OFFICE OF
AIR QUALITY PLANNING
AND STANDARDS

SUBJECT: 2002 Base Year Emission Inventory SIP Planning: 8-hr Ozone, $PM_{2.5}$ and Regional Haze Programs

FROM: for Lydia N. Wegman, Director
Air Quality Strategies and Standards Division

Peter Tsirigotis, Director P Tsirigotis
Emissions, Monitoring, and Analysis Division

TO: Regional Air Division Directors

The EPA anticipates that nonattainment designations for the 8-hour ozone national ambient air quality standards (NAAQS) will occur in 2004, and the designations for the fine particles ($PM_{2.5}$) NAAQS will occur in the 2004-2005 time frame. Within 3-4 years after designations are promulgated, States will need to submit new attainment demonstration State implementation plans (SIPs) for the new NAAQS. A key element in the overall SIP planning process is the need for updated statewide emission inventories. This memorandum identifies 2002 as the anticipated emission inventory (EI) base year for the SIP planning process to address these pollutants. Identifying the base year at this time gives certainty to States, and the selection of 2002 harmonizes dates for other reporting requirements, e.g., EPA's Consolidated Emissions Reporting Rule (CERR) that requires submission of EI every three years; 2002 is one of the required years for such updates.

The Agency encourages States to take early action to reduce emissions of pollutants that cause violations of the NAAQS for ozone (the 8-hour standard) and $PM_{2.5}$, and that cause regional haze. States will be able to take credit for emission reductions that occur after the 2002 base year, including reductions that occur before the deadlines for submission of these SIPs. As a matter of policy, EPA seeks to avoid penalizing States for moving forward early to address these problems. Attached is additional information.

The EPA is aware that some areas have already begun on a voluntary basis to model for purposes of the 8-hour ozone standard. These areas may continue to use modeling from previous base years for each set of meteorological episode conditions for use in their SIP submittals if these studies are still applicable for an attainment demonstration. The 2002 EI, however, needs to be factored into this analysis. For example, the 2002 inventory would be a good choice for use in modeling "current" emissions. As described in the modeling guidance, predictions for the current emissions and predictions for the future year emissions are used in the modeled attainment test[1]. Furthermore, for reasonable further progress (RFP) purposes, the 2002 EI needs to be used as the base year.

Please make this guidance available to the appropriate contacts in your State and local air agencies. Questions on this should be directed to (for ozone) Annie Nikbakht at 919-541-5246 or (for $PM_{2.5}$) Rich Damberg at 919-541-5592.

[1]U.S. EPA, (1999), "*Guidance onthe use of models and other analyses in attainment demonstrations for the 8-hour ozone NAAQS,*" DRAFT, May 1999, Web site: http://www.epa.gov/tnn/scram, under Guidance/Support, file name: O3TEST.

Attachment

Background

The EPA anticipates that designations for the 8-hour ozone NAAQS will occur in 2004, and the designations for the $PM_{2.5}$ NAAQS will occur in the 2004-2005 time frame. The Clean Air Act (CAA) requires States to submit attainment demonstration SIPs for the 8-hour ozone standard within 3 to 4 years (depending on classification), and within 3 years for the $PM_{2.5}$ standard. Therefore, EPA anticipates that SIPs will be due in 2007 or 2008[2] for both NAAQS programs. For regional haze, most States (i.e., those participating in regional planning organizations) will have SIPs due at the same time as $PM_{2.5}$ SIPs. We anticipate that technical analyses in support of these SIPs, such as regional scale air quality modeling, will need to begin no later than the 2004 time frame. Updated statewide emissions inventories will be an important component used in these analyses. In addition, for many of the required SIPs, emissions in upwind States will also be an important input to necessary technical analyses.

For the 8-hour ozone, $PM_{2.5}$, and regional haze program areas, there are statutory and regulatory provisions related to prospective and/or retrospective demonstrations of progress in reducing emissions and/or improving air quality, although the exact provisions differ somewhat across programs. We have considered the statutory and regulatory provisions applicable to each of these program areas, and have concluded that in each case 2002 is an appropriate base year for program requirements related to progress. In addition, there are practical reasons for choosing 2002, as explained below.

Therefore, even though EPA has not developed final rules or guidance for implementation of either the 8-hour ozone NAAQS or the $PM_{2.5}$ NAAQS, EPA believes that 2002 should be the base year inventory for these SIP planning efforts, including for regional haze SIPs. Using the 2002 inventory as the base year will also ensure that the inventory reflects one of the years used for calculating the air quality design values on which designation decisions are based, as well as one of the years in the 2000-2004 period used to establish baseline visibility levels for the regional haze program. Our reasoning is explained in more detail below for each program area.

The year 2002 is also suitable as the principle or one of the principle years used for air quality model validation.

The practical reasons for choosing 2002 have to do with the requirements of the CERR (67 Federal Register 39602), which was finalized on June 10, 2002, and with the schedule of EPA's own work on the National Emissions Inventory. The CERR requires States to submit

---

[2]The EPA is still working on the implementation guidance that will address the extent to which subparts 1 and 2 of the CAA apply for purposes of the 8-hour ozone NAAQS. Subpart 1 provides up to three years after nonattainment designation for States to submit attainment and reasonable further progress (RFP) SIPs, while subpart 2 provides 3 to 4 years, depending on an area's classification, for States to submit those plans.

emissions inventories for all criteria pollutants and their precursors every three years, on a schedule that includes the emissions year 2002. The due date for the 2002 emission inventory is established in the CERR as June 2004. Therefore, each State should have information available some time before this date to develop the in-state emissions inventory needed for technical analyses during 2004. In addition, EPA plans to make its initial version of the 2002 National Emission Inventory (NEI) available to the states by December 2003, based on 2002 data on emissions from electric generating units, preliminary 2002 vehicle miles traveled information from the Federal Highway Administration, and growth and control projections starting with the 1999 NEI for other source types. This preliminary 2002 NEI can be used in 2004 by each State needing emission estimates for upwind States. The EPA's final 2002 NEI, which will merge and augment the state-by-state inventories received in 2004, will be ready by the summer of 2005. Depending on where they are in their work, States may wish to switch to the newer estimates of upwind-states' emissions, and certainly should at least consider how the emission estimates for upwind States have changed.

Alternatively, some regional groupings of States may exchange and merge their 2002 inventories directly, prior to completion of EPA's final 2002 NEI. We will be consulting with multi-state organizations about the 2002 inventory process so that work is not duplicated unnecessarily.

<u>8-hour Ozone NAAQS</u>

Under the 8-hour ozone standard, EPA anticipates that many areas designated nonattainment for the 8-hour ozone NAAQS will need to comply with the rate of progress (ROP) requirement in Subpart 2 of the CAA, which applies to areas classified moderate or above. Any area not subject to the subpart 2 ROP requirement would be subject to the more general requirement under subpart 1 to make RFP. Both ROP and RFP consider progress made from a baseline inventory. As enacted in 1990, Subpart 2 provided that the base-year inventory would be 1990. See, CAA section 182(b)(1)(B). Thus, for 1-hour ozone nonattainment areas classified moderate or higher, ROP reductions for the target of 1996 were considered to be a 15 percent reduction of volatile organic compound (VOC) emissions from the 1990 baseline year. Similarly, for each three-year period following 1996 up to its attainment date, a serious or above nonattainment area was required to achieve an additional 9 percent reduction in VOC emissions.[3] Under the 8-hour ozone standard, EPA anticipates that, consistent with the above discussion, a 2002 base year emission inventory would be used as the baseline from which future target levels of emissions would be calculated. Therefore, any emission reductions that the State initiates after 2002 would be creditable toward the ROP or RFP requirements.

---

[3] The CAA provides that nitrogen oxides (NO) emission reductions may be substituted for VOC emission reductions for these subsequent three-year periods under prescribed circumstances. See CAA section 182(c)(2)(C).

For areas subject to the subpart 2 ROP requirement, section 182(b)(1)(D) places constraints on the use of emission reduction credits from certain pre-1990 programs even though those programs might achieve additional reductions in the years following 1990, i.e., the federal motor vehicle emission control program, Reid Vapor Pressure programs, corrections required to pre-existing reasonably available control technology (RACT) rules, and inspection and maintenance (I/M) program corrections. While these limitations would still apply for purposes of credit for SIPs designed to meet the 8-hour ozone NAAQS, EPA does not believe it is legally required and does not plan to expand the list of programs for which credit is precluded. Subpart 1 does not establish any limits on the creditability of measures for purposes of RFP and EPA does not anticipate establishing any regulatory limits on the creditability of emission reductions. Thus, EPA does not anticipate establishing any additional constraints on crediting emission reductions achieved in years following the 2002 base year. Therefore, apart from those programs listed in the CAA, we believe that States can take credit for other emission reductions that occur after the 2002 base year.

$PM_{2.5}$ NAAQS

The EPA anticipates that States will be required to implement the $PM_{2.5}$ NAAQS under Subpart 1 since the more specific provisions in Subpart 4 that address particulate matter expressly apply only to PM_{10}. As provided above, Subpart 1 does not place limits on the types of controls that are creditable for purposes of the RFP requirement. As with the 8-hour ozone NAAQS, EPA does not anticipate establishing any regulatory constraints limiting creditability of emission controls. Subpart 1 generally calls for States to submit plans including emission reduction measures designed to attain the NAAQS within 3 years after a nonattainment designation. It also includes a reasonable further progress (RFP) requirement, but does not have a specific percent reduction requirement as there is in the ROP requirement of Subpart 2. The exact form of the RFP requirement for $PM_{2.5}$ has yet to be established, but it is expected that any emission reductions that occur after the base year of 2002 would be credited toward the emission reductions needed by the State under its attainment demonstration and toward the reductions needed to meet the RFP requirement.

Regional Haze Program

The regional haze program calls for States participating in regional planning organizations to submit SIPs in 2007-8 that contain progress goals for every class I area and emission reductions strategies needed to meet these goals. Progress in improving visibility is tracked from baseline conditions (established using air quality monitoring for the 2000-2004 period). If 2002 is used as the base year for planning purposes, then States can take credit for emission reductions that are achieved before the 2007-2008 SIP due date.

Credits in General

It should be noted that EPA cannot provide "double credit" for an emission reduction for purposes of RFP or ROP. For instance, if a program or rule results in emission reductions prior to or in the base year, those reductions would be considered in calculating the base year emissions inventory and thus could not be counted as emission reductions from the base-year level. Such reductions would likely lower ambient pollutant concentrations, however, and would be important in terms of determining an area's designation and, if designated nonattainment, could affect the area's classification and thus its planning obligations. For example, emission reductions in NOx or VOC achieved prior to or during 2002 could have already resulted in the area having a lower ozone design value, which is the measure of whether the area is violating the 8-hour ozone standard and, if so, by how much. Reductions from such measures in years beyond the base year would be creditable towards ROP SIPs. These concepts of credit were discussed in the January 29, 2001, memorandum from John Seitz entitled "Near-Term Discretionary Emission Reductions for Ozone NAAQS–Clarification," which addressed the 1-hour ozone standard, but which are also conceptually applicable to implementation of the 8-hour ozone standard.

However, post-2002 emission reductions that benefit ozone, PM2.5 and regional haze can be credited toward the RFP requirements for each of these programs.

MEMORANDUM

OFFICE OF
AIR AND RADIATION

SUBJECT: Designations for the Fine Particle National Ambient Air Quality Standards

FROM: Jeffrey R. Holmstead
Assistant Administrator

TO: Regional Administrators, Regions I-X

This memorandum provides guidance to State and local air pollution control agencies and Tribes on the process for designating areas for the purpose of implementing the fine particle national ambient air quality standards. The EPA plans to issue final designations on December 15, 2004. This memorandum describes the process for developing State and Tribal recommendations on designations and the time line for EPA action leading to the final designations.

The EPA promulgated the air quality standards for fine particulate matter (known as $PM_{2.5}$) on July 18, 1997 (62 Federal Register 38652). The standards were based on a number of health studies showing that increased exposure to $PM_{2.5}$ is correlated with increased mortality and a range of serious health effects, including aggravation of lung disease, asthma attacks, and heart problems. Estimates show that attainment of these standards would result in tens of thousands fewer premature deaths each year and would prevent tens of thousands of hospital admissions and millions of work absences and respiratory illnesses in children annually. The designation process for $PM_{2.5}$ that is outlined below is the next step toward developing and implementing emission control programs that will address this important public health problem.

The first step in the designation process is the submittal of State and Tribal recommendations. The EPA requests that States and Tribes provide a list of recommended designations to EPA by February 15, 2004. The EPA plans to announce its intended designations in July 2004 and will provide 120 days for States and Tribes to comment on any modifications that EPA makes to the recommended designations. We plan to publish final $PM_{2.5}$ designations for all areas on December 15, 2004. We also intend to propose and finalize its implementation rule for $PM_{2.5}$ early enough to be taken into consideration during the designation process. The EPA hopes that by following a designation schedule for $PM_{2.5}$ similar to that for the 8-hour ozone program, the States and Tribes will be able to harmonize area boundaries and future control strategies to the extent possible.

As explained in this guidance, we intend to apply a presumption that the boundaries for urban nonattainment areas should be based on Metropolitan Area boundaries. A metropolitan area, as defined by the Office of Management and Budget, may consist of a single Metropolitan Statistical Area in some cases, and a Consolidated Metropolitan Statistical Area in other cases. These metropolitan areas provide presumptive boundaries for the geographic extent of urban areas. The presumptive use of metropolitan area boundaries to define urban nonattainment areas is based on recent evidence that violations of the $PM_{2.5}$ air quality standards generally include a significant urban-scale contribution as well as a significant larger-scale regional contribution. For rural areas that are identified as violating the $PM_{2.5}$ standards, the guidance sets forth EPA's presumption that the full county should be designated nonattainment. The approach taken in this guidance is similar to our approach to designations for the 8-hour ozone standard, and we urge States and Tribes to harmonize their ozone and $PM_{2.5}$ designation recommendations where appropriate.

Two attachments provide additional information and guidance. Attachment 1 is a time line of important dates in the fine particle NAAQS implementation process. Attachment 2 is a series of questions and answers providing more detailed guidance, including discussion of several factors to be considered in evaluating whether modifications to nonattainment area boundaries are appropriate.

This memorandum provides EPA's current views on how boundaries should be determined for designations. This guidance is not binding on States, Tribes, the public, or EPA. Issues concerning nonattainment area boundaries will be addressed in actions to designate nonattainment and attainment/unclassifiable areas under section 107 and section 301(d) of the Clean Air Act (Act). When EPA promulgates designations, that action will be final and binding on States, Tribes, the public, and EPA as a matter of law.

Staff in EPA's regional offices and the Office of Air Quality Planning and Standards are available for assistance and consultation throughout the designation process. Questions on this guidance may be directed to Tom Rosendahl at 919-541-5314 or Rich Damberg at 919-541-5592. The Regional Offices should make this guidance available to their States and Tribes and work closely with them to ensure they submit their area recommendations and supporting information by February 15, 2004.

ATTACHMENT 1

TIME LINE FOR $PM_{2.5}$ NAAQS IMPLEMENTATION PROGRAM	
Date	**Item**
September 2003	EPA issues proposed $PM_{2.5}$ implementation rule
February 15, 2004	State and Tribal recommendations due for $PM_{2.5}$ designations - Recommendations can be based on 2000-2002 data
July 2004	EPA notifies States and Tribes concerning any modifications to their recommendations.
September 2004	EPA issues final $PM_{2.5}$ implementation rule
December 15, 2004	EPA issues final $PM_{2.5}$ designations.
December 2007	State implementation plans are due for $PM_{2.5}$ nonattainment areas (3 years after designation date).
December 2009-2014	Date for attaining $PM_{2.5}$ standards (5 years after designation date). - An extension of up to five years is possible with an adequate demonstration.

ATTACHMENT 2

GUIDANCE ON NONATTAINMENT AREA DESIGNATIONS FOR $PM_{2.5}$

1. What are the underlying requirements for designating areas for the $PM_{2.5}$ NAAQS?

Requirements for area designations are found in section 107 of the Clean Air Act (Act). Upon promulgation of a new or revised national ambient air quality standard (NAAQS)[1], States are required under section 107(d) of the Act to submit to EPA a recommended list of areas for designation as attainment, nonattainment, or unclassifiable. While the language of Section 107 specifically addresses States, EPA will follow the same process for Tribes to the extent practicable, pursuant to Sections 110(o) and 301(d) of the Act and the Tribal Authority Rule, or TAR.[2]

Section 107(d) specifies that nonattainment areas shall include "any area that does not meet (or that contributes to ambient air quality in a nearby area that does not meet) the national primary or secondary ambient air quality standard for the pollutant." Interpretation of this requirement is a key purpose of this guidance.

Section 107 further specifies a timetable for action on designations. Under section 107(d)(1), States are to submit recommendations within one year after promulgation of a new or revised standard. Under section 107(d)(1)(B)(ii), if EPA intends to promulgate a designation that deviates from the State recommendation, it must notify the State at least 120 days before promulgating the modified designation, and EPA must provide the State the opportunity to comment on the potential modification. EPA should promulgate designations within two years after promulgation of a new or revised standard, with a possible one year extension if EPA has insufficient information.

The Transportation Equity Act for the 21st Century (TEA-21) of 1998 amended the timetable for $PM_{2.5}$ designations, based on the recognition that the monitoring network first needed to be deployed to collect sufficient monitoring data to designate areas. Under section 6102(c)(1) of TEA-21, States are required to submit recommended area designations to EPA within 1 year after receipt of 3 years of air quality monitoring data obtained with federal reference (or equivalent) monitoring methods. Section 6102(d) requires EPA to promulgate designations within 1 year after State recommendations are due, but no later than December 31, 2005. Although the TAR provides Tribes with flexibility in meeting the schedules set forth in

---

[1] EPA promulgated the NAAQS for $PM_{2.5}$ on July 18, 1997. See 62 Federal Register 38652. The annual standard for $PM_{2.5}$ was set at a level of 15 $\mu g/m^3$, based on the 3-year average of annual arithmetic mean $PM_{2.5}$ concentrations. The 24-hour standard was set at a level of 65 $\mu g/m^3$, based on the 3-year average of the 98th percentile of 24-hour $PM_{2.5}$ concentrations.

[2] The "Tribal Authority Rule," promulgated on February 12, 1998, specifies that Tribes shall be treated as States in selected cases as appropriate. See 63 FR 7254, codified at 40 Code of Federal Regulations (CFR) Part 49 (1998).

the Act, EPA has the obligation to designate areas consistent with the schedules in the Act. Therefore, EPA will designate Tribal areas, in consultation with the Tribes, on the same schedule as State designations. State implementation plans designed to meet the standards are then due within three years of the date of designation (e.g. December 2007) in accordance with section 172 of the Act.

2. What are the key milestones of the $PM_{2.5}$ designations process?

The milestones of the $PM_{2.5}$ designation process are listed in Attachment 1. In developing these milestones, we considered that implementation of the TEA-21 schedule for designations could be complicated by the variety of dates on which various locations first have 3 years of data available. Some sites had 3 years of data available as of July 2002, other sites did not have 3 years of data until later in 2002, and some sites will not have 3 years of data until July 2003. This approach could result in designations occurring between July 2004 and July 2005. EPA believes that a staggered designation schedule, which would yield staggered implementation plan deadlines, would hamper the regional and metropolitan area-based coordination that is needed among various governments and stakeholders. Therefore, this guidance contains single dates for State/Tribal recommendations and final designations by EPA.

EPA requests that all State and Tribal recommendations be submitted by February 15, 2004. Consistent with TEA-21 time frames, EPA plans to designate all areas by December 15, 2004. States and Tribes will be able to use the 2000-2002 data in their recommendations. Areas should be identified as "nonattainment" (violating a standard or contributing to nearby violations), or as "attainment/unclassifiable" (either meeting the standard or having insufficient data to determine air quality, and not contributing to nearby nonattainment). EPA intends to promulgate area designations in terms of these two categories. State recommendations do not apply to Indian country.

After EPA evaluates the recommendations it receives, EPA will notify States and Tribes of any modifications it intends to make to their recommendations at least 120 days before the designations are to be finalized.[3] If a State or Tribe disagrees with any change, it may provide information to EPA to demonstrate why it believes that the proposed modification is inappropriate, and EPA will consider this information in developing the final list of area designations. In their comments, States and Tribes may take into account the 2001 to 2003 monitoring data, which EPA expects to be available before comments are due. As noted above, EPA's policy is to use the most recent three years of data available at the time of designations.

---

[3]EPA's legal obligation to provide 120 days notice of modifications applies only to those Tribes that have sought and received formal authority to recommend designations pursuant to the Tribal Authority Rule. However, EPA is soliciting Tribal recommendations and intends to provide 120 days notice of any modifications irrespective of whether a Tribe has this formal authority.

EPA plans to promulgate final designations on December 15, 2004 and intends to consider the 2001 to 2003 data in making these designations.

The EPA is committed to ensuring that all stakeholders have an opportunity to participate in the designation process for the $PM_{2.5}$ NAAQS, and that State, local and Tribal officials have ample time to comply with obligations that are triggered by designations. States and Tribes are encouraged to involve their stakeholders in developing their recommendations. Regional Offices should work with States and Tribes, particularly for areas where a monitor is recording a violation of the $PM_{2.5}$ standards. If a State or Tribe does not provide any designation recommendations for specific areas, EPA will promulgate the designations it deems appropriate.

3. How are violations identified?

The first step in defining nonattainment areas is to identify monitoring sites at which air quality does not meet either the annual or 24 hour standard for $PM_{2.5}$. Appendix N to 40 CFR Part 50 specifies the procedures to be used to analyze whether air quality at any site meets the air quality standards. Procedures associated with data handling and calculations for comparing data to the $PM_{2.5}$ standards are described in more detail in the "Guideline on Data Handling Conventions for the PM NAAQS" (EPA-454/R-99-008, 1999). The EPA's designation of areas will be based on the most recent 3 consecutive calendar years of air quality data from Federal reference or equivalent method monitors. Data used must be quality-assured and meet 40 CFR part 58 requirements (e.g., for monitor siting).

Many areas collect additional data on particulate matter composition using the Interagency Monitoring for Protecting Visual Environments (IMPROVE) protocol or using methods of the speciation trends network. These methods are not Federal reference methods or equivalent methods, and data collected according to these methods should not be used to determine the existence of a violation. However, as noted in 40 CFR 58 (Appendix C, section 2.9) with respect to IMPROVE protocol monitors, these methods may be used to estimate background concentrations and thus may be used to assess the geographic extent of the area contributing to a nonattainment situation.

The air quality standards for $PM_{2.5}$ specify two exceptional circumstances in which concentrations above the level of the standard are not to be interpreted as violating the standard. The first exception is that sites that monitor source-oriented hot spots in some cases should be assessed only with respect to the 24-hour standard, not the annual average standard. In 40 CFR Part 58 (Appendix D, section 2.8.1.2.3), EPA states that monitoring sites representing unique localized conditions not found elsewhere in the area should not be compared with the annual average standard. For sites that States or Tribes have designated as hot-spot sites, EPA must review whether available evidence confirms that the annual average concentrations at the site are in fact unrepresentative of conditions elsewhere in the region. If so, data from the site will not be compared against the annual standard, but it will be compared against the 24-hour standard.

The second exception arises when the option of spatial averaging is applied, which may result in a group of monitors collectively indicating attainment of the annual average standard, even though individual monitors in the group may show average concentrations which do not meet the standard. Conversely, spatial averaging could indicate nonattainment for the area even though some monitors show concentrations which meet the standard. Appendix N of 40 CFR Part 50 offers the option of applying spatial averaging in the analysis for the annual average standard. For a State or Tribe to apply spatial averaging, it must have previously designated $PM_{2.5}$ monitors for spatial averaging as an element of its $PM_{2.5}$ monitoring plan, and it must have provided a suitable opportunity for the public to comment on this intent.[4]

Monitors with data to be averaged must satisfy detailed criteria given in 40 CFR Part 58 (Appendix D, section 2.8.1.6). Sites within an identified area that meet these criteria will be addressed on a spatially averaged basis only if the State or Tribe opts to do so. For monitors that satisfy these criteria, the procedures for averaging the qualifying data are given in Appendix N to 40 CFR Part 50 and the aforementioned data handling guidance. A determination would be made as to whether the spatially averaged annual average meets or does not meet the annual average standard, irrespective of whether concentrations at any individual site meet or do not meet the annual standard.

4. How should boundaries of urban nonattainment areas be determined? Are there presumptive boundaries for nonattainment areas?

As noted above, a nonattainment area must be defined not only to include the area that is violating the standard, but also to include the nearby source areas that contribute to the violation. Thus, a key factor in setting boundaries for nonattainment areas is determining the geographic extent of nearby source areas contributing to the nonattainment problem. For each monitor or group of monitors that exceed a standard, nonattainment boundaries must be set that include a sufficiently large area to include both the area judged to violate the standard and the source areas that contribute to these violations. Evaluations of source areas must account for sources of $PM_{2.5}$ precursors (such as sulfur dioxide, nitrogen oxides, ammonia, and some volatile organic compounds) as well as sources of direct $PM_{2.5}$ emissions.

EPA has examined various evidence addressing the typical geographic scale of source areas that contribute to violations of the $PM_{2.5}$ standard. This evidence indicates substantial contributions to violations of the $PM_{2.5}$ standard both from long-range transport[5] and from the collection of urban sources dispersed within metropolitan areas. To assess the metropolitan scale

---

[4] See 40 CFR Part 58.20(f) and 40 CFR Part 58.26(e) for information about public notification and public comment requirements associated with spatial averaging.

[5] See discussion of long-range transport of sulfate and nitrate particles in supporting materials for the Clear Skies Act at http://www.epa.gov/clearskies/.

contribution, EPA examined the geographic distribution of total $PM_{2.5}$ concentrations in and near many metropolitan areas. EPA found an association of higher $PM_{2.5}$ concentrations with greater levels of urban activity. Comparisons of rural versus urban concentrations of the components of $PM_{2.5}$ indicate that certain components (such as carbonaceous particles and nitrates) resulting in part from urban emissions are found in significantly higher concentrations in urban areas.[6] These "urban emissions" arise from human activities, such as motor vehicle use and home heating as well as industrial activities, that occur with greater density in more populated areas.

The metropolitan area, as delineated by the Office of Management and Budget (OMB), provides a presumptive definition of the populated area associated with a core urban area.[7] Accordingly, EPA believes that the metropolitan area provides a presumptive definition of the source area that contributes to a $PM_{2.5}$ nonattainment problem. For this reason, EPA believes that the Metropolitan Area should serve as the presumptive boundary for urban $PM_{2.5}$ NAAQS nonattainment areas. This presumption reflects EPA's view that, in the absence of evidence to the contrary, violations of the $PM_{2.5}$ NAAQS in urban areas may be presumed attributable at least in part to contributions from sources distributed throughout the Metropolitan Area. This approach parallels the presumptive metropolitan area boundaries established in the 1990 Amendments to the CAA for certain ozone nonattainment areas.

"Metropolitan areas" are defined by the Office of Management and Budget based on data collected by the U.S. Bureau of the Census. In each case, a metropolitan area includes a core urban area plus the full set of associated nearby communities. These areas in some cases include a single Metropolitan Statistical Area (MSA) that is not associated with and is typically not contiguous with any other MSA, and in other cases include multiple contiguous Primary Metropolitan Statistical Areas (PMSA) which collectively form a Consolidated Metropolitan Statistical Area. In Metropolitan Areas consisting of a single MSA, EPA presumes the entire MSA should be designated as nonattainment. In Metropolitan Areas consisting of multiple PMSA's which collectively form a Consolidated Metropolitan Statistical Area, EPA presumes the entire Consolidated Metropolitan Statistical Area should be designated nonattainment.

EPA anticipates that OMB will publish revised metropolitan area lists later in 2003. Unfortunately, this publication may not occur early enough for States and Tribes to consider the revised lists in the development of recommended designations for $PM_{2.5}$. Furthermore, EPA seeks to maximize consistency between designations for $PM_{2.5}$ and designations for the 8-hour ozone standard. The earlier timetable for ozone designations makes it even less likely that revised metropolitan area lists will be available for State and Tribal consideration in recommending

---

[6] V. Rao, N. Frank, A. Rush, F. Dimmick, "Chemical Speciation of $PM_{2.5}$ in Urban and Rural Areas", in the Proceedings of the Air & Waste Management Association Symposium on Air Quality Measurement Methods and Technology, San Francisco, November 13-15, 2002.

[7] For further information on the definitions of metropolitan areas, see: http://www.census.gov/population/www/estimates/metroarea.html.

ozone designations. Therefore, EPA anticipates relying on the current metropolitan area definitions, published by OMB on June 30, 1999, in establishing presumptive nonattainment area boundaries.

EPA will consider State, local, and Tribal recommendations of nonattainment area boundaries that deviate from metropolitan area boundaries based on various factors. These factors are discussed in question 5 below. Consideration of these factors may warrant a nonattainment area that has additions and/or deletions relative to OMB's defined metropolitan area.

Boundaries used for implementation of the 8-hour ozone standard may also be an important factor in determining boundaries for $PM_{2.5}$ nonattainment areas. Indeed, there are many areas that violate both the 8-hour ozone and the $PM_{2.5}$ standards, and States and Tribes may wish the nonattainment boundaries for the two pollutants to be identical in order to coordinate air quality planning, control strategy development, and the implementation of the transportation conformity program.

We recognize that, unlike ozone nonattainment problems, there are situations where nonattainment of the $PM_{2.5}$ NAAQS can arise on a very localized basis. For example, violations can be caused by the emissions from a single major source or set of sources, in some cases exacerbated by severely restricted atmospheric dispersion (such as a narrow mountain valley). In such cases, the State or Tribe should further investigate the causes of the violation and the geographic extent of the violation. The recommended boundaries of the nonattainment area should then reflect a case-specific judgment of the area sufficient to include the areas violating the $PM_{2.5}$ NAAQS plus any additional source areas contributing to the violation. The State or Tribe will need to provide an adequate justification demonstrating that a smaller area would include the full area that is violating the standards and all nearby source areas that contribute to the violation. EPA expects there to be a limited number of situations of this type.

5. What factors will EPA consider as the basis for a State or Tribal request for an alternative urban area definition?

In some cases, a State or Tribe may find that a violation of the $PM_{2.5}$ standard is attributed to a significant metropolitan-scale component and yet believe that the Metropolitan Area does not appropriately define the area that should be designated nonattainment. EPA will consider requests for urban nonattainment area definitions that deviate from OMB's metropolitan area definitions on a case-by-case basis, considering the factors described below. These factors resemble the factors identified in previous EPA guidance on 8-hour ozone nonattainment boundaries, though EPA will make its decisions based on the distribution of sources contributing to $PM_{2.5}$ concentrations. EPA will apply these same factors in evaluating boundary modifications for both States and Tribes. $PM_{2.5}$ is a regional pollutant, and sources of $PM_{2.5}$ and its precursors are numerous and located over a broad area. For this reason, EPA believes it would be unlikely that we would designate any area as attainment that is surrounded on all sides by nonattainment areas.

EPA will consider the following factors in assessing whether to exclude portions of a metropolitan area and whether to include additional nearby areas outside the metropolitan area as part of the designated nonattainment area:

- Emissions in areas potentially included versus excluded from the nonattainment area
- Air quality in potentially included versus excluded areas
- Population density and degree of urbanization including commercial development in included versus excluded areas
- Traffic and commuting patterns
- Expected growth (including extent, pattern and rate of growth)
- Meteorology (weather/transport patterns)
- Geography/topography (mountain ranges or other air basin boundaries)
- Jurisdictional boundaries (e.g., counties, air districts, Reservations, etc.)
- Level of control of emission sources

Analyses of these factors may suggest nonattainment boundaries that are either larger or smaller than the metropolitan area. A demonstration supporting the designation of boundaries that are less than the full metropolitan area must show both that violations are not occurring in the excluded portions of the metropolitan area and that the excluded portions are not source areas that contribute to the observed violations. A State or Tribal submittal that only addresses whether violations are occurring throughout the area will not suffice as a justification for designating a nonattainment area smaller than the metropolitan area. States and Tribes are encouraged to justify such recommendations by addressing all of the factors identified above. Recommendations to designate a nonattainment area larger than the metropolitan area should also be based on an analysis of these factors. EPA will consider these factors in evaluating State and Tribal recommendations and assessing whether any modifications are appropriate.

Air quality dispersion modeling and data interpolation techniques can be useful tools to help assess how air quality in unmonitored areas compares to air quality at monitoring sites. Accordingly, these tools can help assess the geographic area violating and/or contributing to a violation of the standards. EPA and others are undertaking various efforts to improve the reliability of these tools. In determining whether an analysis appropriately justifies modified nonattainment area boundaries, EPA will give particular consideration to the reliability of the relevant modeling or interpolation technique.

6. How should designation recommendations, including boundaries, be addressed when more than one State or Tribe might be affected?

Where more than one State or Tribe is involved in an area, close coordination is needed among the affected States and Tribes prior to the time the recommendation is made. In addition, the EPA Regional Office should coordinate where an area may be located in States or tribal lands located in two or more regions. There is a strong presumption that interstate areas making up one metropolitan area will be designated as one nonattainment area. The EPA strongly encourages States and Tribes involved in multi-jurisdictional areas to make consistent and coordinated boundary recommendations.

7. How will EPA address rural areas?

Previous questions have addressed urban areas, presumptively defined as metropolitan areas surrounding core cities, with potential boundary adjustments based on a variety of factors. This question addresses rural areas, defined here to mean counties or areas not included in or adjacent to such urban areas. An area found to violate the standard that is adjacent to a metropolitan area will generally be designated as part of that urban nonattainment area and would not be treated as rural for purposes of this guidance.

As with urban areas, the first step in determining attainment status for rural areas is to evaluate available air quality data measured by Federal reference method monitors. The second step is to assess the boundaries of the airsheds represented by the rural monitors and determine the source areas contributing to air quality at these monitors. For cases in which rural data indicate nonattainment, the nonattainment area again must be sufficient to include the full area that is violating the standards as well as any nearby source areas that are contributing to the violation.

When a rural monitor violates the standard, EPA intends to apply a presumption that the nonattainment area shall include the full county in which the monitor is located. EPA will consider recommendations to adjust rural area nonattainment boundaries based on the same factors as it applies to urban areas, as discussed in question 5 above. Using these factors, a State or Tribe that recommends that a smaller area should be designated nonattainment should provide convincing evidence that the monitor is not representative of the full county, that the excluded portions of the county are not source areas contributing to the nonattainment, and that the excluded portions of the county are meeting the standard. Similarly, a State or Tribe may recommend that a larger area be designated nonattainment based on technical information relevant to these factors. Nevertheless, as discussed above, if nonattainment is demonstrably very localized and is attributable to localized sources, EPA intends to establish nonattainment area boundaries based on a case-specific evaluation of the nature and extent of the problem.

8. What additional documentation should a State or Tribal government submit concerning the nonattainment area recommendations?

In addition to technical information documenting the recommendation for area boundaries noted in question number 5 above, the EPA is requesting that each State or Tribe in its submission provide certain air quality data and geographic information to support its nonattainment area recommendation. The EPA is asking for the following information:

For nonattainment areas:

a. $PM_{2.5}$ design value for the area.
b. Three year period represented by the design value, e.g., 2000-2002
c. Design value monitoring site location(s) and identification number(s).

For attainment/unclassifiable AND nonattainment areas:

d. Names of counties and tribal lands included, and
e. If partial counties or portions of tribal lands are included, the boundary definition/description as outlined below.

If the recommended nonattainment area boundary is smaller than the metropolitan area definition, the State or Tribe should document its rationale for selecting the nonattainment area boundary. The documentation should address how all the factors discussed in question number 5 (such as population, traffic and commuting patterns, commercial development, projected growth, prevailing meteorology, nearby sources and air quality, and any other relevant or technical justification factors) affect the drawing of boundaries for each county or other sub-area not included in the recommended nonattainment area. In particular, where the recommended area boundary consists of parts of counties, metropolitan areas, or tribal lands, the State or Tribe must provide a technical analysis for its recommendation, explaining how the boundary is consistent with §107 (d)(1) of the Act.

If the recommendation includes any partial counties, the EPA is requesting a legal definition of the area, a detailed hard copy map, and, because EPA plans to map each area, a digitized latitude and longitude description. The submittal should include the names of contacts for this information.

The EPA envisions making information on designation recommendations available electronically. Therefore, EPA requests that each State submit its designation recommendations, supporting documentation, and boundary information and associated maps to EPA in both a detailed written form and in electronic form.

9. How is EPA addressing Tribal concerns about the designations process?

Tribes are encouraged, but not required, to submit designation recommendations for their reservations or other areas under their jurisdiction to EPA. The TAR offers flexibility to Tribes for specific plan submittal and implementation deadlines for NAAQS-related requirements, including but not limited to such deadlines in CAA sections 110(a)(1), 172(a)(2), 182, 187, 189, and 191. However, EPA is required by the Act to promulgate area designations according to a timetable. Therefore, if a Tribe wishes to participate in the designation process they must submit a recommendation in time for EPA to consider that recommendation when making a designation. In cases where Tribes do not make a recommendation, the EPA, upon consultation with the respective Tribe(s), will promulgate the designation it deems appropriate.

EPA has discussed designation issues with many Tribal representatives and we recognize that there are several issues of particular concern to Tribes. Some Tribes have expressed concern that where a violation is monitored in a metropolitan area that includes tribal lands, the tribal lands presumptively should not be part of the urban nonattainment area, because the tribal lands often are not politically and economically integrated with the urban area. EPA will address this concern on a case-by-case basis. Upon request, EPA will help any Tribe obtain relevant information addressing the factors described under question 5 above. As with State lands, EPA will use this information to help judge whether the tribal lands are meeting the air quality standards and whether the tribal lands are a source area contributing to nonattainment in the metropolitan area. EPA will designate the tribal lands based on this information.

Some Tribes have expressed concern about the use of monitors located on State lands to establish designations for tribal lands. Given EPA's obligation to promulgate designations for all locations, EPA by necessity must judge the air quality of unmonitored locations on the basis of monitoring data from other locations. Where a monitor indicates a violation of an air quality standard, EPA will designate a nonattainment area that includes unmonitored areas either that EPA judges also to be violating the standard or that EPA judges to be a nearby source area contributing to the nonattainment. Some Tribes have also raised concerns with the designation process that they may not have the resources to do the detailed analysis necessary to prepare their recommendations. EPA offers to work with Tribes on their recommendations upon request.

MEMORANDUM

SUBJECT: Additional Guidance On Defining Area Boundaries for PM-2.5 Designations

FROM: Lydia N. Wegman, Director
Air Quality Strategies and Standards Division (C504-01)

TO: Air Division Directors, Regions I-X

This memorandum provides additional guidance for determining boundaries of PM-2.5 areas in the PM-2.5 designations process. Our April 2003 boundary guidance establishes the metropolitan area (i.e. the larger of the Consolidated Metropolitan Statistical Area (CMSA) or Metropolitan Statistical Area (MSA)) as the presumptive boundary for PM-2.5 nonattainment areas[1]. The boundaries of CMSAs and MSAs, which were delineated by the Office of Management and Budget (OMB) in 1999, include populated areas associated with core urban areas. Our April 2003 guidance recognized that OMB planned to publish revised urban area definitions sometime in 2003, but, because the specific release date was not known at that time, the guidance stated that the Environmental Protection Agency (EPA) anticipated using the 1999 definitions for the PM-2.5 designation process.

