level II Protocol for Recording Vegetation (EEP 2006).

B. STREAM METHODOLOGY

The stream monitoring activities included longitudinal survey, cross-sectional surveys, detailed stream walk analysis, problem area identification, hydrology monitoring and photo documentation.

Longitudinal Profile

A longitudinal profile will be measured annually throughout the five-year monitoring period. The profile will be measured along a representative length of restored channel. Measurements will include thalweg, water surface, bankfull, and top of low bank. Each of these measurements will be taken at the head of each feature, for example, shallow, pool, and the max pool depth. The survey will be tied to a permanent benchmark.

Cross Sections

Two permanent cross sections will be installed per 1,000 linear feet of stream restoration work, with one located at a riffle and one located at a pool. Each cross section will be marked on both banks with permanent pins to establish the exact transect used. A common benchmark will be used for cross sections to facilitate easy comparison of year-to-year data. The annual cross-section survey will include points measured at all breaks in slope, including top of bank, bankfull, inner berm, edge of water, and thalweg, if the features are present. Riffle cross sections will be classified using the Rosgen stream classification system.

Hydrology

The occurrence of bankfull events within the monitoring period will be documented by the use of manual crest gauges, auto-logging crest gauges, and photographs. The three crest gauges will record the highest watermark between site visits, and the gauges will be checked quarterly to document high flows. Digital images will be used to document the occurrence of debris lines and sediment deposition on the floodplain during monitoring site visits.

Photo Reference Stations

Photographs will be used to subjectively evaluate channel aggradation or degradation, bank erosion, success of riparian vegetation and effectiveness of erosion control measures.

C. WETLAND METHODOLOGY

Two automated HOBO groundwater gauges, one tipping bucket rain gauge, and one funnel rain gauge were installed prior to the beginning of the first growing season. Two additional automated groundwater gauges were installed in a reference wetland. Groundwater gauges are installed to a minimum depth of 40 inches below the ground surface. The monitoring protocol for the site specifies that automated monitoring stations will be downloaded and checked for malfunctions on a quarterly basis. During quarterly site visits, manual groundwater gauges are read, crest gauge readings are taken, and cumulative rainfall totals are collected from the on-site rain gauges. During the 2010 growing season, all automated loggers performed well with no periods of missing data.

Automated Gauges

*Rockwell Pastures Site
NCEEP Project Number D-000624
Environmental Banc and Exchange.
September 2010*

HOBO automatic groundwater gauges record water table elevations four times daily at 06:00, 12:00, 18:00, and 24:00. These automatic gauges employ pressure sensors that record water elevation above the bottom of the sensor (with atmospheric pressure compensation). The calibration water table depth is recorded at quarterly downloads. To determine wetland hydroperiods, the automatically recorded data are compared to the calibration data to determine a standard correction factor between the calibration gauge and the automatic gauge for each location. The standard correction factor is applied to correct daily readings. The corrected daily readings are used to determine wetland hydroperiods.

Data Interpretation

Wetland hydroperiods are calculated for four daily water table depth elevations. A hydroperiod is calculated if the water table is equal to or less than 12 inches below ground surface for at least 24 hours. If a gauge falls below -12 inches for four consecutive readings (24 hours) then the hydroperiod ends at the last reading within 12 inches of the ground surface. If a gauge falls below -12 inches for only three readings then maintains a reading above -12 inches for a minimum of 24 hours, the hydroperiod is calculated continuously. This methodology accounts for minor technical malfunctions experienced by the automatic gauges.

RECOMMENDATIONS AND CONCLUSIONS

The Rockwell Pastures Site remained stable through Monitoring Year 2. Only three problem areas on UT1 were recorded in which a headcut was forming and two minor erosion areas. The head cut is located in a stream segment where no mitigation credits are being generated. One problem area on UT 4 was recorded with right bank erosion at station 437+00. These problems do not create a systemic stability issue; however, the conditions will continue to be observed during Year 3 Monitoring. All structures and banks appeared to be stable and in good condition. The Rockwell Pastures Site is on track to meet the stream stability success criteria as specified in the Restoration Plan.

High planted stem densities were found for all the vegetation plots at the Rockwell Pastures Site. Stem densities were well above the interim success criteria of 320 stems per acre at the end of Monitoring Year 3. The average stem density (excluding livestakes) across all vegetation plots was 626 stems per acre. Three vegetation problem areas were noted during Monitoring Year 2 activities. These areas consist of sparse vegetation along stream banks and floodplain and one area within the easement. These areas had been sprayed with an herbicide weed killer. These vegetation problem areas will continue to be observed during Monitoring Year 3; however, they create no threat to achieving the vegetation success criteria. The Rockwell Pastures Site is on track to meet the vegetative success criteria as specified in the Restoration Plan.

Both automated HOB0 groundwater gauges met the success criteria for the 2010 growing season. AW1 and AW2 have exceeded the seven percent hydrology success criteria with 9 and 14 percent of the growing season displaying jurisdictional wetland hydrology (saturation within 12 inches of the soil surface). The Rockwell Pastures Site is on track to meet the wetland success criteria as specified in the Restoration Plan.

1. Vegetation Survey Data Tables

Table A.1 CVS Entrytool Metadata

Report Prepared By	George Lankford
Date Prepared	8/3/2010 15:36
database name	Year 1 Rockwell_cvs-eep-entrytool-v2.2.6.mdb
database location	I:\Projects\EBX\2009000800RA\Documents\Monitoring Reports\2010\Vegetation Data
computer name	RAL1403
file size	34770944
DESCRIPTION OF WORKSHEETS IN THIS DOCUMENT-----	
Metadata	Description of database file, the report worksheets, and a summary of project(s) and project data.
Proj, planted	Each project is listed with its PLANTED stems per acre, for each year. This excludes live stakes.
Proj, total stems	Each project is listed with its TOTAL stems per acre, for each year. This includes live stakes, all planted stems, and all natural/volunteer stems.
Plots	List of plots surveyed with location and summary data (live stems, dead stems, missing, etc.).
Vigor	Frequency distribution of vigor classes for stems for all plots.
Vigor by Spp	Frequency distribution of vigor classes listed by species.
Damage	List of most frequent damage classes with number of occurrences and percent of total stems impacted by each.
Damage by Spp	Damage values tallied by type for each species.
Damage by Plot	Damage values tallied by type for each plot.
Planted Stems by Plot and Spp	A matrix of the count of PLANTED living stems of each species for each plot; dead and missing stems are excluded.
PROJECT SUMMARY-----