OMB subsequently issued revised urban area definitions on June 6, 2003. The definitions established core-based statistical areas (CBSAs) (or CBSAs, comprised of "metropolitan" and "micropolitan" areas), and combined statistical areas (CSAs) (or CSAs, comprised of two or more core-based statistical areas)[2]. While we are not requiring States and Tribes to use the recently-defined CSA and CBSA as the presumptive boundaries for determining PM-2.5 nonattainment areas, we ask that in your review of State and Tribal recommendations that you assess all counties included in any relevant CSA or CBSA under the 2003 definitions, as well as
any adjacent counties, using the 9 factors identified in the April 1, 2003 guidance. We believe this approach is appropriate because the new OMB definitions group together counties having a

[1] Memorandum from Jeffrey R. Holmstead, Assistant Administrator, to EPA Regional Administrators, "Designations for the Fine Particle National Ambient Air Quality Standards," April 1, 2003.

[2] A list of the 2003 OMB metropolitan area definitions and associated information may be found at: http://www.census.gov/population/www/estimates/metroarea.html.

high degree of social and economic integration with a central core area, reflecting the latest technical information available about significant growth and commuting rates. While EPA is not requiring that States use the 2003 OMB boundary definitions as the presumptive boundaries, please ask that your respective States and Tribes fully document the basis for their recommendations, using the 9 factors identified in the April 2003 guidance.

All other information contained in the April boundary guidance continues to apply, and States and Tribes should continue to follow the guidance in making the boundary recommendations by February 15, 2004, as required in our guidance and the Consolidated Appropriations Bill for FY-2004.[3] In addition, as we requested in the April 2003 guidance we encourage States and Tribes to make every effort to process the 4th quarter 2003 air quality data as quickly as possible so it can be taken into account in the February recommendations. Also, stated in the April 2003 guidance, EPA will make available on our website information submitted in connection with designation recommendations. Therefore, we request that each State and Tribe submit to EPA its designation recommendations, description of the proposed area boundaries, associated maps, and other supporting documentation in electronic format as well as in a hard-copy format.

The Regional Offices should share this additional guidance with States and Tribes and work closely with them to resolve any issues related to the submittal of their area recommendations and supporting information. Staff in OAQPS are available to provide assistance and consultation throughout the designation process. Questions related to this memorandum may be directed to Larry Wallace of my staff at 919-541-0906 or Rich Damberg at 919-541-5592.

RE: Recommendations for $PM_{2.5}$ Non-attainment Designations

Dear Mr. Palmer:

Pursuant to the requirements of the federal Clean Air Act and on behalf of Governor Michael F. Easley, I am submitting to you and your colleagues at EPA the State of North Carolina's recommendations for $PM_{2.5}$ designations.

The attached table presents North Carolina's recommendations for the designation status of each county within the State. These recommendations are based on the most recent three years of data (2001-2003). During this period, violations of the $PM_{2.5}$ standard occurred at only two monitors within the State. There is one violating monitor each in Davidson and Catawba counties.

Davidson County is located in the Greensboro-Winston-Salem-High Point metropolitan statistical area (MSA). All other monitors within the MSA have measured attainment of the standard, thus we recommend that only Davidson County be designated non-attainment.

Catawba County is located in the Unifour MSA. To be consistent with our 8-hour ozone designation, we are recommending that only the MPO planning boundary of Catawba County be designated non-attainment. The MPO planning boundary within this county captures eighty percent of the population. The remainder of the county is rural with an average township population density ranging from less than 100 to just over 200 persons/square mile. A more detailed technical discussion of the $PM_{2.5}$ boundary recommendations from our Division of Air Quality (DAQ) Director, Keith Overcash, will follow this letter by February 20, 2004.

With respect to these two counties, our $PM_{2.5}$ boundary recommendations are the same as our recommendations for 8-hour ozone boundaries. Also, as we did with the 8-hour ozone recommendations, we followed EPA's published guidance concerning the circumstances under which States may vary from the presumptive MSA boundary. Before the guidance was published, EPA accepted and approved in 1990 an approach that had partial MSA's and partial

1601 Mail Service Center, Raleigh, North Carolina 27699-1601
Phone: 919-733-4984 / FAX 919-715-3060 / Internet: www.enr.state.nc.us/ENR/

counties for the one-hour ozone designations.

As I stated in my February 6, 2004 8-hr ozone boundary recommendation letter, I believe that the presumptive use of MSA boundaries in a case like this fails to take into account the fact that MSAs are established for statistical data purposes which are different from air pollution control concerns. In the December 27, 2000 Federal Register notice, the Office of Management and Budget states:

> "In order to preserve the integrity of its decision making with respect to reviewing and revising the standards for designating areas, OMB believes that it should not attempt to take into account or anticipate any public or private sector non-statistical uses that may be made of the definitions. It cautions that Metropolitan Statistical Area and Micropolitan Statistical Area definitions should not be used to develop and implement Federal, state and local nonstatistical programs and policies without full consideration of the effects of using these definitions for such purposes."

An example of an air quality designation consequence that goes well beyond merely a "statistical" data purpose is the requirement that new or modified major sources of pollution must install the "lowest achievable emission rate" (LAER) level of control and must offset all emissions increases upon designation of non-attainment.

North Carolina is committed to conserving and protecting our natural resources and maintaining a high quality environment for the health, well-being and benefit of all. We believe that improving air quality is critical to the health of our citizens and that our future growth, prosperity and quality of life will be threatened if we do not remain diligent. We look forward to continuing to work with EPA and others to attain the $PM_{2.5}$ standard everywhere in North Carolina and to establish appropriate boundaries for $PM_{2.5}$ non-attainment areas.

Sincerely,

Bill

William G. Ross, Jr.

Re: North Carolina $PM_{2.5}$ Nonattainment Boundaries

Dear Administrator Leavitt:

I am writing to express concerns over the Environmental Protection Agency's recent proposal to use an emissions-weighted approach to define $PM_{2.5}$ nonattainment boundaries, which was announced three months after the states had submitted boundary recommendations. This late notice of a new approach is contrary to the spirit of the established nonattainment designation process under which states use their more thorough knowledge of the monitoring network as well as other local and regional circumstances to propose nonattainment boundaries based upon guidance provided by EPA. By departing from its original April 2003 guidance at this late point in the process, EPA is retroactively changing the rules we have followed.

While North Carolina is still reviewing the emissions-weighted approach, we already have concerns with its failure to take into account prevailing wind directions during the calendar quarters in which $PM_{2.5}$ values are higher, as well as its assumption that emissions impact a monitor equally throughout the year, regardless of the monitor's location and its distance from the source.

The most glaring immediate concern, however, is that boundary decisions based on this new approach would ignore the pollution reductions already required by the North Carolina Clean Smokestacks Act. According to staff in EPA Region 4, Rutherford County, which is neither an MSA county nor has a violating monitor, would be included as part of the Hickory nonattainment area simply because there is a power plant located in this largely rural county. There are apparently at least three other counties (Rowan and Rockingham outside the MSA and Stokes within the MSA) that are being considered for inclusion in the Triad nonattainment area for the same reason. This proposal ignores the landmark Clean Smokestacks legislation passed by the North Carolina General Assembly in 2002. What additional controls, other than those already prescribed by the Clean Smokestacks Act, would we as a state or you as EPA impose on these counties? In fact,

1601 Mail Service Center, Raleigh, North Carolina 27699-1601
Phone: 919-733-4984 \ FAX: 919-715-3060 \ Internet: www.enr.state.nc.us/ENR/

the inclusion of these four counties in the nonattainment areas for North Carolina will not result in any change in our strategy to reduce emissions that cause the fine particle exceedances in this state and will only result in tagging the subject counties with the consequences of nonattainment.

In addition, EPA has indicated that two of our counties, Forsyth and Guilford, both with attaining monitors, would be part of the nonattainment area due to the violating monitor in Davidson County. Stokes County would also be named, as would Randolph County because of their weighted emission scores. Again, the emissions-weighted approach is not addressing the attaining ambient data in two of the counties, nor the wind direction during the quarters in which $PM_{2.5}$ values are higher.

I strongly encourage your consideration of these comments before the letters are sent to the States later this month. Please call me at (919) 715-4105 should you wish to discuss this issue further.

Sincerely,

William G. Ross, Jr.

JUN 29 2004

4APT-APB

Honorable Mike F. Easley
Governor of North Carolina
State Capitol
20301 Mail Service Center
Raleigh, NC 27699-0301

Dear Governor Easley:

Fine-particle pollution represents one of the most significant barriers to clean air facing our nation today. These tiny particles – about 1/30th the diameter of a human hair – have been scientifically linked to serious human health problems. Their ability to be suspended in air for long periods of time makes them a public health threat far beyond the source of emissions. An important part of our nation's commitment to clean, healthy air deals with reducing levels of this fine particle or PM2.5 pollution.

In February, your State submitted its recommended boundaries for PM2.5 attainment and nonattainment areas. We have thoroughly reviewed your recommendations and the technical information you have submitted to support your recommendations. We appreciate the effort your State has made to develop this supporting information. Consistent with the Clean Air Act, this letter is to notify you that based on the information contained in your submittal, EPA intends to make modifications to recommended designations and boundaries in your State.

The detailed enclosure contains a description of areas where EPA intends to modify your State recommendations, and the basis for such modification. Should you have additional information that you wish to be considered by EPA in this process, we request that you provide it to us by September 1.

You will hear from us again in November when EPA takes the final step in the PM2.5 designation process and determines those areas that are in attainment and meet the fine particle standards and those areas that do not meet them. For areas in attainment, the challenge will be not only to maintain, but also to continue the progress you have made toward clean air. It is a commitment to no backsliding in your State's clean air status for fine particles. EPA will also issue a proposed fine particle implementation rule prior to final designations, which will allow you to proceed with planning to achieve clean air.

The Bush Administration is addressing fine particle pollution with a comprehensive national clean air strategy. This strategy includes EPA's recent rule to reduce pollution from nonroad diesel engines, and the proposed rule to reduce pollution from power plants in the eastern U.S. These two rules are important components of EPA's efforts to help States and localities meet the more protective national fine-particle and 8-hour ozone air quality standards. Together these rules will help all areas of the country achieve cleaner air.

Should you or your staff have any questions, I invite you to contact Beverly H. Banister, Director, Air Pesticides and Toxics Management Division, at 404/562-9077, or Kay T. Prince, Chief, Air Planning Branch, at 404/562-9026. We look forward to a continued dialogue with you as we work together to implement the PM2.5 standards.

Sincerely,

J. I. Palmer, Jr.
Regional Administrator

Enclosure

cc: Keith Overcash, NCDENR

Enclosure for 120 Day Letter
Justification for Modifications to State Recommendations
PM2.5 Nonattainment Areas
State of North Carolina

An Explanation of EPA's 9-Factor Analysis

Factor 1. Emissions in areas potentially included versus excluded from the nonattainment area:

The analysis for factor 1 looks at emissions of carbonaceous particles ("carbon"), inorganic particles ("crustal"), SO2 , and NOx. EPA computed a composite emission score for each county by multiplying the county's emissions as a fraction of the metropolitan area emissions for each of these pollutants times a corresponding air quality weighting factor. The air quality weighting factors for each area are given below and reflect the percentages of the total estimated "urban excess" value found as, respectively, carbonaceous particles, miscellaneous inorganic particles ("crustal material"), ammonium sulfate, and ammonium nitrate. These scores add to 100 for the metropolitan area counties. Composite scores were also calculated for counties adjacent to the metropolitan area. Tables presented under factor 1 present the emissions of carbonaceous particles, inorganic particles, SO2 , and NOx and the composite emission scores for the counties in the corresponding metropolitan area and adjacent counties. Metropolitan area counties are in bold. Emissions data indicate the potential for a county to contribute to observed violations, often making the emissions data the most important factor in assessing boundaries of nonattainment areas.

"Urban excess" values are derived by comparing urban monitored component concentrations against rural monitored component concentrations. Concentrations of the four PM2.5 components are obtained from local data if available (or, if necessary, from the nearest available urban site), and are compared to available rural concentrations. The monitoring sites used for this purpose are identified below. Although this information is air quality information, it is presented under Factor 1 due to its integration into the analysis of emissions information.

Factor 2. Air quality in potentially included versus excluded areas:

The air quality analysis looks at the annual averaged design value for each area based on data for 2001 to 2003. Counties without monitors are not listed.

Factor 3. Population density and degree of urbanization including commercial development in included versus excluded areas:

Tables presented under factor 3 show the 2003 population for each metropolitan area, as well as the population density for each county in that area. Population data indicate the likelihood of population-based emissions that might contribute to violations.

Factor 4. Traffic and commuting patterns:

The traffic and commuting analysis looks at the number of commuters in each county who drive to another county within the metropolitan area ("Number"), the percent of total commuters in each county who commute to other counties within the metropolitan area ("percent"), as well as the total Vehicle Miles Traveled (VMT) for each county in thousands of miles. A county with numerous commuters is generally an integral part of the area, and would be an appropriate part of the domain of some mobile source strategies, thus warranting inclusion in the nonattainment area.*

**Note that the percent of commuters traveling to counties within the metropolitan area is based on the total number of commuters from that county. This total includes commuters who may travel outside the metropolitan area from their county of origin.*

Factor 5. Expected growth:

The expected growth analysis looks at the percent growth for counties in each metropolitan area from 1990 to 2000.

Factor 6. Meteorology:

The meteorology analysis looks at wind data gathered over a ten year period by the National Weather Service. Tables presented under factor 6 list the year round average prevailing wind directions by quadrant for each county in the corresponding metropolitan area. These data show that annual average PM2.5 concentrations are influenced by emissions in any direction at various times, but these data may also suggest that emissions in some directions relative to the violation may be more prone to contribute than emissions in other directions.

Factor 7. Geography/topography:

The geography/topography analysis looks at physical features of the land that might have an effect on the airshed, and therefore, the distribution of particulate matter over an area. The State of North Carolina has no such features that significantly influenced EPA's recommended nonattainment areas.

Factor 8. Jurisdictional boundaries:

The analysis of jurisdictional boundaries looks at the planning and organizational structure of an area to determine if the implementation of controls in a potential nonattainment area can be carried out in a cohesive manner.

Factor 9. Level of control of emission sources:

The level of control analysis looks at what controls are currently implemented in each area.

Below is the nine factor analysis for Greensboro-Winston-Salem-High Point, NC. The Greensboro-Winston-Salem-High Point, NC Metropolitan Statistical Area (MSA) contains the counties of Stokes, Guilford, Davidson, Forsyth, Randolph, Alamance, Yadkin, and Davie.

In February 2004, North Carolina recommended that the entire county of Davidson, be designated as nonattainment for the Fine Particulate Matter Standard. The table below shows the State recommendations and EPA modifications for the Particulate Matter(PM 2.5) nonattainment area in Greensboro-Winston-Salem-High Point, NC. EPA is recommending Davidson County be designated nonattainment because it has a violating PM 2.5 monitor. The MSA counties of Guilford, Stokes, Forsyth and Randolph are also being recommended as nonattaiment. Guilford, Forsyth and Randolph counties are adjacent to Davidson County and have large populations and large emissions. Stokes has significant power plant emissions. EPA agrees that Alamance, Davie, Yadkin, Rowan, Chatham, Rockingham, and Iredell Counties be designated attainment/unclassifiable. Alamance is an MSA county with an attaining monitor of 13.7 micrograms per cubic meter ($\mu g/m^3$), 75 % of the commuters remain in Alamance County and the county has low emissions. Davie and Yadkin are MSA counties that do not contain PM 2.5 monitors, have low populations, and low commuting into Davidson. There is significant distance between the violating monitor and the counties of Iredell and Yadkin. Rowan and Iredell are adjacent to the MSA, do not contain PM 2.5 monitors and are a part of the Charlotte-Gastonia-Rock Hill nonattainment area for ozone. Rowan and Rockingham both have small power plants and there are attaining monitors in counties between the SO_2/NOx sources in Rowan and Rockingham counties and the violating monitor. Chatham is an adjacent county to the Greensboro-Winston-Salem-High Point MSA with an attaining monitor of 12.2 $\mu g/m^3$, has low population, and part of the county is in the Raleigh-Durham-Chapel Hill nonattainment area for ozone. The remaining adjacent counties all have low emissions, low population and low VMT, indicating they should be attainment/unclassifiable.

Area	EPA Recommendation	State Recommendation
Greensboro-Winston-Salem-High Point, NC	**Full Counties:** Stokes, Guilford, Davidson, Forsyth, and Randolph	**Full Counties:** Davidson

The following is a brief summary of the 9 criteria:

The following table has 2001 $PM_{2.5}$, SO_2, NOx, VOC, and Ammonia (Amm) emissions in tons, and weighted emissions scores for the Greensboro-Winston-Salem-High Point Area and surrounding counties. The MSA counties are in **bold**.

		PM 2.5	SO_2	NOx	VOC	Amm	Weighted emissions score	Cumulative Weighted emissions score
NC	**Stokes**	**4,821**	**83,409**	**35,936**	**2,566**	**357**	**32.8**	**32.8**
NC	**Guilford**	**2,418**	**2,833**	**19,068**	**34,464**	**1,178**	**17.6**	**50.4**
NC	**Davidson**	**1,951**	**1,398**	**11,281**	**14,970**	**632**	**12.9**	**63.3**
NC	**Forsyth**	**1,559**	**5,885**	**14,552**	**20,679**	**722**	**11.7**	**75.0**
NC	**Randolph**	**1,370**	**907**	**5,898**	**10,307**	**4,014**	**9.5**	**84.5**
NC	**Alamance**	**1,181**	**749**	**5,618**	**8,967**	**730**	**8.2**	**92.7**
NC	**Yadkin**	**606**	**318**	**2,061**	**2,247**	**896**	**4.0**	**96.7**
NC	**Davie**	**508**	**205**	**1,959**	**3,278**	**448**	**3.3**	**100.0**
NC	Rowan	2,012	12,465	11,681	11,323	726	13.4	
NC	Chatham	1,714	11,605	5,823	4,734	3,012	11.7	
NC	Rockingham	1,555	6,263	12,227	8,770	523	11.2	
NC	Iredell	1,537	1,365	11,065	10,346	2,090	10.8	
NC	Surry	1,224	1,238	5,055	7,478	1,811	8.5	
VA	Pittsylvania	980	1,828	7,490	4,149	581	7.2	
NC	Moore	956	409	3,197	6,519	2,396	6.9	
NC	Wilkes	966	647	2,890	5,097	5,300	6.6	
NC	Orange	857	756	6,264	6,751	572	6.4	
VA	Henry	818	535	3,811	10,517	197	5.6	
NC	Stanly	795	3,129	2,891	4,581	1,460	5.3	
NC	Montgomery	516	484	1,631	4,175	1,246	3.6	
NC	Caswell	483	199	1,071	1,622	155	3.2	
VA	Patrick	408	176	1,039	1,363	214	2.8	
VA	Carroll	378	509	2,305	1,986	441	2.7	
VA	Grayson	291	95	819	952	405	2.0	
NC	Alleghany	217	190	379	590	425	1.4	

Based on the analysis for this factor, there appears to be emissions in Stokes, Guilford, Forsyth, and Randolph counties that contribute to the air quality in Davidson County, resulting in a violating monitor there. This analysis shows that the adjacent counties of Rowan, Chatham, Rockingham, and Iredell have emissions that may contribute to the violation in Davidson County.

However, these counties are more distant from the violating monitor. Chatham County has an attaining monitor and is part of the Raleigh MSA. Rowan and part of Iredell County are in the Charlotte ozone nonattainment area.

Factor 2: Air Quality in potentially included versus excluded areas

		2001-2003 Design Value
NC	**Guilford**	**14.1**
NC	**Davidson**	**15.8**
NC	**Forsyth**	**14.6**
NC	**Alamance**	**13.7**
NC	Chatham	12.2
NC	Orange	13.1
NC	Montgomery	12.1
NC	Caswell	13.3

There are six monitors in the MSA (two in Guilford, and two in Forsyth counties and one in Davidson, and Alamance counties) and five monitors in the adjacent counties. The monitor in Davidson County, is violating the Particulate Matter Standard of 15.0 micrograms per cubic meter ($\mu g/m^3$). All other monitors in this area are attaining the Particulate Matter Standard.

Factor 3: Population Density and Degree of Urbanization including commercial development in included versus excluded areas

The following table has the populations for the counties in the Greensboro-Winston-Salem-High Point area and adjacent counties with significant weighted emissions scores.

		2002 Population	% Population of MSA	Population Density (pop./ mi^2)
NC	**Stokes**	**44,984**	**3.5**	**100**
NC	**Guilford**	**430,937**	**33.5**	**663**
NC	**Davidson**	**151,238**	**11.6**	**274**
NC	**Forsyth**	**314,933**	**24.5**	**768**
NC	**Randolph**	**134,217**	**10.4**	**170**
NC	**Alamance**	**135,893**	**10.6**	**315**
NC	**Yadkin**	**37,329**	**2.9**	**111**
NC	**Davie**	**36,734**	**2.9**	**139**
NC	Rowan	133,359		261
NC	Chatham	53,893		79
NC	Rockingham	92,778		164

NC	Iredell	130,178		227

Based on the analysis for this factor, there appears to be significant populations in Guilford, Forsyth, Davidson, Rowan, Iredell, Randolph and Alamance counties, indicating potential contribution.

Factor 4: Traffic and commuting patterns

Commuting Information

Total commuters in Davidson County: 72,893
Commuters in Davidson County, NC, who work in Davidson County: 40,621 (56%)

Total commuters in Forsyth County: 147,838
Commuters in Forsyth County, NC, who work in Forsyth County: 119,233 (81%)
Commuters from Forsyth County, NC to Davidson County, NC: 4,136 (3%)

Total commuters in Guilford County: 213,079
Commuters in Guilford County, NC, who work in Guilford County: 187,150 (88%)
Commuters from Guilford County, NC to Davidson County, NC: 2,982 (1%)

Total commuters in Randolph County: 65,803
Commuters in Randolph County, NC, who work in Randolph County: 38,637 (59%)
Commuters from Randolph County, NC to Davidson County, NC: 2,607 (4%)

Total commuters in Stokes County: 21,709
Commuters in Stokes County, NC, who work in Stokes County: 6,330 (29%)
Commuters from Stokes County, NC to Davidson County, NC: 252 (1%)

The counties of Davie and Rowan have a small number of commuters and very few of them commute to Davidson County. Chatham, Yadkin, Iredell, and Rockingham counties have a low number of commuters and most of them stay within their counties.

Based on commuting patterns, Forsyth and Guilford appear to have the most impact on the violating monitor in Davidson County. However, the impact on the monitor from commuting appears to be small.

The following table contains the vehicle miles traveled (VMT) for the counties in the Greensboro-Winston-Salem-High Point area and some adjacent counties with significant emissions. (MSA counties are in **bold**).

		2002 VMT (thousands of miles)
NC	**Stokes**	**415**
NC	**Guilford**	**5,096**
NC	**Davidson**	**1,765**
NC	**Forsyth**	**3,832**
NC	**Randolph**	**1,486**
NC	**Alamance**	**1,575**
NC	**Yadkin**	**520**
NC	Davie	476
NC	Rowan	1,654
NC	Chatham	434
NC	Rockingham	923
NC	Iredell	1,901

Based on total VMT, there appears to be contribution to air quality in Davidson County from Guilford, Davidson, Forysth, Rowan, Iredell, Randolph and Alamance counties. However, there is very low or no commuting into Davidson County from Rowan. Iredell, and Alamance Counties

Factor 5: Expected growth

The following table has the population and population growth on a percentage basis figures for counties in the Greensboro-Winston-Salem-High Point MSA and some adjacent counties with significant emissions. As noted above, Chatham County is part of the Raleigh MSA, and Iredell and Rowan Counties are in the Charlotte rather than the Greensboro ozone nonattainment area.

		2002 Population	Growth '90-'00	% Change '90-'00
NC	**Stokes**	**44,984**	**7,488**	**20**
NC	**Guilford**	**430,937**	**73,628**	**21**
NC	**Davidson**	**151,238**	**20,569**	**16**
NC	**Forsyth**	**314,933**	**40,189**	**15**
NC	**Randolph**	**134,217**	**23,908**	**22**
NC	**Alamance**	**135,893**	**22,587**	**21**
NC	**Yadkin**	**37,329**	**5,860**	**19**
NC	**Davie**	36,734	6,976	25
NC	Rowan	133,359	19,735	18
NC	Chatham	53,893	10,570	27
NC	Rockingham	92,778	5,864	7

NC	Iredell	130,178	29,729	32

Based on the analysis for this factor, there appears to be significant growth in Davidson, Guilford, Forsyth, Alamance, Randolph, Rowan, Chatham, and Iredell counties indicating a potential contribution to the air quality in Davidson County.

Factor 6: Meteorology

The following meteorological information was provided by North Carolina. This summarizes the wind directions for the MSA during the time periods when PM2.5 values are the highest.

Summertime: southwesterly winds and recirculating patterns dominate. Main urban areas of influence include Charlotte, the Triad, and Hickory.

Wintertime: More northerly and stronger northwesterly winds observed that during the summer. High PM2.5 is generally observed prior to frontal passages when high pressure is in control or during strong nocturnal low-level temperature inversions. Year-round trajectories indicate influence from nearby states.

The information provided is not sufficient to provide a compelling argument to exclude counties based on prevailing winds.

Factor 7: Geography/topography

There are no significant topographical issues associated with this MSA. Chatham, Iredell, and Rockingham counties are one or more counties away from Davidson county. Additionally, there is one or more attaining monitors between the major emissions sources in these counties and the violating monitor, indicating no contribution.

Factor 8: Jurisdictional boundaries

The 8-hour nonattainment boundary designation for the Greensboro-Winston-Salem-High Point area includes the entire counties of Davidson, Davie, Forsyth, Guilford, Alamance, Caswell, Randolph, and Rockingham. Davie, Alamance, Caswell, and Rockingham were designated nonattainment for ozone because they contained violating monitors not because they were found to be contributing. Rowan county and a portion of Iredell county were designated nonattainment for the ozone standard as apart of the Charlotte-Gastonia-Rock Hill MSA area. Due to significant NOx controls, Stokes County was determined not to contribute to the ozone violations.

Factor 9: Level of control of emission sources

Belews Creek is the largest coal-burning station owned by Duke Power located in Stokes County, NC. Duke Power completed the first phase of its massive Selective Catalytic Reduction (SCR) project at Belews Creek Steam Station that will reduce the power plant's nitrogen oxide emissions by over 90 percent. No scrubbers are installed at this time, but are scheduled to be installed in 2009.

The state initiatives are listed below:
NOx SIP Call
The Clean Smokestacks Act
Clean Air Bill
On Board Diagnostics II Emissions Inspection Program
$PM_{2.5}$ Forecasting

Hickory-Morganton-Lenoir, NC

The following is the nine factor analysis for Hickory-Morganton-Lenoir, NC. The Hickory-Morganton-Lenoir, NC Metropolitan Statistical Area (MSA) contains the counties of Catawba, Caldwell, Burke, and Alexander.

In February 2004, North Carolina recommended that the Unifour Metropolitan Planning Organization's (MPO) Planning Boundary in Catawba County, be designated as nonattainment. The table below shows State Recommendations and EPA recommended modifications for the Particulate Matter 2.5 (PM 2.5) nonattainment area in the Hickory-Morganton-Lenoir area. EPA is modifying the recommendation to include the entire county of Catawba and partial county boundaries in Burke and Caldwell Counties. Catawba County has a violating PM 2.5 monitor. The partial county boundaries in Burke and Caldwell Counties follow the MPO boundary lines which were the boundaries determined in the 8-hour ozone designation in April 2004 for the two counties. Over 20 percent of the commuters from Burke and Caldwell counties commute to Catawba County and both counties contain population levels that indicate contribution. EPA agrees that the MSA county of Alexander and the adjacent counties of Rutherford, Iredell, Cleveland, and Wilkes be designated attainment/unclassifiable. These counties have low population, and are low commuting into Catawba County, distant from the violating monitor in Catawba County. The remaining adjacent counties all have low emissions and low population, indicating they should be attainment/unclassifiable.

Area	EPA Recommendation	State Recommendation
Hickory-Morganton-Lenoir	**Full Counties:** Catawba, **Partial Counties:** Burke and Caldwell	**Full Counties:** None **Partial Counties:** Catawba

The following is a brief summary of the 9 criteria for the Hickory-Morganton-Lenoir MSA and surrounding counties . These analyses were based on existing available data.

Factor 1: Emissions in areas potentially included versus excluded from the nonattainment area

The following table has 2001 $PM_{2.5}$, SO2, NOx, VOC, and Ammonia (Amm) emissions in tons, and weighted emissions scores for the Hickory-Morganton-Lenoir Area and surrounding counties. The Metropolitan Statistical Area (MSA) counties are in **bold**.

	PM 2.5	SO_2	NOx	VOC	Amm	Weighted emissions score	Cumulative Weighted emissions score
Catawba	**5,153**	**78,620**	**27,968**	**19,760**	**886**	**59.7**	**59.7**
Caldwell	**1,104**	**634**	**3,530**	**11,122**	**391**	**18.1**	**77.8**
Burke	**1,198**	**877**	**4,601**	**7,721**	**562**	**17.0**	**94.8**
Alexander	**365**	**349**	**988**	**3,312**	**1,217**	**5.1**	**99.9**
Rutherford	2,323	30,023	12,135	4,847	254	28.4	
Iredell	1,537	1,365	11,065	10,346	2,090	25.3	
Cleveland	1,258	1,261	4,975	6,591	1,240	18.4	
Wilkes	966	647	2,890	5,097	5,300	15.3	
Mc Dowell	751	373	3,675	4,230	214	13.6	
Lincoln	785	513	2,880	4,556	645	10.8	
Watauga	541	352	1,523	2,370	341	8.5	
Avery	269	163	730	985	77	4.4	

Based on the analysis for this factor, there appears to be emissions in the MSA counties of Caldwell and Burke, counties that contribute to the violation in Catawba County. Although there are large SO_2 emissions in Rutherford county, adjacent to Burke, the source is distant from the violating monitor.

Factor 2: Air Quality in potentially included versus excluded areas

	2001-2003 Design Value
Catawba	**15.5**
Mc Dowell	14.2
Watauga	10.9

There is one monitor in this area, in Catawba County, which is violating the particulate matter standard of 15.0 micrograms per cubic meter ($\mu g/m^3$). Two adjacent counties contain monitors attaining the standard.

Factor 3: Population Density and Degree of Urbanization

The following table has the populations for the counties in the Hickory-Morganton-Lenoir area and adjacent counties with significant emissions. (MSA counties are in **bold**.)

	2002 Population	% Population of MSA	Population Density (pop./ mi^2)
Catawba	**146,690**	**42.0**	**367**
Caldwell	**78,513**	**22.5**	**166**
Burke	**89,638**	**25.7**	**177**
Alexander	**34,400**	**9.8**	**132**
Rutherford	63,287		112
Iredell	130,178		227
Cleveland	97,960		211
Wilkes	66,773		88

Based on the analysis for this factor, there appears to significant populations in Catawba, Iredell, Cleveland, Caldwell and Burke counties, indicating potential contribution.

Factor 4: Traffic and commuting patterns

Commuting Information

Total commuters in Catawba County: 73, 984
Commuters in Catawba County, NC, who work in Catawba County: 62, 459 (84%)

Total commuters in Rutherford County: 27, 673
Commuters in Rutherford County, NC, who work in Rutherford County: 21, 812 (79%)
Commuters from Rutherford County, NC to Burke County, NC: 305 (1%)

Total commuters in Caldwell County: 38, 970
Commuters in Caldwell County, NC, who work in Caldwell County: 26, 932 (69 %)
Commuters from Caldwell County, NC to Catawba County, NC: 8,011 (21 %)

Total commuters in Burke County: 42,214
Commuters in Burke County, NC, who work in Burke County: 29, 123 (69%)

Commuters from Burke County, NC to Catawba County, NC: 8,366 (20%)

Total commuters in Alexander County: 31, 041
Commuters in Alexander County, NC, who work in Alexander County: 24, 270 (51%)
Commuters from Alexander County, NC to Catawba County, NC: 5,679 (32%)

Most of the commuters in Iredell, Cleveland and Wilkes counties commute within their counties and very few of them commute to Davidson County.

Based on commuting patterns, Caldwell, Alexander and Burke counties appear to have the most potential impact on the violating monitor in Catawba county.

The following table contains the vehicle miles traveled (VMT) for the counties in the Hickory-Morganton-Lenoir MSA and some adjacent counties with significant weighted emissions scores. (MSA counties are in **bold**.)

	2002 VMT (thousands of miles)
Catawba	**2,048**
Caldwell	**738**
Burke	**1,112**
Alexander	**229**
Rutherford	606
Iredell	1,901
Cleveland	1,125
Wilkes	619

Based on the analysis for this factor, Burke County has VMT that appears to contribute to the air quality in Catawba County. Although the adjacent counties of Iredell and Cleveland have significant levels of VMT, there is little commuting to Catawba County from these counties.

Factor 5: Expected growth

The following table has the population and population growth figures for counties in the Hickory-Morganton-Lenoir MSA and some adjacent counties with significant emissions.

	2002 Population	Growth '90-'00	Pct change '90-'00
Catawba	**146,690**	**23,273**	**20**
Caldwell	**78,513**	**6,706**	**9**
Burke	**89,638**	**13,404**	**18**
Alexander	**34,400**	**6,059**	**22**
Rutherford	63,287	5,981	11
Iredell	130,178	29,729	32
Cleveland	97,960	11,573	14
Wilkes	66,773	6,239	11

Based on the analysis for this factor, there appears to be significant growth on a percentage in Catawba and Alexander Counties in the MSA and adjacent Iredell County, indicating a potential contribution to the air quality in Catawba County. Although the percentage growth is high for the Iredell County, it is more closely associated with the Charlotte area.

Factor 6: Meteorology

The following meteorological information was provided by North Carolina. This summarizes the wind directions for the MSA during the time periods when $PM_{2.5}$ values are the highest.

Summertime: southwesterly winds and recirculating patterns dominate. Main urban areas of influence include Charlotte, the Triad, and Hickory.

Wintertime: More northerly and stronger northwesterly winds observed that during the summer. High PM2.5 is generally observed prior to frontal passages when high pressure is in control or during strong nocturnal low-level temperature inversions. Year-round trajectories indicate influence from nearby states.

The information provided is not sufficient to provide a compelling argument to exclude counties based on prevailing winds.

Factor 7: Geography/topography

There are no significant topographical issues associated with this MSA.

Factor 8: Jurisdictional boundaries

The 8-hour nonattainment boundary designation for the Hickory-Morganton-Lenoir area includes the entire counties of Alexander and Catawba and partial counties of Burke and Caldwell. The nonattainment designation in Burke and Caldwell counties are along the Unifour Metropolitan Planning Organization boundaries. Catawba County is located geographically between Alexander and Lincoln Counties, which both have monitors violating the 8-hour ozone standard.

In Catawba County, a second monitor was operated approximately 10 miles southwest of the current violating Hickory monitor. This monitor was further removed from a major highway. The location of this monitor at a rescue squad and was not able to continue at that location. While in existence for seven quarters, this monitor showed an average of 1.89 $\mu g/m^3$ lower than the current violating monitor. Therefore, the state believes that this monitor would have continued to show attainment/unclassifiable if it remained in existence to collect three years of data.

Factor 9: Level of control of emission sources

Duke Power - Marshall Steam Station (Catawba County)

No scrubbers are installed at this time. However, in 2004, Duke Power began installation of flue gas desulfurization (scrubber) equipment. This equipment will lower sulfur dioxide emissions by approximately 90 percent. The project is scheduled for completion in 2007.

The state initiatives are listed below:
NOx SIP Call
The Clean Smokestacks Act
Clean Air Bill
On Board Diagnostics II Emissions Inspection Program
$PM_{2.5}$ Forecasting

NCDENR

Mr. James I. Palmer, Jr.
Regional Administrator
U.S EPA, Region 4
61 Forsyth Street
Atlanta, Georgia 30303

RE: $PM_{2.5}$ Non-attainment Designations

Dear Mr. Palmer:

In your June 29, 2004 letter, you provided North Carolina with EPA's response to our state's $PM_{2.5}$ non-attainment boundary recommendations. North Carolina has been a leader among states with regard to improving air quality and remains committed to the continued improvement of air quality and the protection of its citizens. The non-attainment boundary recommendations made by EPA include several counties that North Carolina continues to believe should be designated attainment for $PM_{2.5}$. Below, I state why North Carolina believes that these counties should be designated attainment. I also urge you to consider again the discussion and technical documents presented in our initial February 2004 submissions. In addition, please find attached our $PM_{2.5}$ Designation Response Technical Support Document.

In the Greensboro/Winston-Salem/High Point area, EPA recommends that the entire counties of Stokes, Guilford, Davidson, Forsyth and Randolph be designated non-attainment. North Carolina originally recommended Davidson County only as the $PM_{2.5}$ non-attainment boundary. We continue to believe that only Davidson County should be designated as non-attainment.

North Carolina believes that Stokes County should be designated attainment for the following reasons. While Stokes County contains the Belews Creek power plant, an analysis of forward trajectories indicates that emissions from Belews Creek do not frequently impact the $PM_{2.5}$ monitor in Davidson County. There are also $PM_{2.5}$ monitors currently attaining the standard in Forsyth County that lie between Stokes County and the non-attaining monitor in Davidson County. Even if the Belews Creek facility is affecting the Lexington area, significant NOx controls have already been installed on the plant. Selective catalytic reduction systems have already been installed on units 1 and 2 at the Belews Creek facility, and additional burner technology has been added at unit 2. This NO_x control technology began operation in 2003 and 2004. Consequently, the NO_x emissions will decrease from 43,567 tons per year to 7,022 tons per year and new SO_2 controls will be installed over the next several years as a result of the Clean Smokestacks Act. SO_2 emissions from Belews Creek will be reduced by nearly 90% in the next several years as these controls become fully operational.

1601 Mail Service Center, Raleigh, North Carolina 27699-1601
Phone: 919-733-4984 \ FAX: 919-715-3060 \ Internet: www.enr.state.nc.us/ENR

Also, Stokes County is an extremely rural county, and therefore has very little mobile emissions. North Carolina believes that the current and future controls on the Belews Creek facility, the apparent small impact of Belews Creek on Davidson County, and the rural nature of the county support designating Stokes County in attainment for $PM_{2.5}$. If EPA continues to believe that Stokes County should be designated non-attainment because of Belews Creek, North Carolina recommends that only the Sauratown Township where the Belews Creek power plant is located be designated non-attainment.

North Carolina believes that Randolph County should be designated attainment for several reasons. The EPA L-Factor ranking for Randolph County is the lowest of the counties recommended by EPA to be designated non-attainment. Randolph County is also predominately downwind of Davidson County during the summer months when $PM_{2.5}$ concentrations are the highest and therefore emissions from Randolph County would not be expected to contribute significantly to $PM_{2.5}$ concentrations in Davidson County during those months. The majority of emissions within Randolph County are mobile emissions and less than 5% of the workforce commutes into Davidson County. Furthermore, the mobile source emissions will be addressed by federal rules such as heavy-duty engine standards and low sulfur diesel.

Guilford and Forsyth counties each contain $PM_{2.5}$ monitors that are attaining the standard based on current design values. The counties also lie to the north and northeast of Davidson County, which makes Guilford and Forsyth counties predominately downwind of Davidson County during the summer months when $PM_{2.5}$ is the highest. The majority of emissions from these counties are mobile, and therefore these counties and surrounding counties will benefit from federal rules addressing mobile emissions as well as the expanded North Carolina motor vehicle inspection program. They will also benefit from local measures aimed at reducing mobile emissions as part of the Early Action Compact (EAC) effort in the Triad area.

North Carolina has an analysis that shows $PM_{2.5}$ concentration and its relationship to population density in the Triad area. The Lexington monitor does not behave the same as surrounding monitors when considering the population around the monitoring site. The analysis suggests that the higher concentrations of $PM_{2.5}$ in Davidson County are the result of local factors rather than broader population-related regional influences and therefore the addition of counties beyond just Davidson County will not help the monitor attain the standard. Please see appendix for details.

Finally, with regard to the Lexington monitor, there has been a downward trend in the $PM_{2.5}$ concentrations since 1999. We believe that this in considerable part reflects some reductions in the emission of pollutants in certain upwind states over that period. EPA itself has already concluded that these out-of-state sources contribute significantly to elevated $PM_{2.5}$ in North Carolina. We expect that the downward trend should continue at this site as more emissions reductions are expected due to implementation of the Clean Smokestacks Act, NOx SIP call rules, federal heavy-duty engine standards and new fuel standards. We anticipate further improvement in Lexington monitor air quality will result from positive action by EPA on North Carolina's section 126 petition, as well as actual promulgation of the proposed Clean Air

Interstate Rule, both of which will further reduce the contribution from upwind, out-of-state sources to the Lexington area's non-attainment and maintenance problems.

For the reasons stated herein, North Carolina believes that only Davidson County should be designated non-attainment, while Stokes, Randolph, Guilford and Forsyth counties should be designated as attainment for $PM_{2.5}$.

With regard to the non-attaining monitor in Hickory, North Carolina continues to oppose a non-attainment designation for any area beyond the metropolitan planning organization boundary of Catawba County. There is little to be gained by including the partial counties of Burke and Caldwell in the non-attainment area for the Hickory region for several reasons. Catawba County emissions are significantly higher than both Burke and Caldwell counties in the L-Factor analysis. The bulk of emissions from these counties is from the mobile sector and therefore will benefit from state and federal rules addressing mobile emissions. There would be little to no additional opportunity to reduce mobile emissions by designating Burke and Caldwell counties as non-attainment.

A non-attainment designation for $PM_{2.5}$ would place significant additional burdens on Burke and Caldwell counties since these counties are already participating in an EAC for ozone. These counties are making progressive strides to reduce emissions as part of the EAC effort and North Carolina feels that a designation of non-attainment for these counties would do little to reduce $PM_{2.5}$ in Catawba County. North Carolina believes the recommendation to designate only Catawba County as non-attainment is appropriate, while Burke, Caldwell and the non-MPO parts of Catawba counties should be designated as attainment for $PM_{2.5}$.

Furthermore, on the basis of air quality data for 2004 gathered to date, North Carolina believes there is a significant probability that the Hickory monitor will attain the standard based on complete 2002-2004 data. We expect that it will be possible to maintain this attainment status as more emissions reductions are expected due to implementation of the Clean Smokestacks Act, NOx SIP call rules, federal heavy-duty engine standards and new fuel standards. We are also anticipating needed reductions from upwind out-of-state sources from the proposed Clean Air Interstate Rule, North Carolina's section 126 petition and other initiatives, which will help Davidson County as well. EPA already has concluded that these out-of-state sources contribute significantly to elevated PM2.5 in North Carolina.

North Carolina therefore suggests that EPA designate the Hickory area as "unclassifiable", if the designation is made before December 31, 2004. The designation for this area as attainment can then be finalized in February 2004 using the 2002-2004 data, assuming that it in fact shows what we anticipate. Alternatively, if the designation is made after December 31, 2004, the designation should be based on the 2002-2004 data. This approach would conserve significant federal, state and local resources by avoiding the need for the redesignation demonstration, as well as transportation conformity, in an area that is already attaining the $PM_{2.5}$ standard.

Finally, on June 21, 2004, I wrote to the Administrator to register our concerns regarding the recently introduced emissions-weighted approach for nonattainment boundary delineation. I reiterate those comments here. In particular, the emissions-weighted analysis fails to account for prevailing wind directions during the periods when $PM_{2.5}$ values are higher, assumes incorrectly that emissions impact a monitor equally throughout the year, fails to consider distance between emissions and the monitors, and fails to recognize any effects from the significant reductions resulting from North Carolina's Clean Smokestacks Act. The most glaring demonstration of the weakness of the emissions-weighted approach is that some counties EPA intends to designate as nonattainment under this approach actually are in attainment according to monitors located in those counties. Moreover, this emissions-weighted analysis was introduced late and so could not be addressed by the Governors in their initial recommendations. This runs counter to the state-federal interactive process prescribed by law. For these reasons, the State believes that the use of the emissions-weighted approach is arbitrary and should not influence the final delineation of nonattainment area boundaries.

North Carolina is proud to be a leader in the improvement of air quality and is committed to the continued improvement of air quality within its borders. We have invested significant resources in understanding the nature of our air quality issues and feel confident that our recommendation to designate only Davidson and Catawba counties is sufficient for the state and EPA to continue the work toward protecting the health of our citizens. We know that you and your colleagues will give these comments careful attention as EPA evaluates and makes the final decisions on $PM_{2.5}$ boundaries later this year. We appreciate that careful attention because we also appreciate the nature and extent of the challenge EPA faces in making these decisions across the nation.

Sincerely,

William G. Ross, Jr.

STATE OF NORTH CAROLINA
OFFICE OF THE GOVERNOR
20301 MAIL SERVICE CENTER
RALEIGH, NC 27699-0301

MICHAEL F. EASLEY
GOVERNOR

September 9, 2004

The Honorable Michael Leavitt
Administrator
US Environmental Protection Agency
1200 Pennsylvania Ave., N.W.
Washington, D.C. 20460

Dear Administrator Leavitt:

I am writing concerning your agency's response to North Carolina's PM 2.5 non-attainment boundary recommendations. As you know, North Carolina has been a leader among states in improving air quality through aggressive programs to cut emissions from both coal-fired power plants and mobile sources. No state in America is more committed to solving the problems posed by particulate emissions and other harmful pollutants. But we are committed to doing so wisely, in a manner that does not unnecessarily harm our state's favorable business climate.

In its letter of June 29, 2004, EPA has provided flawed analysis to support far-reaching PM 2.5 nonattainment designations surrounding two isolated, non-attaining monitors in Hickory and Lexington, North Carolina. According to North Carolina's analysis, which is included in the attached letter from Secretary of Environment Bill Ross, these broad designations will not help solve the non-attainment problem at these two monitors. In fact, they are unlikely to have an appreciable effect on North Carolina's efforts to improve air quality.

These excessive non-attainment designations will, however, have a significant dampening effect on economic development efforts in the Triad and further west in the Hickory/Morganton/Lenoir area. These two areas of our state have been hit particularly hard by manufacturing job losses associated with unfair federal trade policies. Both areas are turning a corner now, but they can ill afford non-attainment designations that can undermine their ability to bring jobs to their communities – particularly when there is no beneficial effect.

With this in mind, I urge you to narrow your non-attainment designation to Davidson County and the MPO portion of Catawba County surrounding the Hickory monitor. Thank you for your attention to this request. If there is anything that my office can do to assist you in your decisionmaking process in the coming months, I trust that you will let me know.

With kindest regards, I remain

Very truly yours,

Michael F. Easley

DEC 14 2004

OFFICE OF
AIR QUALITY PLANNING
AND STANDARDS

MEMORANDUM

SUBJECT: Clean Data Policy for the Fine Particle National Ambient Air Quality Standards

FROM: Stephen D. Page, Director
Office of Air Quality Planning and Standards

TO: Air Division Directors, Regions I-X

Purpose

In December 2004, EPA is designating areas as nonattainment with the national ambient air quality standards (NAAQS) for fine particles. This policy memorandum addresses the requirements for those nonattainment areas that, prior to the date that their State Implementation Plans (SIPs) are due, demonstrate that they are attaining the fine particle standard. Specifically, it addresses whether such areas must submit certain portions of the plans – those addressing reasonable further progress (RFP), attainment demonstrations and contingency measures as required in section 172 (c) of the Clean Air Act (CAA). This memorandum also describes the process by which EPA will determine whether an area is attaining the PM2.5 standard.

Background & Policy

EPA established NAAQS for fine particles in 1997. EPA expects to make final attainment, unclassifiable, and nonattainment designations in December 2004. Nonattainment areas must submit their SIPs within 3 years of the effective date of the designations (i.e. March 2008). Areas must attain the standard as expeditiously as practicable. Presumptively, attainment should be achieved within 5 years of designation, although EPA may grant an attainment date extension of up to 5 additional years based on the severity of the nonattainment problem and the availability of emissions controls. Thus, attainment dates will range from 5 to 10 years from the date of designation (i.e. 2010 to 2015). Attainment must be determined based on the 3 calendar years prior to the attainment date.

Because PM2.5 exposure is linked to significant health effects, EPA encourages States to achieve reductions in PM2.5 and its precursor emissions as early as possible, especially in areas that are expected to be designated as nonattainment. Public health in these areas will improve as levels of fine particles decline. By meeting the standard, they will reduce the incidence of premature mortality, hospital admissions, missed days of work and school, and other adverse respiratory and cardiac effects in children and adults.

With these benefits in mind, we have reviewed the CAA to determine whether an area that is originally designated as nonattainment must still submit certain SIP requirements if the area has 3 consecutive calendar years of air quality data showing that it meets the PM2.5 standards prior to its required SIP submittal date. We believe that such areas may be exempt from making submissions for RFP, attainment demonstrations, and contingency measures – as long as those areas continue to meet the standard. However, if such an area is determined to violate the standards prior to being redesignated to attainment, the area will be required to address the pertinent requirements when it submits its SIP to EPA. EPA encourages States to take action to redesignate areas that are attaining the standard as expeditiously as practicable. In order to assist in this process, EPA will be reviewing the possibility of developing a "Limited Maintenance Plan Policy" for PM2.5 areas, which may be used in conjunction with the Clean Data Policy to assist States in getting areas redesignated to attainment in an expeditious manner.

Interpretation and Legal Rationale

The SIP provisions that are the subject of this policy are those addressing RFP, attainment demonstrations, and contingency measures. EPA previously has interpreted that the general provisions of the CAA subpart 1, part D (§§171 and 172) do not require an ***ozone*** nonattainment area to include these provisions in its SIP if that area meets the ozone standard. We believe it is appropriate to make the same interpretation for PM2.5. Our rationale is as follows:

1) **Reasonable Further Progress:** Section 171 (1) states that, for the purposes of part D, Reasonable Further Progress means:

   "such annual incremental reductions in emissions of the relevant air pollutant as are required by this part or may reasonably be required by the Administrator for the purpose of ensuring attainment of the applicable NAAQS by the applicable date."

If an area has 3 consecutive calendar years of air quality data showing it has attained the standard before the SIP due date, the purpose of the RFP requirement will have been fulfilled, and we believe the area does not have to address RFP in its SIP.

We took this view with respect to the general RFP requirement [CAA §172(c)(2)] in the "General Preamble for the Implementation of Title I of the Clean Air Act Amendments of 1990" (General Preamble) (see 57 FR 13498, April 16, 1992), and we are now extending that interpretation to PM2.5. In the General Preamble, EPA stated that:

> *"requirements for RFP will not apply in evaluating a request for redesignation to attainment since, at a minimum, the air quality data for the area must show that the area has already attained. A showing that the State will make RFP toward attainment will, therefore, have no meaning at that point"* (see 57 F R 13564).

2) Attainment Demonstrations

This interpretation also is consistent with our previous interpretation of §172(c) requirements in the General Preamble as they pertain to ozone attainment demonstrations. EPA stated that no other measures to provide for attainment would be needed by areas seeking redesignation to attainment since *"attainment will have been reached"* (see 57 FR 13564; also Calcagni memorandum, September 4, 1992). If an area has attained the standard before the SIP due date, we believe the area does not have to include an attainment demonstration in its SIP.

3) Contingency Measures

Similar reasoning applies to the contingency measures SIP requirement, which is linked with both the attainment demonstration and RFP requirements. EPA previously has interpreted the contingency measures requirement of §172(c)(9) as no longer being applicable once an area has attained the standard, because those *"contingency measures are directed at ensuring RFP and attainment by the applicable date"* (see 57 FR 13564). Areas attaining the PM2.5 standard before their SIP due dates will not have to address contingency measures in their SIPs.

Each of these interpretations applies only as long as a nonattainment area continues to monitor attainment of the standard. If such an area violates the PM2.5 NAAQS, the area would again be required to submit the pertinent SIP sections. Therefore, a determination that an area need not submit one or more parts of a SIP **amounts to a suspension of the requirement <u>as long as the area continues to attain the standard</u>.** If EPA ultimately redesignates the area to attainment, then the area will be entirely relieved of these requirements (to the extent they are not the basis for the area's maintenance plan).

<u>**Consequences for Redesignations, Sanctions and Conformity**</u>

Redesignation: A determination that an area has met the PM2.5 NAAQS is not equivalent to a redesignation to attainment. Attainment of the standard is only one of the criteria an area must satisfy in order to be redesignated [CAA §107(d)(3)(E)]. The State also must submit, and receive full approval of a request that satisfies all of the criteria for redesignation, including the requirements to:

- demonstrate that the improvement in the area's air quality is due to permanent and enforceable reductions;

- have a fully approved SIP that meets all of the applicable requirements under section 110 and part D; and
- have a fully approved maintenance plan.

The SIP submissions for RFP, attainment demonstration, and contingency measures discussed in this memorandum would not be required in order for an area's redesignation request to be approved, provided that the area is attaining the PM2.5 standard. However, if an area again violates the standard before EPA takes final action on that area's redesignation request, EPA could not redesignate the area, and the SIP requirements would once again apply. Areas that are redesignated are relieved of all nonattainment requirements.

Sanctions: If EPA determines that an area is attaining the PM2.5 standard, thereby suspending the SIP submission requirements discussed above would be suspended, and any sanction clock related to those SIP requirements would be stopped.

Conformity: An area determined to be attaining the standard under this policy will be required to use the applicable regional emissions test, as required in the transportation conformity rule at 69 FR 40004 (July 1, 2004). This rule addresses the specific emissions tests for transportation plan and TIP conformity determinations that occur before and after a PM2.5 SIP having motor vehicle emissions budgets is established.

<u>**New Source Review (NSR)**</u>

An attainment determination pursuant to this policy will not relieve an area of its responsibility to meet the requirements of EPA's NSR regulations. All NSR requirements would continue to apply to any area designated as nonattainment.

<u>**Process for Determining Attainment**</u>

Regional offices make determinations – EPA Regional Offices will conduct individual rulemakings for each area seeking an attainment determination under this policy. Once the area has demonstrated that it is meeting the PM2.5 standard, the Regional Office will issue a binding determination that the area has attained the standard and need not make the SIP submittals discussed above.

Three years of clean data required – To demonstrate that it is meeting the standard, a nonattainment area must have 3 consecutive years of air quality monitoring data (e.g. 2004-2006, for areas that have a SIP submittal date of February 2008) that show the area had clean air quality that precede the areas required SIP submittal date. The data must be complete and quality-assured, consistent with 40 CFR part 58 requirements, and other relevant EPA guidance. The State also must ensure that the data are properly submitted to the Air Quality Subsystem of

EPA's Aerometric Information Retrieval System. The State should notify its EPA Regional Office that it believes a nonattainment area is attaining the PM2.5 standard and petition for an attainment determination under this policy. EPA believes that the determination of attainment for an area should be consistent with the manner that the area was designated as nonattainment[1].

Entire multi-state areas must have clean air to be eligible – Multi-state nonattainment areas must demonstrate attainment for the entire nonattainment area in order for EPA to suspend any of the SIP requirements covered by this policy. EPA will not suspend any requirements based on a determination that part of a nonattainment area is monitoring attainment. If the multi-state nonattainment area involves more than one EPA Region, the appropriate Regional Offices should coordinate these efforts in making any attainment determinations.

Areas must continue to meet PM2.5 standard – Areas that are determined to attain the PM2.5 standard under this policy must continue to monitor clean air. The State must continue to operate an appropriate air quality monitoring network, in accordance with EPA regulations, to verify the attainment status of the area (see 40 CFR part 58).

A violation means SIP requirements apply – If EPA determines that an area has violated the PM 2.5 standard, the area would again be required to submit the pertinent requirements under the SIP for the area. EPA would notify the State of that determination and would also provide notice to the public in the Federal Register. Areas subject to such a determination would receive a reasonable amount of time to address the RFP, attainment demonstration and/or contingency measure requirements and submit revisions to their SIPs. EPA would establish this SIP submittal date on a case-by-case basis, taking into account individual circumstances surrounding the particular SIP provisions at issue.

Areas remain subject to other EPA requirements – Attainment determinations under this policy do not shield an area from other required actions, such as provisions to address pollution transport, which could require emission reductions at sources or other types of emission activities contributing significantly to nonattainment in other areas or States, or interfering with maintenance in those areas. EPA has the authority to require emissions reductions as necessary and appropriate to deal with transported air pollution [see CAA §§110(a)(2)(D) and 110(a)(2)(A).]

---

[1] Areas that are designated based upon violations identified at specific monitors located within a given area should also be used in the determination of attainment for the area. The use of spatial averaging should only be used in determinations of attainment for an area where the technique was also used in designating the area as nonattainment initially.

If you have any questions about this policy, please contact Larry Wallace of my staff, at (919) 541-0906, or Rich Damberg at (919) 541-5592.

WASHINGTON, D.C. 20460

December 17, 2004

THE ADMINISTRATOR

The Honorable Michael Easley
Governor, State of North Carolina
20301 Mail Service Center
Raleigh NC 27699-0301

Dear Governor Easley:

Thirty-four years ago this month, the first Clean Air Act signaled the beginning of our country's resolve to dramatically improve air quality. Today, we celebrate our accomplishments which have enabled us to breathe the cleanest air we have ever measured. As 2004 comes to a close, I am pleased to report that this has been a remarkable year for protecting and improving the country's air quality.

The Bush Administration has made implementation of a national clean air strategy a top priority by implementing more protective air quality standards for ozone and fine particles and designing national tools to help meet those standards. Legislation and regulation will be the centerpiece of the President's clean air and clean energy strategy as we move forward. Together, we are on the path to make this generation one of the most productive periods of air quality improvement in our nation's history.

An important part of our nation's commitment to clean, healthy air is reducing the levels of fine-particle or PM2.5 pollution. Fine-particle pollution represents one of the most significant barriers to clean air facing our nation today. These tiny particles, about $1/30^{th}$ the diameter of a human hair, lodge deep in our lungs, and have been associated with heart attacks, chronic bronchitis, asthma attacks and missed days of school and work.

Key to the reduction of particle pollution is implementation of the fine particle standards and identification of the areas of the country needing additional work to meet the standards. We take the first of those important steps today, identifying the areas in your state that do not meet the fine particle standards. Those parts of your state designated as "nonattainment" will require more actions to achieve a common goal of cleaner, healthier air (a list of nonattainment areas is attached). For areas in your state that attain the standard you will need to continue your progress to sustain clean air.

To assist you, we have both proposed and instituted rules as part of our national clean air strategy that will bring the vast majority of the country into attainment with the standards over the next decade. Our clean air/clean energy strategy, including Clear Skies legislation and the Clean Air Rules, will cut power plant emissions of sulfur dioxides, nitrogen oxides and mercury by nearly 70 percent when fully implemented, and will reduce emissions from off-road diesel fuels, vehicles and engines by over 90 percent — those black puffs of exhaust smoke are going to be a thing of the past. Together, these Clean Air Rules will build on the tremendous progress made in previous decades, and do it in record time.

The last several decades have seen a growing commitment to clean air coupled with a progression of science and technology that has informed our decision-making and driven our actions. I think of our clean air history as a relay where a baton is passed from generation to generation and from Administration to Administration. This Administration has made a commitment to accelerate our clean air progress so that all Americans live healthier, longer, more productive and prosperous lives.

Sincerely,

/s/

Michael O. Leavitt

RE: $PM_{2.5}$ Non-attainment Designations

Dear Mr. Palmer:

In the January 5, 2005 Federal Register notice on $PM_{2.5}$ non-attainment boundaries, EPA indicated that State submittal of complete, quality assured, certified 2004 data for the purpose of showing a change in the non-attainment boundary was appropriate. Therefore, North Carolina would like to provide the data for the three counties that were designated as non-attainment for $PM_{2.5}$: Catawba, Davidson, and Guilford[1]; and to request that Guilford be re-designated as attainment.

Despite the fact that the Guilford County monitor attained the $PM_{2.5}$ standard with a 2001-2003 design value of 14.0 $\mu g/m^3$, a value significantly below the ambient standard, this county was designated as non-attainment. The 2002-2004 data show a design value of 13.7 $\mu g/m^3$, which demonstrates that the air quality in Guilford County is well below the NAAQS. As I stated in earlier correspondence on the $PM_{2.5}$ non-attainment boundary issue, I believe that Guilford County should be designated attainment. We have indicated previously our reasons why we believe including Guilford

[1] Catawba County's monitor is located in Hickory. The 2001-2003 design value for this monitor is 15.5 micrograms per cubic meter ($\mu g/m^3$). The 2002-2004 design value for this monitor is 15.1 $\mu g/m^3$. North Carolina had anticipated this area would attain the $PM_{2.5}$ standard with the 2004 data. The values are very close to the $PM_{2.5}$ standard, but unfortunately still violating. However, North Carolina believes it is likely that this area will attain with the 2005 data. North Carolina will begin work on the re-designation package as early as September 2005. We request that if EPA intends to issue re-designation guidance, that this be accomplished by mid-2005 so that the guidance is available when we are beginning the re-designation process. In any event, we intend to consult with EPA early in the process in order to ensure that our request can be processed as quickly as possible.

The Davidson County monitor has a similar downward trend in $PM_{2.5}$ values. The 2001-2003 design value for the Lexington site is 15.8 $\mu g/m^3$. The 2002-2004 design value for this site is 15.4 $\mu g/m^3$. Again, while this site did not attain the $PM_{2.5}$ standard, the value is still on a downward trend. We are hopeful that air quality will continue to improve in Davidson County and the Lexington monitor will attain the $PM_{2.5}$ standard with the inclusion of 2005 data. If so, we intend, as with Catawba County, to seek expeditious re-designation of the area. We reiterate that, if EPA intends to issue re-designation guidance, it should release such guidance before September 2005.

1601 Mail Service Center, Raleigh, North Carolina 27699-1601
Phone: 919-733-4984 \ FAX: 919-715-3060 \ Internet: www.enr.state.nc.us/ENR

County in the non-attainment area is arbitrary and unlawful. I request that you again review my September 8, 2004 letter, in light of the fact that the design value in Guilford continues to be well below the standard.

From our previous comments, I reiterate that, while the mobile source emissions in Guilford County are greater than in other counties in this area, mobile source emissions will continue to decrease through implementation of federal rules addressing mobile sources as well as the expanded North Carolina motor vehicle inspection program. The mobile emissions will also decrease due to local measures included as part of the Early Action Compact (EAC) effort in the Triad. The most direct influence of these reductions will be reduced ambient concentrations in Guilford County at the monitor already demonstrating compliance with the $PM_{2.5}$ standard.

Unfortunately for the citizens of Guilford County, EPA has reached the puzzling conclusion that sources in this attaining county are contributing to pollution in another county which lies in a direction opposite the prevailing winds. This conclusion is supported neither by the facts nor reason, and therefore I ask that it be withdrawn. The EPA analysis appears to rely primarily on the fact that Guilford County has a relatively larger and more urban population and produces relatively larger quantities of $PM_{2.5}$ and $PM_{2.5}$ precursors. But EPA fails to adequately consider that, for example, Guilford County's air quality complies with the $PM_{2.5}$ NAAQS and, indeed, is improving with respect to the pollutant $PM_{2.5}$. The only evidence shows that federal, state, and local controls already in place continue to reduce $PM_{2.5}$ concentrations in Guilford County and surrounding counties. While we share a common interest in assuring clean air in Davidson County, it is entirely unclear what additional measures you would recommend be imposed and how those measures would have a meaningful impact on air quality in Davidson County.

EPA's own data indicate that regional sources account for a great deal of the elevated $PM_{2.5}$ levels in the east and southeast. For this reason, EPA has in fact proposed to find that power plant emissions throughout the region should be regulated -- by the Clean Air Interstate Rule. All available data and analysis indicate that a non-attainment designation for Guilford County will have little if any effect on the $PM_{2.5}$ levels in Davidson County, and whatever effect it does have will be dwarfed by other emissions reductions programs. A more sensible approach would be to require significant regional emission reductions from large sources in the near term, which would help both Davidson County and Catawba County attain and then maintain the $PM_{2.5}$ standard. I ask that EPA not penalize Guilford County for a problem that it can do little if anything to rectify.

North Carolina is proud to be a leader in the improvement of air quality and is committed to the continued improvement of air quality within its borders. Part of our successful strategy in North Carolina has been the deployment of our limited resources in an efficient manner. Unfortunately, the designation of Guilford County as nonattainment will result in the expenditure of unnecessary resources in an area that has already demonstrated compliance with the NAAQS. I want to see all areas of the State attain the $PM_{2.5}$ standard as quickly as possible. I trust that these comments will be considered as EPA moves forward with implementation of the $PM_{2.5}$ standard.

Sincerely,

Bill

William G. Ross, Jr.

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
WASHINGTON, D.C. 20460

DEC 5 2005

THE ADMINISTRATOR

William G. Ross, Jr., Secretary
North Carolina Department of Environment
and Natural Resources
1601 Mail Service Station
Raleigh, NC 27699-1601

Dear Secretary Ross:

Thank you for your letter of February 22, 2005, concerning fine particulate matter (PM2.5) designations and Guilford County, North Carolina. In your letter, you provided 2004 monitoring data for Davidson, and Guilford Counties, and requested that the Environmental Protection Agency (EPA) designate Guilford County as attainment for the PM2.5 National Ambient Air Quality Standard (NAAQS). For the reasons set forth herein, EPA denies your request.

In determining an area's designation, we rely on the Clean Air Act (CAA) definition of a nonattainment area in section 107(d)(1)(A)(i): an area that is violating an ambient standard or an area that is contributing to a nearby area that is violating the standard. If an area meets this definition, EPA is obligated to designate the area as nonattainment. On April 1, 2003, EPA issued guidance for states and tribes to use in identifying areas that meet or do not meet EPA's national air quality standards for PM2.5. In making designations, we used the most recent 3 years of monitoring data. Once we determined that a monitor was recording a violation, the next step was to determine if there were any nearby areas that were contributing to the violation and include them in the designated nonattainment area. In making this determination, we reviewed all available technical data related to nine factors set out in the April 1, 2003, guidance such as air quality, source locations and emissions, meteorology, terrain, population, commuting, and growth in the area. The technical support analyses for all nonattainment areas are located on EPA's web site at: http://epa.gov/pmdesignations/documents/final/TSD/Ch6.pdf.

Based on the analysis of all factors for the Greensboro area, EPA determined that Guilford County was contributing to the violating monitor in adjacent Davidson County. Our analysis showed that Guilford County had sufficient emissions and emission sources to contribute to the ambient air quality in Davidson County. For example, Guilford County has the largest population of any county in the area, accounting for over one third of the metropolitan statistical area's total population, as well as significant population growth. Additionally, Guilford County commuters total by far the highest vehicle miles traveled in the area. These factors indicate that Guilford County has significant sources of emissions. EPA further found that Guilford County has sufficient emissions of PM2.5

and precursor pollutants sulfur dioxide (SO2), nitrogen oxides (NOx), and volatile organic compounds (VOC) to contribute to the ambient air quality in Davidson County.

2002-2004 Data

In EPA's January 5, 2005, Final Designation Notice, we invited states to submit, by February 22, 2005, complete, quality assured, certified 2004 data that suggests a change in designation of an entire nonattainment area is appropriate for any area within the State. EPA stated that it would change an area's designation if inclusion of 2004 data showed that every county in an area was neither monitoring a violation of the standards nor contributing to a violation of the standards of a nearby area. We stated this because as long as there is a continuing violation of the standards, those areas that are contributing to the violation need to be part of the nonattainment area for controls designed to achieve the standard.

In your February 22, 2005, letter, you provided complete, quality assured, certified 2004 data for Davidson and Guilford Counties and noted that data from the PM2.5 monitor in Guilford County was below the annual average PM2.5 standard of 15.0 $\mu g/m^3$. Your letter did not conform to EPA's January 5 offer to revisit designations based on 2004 data and was not addressed in EPA's April 5, 2005, Supplemental Notice. Instead, EPA has evaluated your letter and is responding to it separately here as a petition for reconsideration.

The 2004 data provided in your letter, while being new in the sense that it was not available to be considered in EPA's final designation of Guilford County, does not provide any new information that would compel EPA to reach a different conclusion regarding Guilford County's nonattainment status based upon its contribution to air quality in Davidson County. While the 2004 data show a decrease in Guilford County's design value, this demonstrates the continuation of a trend already in existence at the time EPA made its final designations. EPA is pleased that this monitor continues to show decreasing design values; however, nothing about the 2004 monitor data changes EPA's evaluation of Guilford County's contribution to Davidson County's air quality.

Meteorology

In your letter, you characterize as "puzzling" EPA's finding that emission sources in Guilford County contribute to the ambient air quality of Davidson County, which "lies in a direction opposite the prevailing winds." We understand your perspective and believe that EPA and North Carolina are viewing the wind data differently.

North Carolina submitted information prior to EPA making the final determination of the nonattainment boundary for the Greensboro area which included a discussion of wind patterns and other meteorology. The State's analysis showed that wind direction varies based on season, with influence coming from different directions at different times of year. In your letter, you focused on the wind pattern during the summer months, which shows prevailing winds from Guilford County generally away from Davidson County.

EPA analyzed the wind patterns, from all times of the year, in the area and found that there is influence on the Davidson County monitor from varying directions, including from the direction of Guilford County. While your assertion that the prevailing wind patterns from Guilford County are away from Davidson County is generally true in the summer months, EPA's analysis of year-round wind patterns found that the second strongest contribution to Davidson County is from the northeast, the direction of Guilford County. Attachment 1 is a pollution rose diagram for the violating monitor located in Davidson county. Each dot in the diagram represents a daily PM2.5 concentration (from the 2001-3 period) and the average wind direction and wind speed for that day. It shows that there were a number of days in the period when PM2.5 contributions toward the Davidson county monitor came from the northeast (the direction of Guilford county).

Regional Controls

In your letter, you discussed future regional controls, such as EPA's Clean Air Interstate Rule (CAIR), as providing reductions in PM2.5 levels in the east and southeast. EPA agrees that regional controls, such as CAIR, will provide reductions in elevated PM2.5 levels in the southeast, and we agree that CAIR will provide an important tool for reducing ambient PM2.5 levels across the region. However, regional control programs do not substitute for area-specific attainment demonstrations and are not designed to achieve to help a specific nonattainment area attain the national standards. For nonattainment areas, we rely on an area-specific control strategy developed by the State which should include a combination of significant regional controls along with specific local controls. In addition, the PM2.5 designations were based on current violations of the standard and associated contributions, not projected future conditions.

EPA understands North Carolina's preference for a smaller nonattainment boundary for the Greensboro-Winston Salem-High Point area and appreciate your commitment to continued improvement of air quality. However, your letter did not provide information that persuades EPA to reconsider its decision. Therefore, your petition for reconsideration is denied.

Sincerely,

Stephen L. Johnson

OFFICE OF
AIR QUALITY PLANNING
AND STANDARDS

MEMORANDUM

SUBJECT: Guidance on SIP Elements Required Under Sections 110(a)(1) and (2) for the 1997 8-hour Ozone and $PM_{2.5}$ National Ambient Air Quality Standards

FROM: for William T. Harnett, Director
Air Quality Policy Division (C539-01)

TO: Air Division Directors, Regions I-X

The purpose of this memorandum is to provide guidance on the "infrastructure" elements for State Implementation Plans (SIPs) required under section 110(a)(1) and (2) of the Clean Air Act (CAA) for the 1997 8-hour ozone and fine particulate matter ($PM_{2.5}$) national ambient air quality standards (NAAQS). Attachment A to this memo provides a list of the basic elements that States must include in their SIPs. To the extent that existing SIPs for ozone and particulate matter already meet these requirements, States need only certify that fact to the Environmental Protection Agency (EPA). To the extent that existing SIPs for ozone and particulate matter fail to address any of these requirements for purposes of the 1997 8-hour ozone or $PM_{2.5}$ NAAQS, States need to make timely SIP submissions to EPA to address these requirements. We anticipate that States will already have approved SIPs in place for ozone that meet the basic requirements of sections 110(a)(1) and (2). For $PM_{2.5}$, however, we anticipate that many States may need to make SIP revisions to ensure that their existing SIPs for prior particulate matter NAAQS are revised to include the new particle size indicator.

Background

On July 18, 1997, the EPA promulgated new and revised NAAQS for ozone and particulate matter. For ozone, EPA revised the NAAQS to provide an 8-hour averaging period (versus a 1-hour averaging period for the pre-existing NAAQS), and set the level of the standard at 0.08 ppm (versus 0.12 ppm for the pre-existing NAAQS). For PM, EPA promulgated a new 24-hour and a new annual NAAQS for $PM_{2.5}$ (particles with an aerodynamic diameter less than or equal to a nominal 2.5 micrometers).[1]

Under sections 110(a)(1) and (2) of the CAA, all States are required to submit plans to provide for the implementation, maintenance, and enforcement of the 8-hour ozone and $PM_{2.5}$ standards. Sections 110(a)(1) and (2) require States to address basic SIP requirements, including emissions inventories, monitoring, and modeling to assure attainment and maintenance of the standards. By statute, SIPs meeting the requirements of sections 110(a)(1) and (2) are to be submitted by States within 3 years after promulgation of a new or revised standard. This being the case, States were required to submit such SIPs for the 1997 standards to EPA no later than July 2000. However, intervening litigation over the 1997 8-hour ozone and $PM_{2.5}$ NAAQS, created uncertainty about how to proceed and, to date, States have not submitted SIPs to meet the basic or infrastructure requirements enumerated in sections 110(a)(1) and (2).

In March of 2004, Earth Justice initiated a lawsuit against EPA for failure to take action against States that had not made SIP submissions to meet the requirements of sections 110(a)(1) and (2), i.e., failure to make a "finding of failure to submit." On March 10, 2005, EPA entered into a Consent Decree with Earth Justice that obligates EPA to make official findings whether States have made required SIP submissions by dates certain. The Consent Decree obligates EPA to determine whether States have made SIP submissions required to meet CAA section 110(a)(2)(D)(i) relating to interstate transport by no later than March 15, 2005. The Consent Decree also obligates EPA to make a determination whether States have made submissions necessary to meet the remaining 110(a)(1) and (2) requirements by December 15, 2007, for the 8-hour ozone NAAQS, and by October 5, 2008, for the $PM_{2.5}$ NAAQS.[2] It should be noted that the latter determinations pertain only to whether the submissions are complete, pursuant to section 110(k)(1)(A), and do not constitute EPA approval or disapproval of such submissions. In addition, the determinations required by the Consent Decree explicitly exclude any determinations regarding: (i)

---

[1] More recently, on December 18, 2006, EPA again revised the standards for particulate matter, tightening the 24-hour $PM_{2.5}$ standard from 65 micrograms per cubic meter ($\mu g/m^3$) to 35 $\mu g/m,^3$ and retaining the current annual fine particle standard at 15 $\mu g/m^3$. EPA also decided to retain the existing 24-hour PM_{10} standard of 150 $\mu g/m^3$ and to revoke the annual PM_{10}. This guidance document applies only to the SIP submission requirements for the 1997 8-hour Ozone and $PM_{2.5}$ NAAQS. EPA will address SIP requirements for the 2006 NAAQS separately, although the Agency notes that the statutory requirements for SIPs for new or revised NAAQS are comparable.

[2] The dates specified in the Consent Decree reflect the anticipated dates for submission of nonattainment area SIPs for each NAAQS, plus six months for EPA evaluation. EPA presumed that States would make SIP submissions meeting the basic requirements of sections 110(a)(1) and (2) for each NAAQS contemporaneously with, or not later than, SIPs meeting the nonattainment area plan requirements. EPA notes that recent decisions by the U.S. Court of Appeals for the District of Columbia concerning the implementation rule for the 8-hour Ozone NAAQS have affected certain nonattainment area SIP requirements. These judicial decisions do not, however, affect States' obligations under the CAA or EPA's obligations under the Consent Decree concerning the infrastructure SIP requirements of sections 110(a)(1) and (2).

submissions required by section 110(a)(2)(C) to the extent that subsection pertains to a nonattainment area new source permit program in part D Title I of the CAA; and (ii) submissions required by section 110(a)(2)(I) for Part D Title I nonattainment area plans.

In accordance with the Consent Decree, EPA has already published a finding that all States had failed to submit new SIPs addressing interstate transport for the 8-hour ozone and $PM_{2.5}$ NAAQS, as required by section 110(a)(2)(D)(i) of the CAA (70 FR 21147, April 25, 2005). That finding initiated a 2-year deadline for the promulgation of a Federal Implementation Plan (FIP) by EPA for each such State unless, prior to that time, each State makes a submission to meet the requirements of Section 110(a)(2)(D)(i) and EPA approves such submission. On May 12, 2005, EPA published the Clean Air Interstate Rule (CAIR) which identifies the degree to which emissions of SO_2 and NO_x in certain States significantly contribute to nonattainment of, or interfere with maintenance of, the 1997 8-hour ozone and $PM_{2.5}$ NAAQS in downwind States, and the reductions that must be achieved in those States to eliminate such contributions.

On August 15, 2006, EPA issued guidance entitled "Guidance for State Implementation Plan (SIP) Submissions to Meet Current Outstanding Obligations Under Section 110(a)(2)(D)(i) for the 8-hour Ozone and $PM_{2.5}$ National Ambient Air Quality Standards." The section 110(a)(2)(D)(i) guidance indicates that States within the CAIR region can satisfy 110(a)(2)(D) by satisfying the requirements of the CAIR, and addresses what other States that are outside of the CAIR region should consider doing to meet the "significant contribution" and "interfere with maintenance" requirements of section 110(a)(2)(D)(i) for the 1997 standards. The section 110(a)(2)(D)(i) guidance also addresses what all States (whether inside or outside of the CAIR region) should consider in making SIP submissions to meet the "prevention of significant deterioration" and "protect visibility" requirements of section 110(a)(2)(D)(i). The SIP submissions addressed by the section 110(a)(2)(D)(i) guidance are those that are necessary to rectify the finding of failure to submit that EPA has already issued for all States for section 110(a)(2)(D)(i).

The guidance contained in this memorandum is intended as a reminder that States must have SIPs for the 1997 8-hour ozone and $PM_{2.5}$ NAAQS that meet all of the requirements of sections 110(a)(1) and (2). Pursuant to the Consent Decree, EPA has an obligation to take action to determine whether States have made such submissions by the dates noted above. Because States should currently be in the process of submitting nonattainment SIPs for the 8-hour ozone standard and working on nonattainment area SIPs for the $PM_{2.5}$ standard, we want to alert them to be sure that their SIPs also meet the basic requirements of sections 110(a)(1) and (2).

Guidance

The EPA believes that the currently-approved section 110 SIPs for ozone may already be adequate in most cases to implement the 8-hour ozone NAAQS. Many of the required section 110(a)(1) and (2) SIP elements relate to the general information and authorities that constitute the "infrastructure" of the ozone air quality management program, and these have been in place since the initial SIPs were submitted in response to the 1970 Clean Air Act. For particulate matter, however, EPA believes that some States may need to adopt language specific to the $PM_{2.5}$ NAAQS to ensure that they have adequate SIP provisions to implement the $PM_{2.5}$ NAAQS, e.g., existing State laws may refer to PM_{10} specifically or to particulate matter more generally, rather than to $PM_{2.5}$. We believe that with one exception, the infrastructure requirements of sections 110(a)(1) and (2) are relatively self explanatory, and past experience with SIPs for other NAAQS should enable States to meet these requirements with assistance from EPA Regions. The one exception is section 110(a)(2)(G) relating to emergency episodes, for which EPA intends to take additional regulatory action to provide necessary numerical limits and concentration levels for emergency episode action plans for $PM_{2.5}$.

States should review and revise, as appropriate, their existing ozone and particulate matter SIPs to ensure that they are adequate to address the 8-hour ozone and $PM_{2.5}$ NAAQS. If a State determines that its existing SIP is adequate, then the State needs to certify, via a letter to the Agency from the Governor or his/her designee, that the existing SIPs contain provisions that address the requirements for the 8-hour ozone and $PM_{2.5}$ NAAQS. If a State determines that its existing ozone or particulate matter SIPs are inadequate, however, then the State needs to submit a SIP revision to make the appropriate changes.

With respect to $PM_{2.5}$, States may find it more advantageous to revise the language in their SIPs to identify "particulate matter" as the pollutant being implemented and define the size fractions as "those that EPA has currently set for the NAAQS" to the extent such an approach would be authorized by State law. This will ensure that the provisions remain adequate in the event that future changes occur to the particulate matter standards. States could also specify both PM_{10} and $PM_{2.5}$ as the size fractions if a State prefers to be more specific.

As an aid to the States in addressing the $PM_{2.5}$ related requirements of Section 110(a)(2)(G) pertaining to emergency episode provisions, EPA intends to take action to revise 40 CFR, Part 51, subpart H (sections 51.150). The rule changes will establish the priority classifications which determine the emergency episode plan requirements for each area and establish a significant harm level (SHL) for $PM_{2.5}$. Until these changes are final, EPA recommends that States rely on relevant information contained in upcoming EPA rule proposals or other EPA-issued interim guidance to satisfy the section 110(a)(2)(G) requirements for $PM_{2.5}$. After EPA issues final rules, EPA will work with States to revise SIP submissions that were based on interim information, as appropriate. States may wish to take advantage of the parallel processing mechanism for making their section 110(a)(2)(G) submittal in the interim while EPA completes rulemakings on the SHL and the emergency episode plan requirements under 40 CFR 51.150.

The SHL for the 8-hour ozone NAAQS will remain unchanged as 0.60 ppm ozone, 2-hr average, as indicated in 40 CFR Part 51.151. EPA believes that the existing ozone-related provisions of 40 CFR Subpart H remain appropriate. Therefore, EPA expects that for purposes of the 1997 8-hour ozone NAAQS, States need only to confirm that they have existing emergency episode plan provisions consistent with EPA's existing regulatory requirements.

By statute, States are required to make SIP submissions to meet the basic requirements of CAA sections 110(a)(1) and (2) within 3 years after promulgation of any new or revised standards. For the 1997 8-hour ozone and $PM_{2.5}$ standards, this deadline was July 2000. By Consent Decree, as noted above, EPA has agreed to make a determination whether or not States have submitted SIPs to meet these requirements by a date certain. In the case of 8-hour ozone SIPs, this date is December 15, 2007. For $PM_{2.5}$ SIPs, this date is October 15, 2008. In order for EPA to evaluate the submissions adequately, EPA requests that States make their certifications of SIP adequacy or SIP revisions as soon as possible and to the extent feasible sufficiently in advance of these dates to allow EPA time to determine whether complete submissions have been made.

If you have any questions concerning this guidance, please contact Mr. David Sanders at (919) 541-3356. Please ensure that the appropriate air agency officials for States in your Region are made aware of this guidance.

Attachment A: Required Section 110 SIP Elements

The SIP elements listed below are required under section 110(a)(1) and (2). Section 110(a)(1) provides the procedural and timing requirements for SIPs. Section 110(a)(2) lists the basic or "infrastructure" elements that all SIPs must contain. We note that this list is not intended to constitute an interpretation of these provisions, or a change of past practice with respect to these provisions, merely a brief description of the required SIP elements.

Emission limits and other control measures: Section 110(a)(2)(A) requires SIPs to include enforceable emission limits and other control measures, means or techniques, schedules for compliance and other related matters. EPA notes that the specific nonattainment area plan requirements of section 110(a)(2)(I) are subject to the timing requirement of section 172, not the timing requirement of section 110(a)(1), and also that SIPs to meet this section are not covered by the Consent Decree.

Ambient air quality monitoring/data system: Section 110(a)(2)(B) requires SIPs to include provisions to provide for establishment and operation of ambient air quality monitors, collecting and analyzing ambient air quality data, and making these data available to EPA upon request.

Program for enforcement of control measures: Section 110(a)(2)(C) requires States to include a program providing for enforcement of all SIP measures and the regulation of construction of new or modified stationary sources to meet prevention of significant deterioration (PSD) and nonattainment NSR requirements.

Interstate transport: Section 110(a)(2)(D) requires SIPs to include provisions prohibiting any source or other type of emissions activity in one State from contributing significantly to nonattainment, or interfering with maintenance, of the NAAQs in another State, or from interfering with measures required to prevent significant deterioration of air quality or to protect visibility in another State. EPA has already issued CAIR to assist States in developing SIPs to meet this requirement for purposes of the 8-hour Ozone and $PM_{2.5}$ NAAQS, and has issued separate guidance to all States on how to comply with each prong of this statutory provision.

Adequate resources: Section 110(a)(2)(E) requires States to provide for adequate personnel, funding, and legal authority under State law to carry out its SIP, and related issues.

Stationary source monitoring system: Section 110(a)(2)(F) requires States to establish a system to monitor emissions from stationary sources and to submit periodic emissions reports.

Emergency power: Section 110(a)(2)(G) requires States to provide for authority to address activities causing imminent and substantial endangerment to public health, including contingency plans to implement the emergency episode provisions in their SIPs.

Future SIP revisions: Section 110(a)(2)(H) requires States to have the authority to revise their SIPs in response to changes in the NAAQS, availability of improved methods for attaining the NAAQS, or in response to an EPA finding that the SIP is substantially inadequate.

Consultation with government officials: Section 110(a)(2)(J) requires States to provide a process for consultation with local governments and Federal Land Managers carrying out NAAQS implementation requirements pursuant to section 121 relating to consultation.

Public notification: Section 110(a)(2)(J) further requires States to notify the public if NAAQS are exceeded in an area and to enhance public awareness of measures that can be taken to prevent exceedances.

PSD and visibility protection: Section 110(a)(2)(J) also requires States to meet applicable requirements of part C related to prevention of significant deterioration and visibility protection.

Air quality modeling/data: Section 110(a)(2)(K) requires that SIPs provide for performing air quality modeling for predicting effects on air quality of emissions from any NAAQS pollutant and submission of such data to EPA upon request.

Permitting fees: Section 110(a)(2)(L) requires SIPs to require each major stationary source to pay permitting fees to cover the cost of reviewing, approving, implementing and enforcing a permit.

Consultation/participation by affected local entities: Section 110(a)(2)(M) requires States to provide for consultation and participation in SIP development by local political subdivisions affected by the SIP.

Subject: Development of Motor Vehicle Emissions Budgets

Dear Transportation Partner:

The North Carolina Division of Air Quality (NCDAQ) is developing the attainment demonstrations for 8-hour ozone and PM2.5 nonattainment areas in North Carolina. The State Implementation Plan (SIP) attainment demonstration submitted to the U. S. Environmental Protection Agency (USEPA) establishes the motor vehicle emissions budgets (MVEBs) that will be used in future transportation conformity demonstrations once approved or deemed adequate by the USEPA. At stakeholder meetings held throughout 2005, NCDAQ presented different approaches for setting MVEBs. As a result of the feedback received by NCDAQ during the stakeholder meetings, the decision was made to develop a policy memo that provides an explanation of NCDAQ's preference for the geographical basis of MVEBs in nonattainment areas and clearly outlines the procedures and timelines for setting those MVEBs.

NCDAQ believes that the MVEBs should be set at the county level. The reason NCDAQ believes this is appropriate is as follows:

- The motor vehicle emissions generated for SIP attainment demonstration are by county; therefore, developing county level MVEBs would maintain consistency with the attainment modeling. County level sub-area MVEBs provide additional assurance that future conformity determinations, transportation plans, and TIPs will produce emission patterns that will achieve and maintain the National Ambient Air Quality Standards (NAAQS).
- County level sub-area MVEBs preserve the growth projected by Metropolitan Planning Organizations (MPOs)/Rural Planning Organizations (RPOs)/North Carolina Department of Transportation (NCDOT). NCDAQ has relied on MPOs/RPOs/NCDOT to provide these future projections of vehicle miles traveled (VMT) in the SIP process and will continue to rely on MPOs/RPOs/NCDOT as the source of this data throughout the MVEB setting process.
- County level sub-area MVEBs would eliminate the requirement for a new conformity analysis for all MPOs/RPOs in the nonattainment area if one of the MPOs/RPOs revises or updates their respective long range transportation plan or transportation improvement program when there are conforming plans in place for the other areas. In a situation where there are conforming plans in place and there are county level sub-area MVEBs, if one MPO in the nonattainment area had a conformity lapse, the neighboring MPOs/RPOs would not be impacted until their next conformity determination was due.

Planning Section
1641 Mail Service Center, Raleigh, North Carolina 27699-1641
2728 Capital Blvd., Raleigh, North Carolina 27604
Phone: 919-715-7670 / FAX 919-715-7476 / Internet: www.ncair.org

- If an area-wide MVEB involving multiple MPOs/RPOs is set and conformity cannot be demonstrated, it could take significantly longer to resolve which projects should be removed from the various plans. If resolution is not reached in a timely manner, it could result in a conformity lapse for the entire nonattainment or maintenance area.

An important component to the SIP development process is interagency consultation. Therefore, NCDAQ requests feedback from the transportation partners on MVEBs development. NCDAQ's preference is not to set MVEBs for areas less than a county boundary since the emission estimates are made on a county level basis. The exception to this would be partial counties designated as nonattainment. Additionally, NCDAQ prefers not setting MVEBs based on MPO/RPO boundaries since this would result in having to update the MVEBs every time the MPO/RPO boundaries change. The process for recommending other approaches is provided below.

- Transportation partners are invited to provide in writing their preferred approach to setting MVEBs. If setting MVEBs for area-wide or multi-county sub-area is the desired approach, then it must be agreed upon by all of the transportation partners that are responsible for conducting conformity analyses for that area. This includes the MPO(s) and NCDOT after consultation with the RPO(s).
- NCDAQ requests that all written submittals outlining a MVEB approach that consists of more than one county (i.e., area-wide or multi-county sub-areas) include a technical explanation as to why the MVEBs should be set as such. This explanation should include information that illustrates the similarities between the counties listed in the approach such as, but not limited to: degree of urbanization, commuting patterns, expected population and VMT, and expected population and VMT growth rates.
- All requests should be submitted for consideration to NCDAQ by **January 16, 2006**. This will allow NCDAQ time to review and respond to the requests prior to finalizing the documentation for the SIP in February 2006.
- Requests should be submitted to the attention of the Attainment Planning Branch Chief, Laura Boothe, 1641 Mail Service Center, Raleigh, NC 27699-1641.

NCDAQ is responsible for submitting the SIP attainment demonstration and ensuring that the measures in the demonstration will allow the area to attain, as well as maintain the NAAQS. Transportation conformity was designed to help ensure that transportation plans, programs, and projects do not produce new air quality violations, worsen existing violations, or delay timely attainment of NAAQS. NCDAQ will take into consideration the recommended approaches from the transportation partners when developing the MVEBs. The transportation partners will have an opportunity to review the draft final MVEB approach prior to the SIP going through the public hearing process.

NCDAQ is committed to working with all of our partners during this process to determine the best course of action in achieving and maintaining air quality goals. If you should have any questions, please contact Laura Boothe of my staff at (919) 733-1488 or laura.boothe@ncmail.net.

Sincerely,

B. Keith Overcash, P.E.

Re: Development of Motor Vehicle Emissions Budgets

Dear Ms. Boothe:

The Greensboro Urban Area Metropolitan Planning Organization (MPO) welcomes the opportunity to comment on the development of the Motor Vehicle Emission Budgets (MVEB) for 8 hour ozone and PM 2.5.

The MPO is in agreement with the methodology laid out in the letter dated September 16, 2005 regarding the development of the MVEB. The MPO agrees that development of motor vehicle emissions at a county-level allows for easier data transference and flexibility in the conformity process.

Thank you for the opportunity to comment and please contact me at (336) 373-3117 should you have any questions or need any additional information.

Sincerely,

Lydia M. McIntyre
Transportation Planning Engineer

To: laura.boothe@ncmail.net

Laura,
On behalf of citizens for Smrth Growth, I am writing to express our support for county level MVEBs and urge you to continue with your traditional method foe setting budgets.
Thanks
Ron

Dear Ms. McIntyre:

Thank you for your letter about setting motor vehicle emission budgets (MVEBs) for the Greensboro-Winston-Salem-High Point fine particulate matter nonattainment area. We greatly appreciate your feedback on the setting of the MVEBs.

We have decided to set county level MVEBs for transportation conformity purposes in this nonattainment area and appreciate your support of this. We believe that county level MVEBS better serve our goals of attaining and maintaining the standard in order to protect public health.

The North Carolina Division of Air Quality is committed to working with all our partners during the State Implementation Plan (SIP) process to determine the best course of action in achieving and maintaining air quality goals. If you should have any questions, please contact Laura Boothe of my staff at (919) 733-1488 or laura.boothe@ncmail.net.

Sincerely,

B. Keith Overcash, P.E.

Subject: Consultation Plan with MVEB for the Hickory NA Area
From: "Phyllis.D.Jones" <Phyllis.D.Jones@ncmail.net>
Date: Tue, 29 Jan 2008 11:12:17 -0500
To: john.tippett@wpcog.org, john.marshall@wpcog.org, lnguyen@dot.state.nc.us, sarahsmith@dot.state.nc.us, "Alena Cook \(Cook, Alena\)" <arcook@dot.state.nc.us>, "Stark, Jill" <Jill.Stark@fhwa.dot.gov>

Good Morning All,

As you know, the NCDAQ is planning on pursuing insignificance for Primary PM_2.5 , NOx, NH_3 , SO_2 , VOC and road dust for the Hickory NA area. When the NCDAQ submits the PM_2.5 SIP for public comment (currently scheduled for 2/11/08), the draft SIP will have two options, one with a Primary PM_2.5 MVEB for Catawba County, and an option without a MVEB. If the option without a MVEB is not approved by EPA, the NCDAQ will have to establish a MVEB for Catawba County. Attached is the consultation plan outlining the MOBILE6.2 parameters used to develop the Primary PM_2.5 MVEB for the Hickory NA area with the MVEB for Catawba County. The MVEB is calculated using the latest speeds, VMT, vehicle age distribution and vehicle count data (used to calculate the vehicle mix) supplied by NCDOT.

MOBILE6.2 is insensitive to the such parameters as temperature, RVP, anti-tampering and I/M commands when calculating PM_2.5 emission factors, therefore, the Primary PM_2.5 emission factor was calculated for a typical summer day (using summertime temperatures, RVP, etc.) and multiplied by 365 days to calculate an annual emission of kg/year. We performed various sensitivity runs with MOBILE6.2 to verify this.

Please provide comments to me by **2/05/08**. I can be reached via phone at 919-715-1246 or e-mail Phyllis.D.Jones@ncmail.net.

Thanks,
Phyllis D. Jones, EIT

PM2.5 SIP MVEB Mobile inputs.doc	**Content-Type:** application/msword **Content-Encoding:** base64

Subject: Consultation Plan with MVEB for the Triad NA Area
From: "Phyllis.D.Jones" <Phyllis.D.Jones@ncmail.net>
Date: Tue, 29 Jan 2008 10:53:05 -0500
To: Scott Rhine <scottr@partnc.org>
CC: Eddie Dancausse <edward.dancausse@fhwa.dot.gov>, Lynorae Benjamin <Benjamin.Lynorae@epamail.epa.gov>, "Terry Arellano, PE" <tarellano@dot.state.nc.us>, George Bridgers <George.Bridgers@ncmail.net>, Amanetta Wood <Wood.Amanetta@epamail.epa.gov>, ward.nacosta@epa.gov, Laura Boothe <laura.boothe@ncmail.net>, Janice Godfrey <Janice.Godfrey@ncmail.net>

Good Morning Scott,

As you know, the NCDAQ is planning on pursuing insignificance for Primary PM_2.5 , NOx, NH_3 , SO_2 , VOC and road dust for the Triad NA area. When the NCDAQ submits the PM_2.5 SIP for public comment (currently scheduled for 2/11/08), the draft SIP will have two options, one with a Primary PM_2.5 MVEB for Davidson and Guilford Counties, and an option without MVEBs. If the option without MVEBs is not approved by EPA, the NCDAQ will have to establish MVEBs for Davidson and Guilford Counties. Attached is the consultation plan outlining the MOBILE6.2 parameters used to develop the Primary PM_2.5 MVEBs for the Triad NA area with MVEBs for each county. The MVEBs are calculated using the latest speeds, VMT, vehicle age distribution and vehicle count data (used to calculate the vehicle mix) supplied by NCDOT.

I would like to note that there are slight differences in the MOBILE6.2 parameters used to develop the MVEBs and the current conformity demonstration. MOBILE6.2 is insensitive to the such parameters as temperature, RVP, anti-tampering and I/M commands when calculating PM_2.5 emission factors. We performed various sensitivity runs with MOBILE6.2 to verify this. Therefore, the Primary PM_2.5 emission factors were calculated for a typical summer day (using summertime temperatures, RVP, etc.) and multiplied by 365 days to calculate an annual emissions of kg/year.

Can you please share this with the Triad NA area partners? Please provide comments to me by **2/05/08**. I can be reached via phone at 919-715-1246 or e-mail Phyllis.D.Jones@ncmail.net.

Mobile Model Settings for Developing the 2009 MVEB in the $PM_{2.5}$ Attainment Demonstration for Catawba, Davidson, and Guilford Counties

Parameter	Details
a. ***Emissions Model Version(s):***	MOBILE6.2
b. ***Emission Model Runs:***	Average annual weekday.
c. ***Time Periods:***	Used daily data from TRM and Rural areas to calculate the annual emissions.
d. ***Pollutants Reported:***	$PM_{2.5}$
e. ***Emissions Budget Year:***	2009
f. ***Vehicle Classes:***	16
g. ***Max/Min Temperatures:***	Annual average 2002 max/min temperatures based upon the data from the Hickory Regional Airport (KHKY) and the Piedmont Triad International Airport (KGSO).

County	2002 Annual Average Max (F)	2002 Annual Average Min (F)
Catawba	70	50
Davidson	70	49
Guilford	70	49

h. ***VMT Mix:*** 2009 statewide vehicle mix based upon the 2006 count data provided by NCDOT using the method in the August 2004 USEPA Emissions Inventory Technical Guidance.

2009 State Vehicle Mix

k. ***Anti-tampering Applicability:*** Applies to vehicles 35 years and newer starting with MY 1975.

l. ***RVP:*** RVP does not impact the MOBILE6.2 $PM_{2.5}$ emission factors, therefore, NCDAQ is using the summertime RVP.

County	**Average Annual RVP (psi)**
Catawba	9.0
Davidson	7.8
Guilford	7.8

m. ***I/M Fraction:*** Will assume 100 percent penetration since MOBILE6.2 $PM_{2.5}$ emission factors are not impacted by I/M.

n. ***Evaluation month:*** July

o. ***VMT:*** TRM and rural spreadsheet where applicable.

Catawba County VMT

Subject: RE: Consultation Plan with MVEB for the Hickory NA Area
From: "John Tippett" <john.tippett@wpcog.org>
Date: Tue, 29 Jan 2008 11:59:49 -0500
To: "Phyllis.D.Jones" <Phyllis.D.Jones@ncmail.net>, "John Marshall" <john.marshall@wpcog.org>, <lnguyen@dot.state.nc.us>, <sarahsmith@dot.state.nc.us>, "Alena Cook (Cook, Alena)" <arcook@dot.state.nc.us>, "Stark, Jill" <Jill.Stark@fhwa.dot.gov>
CC: "Dancausse, Edward" <edward.dancausse@fhwa.dot.gov>, <george.bridgers@ncmail.net>, <janice.godfrey@ncmail.net>, <keith.melton@dot.gov>, <tarellano@dot.state.nc.us>, <Wood.Amanetta@epamail.epa.gov>, <Benjamin.Lynorae@epamail.epa.gov>, <ward.nacosta@epa.gov>, "Laura Boothe" <laura.boothe@ncmail.net>, "Taylor Dellinger" <taylor.dellinger@wpcog.org>

The Mobile 6 factors look reasonable to us at the MPO and we have no other comments. Our knowledge is limited in this area so we will defer to others.
John Tippett
Greater Hickory MPO

Subject: Consultation Plan with MVEB for the Hickory NA Area

Good Morning All,

As you know, the NCDAQ is planning on pursuing insignificance for Primary PM_2.5 , NOx, NH_3 , SO_2 , VOC and road dust for the Hickory NA area. When the NCDAQ submits the PM_2.5 SIP for public comment (currently scheduled for 2/11/08), the draft SIP will have two options, one with a Primary PM_2.5 MVEB for Catawba County, and an option without a MVEB. If the option without a MVEB is not approved by EPA, the NCDAQ will have to establish a MVEB for Catawba County. Attached is the consultation plan outlining the MOBILE6.2 parameters used to develop the Primary PM_2.5 MVEB for the Hickory NA area with the MVEB for Catawba County. The MVEB is calculated using the latest speeds, VMT, vehicle age distribution and vehicle count data (used to calculate the vehicle mix) supplied by NCDOT.

MOBILE6.2 is insensitive to the such parameters as temperature, RVP, anti-tampering and I/M commands when calculating PM_2.5 emission factors, therefore, the Primary PM_2.5 emission factor was calculated for a typical summer day (using summertime temperatures, RVP, etc.) and multiplied by 365 days to calculate an annual emission of kg/year. We performed various sensitivity runs with MOBILE6.2 to verify this.

Please provide comments to me by **2/05/08**. I can be reached via phone at 919-715-1246 or e-mail Phyllis.D.Jones@ncmail.net.

Thanks,
Phyllis D. Jones, EIT

Quarterly average $PM_{2.5}$ values are presented in micrograms per meter cubed ($\mu g/m^3$).

Bolded values represent quarters whose average values exceed the level of the annual PM2.5 National Ambient Air Quality Standard (i.e. greater than 15.0 $\mu g/m^3$).

The Mendenhall site was not in operation during 2000 or 2001.

Italics value represents estimated 4th quarter 2006 data at Mendenhall. There was an extended loss of monitoring data at the Mendenhall site during the 4th quarter of 2006. The NCDAQ has performed an extensive data imputation study to estimate a 4th quarter average concentration such that an appropriate annual average concentration and design value could be calculated. This study, titled "Mendenhall PM2.5 Data Imputation for 4Q2006" can be found in Appendix C.3.

Table 2. Annual Average $PM_{2.5}$ Values ($\mu g/m^3$) for the Hickory and Greensboro-Winston Salem-High Point Nonattainment Areas

Monitoring Site	County	Annual Averages								
		2000	2001	2002	2003	2004	2005	2006	2007	2008
Hickory	Catawba	**17.6**	**16.0**	**15.4**	15.0	15.0	**15.9**	**15.2**	14.5	12.8
Lexington	Davidson	**18.0**	**16.5**	**15.9**	**15.2**	**15.2**	**15.4**	**15.1**	14.6	13.7
Mendenhall	Guilford			13.7	13.3	14.0	14.0	*14.1*	13.0	11.4

Annual average $PM_{2.5}$ values are presented in micrograms per meter cubed ($\mu g/m^3$).

Bolded values represent annual average values that exceed the level of the annual PM2.5 National Ambient Air Quality Standard (i.e. greater than 15.0 $\mu g/m^3$).

The Mendenhall site was not in operation during 2000 or 2001.

Italics value represents a 2006 annual average that used estimated 4th quarter 2006 data at Mendenhall. There was an extended loss of monitoring data at the Mendenhall site during the 4th quarter of 2006. The NCDAQ has performed an extensive data imputation study to estimate a 4th quarter average concentration such that an appropriate annual average concentration and design value could be calculated. This study, titled "Mendenhall PM2.5 Data Imputation for 4Q2006" can be found in Appendix C.3.

Table 3. 3-year Current $PM_{2.5}$ Design Values ($\mu g/m^3$) for the Hickory and Greensboro-Winston Salem-High Point Nonattainment Areas

Monitoring Site	County	Design Values						
		2000-2002	2001-2003	2002-2004	2003-2005	2004-2006	2005-2007	2006-2008
Hickory	Catawba	**16.3**	**15.5**	**15.1**	**15.3**	**15.4**	**15.2**	14.2
Lexington	Davidson	**16.8**	**15.8**	**15.4**	**15.2**	**15.2**	**15.1**	14.5
Mendenhall	Guilford			13.7	13.8	*14.0*	*13.7*	*12.9*

$PM_{2.5}$ design values are presented in micrograms per meter cubed ($\mu g/m^3$).

Bolded values represent design values that exceed the level of the annual PM2.5 National Ambient Air Quality Standard (i.e. greater than 15.0 $\mu g/m^3$).

The Mendenhall site was not in operation during 2000 or 2001. So, the first design value period that can be calculated is 2002-2004.

Italics values represent design values that used estimated 4th quarter 2006 data at Mendenhall. There was an extended loss of monitoring data at the Mendenhall site during the 4th quarter of 2006. The NCDAQ has performed an extensive data imputation study to estimate a 4th quarter average concentration such that an appropriate annual average concentration and design value could be calculated. This study, titled "Mendenhall PM2.5 Data Imputation for 4Q2006" can be found in Appendix C.3.

Table 4. Summary table of $PM_{2.5}$ Values used in for Designations in the Hickory and Greensboro-Winston Salem-High Point Nonattainment Areas

County	FRM Monitoring Site	Year	1st Quarter (Q1)	2nd Quarter (Q2)	3rd Quarter (Q3)	4th Quarter (Q4)	Annual Average	Design Value
Catawba	Hickory	2001	**15.3**	**16.6**	**18.8**	13.2	**16.0**	**15.5**
		2002	13.3	14.3	**21.1**	12.7	**15.4**	
		2003	12.9	**16.1**	**19.3**	11.8	**15.0**	
Davidson	Lexington	2001	14.8	**18.6**	**18.8**	13.6	**16.5**	**15.8**
		2002	14.9	15.0	**19.3**	14.3	**15.9**	
		2003	12.6	**16.1**	**19.1**	12.9	**15.2**	
Guilford	Mendenhall	2001	12.0	**16.7**	**18.0**	12.9	14.9	14.0
		2002	11.7	13.1	**18.3**	11.7	13.7	
		2003	11.6	13.6	**16.5**	11.7	13.3	

$PM_{2.5}$ design values are presented in micrograms per meter cubed ($\mu g/m^3$).

Bolded values represent design values that exceed the level of the annual PM2.5 National Ambient Air Quality Standard (i.e. greater than 15.0 $\mu g/m^3$).

Underline values represent values that incorporate data from the Edgeworth & Bellmeade (37-081-0009) monitoring site. The Mendenhall site replaced the Edgeworth & Bellmeade site in 4th quarter 2001.

Appendix C.2
Air Quality Data Used For Modeling

(This page intentionally left blank)

1. Air Quality Data for 2002

As part of the Visibility Improvement State and Tribal Association of the Southeast (VISTAS) Phase I modeling study, the VISTAS emissions and air quality modeling team of ENVIRON International Corporation, Alpine Geophysics (AG) and the University of California at Riverside (UCR) compiled ambient monitoring data for both gas and particulate species to be used in the VISTAS regional haze model performance evaluation. UCR took the lead in this activity. The contractor's report (found in Attachment C.1) describes the sources of the ambient data and the steps taken in the processing and quality assurance (QA) of the data. In addition, the ambient data is being processed and formatted in preparation for use in software packages designed for the model performance evaluation.

The goal was to preprocess the ambient data and present plots of ambient data on the project website so model performance evaluations when the model simulations were completed. The ambient data are available from the following 9 monitoring networks or databases:

- EPA's AQS (Environmental Protection Agency's Air Quality System) database
- PAMS (Photochemical Assessment Monitoring Stations)
- IMPROVE (The Interagency Monitoring of Protected Visual Environments)
- SEARCH (Southeastern Aerosol Research and Characterization)
- EPA's STN (Speciation Trends Network)
- NADP (National Atmospheric Deposition Program)
- CASTNET (Clean Air Status and Trend Network)
- PM Supersites
- NARSTO SOS99 Aircraft data (for the July 1999 episode only)
- TVA measurement network
- Georgia Institute of Technology Assessment of Spatial Aerosol Composition in Atlanta (ASACA) monitors.

Note that there is some overlap in the above monitoring networks. For example, some data from PAMS (such as ozone and nitrogen oxides) are included in the AQS database, and it appears that the STN network may also include speciated particulate matter data from IMPROVE and other monitoring networks. Attachment C.1 contains maps of many of the existing and planned (as of January 2002) urban and rural fine particulate matter speciation networks. The available data from the above monitoring networks for the three episodes of VISTAS regional haze modeling (July 9-22, 1999, July 7-28, 2001 and January 1- 21, 2002) was obtained. The attempt was made to reconcile data from the various networks and to perform a high level QA of the ambient data. The monitoring networks, the available data, and QA efforts are described in their entirety in the previously mentioned VISTAS report.

Additional data used in the air quality modeling include the Total Ozone Mapping Spectrometer (TOMS). TOMS data is available for 24-hour average and is obtained from http://toms.gsfc.nasa.gov/eptoms/ep.html. The TOMS data is used in the CMAQ radiation model (JPROC) to calculate photolysis rates.

1.1 Quality Assurance – Overview

The VISTAS Phase II emissions and air quality modeling team received emissions, meteorological and air quality data from other VISTAS contractors or other sources. As a first line of QA, a Gatekeeper function was defined to assure the data have been received correctly, evaluate the quality of the data, and document the data received. Separate air quality, meteorological and emissions Gatekeepers have been identified whose roles are defined below. In addition, a Data Management Gatekeeper has been defined who will post data, reports and results to the project website and archive all key data generated in the project.

- **Air Quality Data Gatekeeper**. Obtain air quality data as appropriate for model input development and model performance evaluation and assure quality of all air quality data obtained, consistent with approved QA plan. This gatekeeper will also provide documentation of evaluation and generate IC/BC inputs for CMAQ for all modeling runs.
- **Meteorological Gatekeeper**. Obtain meteorological data, as MM5 or MCIP files, as appropriate for annual 2002 modeling runs and other episode periods and perform data quality checks as approved in QA plan together with appropriate documentation of model performance evaluation activities.

1.2 Quality Assurance of Air Quality Data

In gathering data from the monitoring networks it is assumed that the agency or researcher responsible for collecting the data performed quality assurance on the data. However, it is possible that the data sets may contain erroneous data (i.e., missing data, zeros during calibration, unrealistic values, etc). Due to poor documentation or poor formatting of some data sets it is also possible that mistakes may be made in our processing of the data. To guard against this possibility, a plan to perform a high level QA by visually inspecting time-series plots and scatter plots of the ambient data was developed and is outlined as follows:

<u>Plots of Time Series:</u>

Time series plots are generated for PAMS species. The plots should be inspected for the following:

- Large "jumps" or "dips" in the concentrations
- Periodicity of peaks, calibration carryover
- Unexpected diurnal behavior (i.e., isoprene)
- Unexpected relationships among species
- High single-hour concentrations of less abundant species

Scatter Plots:

Scatter plots may be prepared for the following:

- Total NMOC vs. species group totals, vs. individual species
- Benzene vs. Toluene, Acetylene, Ethane
- Scatter plots comparing data for a single species measured with different sampling methods
- Plots of reconstructed mass versus measured mass (to reveals if anything unusual is happening with the chemical measurements)
- Plots of molal particulate ammonium versus the molal sum of sulfate and particulate nitrate (as a sanity check on the ion balance in the PM chemical measurements)

If data is identified that appears flawed it will be flagged and either corrected if the error is in the processing step, or removed from the data set.

Further detail on the quality assurance of air quality data modeling data can be found in the VISTAS document in Attachment C.1. Additional information on quality assurance procedures can be found in the QAPP, as referenced in Appendix G of the SIP.

1.0 SUMMARY

As part of the VISTAS Phase I modeling study, the VISTAS emissions and air quality modeling team of ENVIRON International Corporation, Alpine Geophysics (AG) and the University of California (UC) are compiling ambient monitoring data for both gas and particulate species to be used in the VISTAS regional haze model performance evaluation. The University of California at Riverside (UCR) is taking the lead in this activity. This report describes the sources of the ambient data and the steps that will be used in the processing and quality assurance (QA) of the data. In addition, the ambient data is being processed and formatted in preparation for use in software packages designed for the model performance evaluation. Our goal is to preprocess the ambient data and present plots of ambient data on the project website so that we can rapidly complete model performance evaluations when the model simulations are completed. As the processing of ambient data are completed, plots of the data are being made available at the project website: http://pah.cert.ucr.edu/vistas/ambient.shtml. A large amount of this data is currently available at the project website, and we are continuing to develop the website to facilitate the display of time series plots.

The ambient data are available from the following 9 monitoring networks or databases:

- EPA's AQS (Air Quality System) database
- PAMS (Photochemical Assessment Monitoring Stations)
- IMPROVE (The Interagency Monitoring of Protected Visual Environments)
- SEARCH (Southeastern Aerosol Research and Characterization)
- EPA's STN (Speciation Trends Network)
- NADP (National Atmospheric Deposition Program)
- CASTNET (Clean Air Status and Trend Network)
- PM Supersites
- NARSTO SOS99 Aircraft data (for the July 1999 episode only)
- TVA measurement network
- Georgia Institute of Technology Assessment of Spatial Aerosol Composition in Atlanta (ASACA) monitors.

Note that there is some overlap in the above monitoring networks. For example, some data from PAMS (such as O3 and NOx) are included in the AQS database, and it appears that the STN network may also include speciated PM data from IMPROVE and other monitoring networks. Appendix A shows maps of many of the existing and planned (as of January, 2002) urban and rural $PM_{2.5}$ speciation networks.

We have obtained most of the available data from the above monitoring networks for the three episodes of VISTAS regional haze modeling (July 9-22, 1999, July 7-28, 2001 and January 1-21, 2002). Although a comprehensive quality assurance and validation effort is beyond the scope of this effort, we are attempting to reconcile data from the various networks and to perform a high level QA of the ambient data. The monitoring networks, the available data, and QA efforts are described below. We expect that during the next two months we will continue to gather and process ambient data, and will rely on expertise from other team members and VISTAS in identifying ambient data. We have not yet investigated the possibility of systematic bias among different analytical methods used in the various networks. However, this is an important subject to be addressed because of the possibility that networks employ different sampling methods.

Measurement data from monitors operated by the Tennessee Valley Authority (TVA) and Georgia Technology's ASACA monitors have not yet been acquired. ASACA has been operating three Particle Composition Monitors and three TEOMS in Atlanta since early 1999. When acquired, these data will be documented on the project website.

2.0 EPA'S AIR QUALITY SYSTEM (AQS)

The Air Quality System (AQS) database is EPA's repository of "**criteria air pollutant**" monitoring data since the 1970s. The **criteria air pollutants** are:

- Carbon Monoxide (CO)
- Nitrogen Dioxide (NO2)
- Sulfur Dioxide (SO2)
- Ozone (O3)
- Particulate Matter (PM_{10} and $PM_{2.5}$)
- Lead (Pb)

Ambient concentrations of these pollutants from more than 4000 monitoring stations are reported to AQS on weekly or monthly basis. While several other monitoring networks (e.g. PAMS, IMPROVE, CASTNet, and etc.) owned and operated by different agencies collect various air pollutants, only **criteria air pollutants** are reported to AQS (as shown in Figure 2-1).

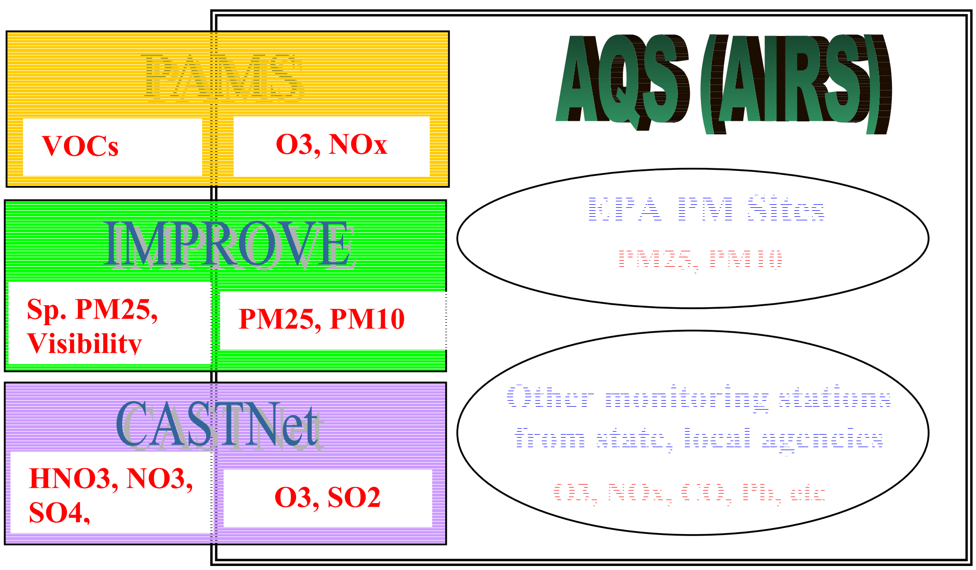

Figure 2-1. Overlap among ambient data collected from several monitoring networks.

Although direct access to full AQS raw data is currently not available, several archived data files can be downloaded from EPA's website http://www.epa.gov/ttn/airs/airsaqs/. Table 2-1 summarizes the data that are currently available and processed for hourly average concentration data from AQS for three VISTAS episodes. We have requested the remaining AQS data from EPA and will process them upon arrival. Note that the AQS includes O3 data from the State/Local/National Air Monitoring Stations (SLAMS).

Table 2-1. Currently* available hourly concentration data from AQS for three VISTAS episode selections.

Period	O_3	$PM_{2.5}$	NO_2	CO	SO_2
July 9-22, 1999	X	X	X	X	X
July 7-28, 2001	X	X			
Jan. 1-21, 2002	X	X			

* Efforts are underway to acquire the NO_2, CO and SO_2 measurements for the July 2001 and January 2002 episodes.

These data are presented on the VISTAS project website, http://www.cert.ucr.edu/vistas/ambient.shtml, under the title of "Ambient data for Model Evaluation", as animated figures that show spatial variation of O_3, $PM_{2.5}$, NO_2, CO and SO_2 concentrations. These data will also be made available as time series plots for each monitor site. The spatial distributions for average species concentrations within each VISTAS episode are shown in Figures 2-2 through 2-10. These plots are intended to be illustrative of the results on the project web page, and for more detailed evaluation please see the ambient data page: http://pah.cert.ucr.edu/vistas/ambient.shtml.
Note that the web page also includes plots that zoom in on the southeastern US domain.

July 9-22, 1999

Hourly O_3 concentrations were available at 1113 stations over USA for July 9-22, 1999. Figure 2-2 shows the distribution of average O_3 concentrations for these stations.

Hourly $PM_{2.5}$ concentrations were available at 25 stations over USA for July 9-22, 1999. Figure 2-3 shows the distribution of average $PM_{2.5}$ concentrations for these stations.

Hourly NO2 concentrations were available at 170 stations over USA for July 9-22, 1999. Figure 2-4 shows the distribution of average NO2 concentrations for these stations.

Hourly CO concentrations were available at 442 stations over USA for July 9-22, 1999. Figure 2-5 shows the distribution of average CO concentrations for these stations.

Hourly SO2 concentrations were available at 563 stations over USA for July 9-22, 1999. Figure 2-6 shows the distribution of average SO2 concentrations for these stations.

July 7-28, 2001

Hourly O_3 concentrations were available at 1113 stations over USA for July 7-28, 2001. Figure 2-7 shows the distribution of average O_3 concentrations for these stations. Hourly $PM_{2.5}$ concentrations were available at 148 stations over USA for July 7-28, 2001. Figure 2-8 shows the distribution of average $PM_{2.5}$ concentrations for these stations.

January 1-21, 2002

Hourly O_3 concentrations were also available at 501 stations over USA for January 1-21, 2002. Figure 2-9 shows the distribution of average O_3 concentrations for these stations.

Hourly $PM_{2.5}$ concentrations were available at 180 stations over USA for January 1-21, 2002. Figure 2-10 shows the distribution of average PM2.5 concentrations for these stations.

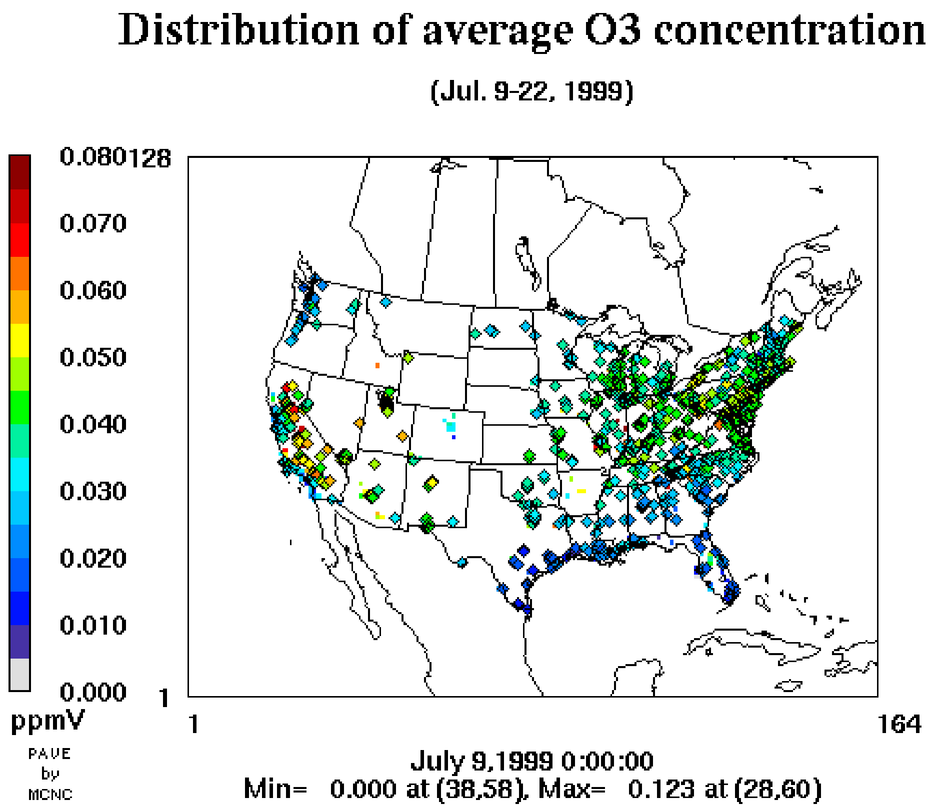

Figure 2-2. Distribution of average ambient O3 concentrations (July 9-22, 1999).

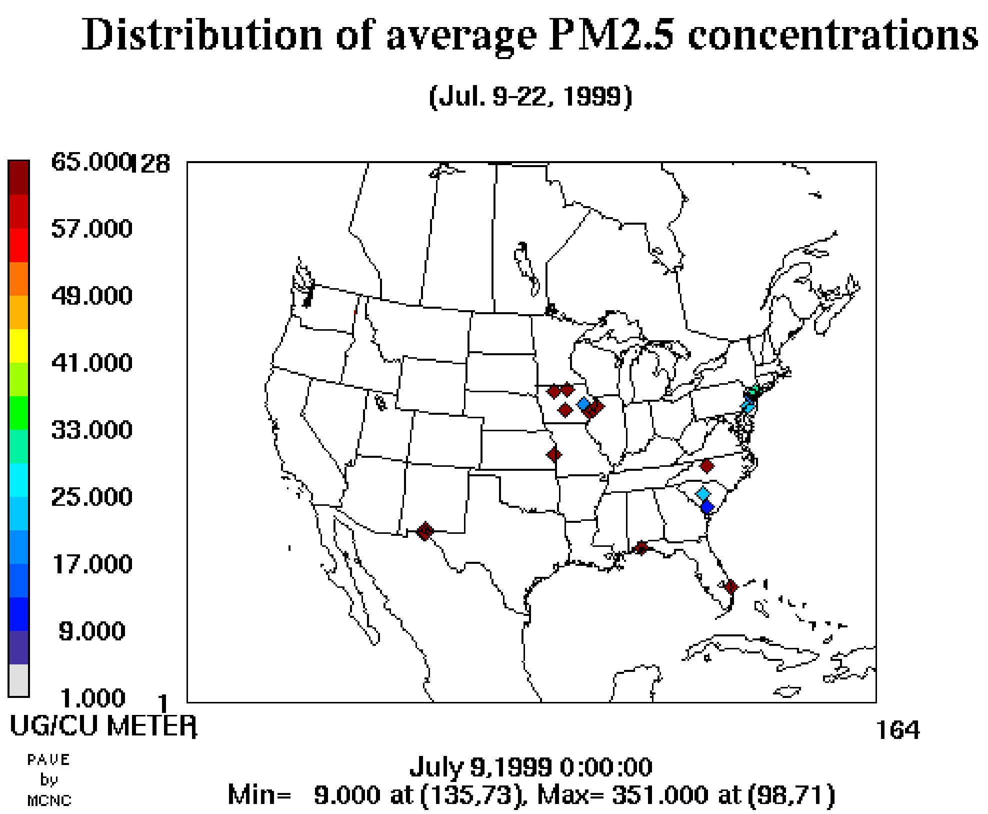

Figure 2-3. Distribution of average ambient $PM_{2.5}$ concentrations (July 9-22, 1999).

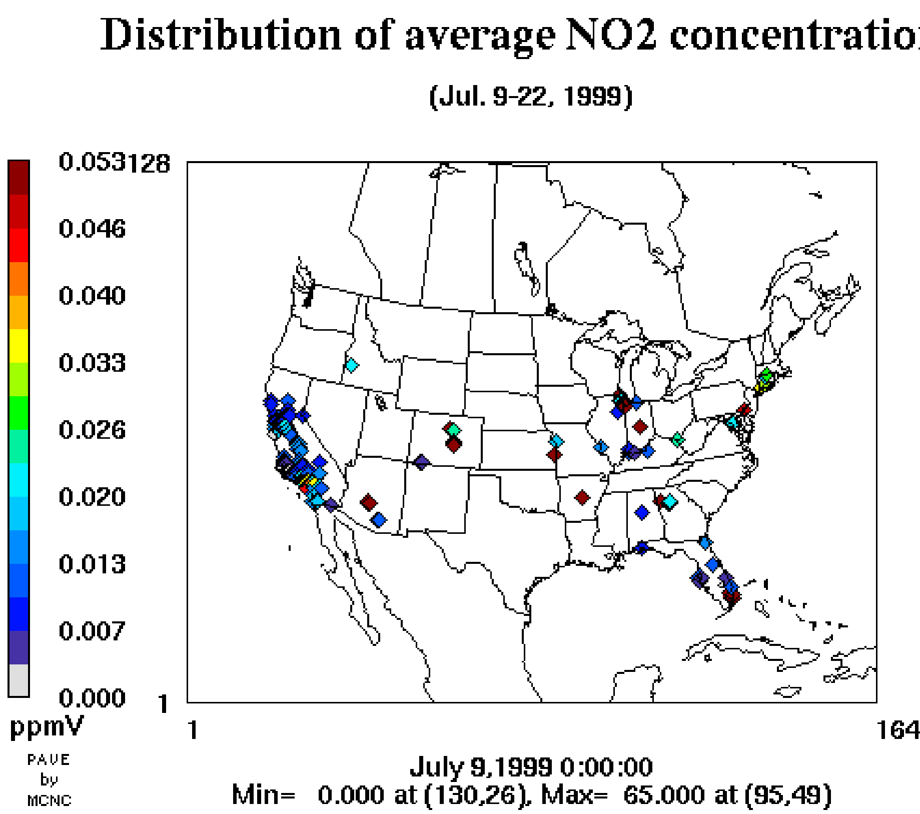

Figure 2-4. Distribution of average ambient NO_2 concentrations (July 9-22, 1999).

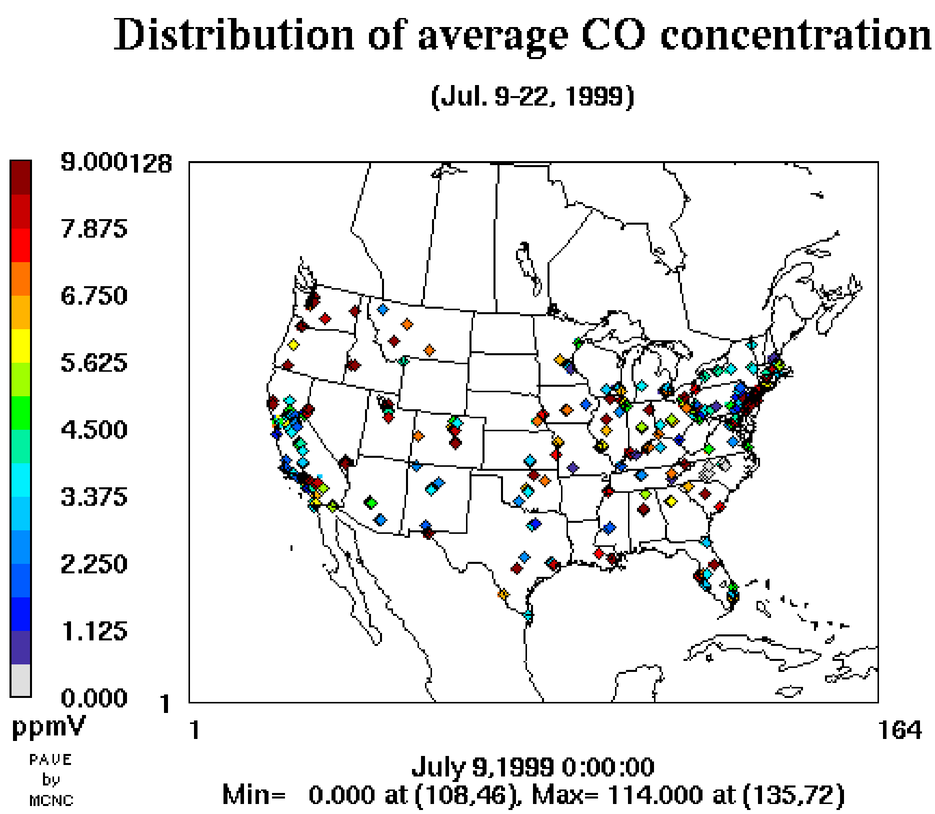

Figure 2-5. Distribution of average ambient CO concentrations (July 9-22, 1999).

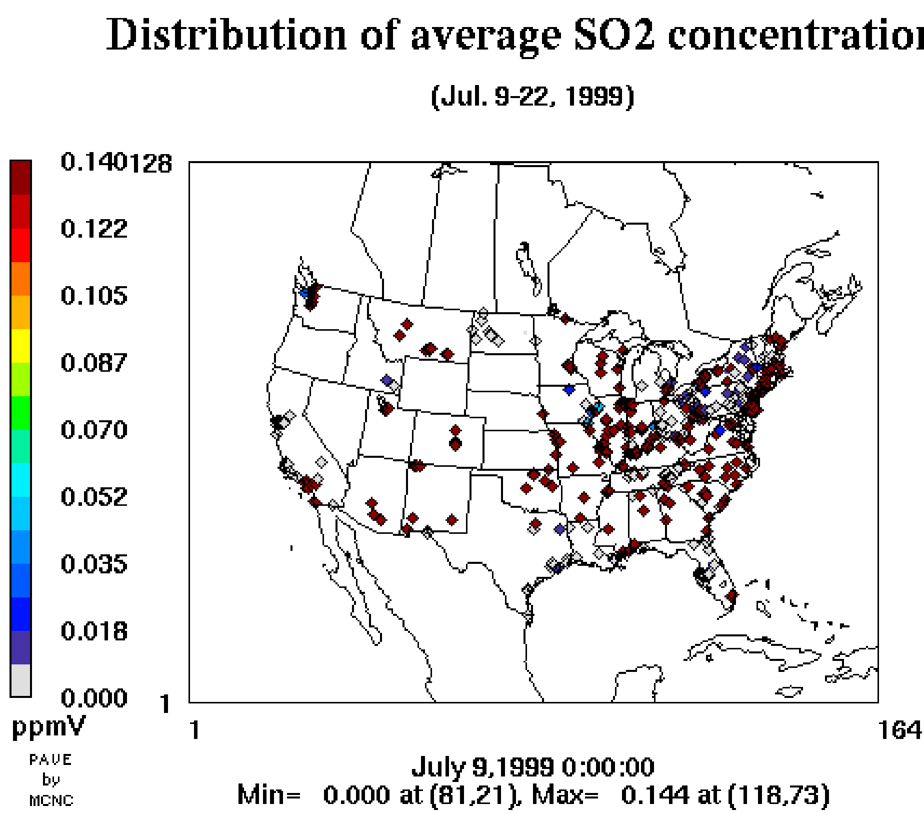

Figure 2-6. Distribution of average ambient SO2 concentrations (July 9-22, 1999).

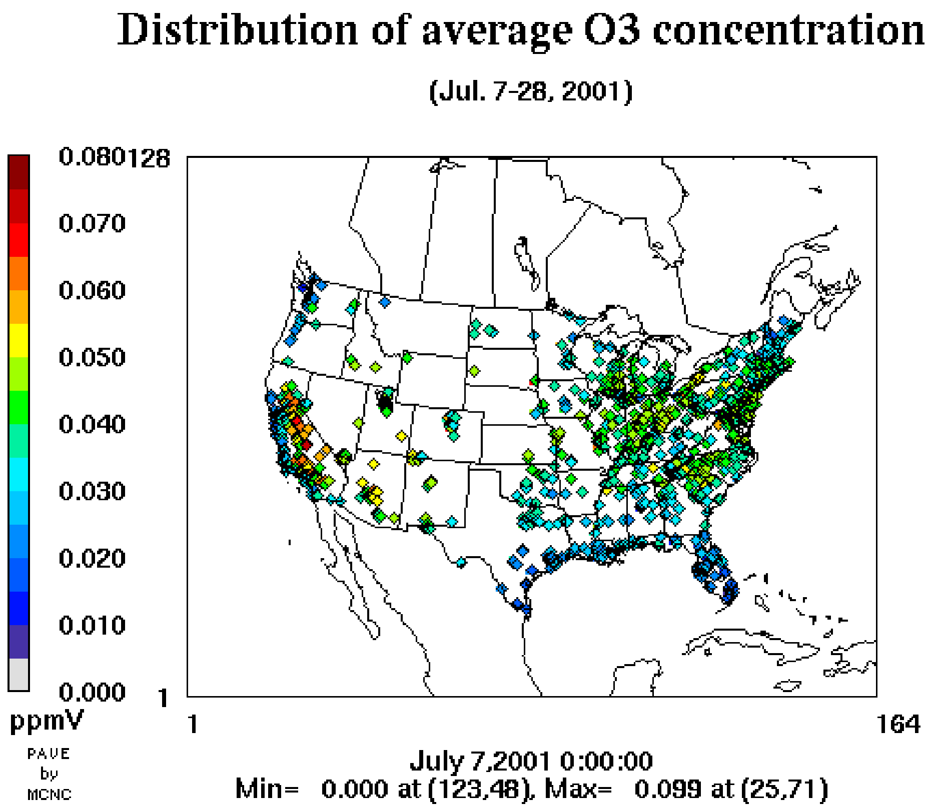

Figure 2-7. Distribution of average ambient O3 concentrations (July 7-28, 2001).

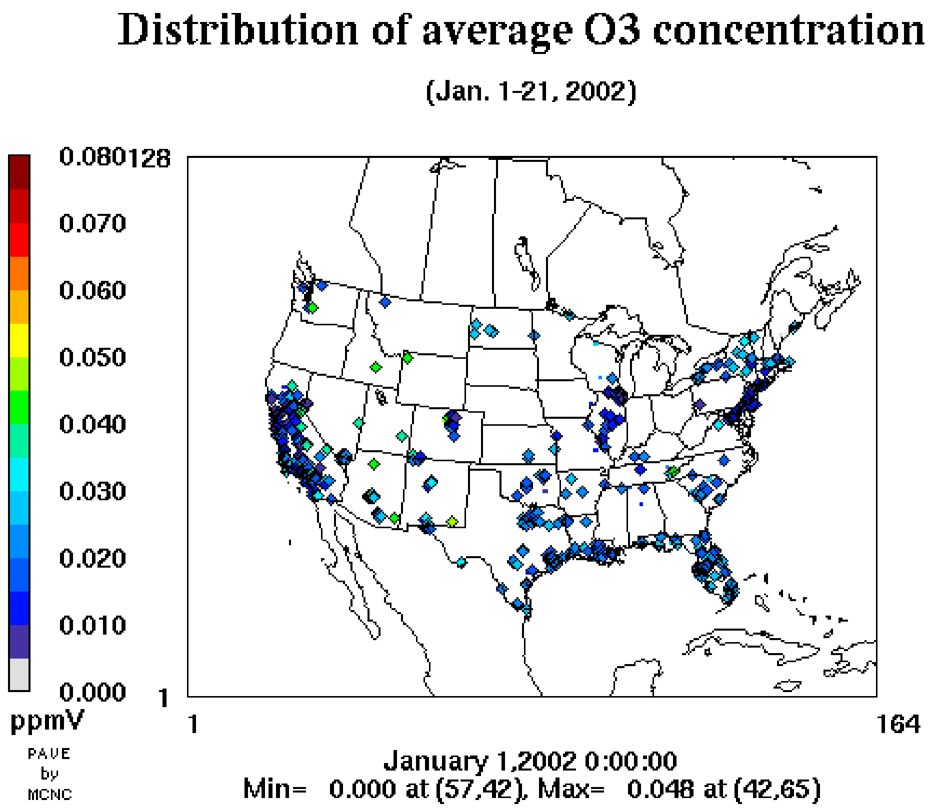

Figure 2-9. Distribution of average ambient O3 concentrations (January 1-21, 2002).

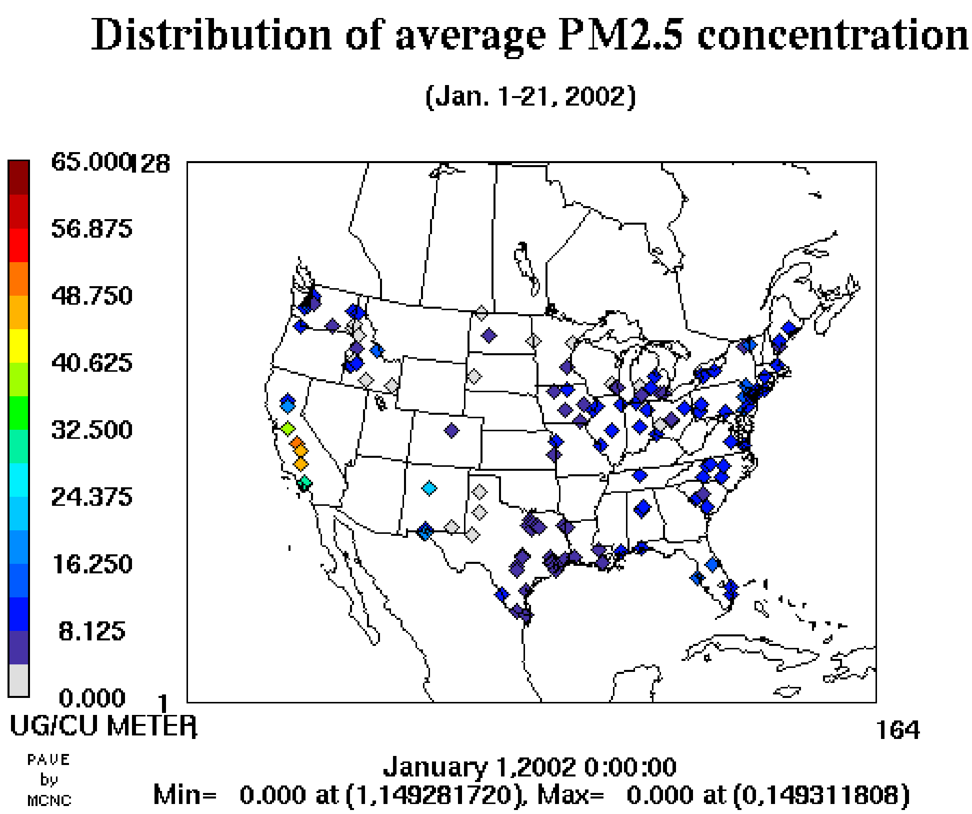

Figure 2-10. Distribution of average ambient PM2.5 concentrations (January 1-21, 2002).

3.0 PHOTOCHEMICAL ASSESSMENT MONITORING STATIONS (PAMS)

In response to the 1990 Clean Air Act Amendments, EPA has required more extensive monitoring of ozone and its precursors in areas with persistently high ozone levels. Photochemical Assessment Monitoring Stations (PAMS) have been established by the States to collect and report detailed data for volatile organic compounds, nitrogen oxides, ozone and meteorological parameters. The EPA lists five objectives for the PAMS program:

1. Provide a speciated ambient air database which is both representative and useful for ascertaining ambient profiles and distinguishing among various individual VOC.
2. Provide local, current meteorological and ambient data to serve as initial and boundary condition information for photochemical grid models, a method that simulates meteorological and physical processes that affect air pollution emissions in the atmosphere.
3. Provide a representative, speciated ambient air database which is characteristic of source emission impacts.
4. Provide ambient data measurements which would allow later preparation of unadjusted and adjusted pollutant trends reports.
5. Provide additional measurements of selected criteria pollutants.

Because different types of ambient monitoring data are required to characterize regional background concentration, emissions sources, and peak pollutant levels, four different types of PAMS sites are used:

- Type I: Upwind and background characterization
- Type II: Maximum ozone precursor emissions impact
- Type III: Maximum ozone concentration
- Type IV: Extreme downwind monitoring

Hourly average concentrations of O_3, NO, NO2, NOx and about 60 species of VOC (volatile organic compounds) are measured at each PAMS station. Archived data files can be downloaded from the website: http://www.epa.gov/ttn/airs/airsaqs/archived%20data/archivedaqsdata.htm. Table 3-1 shows the species names, carbon numbers and molecule weights for 60 species of VOC measured in PAMS. The PAMS data are currently available for VISTAS' two modeling periods of July 9-22, 1999 and Jan. 1-21, 2002. Since some data, such as O3, NO, NO2 and NOx may also be included in the AQS database, we are still considering the best approach to treat these data (i.e., present them with the AQS data only, or with the PAMS data only, or both).

For the data from selected PAMS sites, hourly average concentrations are available for 64 species (Table 2-1) for July 9-22, 1999 and Jan. 1-21, 2002. The animated graphics that show five species (TNMOC, THC, HCHO, acetaldehyde and acetone) concentrations have been put on the VISTAS project website (http://pah.cert.ucr.edu/vistas/ambient.shtml, under the title of "Ambient data for Model Evaluation". Example plots of average concentrations for two important species (HCHO and acetone) are shown in Figures 3-1 through 3-4.

Table 3-1. Species measured in PAMS network.

Name	Description	Carbon number	MWt
NO	NITRIC OXIDE		
NO2	NITROGEN DIOXIDE		
NOX	OXIDES OF NITROGEN		
PAMHC	SUM OF PAMS TARGET COMPOUNDS		
TNMOC	TOTAL NMOC		
ETHAN	ETHANE AKA-METHYLMETHANE	2	30.07
ETHYL	ETHYLENE AKA-ETHENE	2	62.07
PROPA	PROPANE AKA-DIMETHYLMETHANE	3	44.10
PRPYL	PROPYLENE AKA-PROPENE	4	102.09
ACETE	ACETYLENE AKA-ETHYNE	2	26.04

July 9-22, 1999

Hourly HCHO concentrations are available at 92 stations over USA for July 9-22, 1999. Figure 2-11 shows the distribution of average HCHO concentrations during that period of time for these stations.

Hourly Acetone concentrations are available at 130 stations over USA for July 9-22, 1999. Figure 2-12 shows the distribution of average acetone concentrations for these stations.

Jan. 1-21, 2002

Hourly HCHO concentrations are available at 57 stations over USA for Jan. 1-21, 2002. Figure 2-13 shows the distribution of average HCHO concentrations for these stations.

Hourly Acetone concentrations are available at 67 stations over USA for Jan. 1-21, 2002. Figure 2-14 shows the distribution of average Acetone concentrations for these stations.

We have recently obtained more speciated VOC data for additional PAMS sites and are currently evaluating these data.

4.0 INTERAGENCY MONITORING OF PROTECTED VISUAL ENVIRONMENTS (IMPROVE)

The Interagency Monitoring of Protected Visual Environments (IMPROVE) monitoring network consists of air quality data from Class I areas that include national parks and wilderness areas where visibility is deemed an important attribute. There are also IMPROVE protocol monitoring sites that are not located in Class I areas (see Appendix A for locations). This monitoring program is an interagency effort with the U.S. Environmental Protection Agency (USEPA) and the U.S. Department of the Interior (USDOI), including the U.S. Forest Service, U.S. Fish and Wildlife Service, and the Bureau of Land Management. The IMPROVE fine particle network collects $PM_{2.5}$ and PM_{10} samples over a twenty four hour using IMPROVE samplers. The current network consists of over 160 monitoring sites, mainly located in Class I ("Clean Air") areas. Some of the earliest sites have been in operation since March 1988, although most sites were installed in the mid 1990's or later. The PM samples are analyzed for $PM_{2.5}$ mass and its elemental constituents, organics, ions, light absorption and PM_{10} mass.

The objectives of IMPROVE are: (1) to establish current visibility and aerosol conditions in mandatory class I areas; (2) to identify chemical species and emission sources responsible for existing man-made visibility impairment; (3) to document long-term trends for assessing progress towards the national visibility goal; (4) and to provide regional haze monitoring representing all visibility-protected federal class I areas where practical. In 1999 there were 70 IMPROVE sites including 30 sites in Class I areas and an additional 40 sites using the IMPROVE protocol. By 2002 there were approximately 110 IMPROVE sites and 53 IMPROVE Protocol sites.

The standard IMPROVE sampler has four sampling modules, listed below, although some sites only include the Module A:

Module A: $PM_{2.5}$ particles on Teflon are analyzed at UC Davis using the following methods:

- gravimetric mass for $PM_{2.5}$
- hybrid integrating plate/sphere method for optical absorption
- Proton Elastic Scattering Analysis (PESA) for hydrogen
- Proton Induced X-ray Emission (PIXE) for Na-Mn
- X-Ray Fluorescence (XRF) for Fe-Pb

Module B: $PM_{2.5}$ particles on nylon. A denuder before the nylon filter removes nitric acid vapors. These are analyzed by ion chromatography (IC) at Research Triangle Institute for nitrate (NO_3^-), chloride (Cl^-), sulfate (SO_4^{2-}), and nitrite (NO_2^-).

Module C: $PM_{2.5}$ particles on quartz. These are analyzed at Desert Research Institute for carbon using the Thermal Optical Reflectance (TOR) combustion method. A secondary filter at selected sites is used to determine artifacts. These are reported in 8 temperature categories.

Module D: PM_{10} particles on Teflon. All are measured for PM_{10} mass. Approximately 4% are analyzed by the other four methods listed for Module A.

For selected IMPROVE sites, there also are transmissometer data to directly measure light extinction and nephelometer data to provide direct measurements of light scattering.

The IMPROVE data have passed the "Level 0 and Level 1" quality assurance and control procedure conducted by the Crocker Nuclear Laboratory at UC Davis, and are added to the online database after a 30 day period to allow the States, Tribes, FLM's or any other organization a chance to review and comment on the accuracy, credibility, and/or representativeness of aerosol speciation data collected and the reconciliation of any issues these organizations may find. In the past, we have not performed any additional QA of the IMPROVE data, and have simply used the data obtained from the Cooperative Institute for Research in Atmosphere (CIRA) website: http://vista.cira.colostate.edu/improve.

A 24 hour averaging period is used for IMPROVE data. Prior to 2000, two 24 hour samples were collected twice a week, on Wednesday and Saturday. After 2000, 24 hour samples were collected every three days.

Table 4-1 lists the 41 species measured at IMPROVE sites. The IMPROVE data are available for all three VISTAS modeling episodes. The downloaded data have been formatted for evaluation software, and time series plots are also available for download on the project website. Additional QA of these data can be performed, as discussed in Section 10, using time series and scatter plots of these data.

Table 4-1. Species of $PM_{2.5}$ measured in IMPROVE network.

For most species, the IMPROVE data cannot be matched directly to the model gas and PM species because of lumping schemes in the model chemistry. Therefore, it is necessary to convert the ambient data and model species into forms that can be directly compared. Table 4-2 shows the mapping scheme used for the IMPROVE comparison to the model species. Table 4-3 list definitions for CMAQ model species. Definitions for compounds in Table 4-2 include the following: OC is organic carbon; EC is elemental carbon or soot; CM is coarse mass; RCFM is reconstructed fine mass; and Bext_Recon is reconstructed extinction coefficient.

We note that in previous model evaluation for WRAP the sulfate and nitrate were assumed to be full neutralized and that ammonium sulfates and nitrate were represented in CMAQ as 1.375*(ASO4J + ASO4I) +1.29*(ANO3J + ANO3I), respectively. This was used for consistency with the formula used to calculate the model reconstructed extinction coefficient. For VISTAS we propose to use the CMAQ model ammonium mass (ANH4J+ANH4J) explicitly because this provides a more accurate estimate of modeled fine mass.

In previous modeling studies we have not had access to direct measurements of ammonium ion (NH_4^+). VISTAS is funding the Research Triangle Institute (RTI) to measure $NH4^+$ at 10 sites beginning in September, 2002. Prior to September, NH_4^+ data will be available for only 3 sites: Great Smokey Mountains (GRSM), Shenandoah (SHEN), Class I areas, and Dolly Sods (DOSO).

Concerns have been raised regarding the accuracy of the IMPROVE HNO3 data, and we have found that it tends to be lower than HNO3 data from the CASTNET network. However, we do not have a basis for adjusting or rejecting the IMPROVE HNO3 data, and further evaluation of HNO3 data from all monitoring networks is required. In September 2003 EPA will conduct a field study intercomparison of HNO3 methods using a Chemical Ionization Mass Spectrometer as a reference method. This may provide insight into the accuracy of HNO3 methods employed at the different monitoring networks, however, it is unlikely that results from this study will be available in 2003 to affect the VISTAS Phase I modeling.

There are concerns that the coarse mass (CM) IMPROVE measurements may also include some sulfate, nitrate and other species (e.g., sea salt and organics) that occur in the coarse mode. There are two different mechanism by which NO3 can be transferred to the coarse mode: formation of coarse mode sodium nitrate or calcium nitrate, and the ammonium nitrate distributions that can extend in to the coarse mode. In previous CMAQ performance evaluations, all nitrate has been assumed to be in the fine mode. If substantial fractions of nitrate are in the coarse mode, CMAQ would be expected to over predict the mass of fine nitrate. Speciation of the CM fraction is ongoing at several IMPROVE sites to investigate this issue. A coarse mode speciation measurement program was begun in spring, 2002, and it is possible that initial results will be available in fall, 2002.

We are also investigating the modal distributions of the Aitken and accumulation modes in CMAQ. Although these modes are typically assumed to be entirely $PM_{2.5}$, we have found that some of the mass does extend in to the coarse mode.

Table 4-2. Species mappings for IMPROVE species. Note that CMAQ represents fine PM species in two size modes: Aitken nuclei (0.03 to 0.5 µm) and accumulation mode (0.5 to 2.5 µm) and in CMAQ by represented by J and I, respectively. Compounds listed include coarse mass (CM);

Compound	IMPROVE Species	CMAQ Mapping
SO4	SO4	ASO4J + ASO4I
NO3	NO3	ANO3J + ANO3I
NH4$^+$	NH4$^+$	ANH4J + ANH4I

ASOIL	Soil-derived (crustal) coarse materials
ASEAS	Sea salt (only in coarse mode)
ACORS	Unspecified anthropogenic coarse mass
RCFM	Reconstructed fine mass
MT	Mass total
CM	Coarse mass
Bext_recon	Reconstructed extinction coefficient

5.0 SOUTHEASTERN AEROSOL RESEARCH AND CHARACTERIZATION (SEARCH)

SEARCH is a monitoring network for Southeastern Aerosol Research and Characterization. There are 8 monitoring sites located in four states in the SEARCH network whose locations are shown in Figure 5-1. Daily $PM_{2.5}$ data are measured for 46 species, while daily coarse PM data are measured for 18 species in SEARCH network. Archived data file can be downloaded from the website (http://www.atmospheric-research.com/public/index.html). Tables 5-1 and 5-2 show the names for 46 $PM_{2.5}$ species and 18 coarse PM species. The SEARCH data are currently available for two of the VISTAS Phase I modeling episodes (July 9-22, 1999 and July 7-28, 2001).

The frequency of the $PM_{2.5}$ measurements of SEARCH has varied from 1998 to the present. Measurements were made daily at all sites for a little over one year. Subsequently, the measurements frequency varies from daily to every third or sixth day depending on the specific site of interest. Semi-continuous TEOM $PM_{2.5}$ mass measurements have been available since the onset of the program and are reported as hourly averages. Semi-continuous measurements of PM chemical components have been phased in over the years, initially at Jefferson Street (Atlanta) and later at other sites. However, the ARS Data Gap report indicates that such hourly data have not yet been made generally available on the SEARCH web site. We need to determine whether the modeling team has this data or how best to get access to this data.

Table 5-1. $PM_{2.5}$ species measured in SEARCH network.

Name	Name	Name	Name
FRM Mass	PM25 Major Metal Oxides	XRF Pb	Al2O3

Name	Name	Name	Name
Coarse Mass	Chromium	Vanadium	TiO2
Coarse SO4	Copper	Al2O3	Fe2O3
Coarse NO3	Iron	SiO2	Coarse S
Coarse NH4	Manganese	K2O	
CoarseMajorMetalOxides	Nickel	CaO	

For the data from SEARCH network, daily average $PM_{2.5}$ concentrations for 46 species (Table 5-1) and daily coarse PM concentration for 18 species (Table 5-2) are available for two modeling episodes (July 9-22, 1999 and July 7-28, 2001).

We are working with the SEARCH sponsors and scientists to obtain data suitable for model performance evaluation and obtain data for the January 2002 episode. Locations of the SEARCH monitors are shown in Figure 5-1.

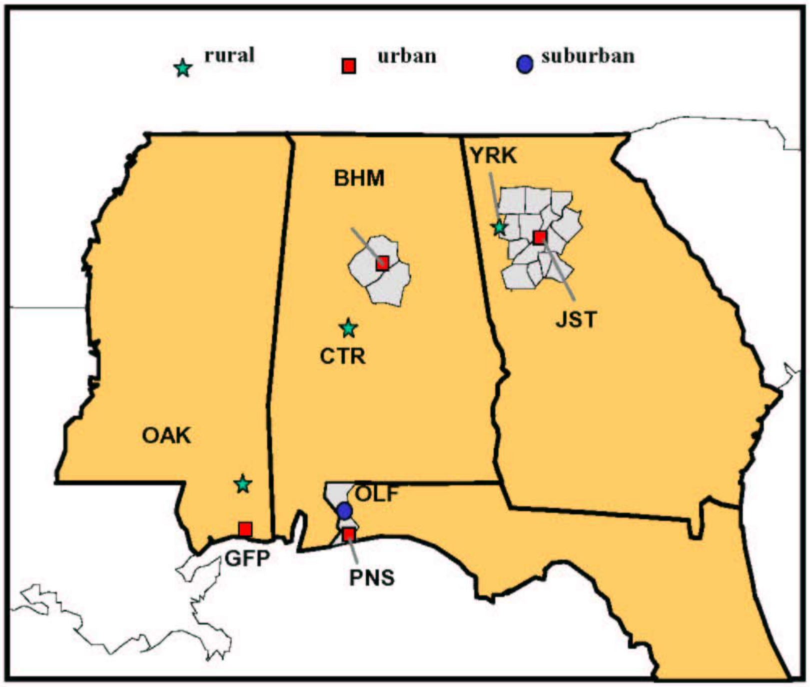

Figure 5-1. Locations of the SEARCH monitoring sites (Source: Atmospheric Research and Analysis, Inc., www.atmopheric-research.com).

6.0 SPECIATION TRENDS NETWORK (STN)

EPA's Speciation Trends Network (STN) includes about 215 monitoring stations nationwide. It appears that among these 215 sites may include IMPROVE sites or other data from other networks. This, however, needs to be verified. Daily $PM_{2.5}$ data are measured for 64 species in the STN network. Some archived STN data files were obtained from the website:http://www.epa.gov/ttn/airs/airsaqs/archived%20data/archivedaqsdata.htm. Additional documentation of the STN and descriptions of the data are still needed. Table 6-1 shows the codes and names for 64 species measured in STN. Locations of the STN monitors, as well as other specified PM monitors, are shown in Appendix A.

Table 6-1. Species of $PM_{2.5}$ measured in STN network.

7.0 NATIONAL ATMOSPHERIC DEPOSITION PROGRAM (NADP)

The National Atmospheric Deposition Program/National Trends Network (NADP/NTN) is designed to measure wet deposition. The network is a cooperative effort between State Agricultural Experiment Stations, the U.S. Geological Survey, U.S. Department of Agriculture, and other governmental and private entities. It includes over 200 sites in the continental United States, Alaska, and Puerto Rico, and the Virgin Islands whose locations are shown in Figure 7-1. The purpose of the network is to collect data on the chemistry of precipitation for monitoring of geographical and temporal long-term trends. The precipitation at each station is collected weekly is analyzed for hydrogen (acidity as pH), sulfate, nitrate, ammonium, chloride, and base cations (such as calcium, magnesium, potassium and sodium). The NADP network includes a quality assurance program, so we expect to use this data without any additional QA.

The major wet deposition network -- the National Atmospheric Deposition Program (NADP) -- has a large array of about 200 stations. Weekly samples of precipitation are collected at these stations and then sent to a single central laboratory for chemical analysis. The weekly sampling network has three severe drawbacks:

Because the NADP program uses a weekly sampling period the data has poor temporal resolution and the sample chemistry can be affected by chemical and biological activity. The NADP also includes the Atmospheric Integrated Research Monitoring Network (AIRMoN) which was designed to study precipitation chemistry trends with greater temporal resolution. Precipitation samples are collected daily from a network of nine wet deposition sites and analyzed for the same constituents as the NADP/NTN samples. AIRMoN also includes a dry deposition network and these are described next. NADP measures weekly deposition of compounds in units of mg/l as well as precipitation in units of l. The PM models will output deposition in terms of hourly mass flux per grid cell (e.g., 12 km x 12 km). The modeled results will be accumulated to weekly deposition fluxes per unit area (e.g., gm/km^2/week). Using the NADP precipitation and information on the NADP Sampler, the NADP deposition measurements will be converted to the same units as the modeled values.

AIRMoN Dry Deposition Data

The AIRMoN program includes both dry and wet deposition components. Figure 7-2 shows the locations of monitoring sites for both programs. The dry deposition data is described at their web page: http://www.arl.noaa.gov/research/projects/airmon_data.html. The description of the AIRMoN dry deposition data from the website is included verbatim here for convenience:

> Dry deposition rates are computed in the AIRMoN network by combining estimates of site-specific and time-evolving deposition velocities with measurements of air concentrations obtained using a weekly sampling protocol. The intent has been to mirror the 0900 Tuesday sample change standards adopted by the National Atmospheric Deposition Program. At times, the AIRMoN dry samples are obtained over substantially different periods, because of

operator absence or problems with instrumentation. The data summaries have been arranged so that each sequential week is represented, even though some of the initial data represent periods longer than a single week.

The AIRMoN concentration sampler is a three-element filterpack, with a leading teflon filter to remove particles, a middle nylon filter to extract nitric acid vapor, and a final doped cellulose filter intended primarily to sample sulfur dioxide. An inlet tube is used to impose a small amount of heat on the incoming air stream, to protect against liquid formation on the filters in periods of high humidities. There is no doubt that this influences the measurement of ammonium nitrate. In practice, any temperature change imposed on collected ammonium nitrate particles will cause some change in the sample, so that any long-term accumulative measurement of related species (such as that reported here) will be susceptible to error because of the effects of the diurnal cycle in air temperature. Tests of the AIRMoN sampling system indicate that particulate ammonium nitrate deposited on the teflon filter is incompletely disassociated with minor consequences on the measurement of nitric acid vapor and of sulfur dioxide, but with major influence on the measurement of nitrate on the doped cellulose filter. For this reason, measurements of nitrate reported here are considered to be unreliable.

It should also be noted that tests indicate that the values associated with nitric acid vapor are underestimates, on the average by 25%. The values listed should be increased accordingly, to correct for this error (due to deposition on the walls of the inlet tube).

Deposition velocities tabulated here are derived using a multi-layer numerical model, driven by field observations of selected key variables (such as wind speed, the standard deviation of the wind direction, surface wetness, incident solar radiation, temperature, humidity, plant species distribution, etc.) It is estimated that these deposition velocities might be in error by as much as 30%.

Weekly average deposition rates are computed as the product of the weekly average deposition velocities and the weekly average concentration, thus omitting consideration of a correlation term that can be significant when air concentrations display a consistent and significant diurnal cycle.

Regarding the last paragraph above, there are in fact large diurnal variations in several trace species of interest, and the errors introduced by this approach should be further investigated. Omitting consideration of a correlation term is likely to introduce additional errors greater than the 30% error mentioned above.

As noted on the AIRMoN web page, there is very large uncertainty in dry deposition estimates, and it is possible that the data on the website will be modified as more is learned about the processes that control dry deposition.

UCR is currently investigating the availability of the NADP and AIRMoN data. We expect to obtain the AIRMoN data from the website, but we still need to determine if other NADP data is available.

AIRMoN Wet Deposition Data:

The AIRMoN wet deposition program is described at the web page:
http://www.arl.noaa.gov/research/projects/airmon_wet.html
The AIRMoN wet deposition monitoring employs a daily sample collection protocol, thus differentiating itself from the weekly operations of the mainstream NADP stations. In practice, daily sampling provides a greatly improved quantification of ammonium deposition. At the National Atmospheric Deposition Program Technical Committee Meeting in 1994 (October 24-27) final decisions were made regarding the AIRMoN-wet quality assurance plan; a system of flags will be used to alert data users to specific problems.

UCR is currently downloading data from both wet and dry AIRMoN networks.

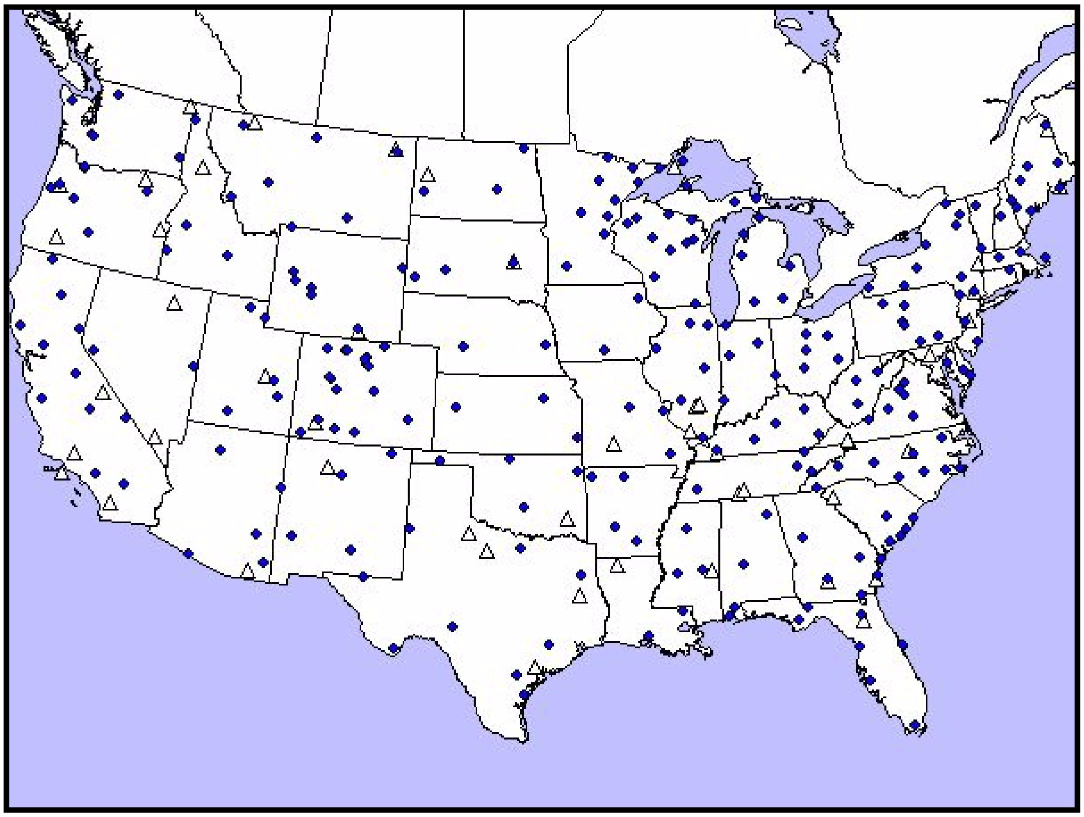

Figure 7-1. Locations of NADP National Trends Network (NTN) monitors (Figure obtained from the EPA NADP website).

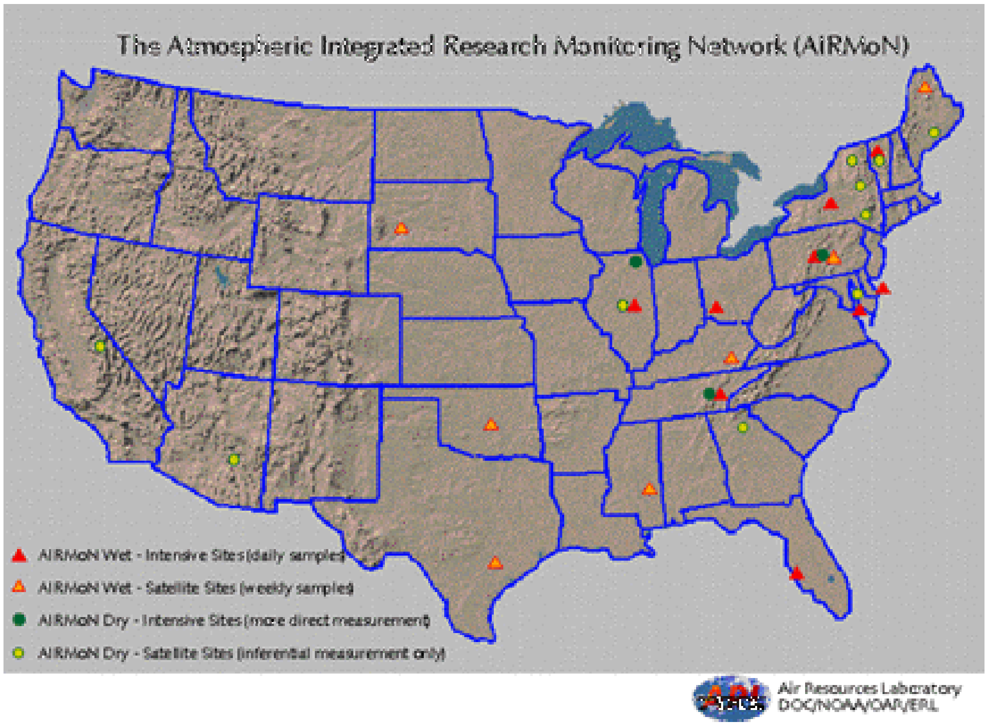

Figure 7-2. Locations of the AIRMoN wet and dry deposition monitoring sites (Figure obtained from the EPA AIRMoN website).

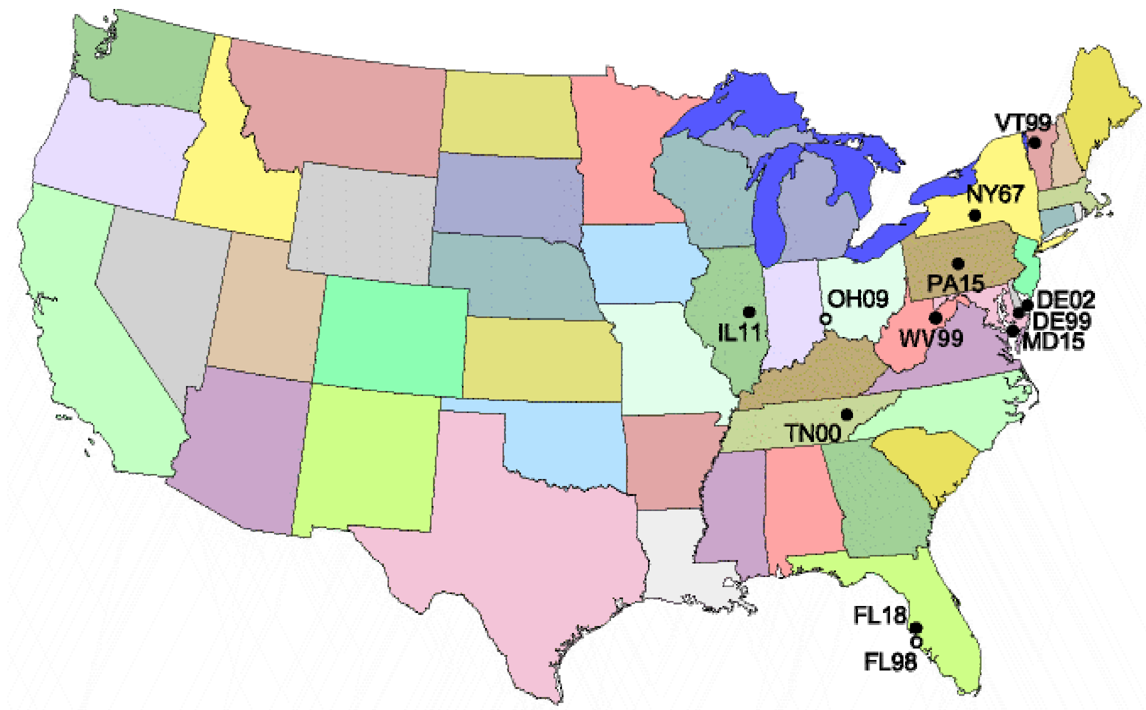

Figure 7-3. Locations of the AIRMoN wet deposition monitoring sites (Figure obtained from the EPA AIRMoN website).

8.0 CLEAN AIR STATUS AND TREND NETWORK (CASTNET)

CASTNET is designed to measure dry deposition and it is comprised of 123 sites across the United States as shown in Figure 8-1. It includes measurements of ambient concentration and meteorology and land use which are then used to calculate dry deposition rates. For the model performance evaluation we will use the ambient concentration measurements to compare with the model. Dry deposition data are measured for 13 species including: TOTAL SO4, TOTAL NO3, TOTAL NH4, CA, MG, NA, K, NSO4, NHNO3, WSO2, WNO3, TOTAL SO2, and TOTAL NO3.

Detailed data collection procedures are described at the EPA CASTNET website: http://www.epa.gov/castnet. In short, atmospheric concentration data are collected at each site with open-faced, 3-stage filter packs. The filter pack contains a Teflon filter for collection of particulate species, a nylon filter for nitric acid and a base-impregnated cellulose (Whatman) filter for sulfur dioxide. Filter packs are exposed for 1-week intervals (i.e., Tuesday to Tuesday) at a flow rate of 1.5 liters per minute (3.0 liters per minute for western sites), and sent to the Harding ESE, Gainesville, FL laboratory for chemical analysis.

All three filters are extracted and analyzed for certain species:

Teflon filter: SO_4^{2-}, NO_3^-, NH_4^+
Nylon filter: SO_4^{2-}, NO_3^-
Cellulose filter (Whatman): SO_4^{2-}, NO_3^-

The sulfate, nitrate and ammonium in the teflon filter extract are interpreted as particulate species (listed above as TSO4, TNO3 and TNH4). The nitrate in the nylon filter extract is interpreted as nitric acid. The sum of sulfate in the nylon and cellulose filter extracts is interpreted as sulfur dioxide (SO2). Any nitrate detected in the cellulose filter extract is not interpreted, since it likely represents a host of oxidized nitrogen species.

Because aerosol nitrate on the teflon filter can revolatilize, the nitrate on the teflon filter represent those particles that have not volatilized during the sampling period. The nitrate on the nylon back filter represents nitric acid that was originally in the atmosphere plus any that was produced through revolatilization of the nitrate particles on the teflon filter. Thus, because of the volatilization losses, the CASTNet particulate nitrate is less than the IMPROVE nitrate. Also, because IMPROVE uses a nitrate denuder to remove ambient nitric acid, the CASTNet total nitrate (the sum of the teflon and nylon filter nitrates) is greater than the IMPROVE nitrate. Details are provided in Appendix G of the 2000 IMPROVE Report and by Ames and Malm [Ames R.B and W.C. Malm, Comparison of sulfate and nitrate particle mass concentrations measured by IMPROVE and the CDN, Atmospheric Environment, 2001, 905-916.] Thus, the IMPROVE and CASTNet nitrate values cannot be directly compared. Moreover, the CASTNet NO3 and HNO3 data cannot be directly compared to the modeled species. In previous applications we have compared the CASTNet data to the model for the sum NO3+HNO3 and we propose to use the same approach for the VISTAS model evaluation.

The CASTNet data have been downloaded from: http://www.epa.gov/castnet/data.html. The CASTNET data are available for all three modeling episodes. The actual start time and collection period varies among sites, so this makes it difficult to automate the model performance evaluation, and additional effort is required to match the sample period with the model output period.

As in the case of the IMPROVE data, measured species can not be compared directly to the models species, and Table 8-1 shows the mapping scheme to be used for comparing the CASTNET data to model species.

Table 8-1. Species mappings for CASTNet species.

Compound	CASTNet Species	CMAQ Mapping
Gaseous HNO_3	NHNO3 (nylon filter)	2176.9*DENS[a]*HNO3
Particulate NO_3	TNO3 (Teflon filter)	ANO3J + ANO3I
Total HNO_3 + NO_3	NHNO3 (nylon filter) + TNO3 (Teflon filter)	2176.9*DENS[a]*HNO3 + ANO3J + ANO3I
Particulate NH_4	TNH4 (Teflon filter)	ANH4I + ANH4J
Gaseous SO_2	TOTAL_SO2	2211.5*DENS*SO2
Particulate SO_4	TSO4 (Teflon filter)	ASO4I + ASO4J

[a] Air density obtained from MCIP outputs

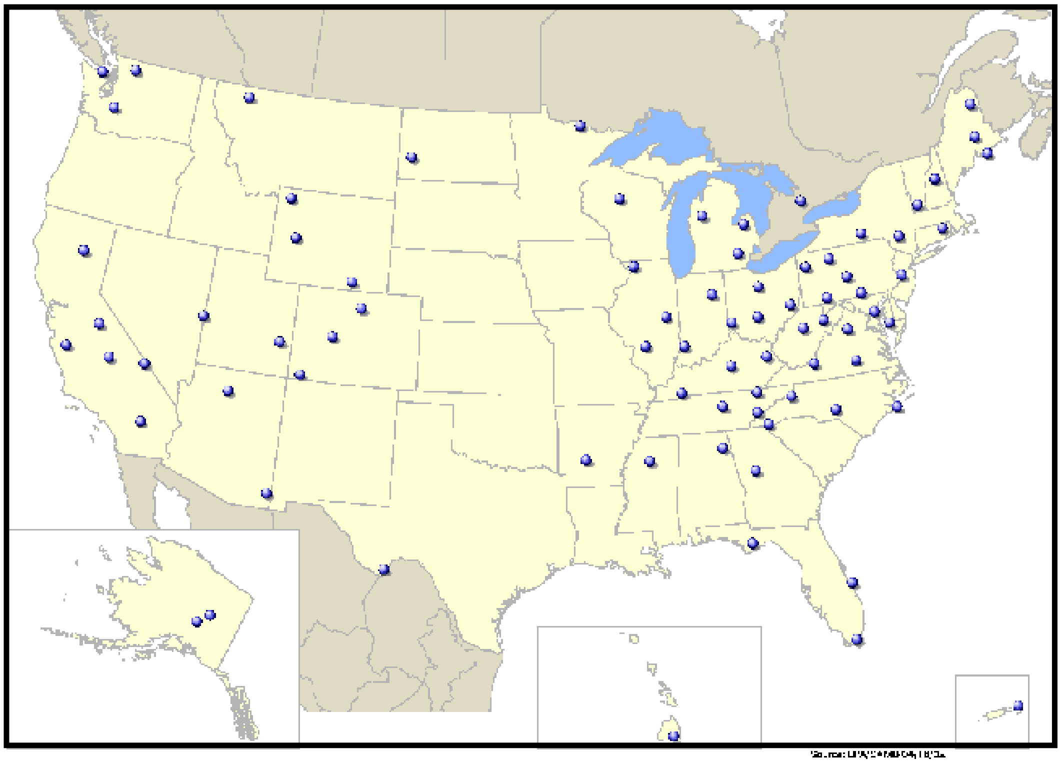

Figure 8-1. Locations of CASTNet monitoring sites (Figure obtained from EPA CASTNet website).

9.0 PM SUPERSITES

There are 8 PM Supersites. The locations of these sites are listed in Table 9-1. The data includes PM size distribution, ions, metal elements, EC, OC, radical, and gaseous pollutants is measured in Supersites. Available data varies with the site. The archived data files can be downloaded from the website (ftp://ftp.supersitesdata.umd.edu).

Eastern Supersites Program (ESP01)

The ESP01 was initially planned as an effort to coordinate an intensive monitoring in July 2001 among the three PM Supersites projects (New York, Pittsburgh, and Baltimore). As other researchers expressed interest in the program it grew in scope and eventually over 30 groups were involved in ESP01. The intensive monitoring program was planned for June 30, 2001 at 0000 hrs to July 29, 2001 at 2400 hrs. The program included an extensive set of gas, PM, PM precursor, photochemical, visibility, and meteorological measurements. The study also included an extensive network of Radar Profilers (NOAA FSL) which will be useful for evaluating transport within and above the boundary layer. EPA plans to centralize all air quality and meteorological data in one location within several relational databases to allow for easy access to the data and to help ensure that modelers and data analysts will be working with uniform databases. Details on data collected at the PM Supersites can be found at www.epa.gov/ttn/amtic/supersites.html. We have contacted Paul Solomon and Marc Pitchford to determine the schedule for releasing this database.

10.0 AIRCRAFT DATA

Of the three episodes selected for Phase I, only during episode 3 (13-21 July 1999) were there research aircraft flights performed that provide aloft meteorological and air quality data suitable for model performance testing. These data were collected during the Southern Oxidants Study (SOS) intensive field program performed principally in Nashville, TN during the summer of 1999. An overview of the SOS/Nashville 1999 aircraft data has been submitted to VISTAS as Appendix A to the Task 2 report (ENVIRON, 2003) and is not repeated here.

Aircraft data are available through the NARSTO Archive and are available online at: http://eosweb.larc.nasa.gov/project/narsto/table_narsto.html. We have downloaded the NOAA WP3 data, but have not yet attempted to process this data for model evaluation. The Brookhaven/DOE data does not appear to be accessible through the NARSTO archive, and we will contact Brookhaven directly to access this data.

11.0 DATA QUALITY ASSURANCE

In gathering data from the monitoring networks we have assumed that QA was performed by the agency or researcher responsible for collecting the data. However, it is possible that the data sets may contain erroneous data (i.e., missing data, zeros during calibration, unrealistic values, etc). Due to poor documentation or poor formatting of some data sets it is also possible that we will make mistakes in our processing of the data. To guard against this possibility, we plan to perform a high level QA by visually inspecting time-series plots and scatter plots of the ambient data as follows:

Plots of Time Series

Time series plots are generated for PAMS species. The plots should be inspected for the following:

- Large "jumps" or "dips" in the concentrations
- Periodicity of peaks, calibration carryover
- Unexpected diurnal behavior (i.e., isoprene)
- Unexpected relationships among species
- High single-hour concentrations of less abundant species

Scatter Plots

Scatter plots may be prepared for the following:

- Total NMOC vs. species group totals, vs. individual species
- Benzene vs. Toluene, Acetylene, Ethane
- Scatter plots comparing data for a single species measured with different sampling methods
- Plots of reconstructed mass versus measured mass (to reveals if anything unusual is happening with the chemical measurements)
- Plots of molal particulate ammonium versus the molal sum of sulfate and particulate nitrate (as a sanity check on the ion balance in the PM chemical measurements)

If we identify data that appears flawed it will be flagged and either corrected if the error is in the processing step, or removed from the data set.

Re: **Mendenhall PM2.5 Data Imputation for 4Q2006**

Contents

List of Tables

List of Figures

Introduction

The North Carolina Division of Air Quality (DAQ) is in nonattainment for Davidson County for PM2.5 from the monitoring station in the city of Lexington (AQS Site ID: 370570002). DAQ has performed design value calculations with the PM2.5 data for 2005-2008 for Lexington. These calculations indicate that the design value for this monitor will be in attainment for this time period and thus DAQ will be applying for PM2.5 nonattainment redesignation. Redesignation requires assessing the PM2.5 data from PM2.5 monitors at Mendenhall (Guilford Co., ID 370810013), Lexington (Davidson Co., ID 370570002) and Hattie (Forsyth Co., ID 370670022).

The design value calculations for 2005-2008 for the Mendenhall site are incomplete because no valid PM2.5 data were collected during the fourth quarter of 2006. This happened because of major complications in having to move the site. DAQ moved the site about 100 yards because a 2 story field house that was constructed immediately adjacent to the monitoring site (unpublished letter to Artra Cooper, 12 December 2006). The construction was started without DAQ's knowledge. When DAQ realized what was happening it was too late to stop the project, the new field house was built, and the site no longer met ambient siting criteria.

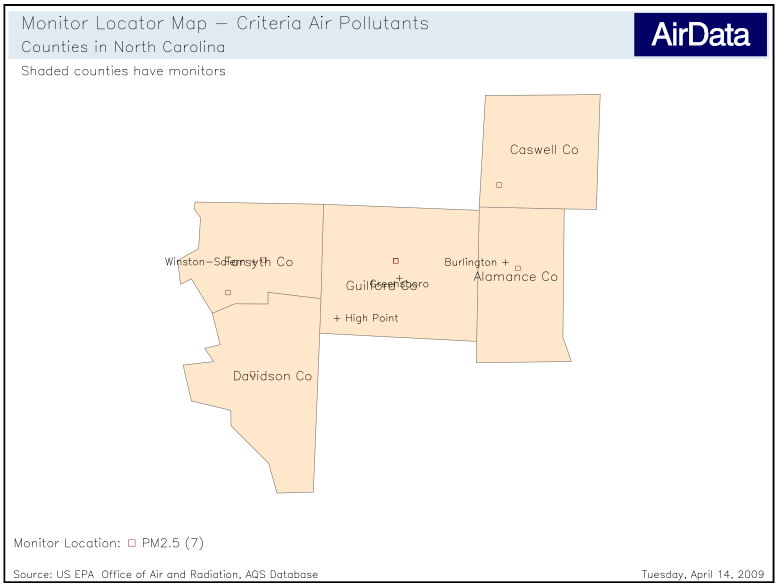

Figure 1 Map of Monitor Locations

Since there were no 4Q2006 data with which to calculate a proper Mendenhall Design value, the DAQ Planning and Ambient staff decided to present to EPA Region IV an estimate of what the missing Mendenhall PM2.5 sample values would have been if they had been properly observed, along with the resulting Design value summary statistics. The estimate is based on linear regression using data acquired during the four years, 2002 through 2005 at surrounding sites including those in the MSA and also Hopedale (Alamance County, ID 370010002) and Cherry Grove (Caswell Co., ID 370330001). These monitor locations are shown in Figure 1 (an extraneous PM2.5 monitoring site at Clemmons, southwest Forsyth County, is also shown for reference but was not used in the analysis).

.

Methods

The estimation procedure is as follows:

1. Fit a linear regression to the 2002-2005 PM2.5 data of the regressors to determine equation coefficients
2. Estimate missing sample values for Mendenhall by substituting the corresponding observed PM2.5 data in 4Q2006 into the regression equation
3. Compute quarterly averages for Mendenhall including the imputed 4Q2006 data using actual data where available and imputed data where provided by the regression procedure
4. Compute weighted averages for each year
5. Compute the completed Design value for Mendenhall derived by averaging the weighted annual means

Results

I applied two regression fits to the data, starting with the most inclusive possible model, using Lexington, Cherry Grove, Hopedale and Hattie Avenue all as predictors. Estimates from this model are shown in Table 1. In this combination, Lexington, Cherry Grove and Hattie Avenue are not significant predictors for Mendenhall.

Table 1 Regression Analysis using the Lexington, Cherry Grove, Burlington and Hattie Avenue PM2.5 data

Call: lm(formula = MH ~ LX + UC + HD + HA, data = MH4q.md3, na.action = na.exclude)

Residuals:

Min	1Q	Median	3Q	Max
-3.763	-1.161	-0.3787	0.5814	11.34

Coefficients:

Regressor	Value	Std. Error	t value	Pr(>|t|)
(Intercept)	0.6105	0.5347	1.1417	0.2565
LX	0.1615	0.1165	1.3861	0.1690
UC	0.0791	0.0947	0.8346	0.4061
HD	0.4782	0.1495	3.1982	0.0019
HA	0.2466	0.1414	1.7445	0.0844

Residual standard error: 2.111 on 93 degrees of freedom
Multiple R-Squared: 0.8798

The second regression removed Cherry Grove and Hattie Avenue from the model. The resulting model had a residual standard error of 2.094 and R^2= 0.877. Both Lexington and Hopedale were significant in this regression, but the intercept term was not significant, so I fit the model with its intercept forced to zero. This model's estimates are shown in Table 2. The regression equation is shown as equation (1)

$$MH = 0.3464 * LX + 0.6322 * HD$$ **(Equation 1)**

I fit (1) to the Lexington and Mendenhall data values acquired during 4Q2006. Table 3 shows the regressors for the 22 days with valid data for both regressors, and the resulting Mendenhall estimates. The average of the 22 imputed samples is 12.92.

Table 2 Regression Analysis using the Lexington and Hopedale PM2.5 data

Call: lm(formula = MH ~ -1 + LX + HD, data = MH4q.md3, na.action = na.exclude)

Residuals:

Min	1Q	Median	3Q	Max
-4.258	-0.9024	-0.1271	0.915	11.67

Coefficients:

Regressor	Value	Std. Error	t value	Pr(>|t|)
LX	0.3464	0.0891	3.8873	0.0002
HD	0.6322	0.0957	6.6042	0.0000

Residual standard error: 2.103 on 107 degrees of freedom

Table 4 shows the quarterly averages for 2004, 2005 and 2006, including the imputed value for 4Q2006 and the 11 actual values for the remaining quarters. Finally Table 5 shows the 3 annual means and the overall Design value result that obtains from them, 14.01.

Table 3 Imputed Raw Data

Table 5 Weighted Annual Means and Design Value

Period	CY2004	CY2005	CY2006	2004-2006 D.V.
Mean	13.97	14.01	14.06	14.01

Discussion

I maintain that the estimated Design value presented in Table 5 is an accurate prediction of the result that would have been obtained from Mendenhall for 2004-2006, had siting conditions not changed during 4Q2006. The imputed average is also the most accurate and appropriate value to use for the 2006-2008 Design value calculations at Mendenhall to assist with the redesignation package for the Lexington site.

Recommendations

Design value calculations for the Greensboro-Winston-Salem-High Point MSA (or any subsequently redefined area that includes Greensboro) for any group of years that includes 2006 should use the imputed 4Q2006 value as a surrogate for the missing “actual” 4Q2006 at the Mendenhall site.

For future consideration, we can *apply* (1) to data acquired after 2006 from Lexington, Hopedale and Mendenhall. We can also repeat the regression fitting exercise using data acquired from the regressor sites in 2007 and later instead of 2002-2005 Either of these actions can be used to demonstrate how well the moved site location “represents” the original location.

1.0 Overview of Fine Particulate Matter Modeling/Analysis Project

1.1. Policy Overview of Fine Particulate Matter National Ambient Air Quality Standards

In July 1997, the United States Environmental Protection Agency (USEPA) issued National Ambient Air Quality Standards (NAAQSs) for fine particulate matter ($PM_{2.5}$). The NAAQSs include an annual standard set at 15 micrograms per cubic meter ($\mu g/m^3$), based on the 3-year average of annual mean $PM_{2.5}$ concentrations and a 24-hour standard of 65 $\mu g/m^3$, based on the 3-year average of the 98^{th} percentile of 24-hour concentrations. A number of events delayed the implementation of the $PM_{2.5}$ NAAQSs.

The new $PM_{2.5}$ standards were challenged by the American Trucking Association, the U.S. Chamber of Commerce, and other state and business groups. The Transportation Equity Act for the Twenty-first Century (TEA-21) delayed the deadline to publish nonattainment designations in order to provide additional time to collect three years of air quality monitoring data.

In February 2001, the United States Supreme Court upheld the USEPA's authority under the Clean Air Act (CAA) to set NAAQSs that protect the American public from harmful effects of air pollution. The United States Supreme Court also sent the case back to the D.C. Circuit Court of Appeals to resolve several additional issues. In March 2002, the D.C. Circuit Court rejected all remaining legal challenges to the 1997 NAAQSs for $PM_{2.5}$.

1.2. Designations

In April 2003, the USEPA provided guidelines to states and tribes for recommending nonattainment area boundaries for the $PM_{2.5}$ NAAQSs. Consistent with the CAA, the guidance instructed states and tribes to begin their analysis of attainment and nonattainment area boundaries based on Metropolitan Area boundaries. A Metropolitan Area was defined as a single Metropolitan Statistical Area (MSA) or a Consolidated MSA, depending on the area. The guidance instructed states to include in nonattainment areas any nearby counties with sources contributing to fine particle pollution in those metropolitan areas. In addition, the guidance recommended that states and tribes consider using common boundaries for areas to be designated as nonattainment for both the $PM_{2.5}$ and 8-hour ozone standards, which will help states and tribes facilitate future planning and implementation activities.

In mid-February 2004, states and tribes recommended $PM_{2.5}$ nonattainment area boundaries to the USEPA. The USEPA revised these recommendations and responded to the states and tribes in late June 2004. On December 17, 2004, the USEPA designated areas for the $PM_{2.5}$ NAAQSs. Two areas in North Carolina were designated nonattainment for the annual $PM_{2.5}$ NAAQS under Section 172 of the CAA as amended. These areas were Hickory (Catawba County) and Greensboro/Winston-Salem/High Point (Davidson and Guilford Counties). The Greensboro/Winston-Salem/High Point area is referred to as the Triad area. Figure 1.2-1 shows the USEPA's final designation of $PM_{2.5}$ nonattainment areas in North Carolina.

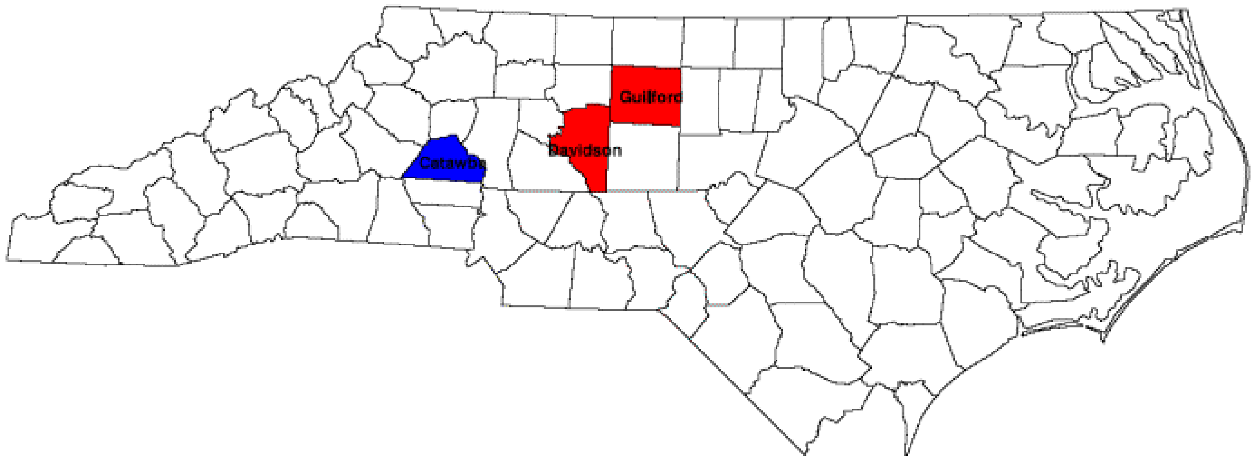

Figure 1.2-1: Designated Annual $PM_{2.5}$ nonattainment areas in North Carolina.

1.3. Participating Organizations

From the conceptual model of $PM_{2.5}$ formation, it is clear that $PM_{2.5}$ is a regional problem, which results in attainment demonstration State Implementation Plan (SIP) modeling to be a substantial undertaking that relies on the interaction of many groups that are affected by overall air quality and that impact the air shed of the affected states. It is imperative to include groups of "stakeholders" from industry, government, and the private sector during the modeling/analysis project. As each group involved brings its own perspective, knowledge, and experience to the modeling process, the ability to model and develop strategies for $PM_{2.5}$ reduction is greatly enhanced. The following organizations were invited to participate in developing the Hickory/Triad $PM_{2.5}$ SIP:

- North Carolina Division of Air Quality (NCDAQ)
- Carolina Environmental Programs – University of North Carolina Chapel Hill
- Barons Atmospheric Modeling Systems
- University of North Carolina at Chapel Hill
- North Carolina State University
- Sonoma Technology, Inc.
- Mecklenburg County Department of Environmental Protection
- USEPA Region 4
- USEPA Office of Air Quality Planning and Standards
- USEPA Office of Research and Development
- North Carolina Department of Transportation
- North Carolina Department of Commerce
- North Carolina Department of Agriculture
- North Carolina State Energy Office
- Progress Energy
- Duke Energy
- Transcontinental Natural Gas Company
- Environmental Defense

- Sierra Club
- Charlotte Department of Transportation
- Furniture Manufacturing Representative
- Chemical Manufacturing Representative
- North Carolina Petroleum Council
- North Carolina Petroleum Marketers' Association
- Centralina Council of Governments
- Catawba Council of Governments
- Representatives from city and county governments in the nonattainment areas

Data and available expertise from participating agencies, organizations, and universities will be utilized in determining projected emissions and control strategies. All data and information will be reviewed and evaluated by the NCDAQ. All stakeholders are invited to contribute emissions projections and control strategy information.

North Carolina will coordinate with various states and other parties as regional modeling is initiated to address the $PM_{2.5}$ standards. Various other regional modeling applications, such as Visibility Improvement and Tribal Association of the Southeast (VISTAS) regional haze modeling, will also be considered. These interactions should provide a forum for discussing the latest improvements and refinements to air quality modeling.

1.3.1. Communication

Communication between the stakeholders is an integral part of completing the modeling/analysis project. Stakeholders need the opportunity to review and comment on documentation, control strategies, and modeling analysis. The NCDAQ will host periodic technical coordination meetings on the SIP process. Consultation meetings on control strategy development and contingency plans will be held as necessary during the process. In general, as issues arise among the participants, special studies will be defined to help resolve all pertinent issues. Documentation will be developed concerning these issues, including methods of resolution and any remaining uncertainties, which will be submitted as part of the SIP.

Due to the far-reaching effects of the $PM_{2.5}$ attainment demonstration, it is important that all interested parties are kept informed on the progress of the modeling. Industries or organizations not directly represented on a modeling committee can monitor progress through the VISTAS website. The NCDAQ will also host several public meetings and focus groups with potentially impacted parties in order to get the most objective and comprehensive input in the development of the final control strategies.

1.3.2. Protocol Modification Procedures

The model configuration, as well as the source of input data and evaluation process, will be determined at the beginning of the process. In the event that the protocol needs to be revised to incorporate new tools or methodologies, an issue paper stating the need for modification will be developed and circulated to all organizations participating in the study. The issue paper will be discussed at the next scheduled technical coordination meeting. The revised protocol would then be developed and submitted to the USEPA for their review.

1.4. Selection of Future Year

A key decision from both a modeling and control strategy standpoint is the selection of the future year by which attainment will be modeled. The future modeling year has been chosen to meet the schedule previously put forth. The time line set by the CAA requires attainment of the annual $PM_{2.5}$ NAAQS be met by April 5, 2010. Since this date is set prior to the completion of the 2010, attainment of the NAAQS would have to be met by at least the end of the 2009. The NCDAQ plans to use 2009 as the future year for attainment modeling, as it would coincide with future year modeling for the annual $PM_{2.5}$ and 8-hour ozone attainment demonstration SIPs and VISTAS regional haze modeling effort.

1.5. Schedule

The NCDAQ will follow the schedule outlined by the CAA, where an attainment demonstration SIP is due for submittal by April 5, 2008. Using a 2009 modeling year, attainment will be demonstrated by at least April 5, 2010 or as expeditiously as practicable.

1.6. Organization of Air Quality Modeling Protocol

The remainder of the protocol documentation is broken down into nine additional sections as follows:

- Section 2 provides a conceptual description of $PM_{2.5}$ formation in North Carolina.
- Section 3 presents details of the $PM_{2.5}$ episode selection process.
- Section 4 details the models that will be used during this modeling project.
- Section 5 describes the model grid specifications.
- Section 6 discusses the emission inventory development.
- Section 7 lays out the quality assurance plan and procedures.
- Section 8 details the tools and procedures for model performance evaluation.
- Section 9 discusses how the control strategies will be designed.
- Section 10 focuses on the model attainment test and supplemental analyses.
- Section 11 lists the references.
- Acronym Attachment follows the final section.

2.0 Conceptual Description of Fine Particulate Matter in North Carolina

2.1. General Description of Particulate Matter

Particulate matter is generally subdivided into two categories, coarse and fine particles, based on the aerodynamic diameter (D_a) of the particle, as opposed to the actual diameter. Actual particles are irregularly shaped, making a diameter measurement problematic. To ease the process, particles are measured base on their D_a, which is defined as the diameter of a spherical particle with equal gravitational settling velocity as the irregularly shaped particle, but with material density of 1gram per cubic centimeter (g/cm^3).

The division between the fine and course categories occurs in the D_a size range between 1 and 3 micrometers (µm), where concentrations are at a minimum. Particles with a D_a greater than the minimum are coarse particles, while those particles less than the minimum are categorized as fine particles. Fine particle are further broken down into the accumulation mode, which includes diameters less than the minimum, but greater than 0.1 µm, and ultrafine mode, which are diameters less than 0.1 µm. The ultrafine mode is further broken down into Aitken mode and nucleation mode. Figure 2.1-1 illustrates the differences between the particle size divisions.

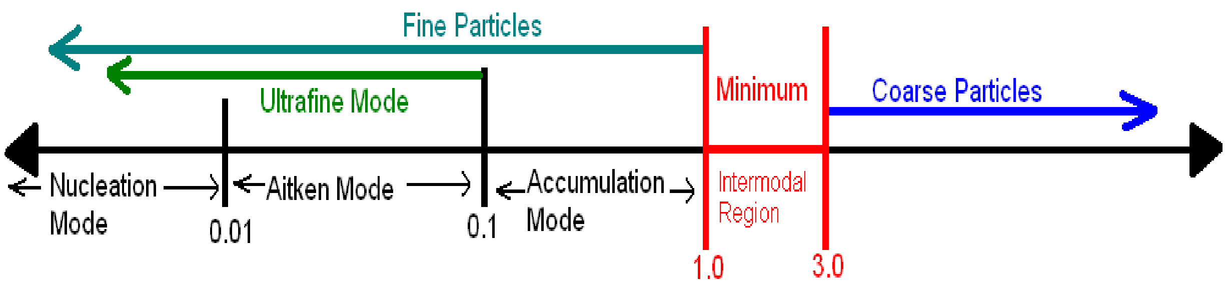

Figure 2.1-1: This figure illustrates the size categories or modes for particulate matter. Values are in units of micrometer.

The ambiguity in the cutoff between fine and coarse particles revolves around the hygroscopic properties of the accumulation mode particles. Under high relative humidity conditions, the particle can grow to sizes on the coarse end of the spectrum due to particle bound water. Under low relative humidity conditions, coarse particles can be fragmented, and the resulting particle will have a $D_a < 2.5$ µm. The USEPA chose the cutoff of 2.5 µm for the development of a NAAQS based on the use of $PM_{2.5}$ in epidemiological studies, and the desire to include the accumulation-mode particles, while recognizing that some coarse particles can occur under particular conditions.

2.2. Composition

Particulate matter can be liquid, solid, or can have a solid core surrounded by liquid. Particulate matter can include material produced by combustion, photochemical reactions, and can contain salt from sea spray and soil like particles. Particles are distinguished based on the method of formation. Primary particles are particles directly emitted into the atmosphere and retain the same chemical composition as when they were released. Secondary particles are those formed through chemical reactions involving atmospheric oxygen (O_2), water vapor, hydroxyl radical (OH), nitrate (NO_3), sulfur dioxide (SO_2), nitrogen oxides (NO_x), and organic gases from natural and anthropogenic sources.

Particulate matter components can include:

- Sulfate
  For fine particles, sulfate is generally a secondary particle, and is usually found in the form of ammonium sulfate.
- Nitrate
  For fine particles, nitrate is generally a secondary particle, and is usually found in the form of ammonium nitrate.
- Ammonium
- Hydrogen ion
- Particle bound water
- Elemental carbon
- Organic compounds
  - Primary organic species (from cooking and combustion)
  - Secondary organic compounds
- Organic materials
  Generally, in the coarse particle and intermodal range, organic materials are primary particulates from organic material includes pollen, spores, and animal debris.
- Crustal material
  Predominately found in coarse particle range, crustal material includes calcium, aluminum, silicon, magnesium, and iron.
- Sea salt
  Sea salt is generally only found at coastal monitoring sites.
- Transitional metals
- Potassium
  For fine particulates, potassium is generally from wood burning or cooking.

2.3. Spatial and Temporal Patterns

2.3.1. Spatial

North Carolina currently has two nonattainment areas for the annual $PM_{2.5}$ NAAQS, which are associated with the Hickory and Lexington monitoring sites located in Catawba and Davidson Counties, respectively. The nonattainment designations were based on the 2001-2003 monitoring data. For that period, the Hickory monitor had an annual $PM_{2.5}$ design value of 15.5 $\mu g/m^3$ and the USEPA designated all of Catawba County as nonattainment. The Lexington monitor had an annual $PM_{2.5}$ design value of 15.8 $\mu g/m^3$, and all of Davidson and Guilford Counties were designated as nonattainment. These two monitoring sites are only tenths of micrograms above the current NAAQS of 15.0 $\mu g/m^3$. The rest of the state was below the NAAQS, with annual averages ranging from 9.6 to 14.9 $\mu g/m^3$. Figure 2.3.1-1 shows a map of

North Carolina with the 2001-2003 annual $PM_{2.5}$ design values. Across the majority of the monitoring sites, including the two violating monitors, the annual average of $PM_{2.5}$ has been on the decline since 1999.

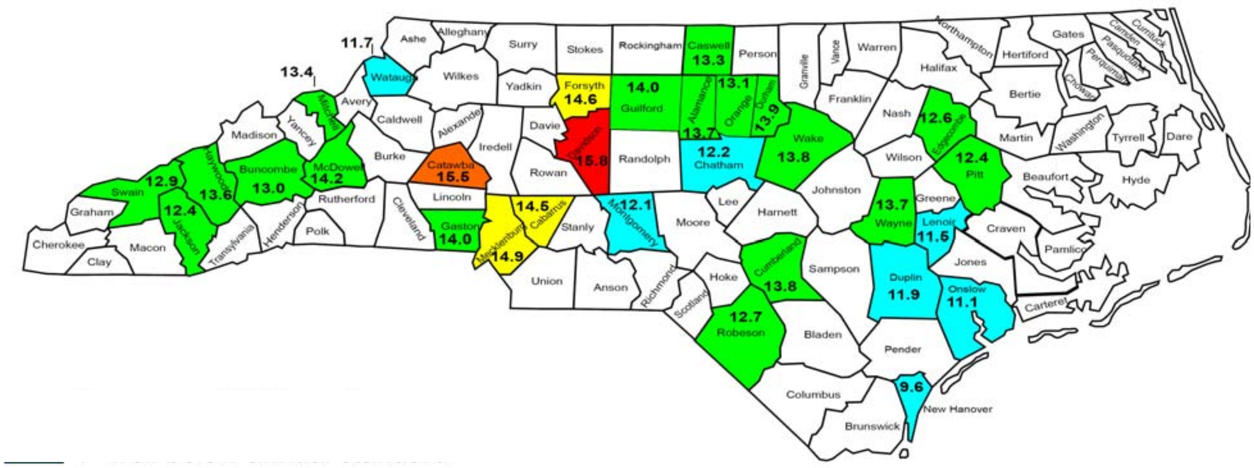

Figure 2.3.1-1: 2001-2003 annual $PM_{2.5}$ design values.

Given that annual average $PM_{2.5}$ concentrations at sites across the state, one can reasonable conclude that $PM_{2.5}$ is a regional issue for North Carolina. An examination of the daily $PM_{2.5}$ conditions across North Carolina again shows similar values across the state on a consistent basis. It is very rare that a site becomes notably higher than a surrounding site, as well as experiences an exceedance of the 24-hour $PM_{2.5}$ NAAQS.

Both nonattainment areas are in the western portion of the state known as the Piedmont Crescent. This portion of the state has the intersection of three major highways, and a higher concentration of coal-fired electric generating boilers than the rest of the state.

2.3.2. Diurnal

The most distinct pattern $PM_{2.5}$ presents is its diurnal pattern. $PM_{2.5}$ levels often increase in the overnight hours and drop off during the day. This increase is, in part, due to the formation of temperature inversions in the lowest layers of the atmosphere near the surface. Inversions commonly form when the air near the surface cools during the overnight period. Once the sun sets, the ground loses heat very quickly, which cools the air that is in contact with the ground. Air is a very poor conductor of heat, which allows the air just above the surface to remain warm. These inversions are referred to as nocturnal inversions.

Conditions commonly found in association with high-pressure systems, namely calm winds and clear skies, contribute to the formation of surface inversions. Calm winds prevent warmer air above the surface from mixing down to the ground, and clear skies increase the rate of radiational cooling at the earth's surface. Additionally, the length of the overnight period greatly affects inversion formation. Winter typically has stronger and more frequent inversions, since the nights are longer and provide a longer period for radiational cooling to occur.

Inversions generally weaken and disappear as the sun rises and warms the surface. However, under certain meteorological conditions, such as strong high pressure over the area, these inversions can persist for several days. In addition, local topographical features can enhance the formation of inversions, especially in valley locations.

Therefore, inversions create a very stable atmosphere where pollutants, such as $PM_{2.5}$, become trapped near the surface. Air quality conditions under the inversion layer are greatly affected by the emissions from electric generating units and other industrial sources. Most electric generating units are in operation 24-hours a day, with a large portion of industrial source operating with either two shifts or around the clock. The second shift production from these facilities occurs just as the nocturnal inversion is setting up. Emissions from production are spewed the atmosphere where they become trapped in the very stable layer created by the inversion. With little mixing occurring, the pollutants begin to build up and concentrations rise as more pollutants are pumped into the atmosphere with overnight production. Pollutants continue to build until the sun warms the surface enough to ‘break’, or mix out, the inversion.

Air quality conditions are further aggravated under the inversion by ‘rush hour’ traffic. The evening commute occurs just as the nocturnal inversion is setting up, contributing some additional $PM_{2.5}$ components to the load from industrial sources. The remnants of the nocturnal inversion are still in place during the bulk of the morning rush hour, allowing for additional vehicle contribution during this time.

2.3.3. Weekly

Preliminary statistical studies indicate both the Hickory Federal Reference Method (FRM) monitoring site and the Lexington FRM site experience similar weekly patterns in $PM_{2.5}$ concentrations. Concentrations generally build from low weekend values to a peaks concentration at week’s end. Figures 2.3.3-1 and 2.3.3-2 show the concentration of $PM_{2.5}$ stratified by day of the week. The black circle on the graph indicates the average concentration for that particular day of the week.

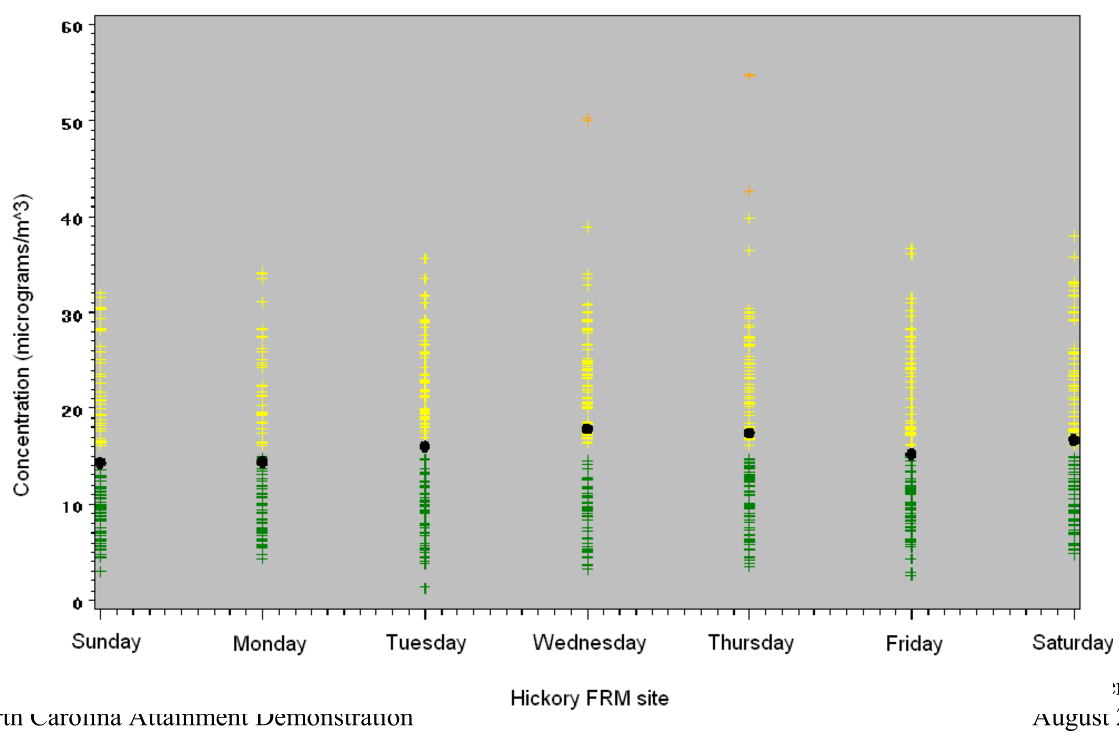

Figure 2.3.3-1: 24-hour average $PM_{2.5}$ concentrations at the Hickory FRM monitor by days of the week. The black circle represents the average concentration for the day.

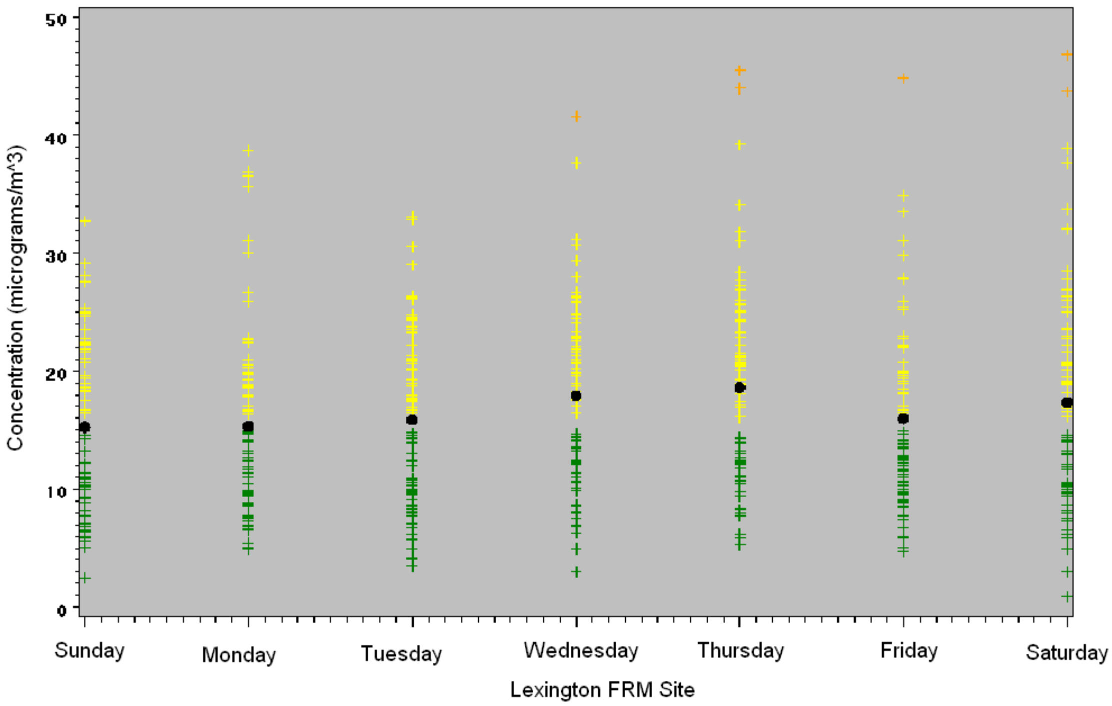

Figure 2.3.3-2: 24-hour average $PM_{2.5}$ concentrations at the Lexington FRM monitor by days of the week. The black circle represents the average concentration for the day.

2.3.4. Seasonal

<u>Summer/Fall</u>

High $PM_{2.5}$ values generally correspond to high temperatures and high atmospheric moisture content (i.e., high relative humidity). Some constituents of particulate matter are hygroscopic, and will collect more water as relative humidity increases. This can lead to very hazy conditions, which limit visibility. Since high temperature and high relative humidity are prevalent in the southeastern United States during the summer and early fall, some of North Carolina's worst particulate matter episodes occur in the months from June to September.

The 24-hour concentrations are typically between 10 and 30 $\mu g/m^3$ during the summer, with spikes as high as 50 $\mu g/m^3$. The season generally has its peak $PM_{2.5}$ concentration in the July to August timeframe, with ammonium sulfate as the primary constituent of $PM_{2.5}$ during this period. Ozone is also of great concern during the summer months. Generally, the same meteorological scenarios responsible for high ozone days also lead to high $PM_{2.5}$ days. Typically, those conditions are characteristic of a surface high pressure area. The approach of a tropical system or a frontal system can also lead to an increase in either pollutant.

High-pressure systems can act to block cold fronts from passing through the area, which would cause an exchange in air mass leading to improved air quality conditions. Regardless of their origin, high-pressure systems produce light winds and little precipitation. These conditions can persist for days allowing for an intense build up of pollutants in the area. Conditions similar to a high-pressure system can be produced by tropical cyclones. Tropical cyclones produce subsidence on their outer edges, which results in light winds, warm temperatures and subsequently, high $PM_{2.5}$ concentrations. Systems that lurk just off the coast, or take a path that grazes the coast can cause subsidence in the western portion of the state.

Pre-frontal conditions can also cause increased $PM_{2.5}$ concentrations as the leading edge of the front acts to collect $PM_{2.5}$, driving up concentrations along its path. During an event with enough steady precipitation, $PM_{2.5}$ can "washout", or remove particulates from the atmosphere, reducing concentrations. However, relief from high $PM_{2.5}$ usually comes after frontal passage when a new air mass enters into the area.

Winter/Spring

$PM_{2.5}$ episodes during the winter and early spring are typically lower in magnitude than those episodes experience in summer and early fall, and are largely driven by nitrates and to a lesser extent by black carbon from combustion. Peak 24-hour averages of particle pollution are generally around 20 to 25 $\mu g/m^3$. The highest $PM_{2.5}$ occurs when high pressure moves overhead, creating and environment of light winds and clear skies. At night, temperatures at the surface cool rapidly and a steep nocturnal temperature inversion forms. Particle pollution accumulates under this inversion, with 1-hour values rising to 25 to 30 $\mu g/m^3$. $PM_{2.5}$ drops the next morning after the sun rises and convective mixing disperses the low level pollutants. The highest daily $PM_{2.5}$ occurs when conditions are clear and calm through the nighttime hours, then cloud cover moves overhead at or just after sunrise, reducing convective mixing and leaving pollution trapped at the surface.

Longer lasting episodes may occur when inversions are created by cold air damming (CAD). CAD events occur frequently during the winter and early spring and are a phenomenon unique to the geography of the Southeast. In a CAD event, a layer of cold air at the surface gets pushed up against the Appalachian Mountains. A low-pressure system to the south then circulates warm moist air over the cold air, creating an inversion. These events are generally accompanied by cloudy skies, little precipitation, and light wind. The stable atmosphere created by CAD events provides an environment conducive for the continual build up of pollution near the surface with little mixing.

Snow and ice cover can also lead to higher concentrations of particle pollution. A snow pack intensifies the radiational cooling at the surface, enhancing the nocturnal temperature inversion and allowing a greater build up of particulates. With the cold temperatures, a greater amount of combustion for heating takes place, which adds more particulates to the air. During the day, the high albedo of the snow suppresses surface heating and convective mixing, preventing the nocturnal inversion from mixing out and keeping particle pollution at high concentrations.

3.0 $PM_{2.5}$ Episode Selection

A crucial step to attainment demonstration modeling is the selection of episodes to model. Several considerations need to be weighed before settling on not only which days to model, but how many days for each episode. This section details the guidance and process by which episodes were selected for the Hickory/Triad $PM_{2.5}$ attainment demonstration SIP.

3.1. Overview of the USEPA Guidance on Particulate Matter

The USEPA's draft guidance for Demonstrating Attainment of Air Quality Goals for $PM_{2.5}$ and Regional Haze (EPA, 2001) sets out specific criteria for the selection of episodes for modeling the attainment of the $PM_{2.5}$ NAAQS. First, episodes should include days encompassing a variety of meteorological conditions. Episodes should also be chosen around days for which there are extensive database air quality and meteorology measurements, including measurements speciated data, and upper air measurements. Finally, a sufficient number of days should be selected to ensure robust attainment tests at violating monitoring sites.

In addition to these primary criteria, the USEPA also suggests a set of secondary criteria that may be used in the selection of episodes. This set of criteria allows states to give preference to previously modeled episodes. This is a very valuable consideration, as the USEPA points out, since it can save modeling resources and effort. The USEPA also recommends selecting episodes that occur during the period corresponding to the 5 year current design value, 2000-2004. Additional considerations include selecting episodes that include weekends and the selection of episodes meeting primary and secondary criteria in all other nonattainment areas, when participating in regional modeling. Using these criteria laid out by the USEPA, the NCDAQ systematically examined the data available to determine the best episodes for modeling.

The USEPA suggests three approaches to $PM_{2.5}$ modeling. The first, and preferred approach, is to use a photochemical model to model an entire year (or more). As an alternative to the preferred modeling, states can model a minimum number of days (at least 15) from each quarter. A second alternative is to classify observed air quality data into groups defined by differences in meteorological conditions, modeling at least three days from each of the identified groups.

3.2. $PM_{2.5}$ Episode Selection

With the advances in computing and storage technologies, and aided by regional modeling efforts, the NCDAQ will model an entire year for the Hickory/Triad $PM_{2.5}$ attainment demonstration, using a photochemical model. By modeling the whole year, several criteria are covered, including the modeling of weekends and a sufficient number of days to ensure a robust modeled attainment test. Modeling a whole year will also accomplish the goal of encompassing a myriad of meteorological conditions that may influence $PM_{2.5}$ concentrations.

Efforts were made to determine an appropriate year to model. One of the secondary criteria would suggest using episodes drawn from 2001-2003, as this period corresponds to the design value period for which nonattainment designations were based. By selecting 2002, the base case year would be the same as our base line (typical) year. This would mean the 2002 emissions inventories would not have to be adjusted to correspond to a different base case year during modeling efforts. Differences between the base case and base line (typical) inventories are explained in Section 6.

Additionally, the selection of 2002 as the base case year also fulfills the secondary criteria, which suggests states give preferential treatment of previously modeled episodes. Through the NCDAQ's work with the VISTAS, the 2002 calendar year is in the process of being modeled as a base case year for regional haze reduction goals.

Though the VISTAS modeling is geared towards Regional Haze on a regional scale, the modeling can easily be applied to the $PM_{2.5}$. The VISTAS modeling employs "one atmosphere" modeling, or modeling of all atmospheric constituents, including particulate matter and ozone. This modeling is done in parallel to capture interactions between various compounds. Since $PM_{2.5}$, along with ozone and regional haze, is being modeled as part of the VISTAS modeling efforts, its data can easily be extracted from the modeling results.

The USEPA guidance suggests that when selecting a representative year, one should examine the annual mean concentration and the pattern of the quarterly mean concentrations. The mean annual concentration of the year chosen as the base case should be close to the 3-year design value at all or most of the monitoring sites. Table 3.2-1 shows the annual average for the Hickory and Triad areas, as compared to both the 2001-2003 design values and the 2002-2004 design values. The mean annual average concentration for the 2002 calendar year is generally close to either design value, usually within ± 0.5 μg/m^3. When examining the patterns of the mean quarterly concentrations, the representative year should follow a similar pattern. Table 3.2-2 shows the mean quarterly concentrations for 2002 and the average of the quarterly mean concentrations from 1999 through 2004. The ambient data for 2002 generally follows the same trends as the quarterly averages; specifically the third quarter has the highest mean concentration, with the lowest concentrations in the first or fourth quarter.

Table 3.2-1: Annual mean concentration and design value for sites in nonattainment areas

Monitoring Site	County	Annual Mean				Design Values		2002 – DV(01-03)	2002 – DV(02-04)
		2001	2002	2003	2004	2001-2003	2002-2004		
Hickory	Catawba	**15.98**	**15.36**	**15.04**	15.00	**15.5**	**15.1**	-0.10	0.22
Lexington	Davidson	**16.45**	**15.88**	**15.17**	**15.18**	**15.8**	**15.4**	0.05	0.47
Mendenhall-1	Guilford		13.72	13.32	13.97	13.2	13.7	0.55	0.05
Mendenhall-2	Guilford		13.79	13.15	14.18	12.9	13.7	0.85	0.08

Note: The last two columns show the difference between the annual average for 2002 and the 2001-2003 design value (DV) and the 2002-2004 DV.

Table 3.2-2: Quarterly mean concentrations for 2002 compared to mean quarterly averages

Monitoring Site	County	1Q.2002	2Q.2002	3Q.2002	4Q.2002	Q1	Q2	Q3	Q4
Hickory	Catawba	13.25	14.32	**21.12**	**12.73**	14.64	15.82	**20.00**	**13.82**
Lexington	Davidson	14.94	15.00	**19.28**	**14.29**	14.67	16.67	**19.42**	**14.61**
Mendenhall-1	Guilford	**11.71**	13.14	**18.29**	11.72	**11.67**	13.70	**17.10**	11.73
Mendenhall-2	Guilford	13.03	14.17	**18.87**	**9.08**	11.95	14.45	**16.84**	**10.87**

Note: Blue numbers indicate the minimum quarter, red numbers indicate highest quarter.

2002 was an active year with numerous poor air quality episodes. Across the Carolinas, instances of high $PM_{2.5}$ values generally coincide with high ozone values since both need similar atmospheric condition to accumulate. Both $PM_{2.5}$ and ozone thrive in stagnant air masses in the summer, which result from reduced wind conditions that limit vertical mixing in the atmosphere. The limited mixing allows pollutants to collect near the surface, driving the concentration of both pollutants up. The 2002 season was examined to verify that it was representative of the nature of $PM_{2.5}$ formation in the Hickory and Triad areas to further support its use in modeling. The following section details the results of the study.

3.3. Episode Classification

Since the NCDAQ is moving towards modeling an entire calendar year, a general discussion of episodes is presented in this section. The same categories of meteorological scenarios exist through out the year.

3.3.1. Definition of a $PM_{2.5}$ Episode

Monitoring sites across North Carolina rarely see instances where the 24-hour NAAQS for $PM_{2.5}$ is violated; making it is difficult to define $PM_{2.5}$ episodes. Further complicating the issue is the fact that North Carolina rarely has days with a 24-hour average $PM_{2.5}$ concentration greater then 40.5 $\mu g/m^3$, which is the lower end cutoff of the Code Orange range of the Air Quality Index (AQI). As an arbitrary method to classify episodes to ensure various meteorological scenarios were selected, days with a 24-hour $PM_{2.5}$ concentration greater than 15 $\mu g/m^3$ (the lower end of the Code Yellow range of the AQI) were flagged for closer examination.

Table 3.3.1-1 lists the 24-hour $PM_{2.5}$ concentrations for the year, with each block as a separate month. Days with a 24-hour concentration greater than 15 $\mu g/m^3$, but less than 30 $\mu g/m^3$, are shade light gray. Days greater than 30 $\mu g/m^3$ are shaded dark gray, and the stippling indicates no data. The tables include the Mendenhall (MNDHL) site in Guilford County, the Lexington (LEX) site in Davidson County and the Hickory (HKY) site in Catawba County. Both the Lexington and Hickory monitors are FRM monitors that report every three days. The Mendenhall is a Tapered Element Oscillating Microbalance (TEOM) monitoring site and reports everyday.

Note: Mendenhall (MNDHL) is a TEOM monitor, with measurements every day. Lexington (LEX) and Hickory (HKY) are FRM monitors, with measurements every 3rd day. White blocks denote $PM_{2.5} < 15\ \mu g/m^3$, light gray 15-30 $\mu g/m^3$, dark gray > 30 $\mu g/m^3$, and stippling denotes missing data.

Meteorological Scenarios (Met) are as follows: Ho – Surface high over NC; Hs – Surface high south of NC; He – Surface high east of NC; Ls – Low pressure passing south of NC; F – Frontal approach; Fst – Front stalled near/over NC; Fsl – slow frontal approach; H-F – High pressure followed by frontal approach; CAD – Cold Air Damming; WS – Winter Storm; T – Tropical system near NC

3.3.2. Episode Classification of the 2002 Season

In reviewing the data in Table 3.3.1-1, it becomes apparent the months of May through October have the days with the highest $PM_{2.5}$ concentrations. The peak concentrations of the year occur during the months of July and August, and remain below 40.7 μg/m^3. There is one isolated episode on December 7, 2002, which had a 24-hour $PM_{2.5}$ concentration of 49.2 and 43.7 μg/m^3 at the Mendenhall and Lexington monitoring sites, respectively. These high values are likely in association with a winter storm that struck North Carolina on December 4th and 5th, and will be discussed further below under the winter storm section.

The column labeled "Met" contains a classification of the weather pattern on that day. The meteorological scenarios are broken down into several categories. One set of categories is based on the location of surface high-pressure systems. Systems are defined as either over North Carolina, to the south of the State, or east of North Carolina. In addition, episodes can be defined by various frontal passage scenarios.

An additional set is defined by the type of frontal approach experienced. A typical frontal approach is capable of producing elevated $PM_{2.5}$, as well as a front stalled near/over North Carolina, slow frontal approach, and high pressure followed by a frontal approach. Winter storms, cold air damming, low-pressure system passing to the south, and tropical systems near North Carolina are additional meteorological scenarios that occur less frequently, but have an impact on $PM_{2.5}$ concentrations in North Carolina. Tropical influence is noted in combination with the main surface feature on land. The following sections discuss the major categories of meteorological scenarios responsible for elevated particulate matter. Table 3.3.2-1 contains a count of each the meteorological scenarios by month for the identified episodes. Several seasonal patterns can be ascertained from Table 3.3.1-1.

Table 3.3.2-1: Count based on the meteorological scenarios associated with elevated $PM_{2.5}$

Met scenario		JAN	FEB	MAR	APR	MAY	JUN	JUL	AUG	SEP	OCT	NOV	DEC	Total
High to south	Hs	1		3	4		2	1						11

	Total	10	7	7	6	11	13	25	19	20	9	6	10	143

High Pressure

Stagnation under high pressure is responsible for, roughly 57% of the noted $PM_{2.5}$ episodes in 2002 (see Table 3.3.2-1). High pressure builds into the southeast, settling nearly over North Carolina. The high leads to clear and calm conditions across the state and most of the region. With light or calm winds and clear skies, the nocturnal surface temperature inversion grows very strong. Particle pollution builds under the inversion, reaching a maximum in the morning hours before the sun induces surface heating to mix out the inversion. Highest particle pollution may occur when clouds build in shortly after sunrise. The clouds diminish the daytime surface heating and reduce the amount of atmospheric mixing, allowing the nighttime inversion layer to persist well into the daylight hours. High-pressure episodes may be quickly followed by a frontal approach (see section below), which can lead to a further rise in particle pollution. If high pressure can remain overhead for 2 to 3 days, $PM_{2.5}$ can rise to 20 to 25 $\mu g/m^3$ in the winter, and as high as 40 $\mu g/m^3$ in the summer.

A milder rise in $PM_{2.5}$ may occur if high pressure is positioned further south, over northern Florida or to the east of Jacksonville. A west to southwest flow develops over North Carolina. The flow has a long history over land, originating from the central Gulf coast region to the lower Mississippi River valley. Since the high pressure is centered further south and/or east, winds remain light to moderate, preventing a strong nocturnal inversion from developing. The winds also mix pollutants within a deeper layer of the atmosphere. Under this scenario, $PM_{2.5}$ generally reaches a maximum between 15 to 20 $\mu g/m^3$.

The winter episodes due to high pressure tend to be transient, lasting 1 to 2 days, because of the farther south position of the jet stream this time of year. Most summertime episodes tend to be of the high overhead or high just to the east variety (see Table 3.3.2-1). This is not surprising that all the eastern high episodes occur during the summer when the Bermudas high positions itself off North Carolina's coast for most of the summer, sometime drifting closer to shore.

Frontal Approach

The second most common meteorological scenarios of the 2002 season involved frontal passage. Approximately 31% of the elevated episodes of 2002 were either classified as frontal approach, front stalled near/over North Carolina, slow frontal approach, or high pressure followed by a frontal approach (See Table 3.3.2-1).

North Carolina experiences numerous frontal passages during the year. Mass convergence ahead of a cold front typically yields a rise in particle pollution. Winds are predominantly from the south and southwest ahead of the front. The level of particle pollution with a frontal approach depends on the speed of the front. The slower moving the front, the more time pollution levels have to rise in an area. The typical fast moving front may cause a rise in $PM_{2.5}$ for a few hours, causing a spike in 1-hour concentrations and a slight surge in the 24-hour concentration.

Slow moving and stalled fronts are slightly less common (see Table 3.3.2-1), but can lead to a more extended rise in $PM_{2.5}$ concentration, leading to elevated 24-hour concentrations. In North Carolina, a fronts tend to slow when a long-wave upper level trough is located over the eastern United States, between the Appalachian Mountains and the Mississippi River. As a cold front plunges southward from Canada into Alabama and Mississippi, it then slows down as it becomes oriented parallel to the upper level flow. In this situation, North Carolina remains within the dirtier air just to the east of the frontal boundary, where mass convergence leads to a buildup of particle pollution. Eventually the cold front pushes south and east of North Carolina, bringing cleaner air into the state. An example of this type of event occurred on November 25, 2002.

Occasionally, an approaching cold front will completely stall over the state and then dissipate. As the front moves into the region, the upper level trough weakens, leaving no upper level dynamics to support the frontal boundary. The high particle pollution associated with the leading edge of the front remains in the region as a weak high-pressure area develops overhead. The stagnant conditions underneath the high pressure cause particle pollution concentrations to remain elevated, and can lead to increased concentrations. An example of this type of event occurred on November 20, 2002.

Winter Storm Followed by High Pressure

In this scenario, low pressure develops along the Gulf coast, and tracks east-northeastward off the Carolina coast. With cold air in place, moderate to heavy snow falls to the north of the storm track, over the Appalachian Mountains and Piedmont. In the wake of the departing storm, high pressure builds over the southeast. The snowfall intensifies the radiational cooling at the surface, enhancing the overnight inversion and allowing a greater build up of particulates. During the day, the high albedo of the snow suppresses surface heating and convective mixing, preventing the nocturnal inversion from mixing out and keeping particle pollution at high concentrations.

Especially severe winter storms may cause extreme rises in $PM_{2.5}$. Severe winter weather may knock out power across a wide region, causing people to use alternative means, such as wood burning, to keep warm. North Carolina experienced a severe ice storm on December 4, 2002. Power was knocked out for several days across a wide swath of the Piedmont. Wood combustion for both residential heating and debris removal caused $PM_{2.5}$ to top out above 40 $\mu g/m^3$. Due to the anomalous nature of severe winter storms, it is not appropriate to include $PM_{2.5}$ concentrations for days immediately following these events.

Cold Air Damming, CAD

Longer lasting episodes may occur with the passage of a 'backdoor' cold front in a moderate CAD regime, which stalls in or near North Carolina. In a CAD scenario, the wind flow around a surface high pressure located over the northeast will push colder air southward to the east of the Appalachian mountains, down into the Carolinas. Meanwhile, low pressure to the west of North Carolina advects warm moist air over the cold air, creating a stable inversion layer at the surface. A stratus cloud layer usually forms as the warm air overrides the cold air. Particle pollution is able to build within the inversion layer, and cloudiness and light wind prevents much significant mixing. Recirculation of pollutants often occurs at the end of CAD events, as the backdoor cold front pushes north.

Lows and Tropical Influence

The final two categories are less common (see Table 3.3.2-1). The presence of tropical system offshore during the late summer to early fall can degrade $PM_{2.5}$ conditions. The systems generally cause subsidence at their outer edge, which acts much like a high-pressure system. Skies are generally clear and calm winds prevail far out from the system's center, allowing pollutants to build up. The subsidence caused by the presence of a tropical system combines with the meteorology present on land (usually a high-pressure system over North Carolina) to drive $PM_{2.5}$ concentration to levels between 15 and 25 $\mu g/m^3$.

The final category involves a low-pressure system passing to the south of the State. These events produce slight elevations in $PM_{2.5}$, with concentrations on the order of 18 $\mu g/m^3$. With only two instances of this type of scenario, it is hard to pin point the exact cause for the slight elevation. The increase in concentration is likely due to the clear conditions setting up the night preceding the low-pressure system passage, leading to the formation of an inversion layer. The low-pressure system approach by morning shrouds the area in cloud cover, making it difficult to erode the inversion layer. The pollutants are trapped at the surface by the inversion layer, but dissipate after the low-pressure system moves east.

4.0 Models and Modeling Configurations

The NCDAQ intends to utilize the same configuration of regional meteorological, emissions processing, and photochemical air quality models used by the VISTAS regional haze modeling study. The underlying science behind each component of the overall modeling system are identified and discussed briefly in this section. Although the configuration of each of the modeling components has been selected as the culmination of intensive study by VISTAS, there remains the possibility that certain algorithms and parameter settings may still be updated prior to the running of the final annual 2002 base case simulation and subsequent model performance testing.

The NCDAQ modeling team will remain in close contact with the VISTAS, as well as other Regional Planning Organization (RPO) regional modeling initiatives throughout the attainment demonstration modeling study, to determine appropriate refinements to the model codes, input databases, and post-modeling analysis procedures. Notable limitations of the models, relevant to their intended purpose in this attainment modeling analysis, will also be evaluated in detail.

4.1. Recommended Models

Based on extensive research of available documentation of the VISTAS Regional Haze modeling analysis, it has been determined by the NCDAQ that the $PM_{2.5}$ attainment demonstration omodeling should utilize the following suite of models:

- **MM5:** The Pennsylvania State University/National Center for Atmospheric Research (PSU/NCAR) Mesoscale Meteorological Model (MM5) is a nonhydrostatic, prognostic meteorological model routinely used for urban- and regional-scale photochemical, fine particulate matter, and regional haze regulatory modeling studies.

- **SMOKE**: The Sparse Matrix Operator Kernel Emissions (SMOKE) modeling system is an emissions modeling system that generates hourly gridded speciated emission inputs of mobile, nonroad mobile, area, point, fire, and biogenic emission sources for photochemical grid models.

- **CMAQ:** The USEPA's Models-3/ Community Multiscale Air Quality (CMAQ) modeling system is a "One-Atmosphere" photochemical grid model capable of addressing ozone, fine particulate matter, visibility, and acid deposition at regional scale for periods up to one year.

4.2. MM5 – Mesoscale Prognostic Model

Over the past decade, researchers at the Pennsylvania State University (PSU) and the National Center for Atmospheric Research (NCAR) have collaborated in the refinement and extension of the PSU Mesoscale Meteorological Model leading to the current version of the system, MM5 (version 3.6, MPP). Originally developed in the 1970s at PSU and first documented by Anthes and Warner (1978), the MM5 modeling system has maintained its status as a state-of-the-science model through enhancements provided by a broad user community (e.g., Chen and Dudhia, 2001; Stauffer and Seaman, 1990, 1991; Xiu and Pleim, 2000). The MM5 modeling system is routinely employed in forecasting projects as well as refined investigations of severe weather. Utilization of MM5 within air quality applications is also a common practice. In recent years, the MM5 modeling system has been successfully applied in continental scale annual simulations for the years 1996 (Olerud et al., 2000), 2001 (McNally and Tesche, 2003), and 2002 (Johnson, 2003). Due to its ongoing scientific development worldwide, extensive historical applications, broad user community support, public availability, and established performance record compared with other applications-oriented prognostic models, MM5 has been selected as the preferred meteorological model for this effort. This section provides an overview of the MM5 and its data input requirements.

4.2.1. MM5 Overview

The non-hydrostatic MM5 model (Dudhia, 1993; Grell et al., 1994) is a three-dimensional, limited-area, primitive equation, prognostic model that has been used widely in regional air quality model applications (Seaman, 2000). The basic model has been under continuous development, improvement, testing, and has been openly peer-reviewed for more than 20 years (Anthes and Warner, 1978; Anthes et al., 1987). It has been used world-wide by hundreds of scientists for a variety of mesoscale studies, including cyclogenesis, polar lows, cold-air damming, coastal fronts, severe thunderstorms, tropical storms, subtropical easterly jets, mesoscale convective complexes, desert mixed layers, urban-scale modeling, air quality studies, frontal weather, lake-effect snows, sea-breezes, orographically induced flows, and operational mesoscale forecasting.

MM5 is based on the prognostic equations for three-dimensional wind components (u – zonal wind component, v – meridional wind component, and w – vertical wind component), temperature, water vapor mixing ratio, and the perturbation pressure. Use of a constant reference-state pressure increases the accuracy of the calculations near steep terrain. The model uses an efficient semi-implicit temporal integration scheme and has a nested-grid capability that can use up to ten different domains of arbitrary horizontal and vertical resolution. The interfaces of the nested grids can be either one-way or two-way interactive. The model is also capable of using a hydrostatic option, if desired, for coarse-grid applications.

MM5 uses a terrain-following non-dimensionalized pressure, or "sigma," vertical coordinate similar to that used in many operational and research models. In the non-hydrostatic MM5 (Dudhia, 1993), the sigma levels are defined according to the initial hydrostatically-balanced reference state so that the sigma levels are also time-invariant. The gridded meteorological fields produced by MM5 are directly compatible with the input requirements of "one atmosphere" air-quality models using this coordinate (e.g., CMAQ). MM5 fields can be easily used in other regional air quality models with different coordinate systems (e.g., Comprehensive Air Quality Model with Extensions - CAMx) by performing a vertical interpolation, followed by a mass-conservation re-adjustment.

Distinct planetary boundary layer (PBL) parameterizations are available for air-quality applications, both of which represent sub-grid-scale turbulent fluxes of heat, moisture and momentum. These parameterizations employ various surface energy budget equations to estimate ground temperature based on the insolation, atmospheric path length, water vapor, cloud cover, and longwave radiation. The surface physical properties of albedo, roughness length, moisture availability, emissivity and thermal inertia are defined as functions of land-use for numerous categories via a look-up table. One scheme uses a first-order eddy diffusivity formulation for stable and neutral environments and a modified first-order scheme for unstable regimes. The other scheme uses a prognostic equation for the second-order turbulent kinetic energy while diagnosing the other key boundary layer terms.

Initial and lateral boundary conditions are specified from mesoscale three-dimensional analyses performed at 12-hour intervals on the outermost grid mesh selected by the user. Additional surface fields are analyzed at three-hour intervals. A Cressman-based technique is used to analyze standard surface and radiosonde observations, using the National Meteorological Center's (NMC) spectral analysis as a first guess. The lateral boundary data are introduced into MM5 using a relaxation technique applied in the outermost five rows and columns of the most coarse grid domain.

A major feature of the MM5 is its use of state-of-science methods for Four Dimensional Data Assimilation (FDDA). The theory underlying this approach and details on how it has been applied in a variety of applications throughout the country are described in depth elsewhere (Stauffer and Seaman, 1990, 1991; Seaman et al., 1992, 1997). Results of detailed performance evaluations of the MM5 modeling system in regulatory air quality application studies have been widely reported in the literature (e.g., Emery et al., 1999; Tesche et al., 2000, 2003), and many studies have involved comparisons with other prognostic models such as the Regional Atmospheric Modeling System (RAMS) and the Systems Application International Mesoscale Model. The MM5 enjoys a far richer application history in regulatory modeling studies compared with RAMS or other models. Furthermore, in evaluations of these models in over 60 recent regional scale air quality application studies since 1995, it has generally been found that the MM5 model tends to produce somewhat better photochemical model inputs than alternative models. For these and other reasons set forth in the MM5 modeling protocol developed by the contractor performing the meteorological modeling, Barons Advanced Meteorological Systems, LLC (BAMS) (Olerud and Sims, 2003), MM5 was selected as the meteorological modeling system for this study.

4.2.2. MM5 Configuration

Based on the extensive sensitivity testing carried out by Olerud and Sims (2003), the MM5 (version 3.6, MMP) configuration to be used by BAMS modelers will consist of the following:

- Nested 36/12 kilometer (km) grids, with 34 vertical layers
- Two way nesting, no feedback
- Initialization and boundary conditions from Eta analysis fields
- Pleim-Xiu (PX) soil model
- Asymmetric Convective Mixing (ACM) PBL model
- Kain-Fritsch 2 cumulus parameterization
- Mixed phase (Reisner 1) cloud microphysics
- Rapid Radiative Transfer Model radiation
- Snow effect turned on
- ETA model sea surface temperature
- 24-category United States Geological Survey (USGS) vegetation datasets
- Thermal roughness by the Garratt method

- Standard FDDA analysis nudging on 36-km and 12-km grid nests

4.2.3. MM5 Evaluation

The MM5 modeling results will be evaluated using plots and statistical analyses to determine if the model performance is adequate for the air quality modeling exercise. Some of the plots and statistics to be generated include:

- Spatial plots of model predictions with the appropriate observations overlaid. These will provide a visual to determine how well such meteorological parameters as temperature, mixing ratios, and winds are being captured by the model.

- Graphical statistical plots for surface temperature, mixing ratio, wind speeds, wind direction, and cloud cover. These will include time series of modeled/observed means, bias/error, and index of agreement.

- Daily accumulated precipitation plots of modeled versus observed.

- Tabular statistics for temperature, winds, mixing ratio, and cloud cover for various domains.

- Comparison of satellite versus modeled cloud images.

- Comparison of surface analysis maps to the MM5 pressure/wind maps

- Comparison of profiler observations with modeled winds

4.2.4. Meteorological Data

Meteorological data are being generated using the MM5 prognostic meteorological model by BAMS. BAMS is operating the MM5 at 5-day increments for 2002 on the 36-km and 12-km grid with a 14-day spin up period for the end of December 2001. The meteorological observations to be used for statistics come primarily from University Corporation for Atmospheric Research's (UCAR's) ds472.0 archive. These data are quality controlled and converted to NetCDF format, thus allowing the data to be visualized on the model fields via Package for Analysis and Visualization of Environmental data (PAVE). Due to the unreliability in precipitation values in the UCAR dataset, precipitation statistics are calculated from the 24-hour gridded accumulations available from the Climate Prediction Center (CPC). However, these fields undergo grid transformation to match our 36-km and 12-km domains from their original 0.25- degree resolution. The statistics are only calculated over cells that MM5 deems to be land since the CPC analyses are derived primarily from rain gauges.

For aloft analyses, standard sounding observations from the National Center for Environmental Predictions (NCEP) ds353.4 archive are processed. These observations are quality controlled and used to produce model/observation skewT sounding plots for selected sites. Additionally, the observations are integrated into sigma levels that match the MM5 specifications and subsequently can be statistically analyzed for performance at sigma levels 9, 17, and 22 (~500m, ~1600m, ~3400m, respectively). Qualitative profiler plots showing model/observed hourly winds are also created based upon the data stored at the Forecast Systems Lab.

4.3. SMOKE Emissions Modeling System

The SMOKE Emissions Processing System Prototype was originally developed at the Micro-computing Center of North Carolina (Coats, 1995; Houyoux and Vukovich, 1999). As with most "emissions models," SMOKE is principally an *emission processing system* and not a true *emissions modeling system* in which emissions estimates are simulated from "first principles." This means that, with the exception of mobile and biogenic sources, its purpose is to provide an efficient, modern tool for converting emissions inventory data into the formatted emission files required by an air quality simulation model. For mobile sources, SMOKE actually simulates emissions rates based on input mobile-source activity data, emission factors and outputs from transportation travel-demand models.

SMOKE was originally designed to allow emissions data processing methods to utilize emergent high-performance-computing as applied to sparse-matrix algorithms. Indeed, SMOKE is the fastest emissions processing tool currently available to the air quality modeling community. The sparse matrix approach utilized throughout SMOKE permits both rapid and flexible processing of emissions data. The processing is rapid because SMOKE utilizes a series of matrix calculations instead of less efficient algorithms used in previous systems. The processing is flexible because the processing steps of temporal projection, controls, chemical speciation, temporal allocation, and spatial allocation have been separated into independent operations wherever possible. The results from these steps are merged together at a final stage of processing.

SMOKE supports area, mobile, fire and point source emission processing and includes biogenic emissions modeling through a rewrite of the Biogenic Emission Inventory System, version 3 (BEIS3). SMOKE has been available since 1996, and it has been used for emissions processing in a number of regional air quality modeling applications. In 1998 and 1999, SMOKE was redesigned and improved with the support of the USEPA for use with the USEPA's Models-3/CMAQ. The primary purposes of the SMOKE redesign were support of: (a) emissions processing with user-selected chemical mechanisms and (b) emissions processing for reactivity assessments.

SMOKE contains a number of major features that make it an attractive component of the modeling system (Seppanen, 2003). The model supports a variety of input formats from other emissions processing systems and models including the Inventory Data Analyzer (IDA), Emissions Modeling System – 2003 (EMS), and the Emissions Preprocessor System 2.x (EPS). It supports both gridded and county total land use scheme for biogenic emissions modeling. Although it is not necessary for our purposes, SMOKE can accommodate emissions files from up to 10 countries and any pollutant can be processed by the system.

Recent computational improvements to SMOKE include:

- Enhanced disk space requirements compared with other emissions processing software

- Run-time memory allocation, eliminating any need to recompile the programs for different inventories, grids, or chemical mechanisms
- Updated Input/Output Applications Programming Interface libraries

A number of science features have been incorporated into the latest version of SMOKE (version 2.0), including:

- Any chemical mechanism can be used to partition pollutants to model species, as long as the appropriate input data are supplied
- Integration with the MOBILE6.2 on-road mobile source emissions model including link based processing
- Support of plume-in-grid processing
- Integration of the BEIS3 emissions factors in SMOKE

Notable features of SMOKE from an applications standpoint include:

- Improved control strategy input formats and designs
- Control strategies can include changes in the reactivity of emitted pollutants, a useful capability, for example, when a solvent is changed in an industrial process
- No third party software is required to run SMOKE, although some input file preparation may require other software
- Integration with Models-3 file formats and settings
- Improved data file formats
- Support of various air quality model emissions input formats (e.g., CMAQ, MAQSIP, UAMIV, UAM-V, REMSAD and CAMx)
- Enhanced quality assurance pre- and post-processing
- Fully integrated with Models-3, which will provide the SMOKE Tool for SMOKE input file preparation
- Enhanced treatment of growth and control factors
- Improved emissions reporting and Quality Assurance (QA) capabilities
- Improved temporal allocation

The Carolina Environmental Program at the University of North Carolina is continuing model development activities with SMOKE. The emissions modeling will employ the SMOKE version 2.0, released on September 30, 2003. The SMOKE executables, scripts and databases may be downloaded through the Community Modeling and Analysis (CMAS) center's Model Clearinghouse.

4.4. CMAQ Modeling System

4.4.1. CMAQ Overview

For more than a decade, the USEPA has been developing the Models-3 CMAQ modeling system with the overarching aim of producing a "One-Atmosphere" air quality modeling system capable of addressing ozone, fine particulate matter, visibility and acid deposition within a common platform (Dennis et al., 1996; Byun et al., 1998a; Byun and Ching, 1999; Pleim et al., 2003). The original justification for the Models-3 development emerged from the challenges posed by the 1990 CAA as amended and the USEPA's desire to develop an advanced modeling framework for "holistic" environmental modeling utilizing state-of-science representations of atmospheric processes in a high performance computing environment (Ching et al., 1998). The USEPA completed the initial stage of development with Models-3 and released the CMAQ model in mid 1999 as the initial operating science model under the Models-3 framework (Byun et al., 1998b). The most recent rendition is CMAQ version 4.4, which was released in October 2004.

CMAQ consists of a core Chemical Transport Model (CTM) and several pre-processors including the Meteorological-Chemistry Interface Processor (MCIP), initial and boundary conditions processors (ICON and BCON), and a photolysis rates processor (JPROC). The USEPA is continuing to improve and develop new modules for the CMAQ model and typically provides a new release each year. In the past, the USEPA has also provided patches for CMAQ as errors are discovered and corrected. More recently, the USEPA has funded the CMAS center to support the coordination, update and distribution of the Models-3 system.

Another reason for choosing CMAQ as the atmospheric model is the ability to do one-atmospheric modeling. Since the NCDAQ will be using the same modeling exercise for both the ozone and $PM_{2.5}$ attainment demonstrations SIPs, as well as the regional haze SIP, having a model that can handle both ozone and fine particulate matter is essential. A number of features in CMAQ's theoretical formulation and technical implementation make the model well-suited for annual particulate matter modeling. In CMAQ, the model approach has been adapted to dynamically represent the particulate matter size distribution using three log-normal modes (two fine and one coarse). Transfer of mass between the aerosol and gas phases is assumed to be in equilibrium and all secondary aerosols (sulfate, nitrate, secondary organic aerosols) are assumed to be in the fine modes. The thermodynamics of inorganic aerosol composition are treated using the ISORROPIA module. Aerosol composition is coupled to mass transfer between the aerosol and gas phases. For aqueous phase chemistry, the Regional Acid Deposition Model (RADM) is currently employed. This scheme includes oxidation of SO_2 to sulfate by ozone, hydrogen peroxide, oxygen catalyzed by metals and radicals. The impact of clouds on the particulate matter size distribution is treated empirically. For wet deposition processes, CMAQ uses the RADM/Regional Particulate Model approach. Particle dry deposition is included as well. CMAQ contains three options for treating secondary organic aerosol (SOA), latest being the Secondary Organic Aerosol Model (SORGAM) that was updated in August 2003 to be a reversible semi-volatile scheme whereby VOC emissions can be converted to condensable gases that can then form SOA and then evaporate back into condensable gases depending on atmospheric conditions.

4.4.2. CMAQ Configuration

The NCDAQ proposes to run CMAQ (version 4.4). The model would be set up and exercised on a nested 36/12-km grid domain, employing one-way grid nesting. That is, boundary conditions for the 12-km grid simulation are extracted from the 36-km run using the CMAQ BCON processor. A total of 19 vertical layers would be implemented, extending up to a region top of 100 mb (approximately 15 km above ground level).

The Piecewise Parabolic Method advection solver would be used along with the spatially varying (Smagorinsky) horizontal diffusion approach and K-theory for vertical diffusion. MM5 meteorological output based on the Pleim-Xiu Land-Surface Model (LSM) and the ACM PBL scheme will be used, and the recently updated CMAQ MCIP2.3 would process the MM5 data using the "pass through" option. The Carbon Bond version 4 (CB4) gas-phase, RADM aqueous-phase, and AERO3/ISORROPIA aerosol chemistry schemes will be used. Treatment of reversible secondary organic aerosols would be simulated by the SORGAM implementation in CMAQ (version 4.4).

Testing completed with VISTAS evaluated three photochemical mechanisms: CB4, CB4-2002 and SAPRC99. CB4-2002 produced nearly identical results as CB4 but took much longer to run since it is only implemented in the slower SMVGEAR (Sparse Matrix Vectorized Gear) chemistry solver, compared to CB4 that is also implemented in the faster Euler Backward Iterative chemistry solver. Thus, CB4-2002 was dropped from consideration. Comparisons of CB4 and SAPRC99 found they produced mostly similar but different model performance. However, no one mechanism performed better than any other mechanism across all species, sites, and periods. The testing only evaluated the mechanism's base case performance, not their response to emission reductions. Given that CB4 runs twice as fast as SAPRC99, the CB4 mechanism was chosen for use.

4.4.3. Initial and Boundary Condition Data

The CMAQ default Initial Concentrations (ICs) will be used along with a ~15 day spin up period to eliminate any significant influence of the ICs. The CMAQ Boundary Conditions (BCs) for the initial simulations will be based on seasonal averages of 3-hour 2001 GEOS-CHEM global simulation model output. VISTAS and other RPOs are finding a 2002 GEOS-CHEM simulation that would be used to define days specific high time resolved (e.g., 3-hourly) CMAQ BCs.

4.5. Model Limitations

All mathematical models possess inherent limitations owing to the necessary simplifications and approximations made in formulating the governing equations, implementing them for numerical solution on fast computers, and in supplying them with input datasets and parameters that are themselves approximations of the full state of the atmosphere and emissions processes. The more important limitations of the various modeling systems to be employed are noted in this section.

4.5.1. MM5

Four different configurations of the MM5 LSM and PBL were evaluated. Depending on the meteorological variable (e.g., winds, temperature, moisture) and location (e.g., mountains, coastal, east, west) different LSM_PBL configurations performed better. The PX_ACM LSM_PBL configuration was selected because it was consistently near the top performing configuration in the southeastern United States across variables and locations and was never the worst-performing configuration. However, there are numerous limitations in the MM5 with the LSM and PBL treatment being some of the most important. The MM5 PX_ACM frequently predicts very low PBL heights that can appear as "holes" in the spatial distribution of PBL heights that do not appear physically realistic and may affect air quality modeling. Although the MM5 PX_ACM configuration model performance in the southeastern United States mostly met performance benchmarks, the performance was much worse in the western United States. Additionally, there is a stochastic component of real world meteorology that is not captured by MM5. For example, for some air pollution episodes stagnation is an important attribute that MM5 fails to simulate well as it tries to organize the flow fields. However, the MM5 model represents approximately 20 years of development by various researchers.

4.5.2. SMOKE

In early testing, a number of undocumented features of the SMOKE 1.5b version necessitated re-runs of the emissions processing software to overcome errors and/or ambiguities in source documentation and QA reporting. It is unclear whether similar conditions will be encountered with the SMOKE 2.0 release. As a full software release, rather than a "beta" version, SMOKE 2.0 is expected to be more robust and more fully-documented than the SMOKE 1.5b release. However, with any newly-released software system, there is the potential for errors and/or ambiguities to affect the emissions modeling schedule. Should problems arise or issues be encountered which would require additional SMOKE runs or potential SMOKE modifications or alternate modeling methods, the NCDAQ will immediately notify stakeholders and make recommendations for resolving the issues. Upon receipt of technical direction from the stakeholders, appropriate corrective action will be taken.

Features are continuing to be developed in the SMOKE emissions model. As it is not as mature as some other emission models (e.g., EMS, EPS, etc.), SMOKE does not include as many features. The NCDAQ will keep abreast of SMOKE development activities to identify new features that will assist in the emissions modeling.

4.5.3. CMAQ

Like all air quality models, a major limitation of CMAQ is the input for emissions, meteorological, and IC/BC data. Key science limitations in the model itself include the nitrate formation chemistry. Testing found the CMAQ nitrate performance suspect with winter overestimations and summer underestimations. Other science limitations in the current version of CMAQ include inadequate treatment of sea salt and the assumption that all secondary particulate matter is in the fine mode. Lack of any two-way grid nesting limits the ability of the model to properly resolve point source plumes or urban photochemistry. Other limitations of CMAQ include its computational requirements, such as the need for excessive disk space.

4.6. Model Input Requirements

Each of the modeling system components has significant database requirements. These data needs fall into two categories: those required for model setup and operation, and those required for model evaluation testing. The main input data base requirements for the meteorological, emissions, and air quality models are identified in the following section.

4.6.1. MM5

The databases required for setting up, exercising, and evaluating the MM5 model for the 2002 season consist of various fixed and variable inputs.

- Topography: High resolution (e.g., 30 sec to 5 min) topographic information derived from the Geophysical Data Center global datasets from the NCAR terrain databases are available for prescribing terrain elevations throughout the 36-km and 12-km grid domain.

- Vegetation Type and Land Use: Vegetation type and land use information on the 36-km grid may be developed using the PSU/NCAR 10 min. (~18.5 km) databases while for the 12-km grids, the USGS data are available.

- Atmospheric Data: Initial and boundary conditions to the MM5 may be developed from operationally analyzed fields derived from the NCEP ETA (40 km resolution) following the procedures outlined by Stauffer and Seaman (1990). These 3-hr synoptic-scale initialization data include the horizontal wind components (u and v), temperature, and relative humidity at the standard pressure levels, plus sea-level pressure and ground temperature. Here, ground temperature represents surface temperature over land and sea-surface temperature over water.

- Water Temperature: Water temperatures required on both 36-km and 12-km grids can be derived from the ETA skin temperature variable. These temperatures are bi-linearly interpolated to each model domain and, where necessary, filtered to smooth out irregularities.

- Clouds and Precipitation: While the non-hydrostatic MM5 treats cloud formation and precipitation directly through explicit, resolved-scale, and parameterized sub-grid scale processes, the model does not require precipitation or cloud input. The potential for precipitation and cloud formation enters through the thermodynamic and cloud processes formulations in the model. The only precipitation-related input required is the initial mixing ratio field that is developed from the National Weather Service (NWS) and NMC datasets previously discussed.

- Multi-Scale FDDA: The standard "multi-scale" data assimilation strategy to be used on the 36-km and 12-km grids will objectively analyze three-dimensional fields produced every 3 hours from the NWS rawinsonde wind, temperature, and mixing ratio data, and similar analyses are generated every three hours from the available NWS surface data.

4.6.2. SMOKE

The databases required to set up and operate SMOKE are as follows:

- Area source emissions in IDA format
- Off-road mobile source emissions in IDA format
- Stationary point source emissions in IDA format
- Utility emissions
    - Continuous Emissions Monitoring (CEM) emissions, day specific for actual 2002
    - 5-year average CEM emissions, day specific for typical 2002
    - Based on Integrated Planning Model (IPM) modeling for future year

- Wildfire emissions
    - Day specific for actual 2002
    - Multi-year average for typical year 2002 and future year
- On-road motor vehicle activity data
- MOBILE6.2 input parameters

Also required for annual modeling are data files specific for:

- Temporal allocation
- Spatial allocation
- Speciation

4.6.3. CMAQ

The CMAQ CTM requires the following inputs:

- Three-dimensional hourly meteorological fields that will be generated by the CMAQ MCIP2.3 processing of the BAMS MM5 output
- Three-dimensional hourly emissions generated by SMOKE
- Initial conditions and boundary conditions
- Topographic information
- Land use categories
- Photolysis rates generated by the CMAQ JPROC processor

5.0 Grid Specifications and Modeling Domains

This chapter summarizes the model domain definitions including the model domain, resolution, map projections and nesting schemes for high resolution sub-domains.

5.1. Horizontal Modeling Domain

A coarse grid continental United States domain with a 36-km horizontal grid resolution will be used as the outer grid domain for MM5 modeling. The CMAQ domain is nested within the MM5 36-km domain. Figure 5.1-1 shows the MM5 horizontal domain as the outer most, blue grid with the CMAQ 36-km domain nested in the MM5 domain. To achieve finer spatial resolution in the VISTAS states, the NCDAQ will also use a one-way nested high resolution grid with a 12-km grid resolution. Figure 5.1-2 shows the 36-km CMAQ continental grid and the high resolution, nested 12-km grid in the VISTAS states. Figure 5.1-3 shows in more detail the 12-km grid for the VISTAS region.

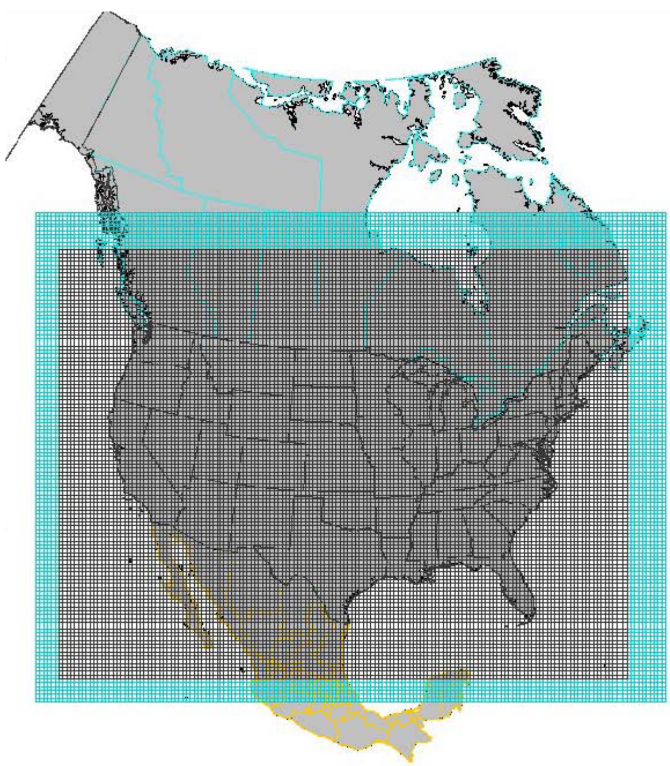

Figure 5.1-1: The MM5 horizontal domain is the outer most, blue grid, with the CMAQ 36-km domain nested in the MM5 domain.

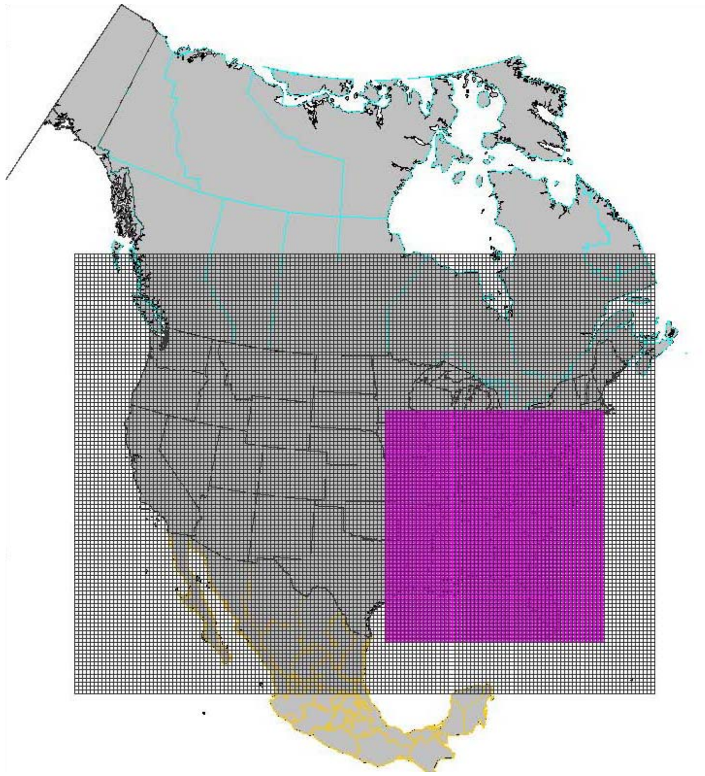

Figure 5.1-2: The 36-km CMAQ continental grid and the high resolution, nested 12-km grid over the VISTAS states.

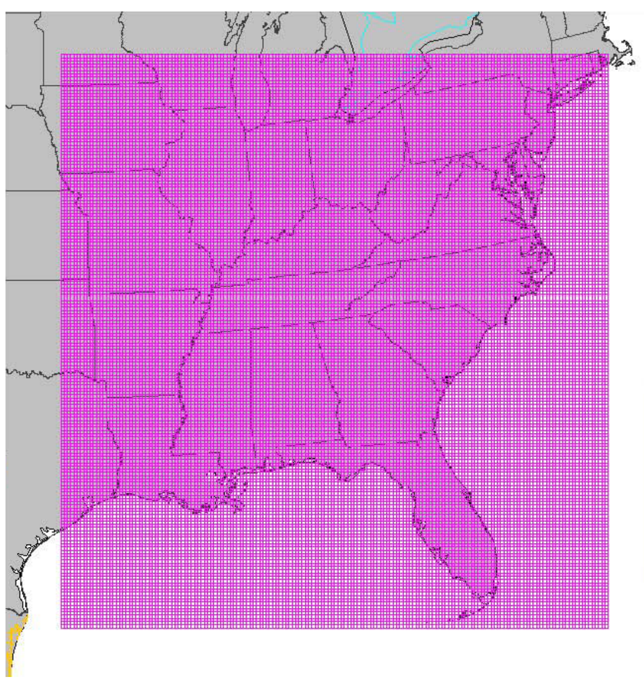

Figure 5.1-3: A more detailed view of the 12-km grid over the VISTAS region.

Both MM5 and CMAQ employ the RPO unified grid definition for the 36-km continental domain. The RPO unified grid consists of a Lambert-Conformal map projection using the map projections parameters listed in Table 5.1-1.

Table 5.1-1: RPO Unified Grid Definition.

PARAMETER	VALUE
projection	Lambert-conformal
1st true latitude (alpha)	33 degrees
2nd true latitude (beta)	45 degrees
x center	- 97 degrees
y center	40 degrees

The MM5 36-km grid includes 164 cells in the east-west dimension by 128 cells in the north-south dimension. The CMAQ 36-km grid includes 148 cells in the east-west dimension and 112 cells in the north-south dimension. Since the MM5 coarse grid is also nested in the Eta grid, there is a possibility of boundary effects near the MM5 boundary that occur as the Eta meteorological variables are being simulated by MM5 and must come into dynamic balance with MM5's algorithms. Thus, a larger MM5 domain was selected to provide a buffer of eight to nine grid cells around each boundary of the CMAQ 36-km domain. This is designed to eliminate any errors in the meteorology from boundary effects in the MM5 simulation at the interface of the MM5 and Eta grids. The buffer region used here exceeds the USEPA suggestion of at least five grid cell buffer at each boundary.

Table 5.1-2 lists the number of rows and columns and the definition of the X and Y origin (i.e., the southwest corner) for the 36-km and 12-km grids for both MM5 and CMAQ. Note that the CMAQ grid is rotated 90 degrees relative to the MM5 grid, so rows and columns are reversed. In Table 5.1-2 "Dot" refers to the grid mesh defined at the vertices of the grid cells while "cross" refers to the grid mesh defined by the grid cell centers. Thus, the dimension of the dot mesh is equal to the cross mesh plus one. Finally, note that the grid definition for the CMAQ MCIP and CMAQ Chemical Transport Model (CCTM) are identical.

Table 5.1-2: Grid Definitions for MM5 and CMAQ.

MODEL	COLUMNS DOT (CROSS)	ROWS DOT (CROSS)	XORIGIN	YORIGIN
MM5 36km	129 (128)	165 (164)	-2952000	-2304000
CMAQ 36km	149 (148)	113 (112)	-2736000	-2088000
MM5 12km	190 (189)	181 (180)	7200	-1656000
CMAQ 12km	169 (168)	178 (177)	108000	-1620000

5.2. Vertical Modeling Domain

The CMAQ vertical structure is primarily defined by the vertical grid used in the MM5 modeling. The MM5 model employed a terrain following coordinate system defined by pressure, using 34 layers that extend from the surface to the 100 mb. Table 5.2-1 lists the layer definitions for both MM5 and for CMAQ. A layer averaging scheme is adopted for CMAQ to reduce the computational cost of the CMAQ simulations. The effects of layer averaging were evaluated in conjunction with the VISTAS modeling effort and were found to have a relatively minor effect on the model performance metrics when both the 34-layer and a 19-layer CMAQ models were compared to ambient monitoring data.

Table 5.2-1: Vertical Layer Definition for MM5 Simulations (Left Most Columns), and Approach for Reducing CMAQ Layers by Collapsing Multiple MM5 Layers (Right Columns)

MM5					CMAQ 19L				
Layer	Sigma	Pres. (mb)	Height (m)	Depth (m)	Layer	Sigma	Pres .(mb)	Height (m)	Depth (m)
34	**0.000**	**100**	**14662**	**1841**	**19**	**0.000**	**100**	**14662**	**6536**

6.0 Development of Emissions Inventories

There are five different emission inventory source classifications; stationary point sources area sources, off-road mobile sources, on-road mobile sources, and biogenic sources. Stationary point sources are those sources that emit greater than a specified tonnage per year and the data is provided at the facility level. Stationary area sources are those sources whose emissions are relatively small but due to the large number of these sources, the collective emissions could be significant (i.e., dry cleaners, service stations, etc.) Off-road mobile sources are equipment that can move but do not use the roadways, i.e., lawn mowers, construction equipment, railroad locomotives, aircrafts, etc. On-road mobile sources are automobiles, trucks, and motorcycles that use the roadway system. Biogenic sources are emissions from natural sources, such as trees, crops, grasses and natural decay of plants.

Emission estimates for stationary point and area sources, as well as for off-road mobile sources are calculated and formatted for processing through the SMOKE emissions processing system, which formats the data into air quality model ready files. On-road mobile source emissions are estimated within the SMOKE system, which uses the USEPA's MOBILE6.2 model, with modeling meteorology and various mobile inputs. The biogenic emissions are also estimated within the SMOKE system, using the USEPA's BEIS model, with modeling meteorology.

In addition to the various source classifications, there are also various types of emission inventories. The first is the actual base year inventory. This inventory is the base year emissions that correspond to the meteorological data, for this modeling effort is 2002. These emissions are used for evaluating the air quality model performance.

The second type of inventory is the typical base year inventory. This inventory is similar to the actual base year, however for sources that may have significant changes from year to year a more typical emission value is used. In this modeling effort, typical emissions were developed for the electric generating units and the wildland fire emissions. The air quality modeling results using these emissions are used in calculating the relative reduction factors used in the attainment demonstration test.

The future year base inventory is an inventory developed for some future year for which attainment of the $PM_{2.5}$ standard is needed. For this modeling project, the future year inventory will be 2009, the last complete year for which the standard must be attained. It is the future year base inventory that control strategies and sensitivities are applied to determine what controls, to which source classifications, must be made in order to attain and maintain the $PM_{2.5}$ standard.

In the sections that follow, the inventories used for each source classifications are discussed.

6.1. Point Source Emissions

The point source emissions will be separated into electric generating units (EGU) and non-EGU categories. The reason for splitting the point source inventory is that the EGU sources account for the majority of the point source NO_x emissions and hour specific data is available for these sources through the USEPA's acid rain database. Using this more refined data will help improve the air quality modeling performance. Annual emissions will be used for the non-EGU sources.

All point sources will be spatially allocated in the domain based on the stationary source geographic coordinates. If a point source is missing its latitude/longitude coordinates, the source will be placed in the center of its respective county.

6.1.1. Electric Generating Units

Actual Base Year Inventory

For EGU sources with the USEPA reported 2002 CEM data or with 2002 hourly emissions provided by stakeholders, actual hourly data will be used. For the sources where the USEPA CEM data are utilized, NO_x, SO_2, and heat input-based hour-specific profiles were developed and applied to NO_x, SO_2, and all other emissions, respectively. The annual emission values that have been provided will be maintained, but will be distributed using hourly to annual profiles. For sources where hour-specific data was provided by stakeholders, this data will be substituted for the USEPA CEM-based emissions and distributions.

To temporally allocate the remaining EGU point sources, the NO_x, SO_2, and heat input data will be collected from the 2002 CEM datasets, and used to develop unit-level temporal distributions. The hourly, day of week, and monthly specific temporal profiles will be used in conjunction with the emissions inventory supplied emissions data to calculate hourly EGU emissions by unit.

Typical Base Year Inventory

Since the NO_x emissions from EGU sources are a significant part of the emissions inventory, a typical base year emissions inventory was developed for these sources to avoid anomalies in emissions due to variability in meteorology, economic and outage factors in 2002. This approach is consistent with the USEPA's modeling guidance.

To develop a typical year 2002 emissions inventory for EGU sources, for each unit the average CEM heat input for 2000 through 2004 was divided by the 2002 actual heat input to generate a unit specific normalizing factor. This normalizing factor was then multiplied by the 2002 actual emissions. The heat inputs for the period 2000 through 2004 were used since the modeling current design values use monitoring data from this same 5-year period.

If a unit was shutdown for an entire year during the 2000 through 2004 period, the average of the years the unit was operational was used. If a unit was shutdown in 2002, but not permanently shutdown, the emissions and heat inputs 2001 (or 2000) were used in the normalizing calculations.

Future Base Year Inventory

As part of the VISTAS modeling, VISTAS and the Midwest Regional Planning Organization (MRPO) contracted with ICF Resources, L.L.C., to generate future year emission inventory for the electric generating sector of the contiguous United States using the IPM. IPM is a dynamic linear optimization model that can be used to examine air pollution control policies for various pollutants throughout the contiguous United States for the entire electric power system. The dynamic nature of IPM enables the projection of the behavior of the power system over a specified future period. The optimization logic determines the least-cost means of meeting electric generation and capacity requirements while complying with specified constraints including air pollution regulations, transmission bottlenecks, and plant-specific operational constraints. The versatility of IPM allows users to specify which constraints to exercise and populate IPM with their own datasets.

Since the modeling is based on the USEPA's prior analyses for which detailed public documentation is available, a summary of only the incremental changes that were proposed by VISTAS and MRPO as part of this analysis are presented here.

The VISTAS analysis is based on the USEPA modeling applications using IPM (V.2.1.6). As per the analytical needs of VISTAS and MRPO, the following changes were made to the underlying assumptions in the USEPA Base Case (V2.1.6):

i) The underlying database in the VISTAS analysis is the USEPA's National Electric Energy Data System Database, with changes based upon the comments and technical directions from VISTAS and MRPO's stakeholders. The changes focused on existing installations of NO_x, SO_2 and particulate matter controls, NO_x emission rates, SO_2 emission limits, capacity of existing units, heat rate and unit identifications of selected units in the VISTAS and MRPO regions.

ii) The analysis covers the period between 2007 and 2030. To make the model size and run time tractable, IPM is run for a number of selected years within the study horizon known as run years. Each run year represents several calendar years in the study horizon, and all calendar years within the study horizon are mapped to their representative run years. Although results are only reported for the run years, IPM takes into account all years in the study horizon while developing the projections.

iii) The Duke Power and Progress Energy control technology investment strategies for complying with North Carolina's Clean Smokestacks Rule were explicitly hardwired in the analysis.

iv) The USEPA's Clean Air Interstate Rule (CAIR) rule implemented as part of this analysis is broadly consistent with the USEPA 40 CFR Parts 51 et. al., Supplemental Proposal for the Rule to Reduce Interstate Transport of Fine Particulate Matter and Ozone, proposed on June 10, 2004. Alabama, Arkansas, Delaware, District of Columbia, Florida, Georgia, Illinois, Indiana, Iowa, Kansas, Kentucky, Louisiana, Maryland, Massachusetts, Michigan, Minnesota, Mississippi, Missouri, New Jersey, New York, North Carolina, Ohio, Pennsylvania, South Carolina, Tennessee, Texas, Virginia, West Virginia, Wisconsin are the states affected by the CAIR SO_2 and the CAIR annual NO_x policies starting 2010. Connecticut is affected by an ozone season NO_x policy. The CAIR plants affected by the annual NO_x policy are capped at 1.6 million tons starting 2010 and 1.33 million tons starting 2015. The power plants affected by the CAIR SO_2 policy have to surrender two Title IV SO_2 allowances for every ton of SO_2 emitted starting 2010 and three Title IV SO_2 allowances for every ton of SO_2 emitted starting 2015.

6.1.2. Non-Electric Generating Units

2002 Base Year Inventory

For the non-EGU sources, the same inventory will be used for both the actual and typical base year emissions inventories. The non-EGU category will use annual emissions, which will be temporally allocated to month, day, and hour using source category code (SCC) based allocation factors. These factors will be based on the cross-reference and profile data supplied with the SMOKE 2.0 version.

The non-EGU sources annual emissions will be the 2002 VISTAS inventory based on the 2002 Consolidated Emissions Reporting Rule (CERR) submitted data for all states in the modeling domain unless a state or RPO provides updated data.

Future Year Base Inventory

The general approach for assembling future year data is to use recently updated growth and control data consistent with the USEPA's CAIR analyses, supplement these data with available stakeholder input, and provide the results for stakeholder review to ensure credibility. To assemble growth/control data needed for the final 2009 inventories, the VISTAS contractor will perform the following activities:

- Use the final 2002 VISTAS inventory as the starting point for the future base year inventory.
- Obtain, review, and apply the most current growth factors developed by the USEPA, based on forecasts from an updated Regional Economic Models, Inc. model (version 5.5) and the latest *Annual Energy Outlook* published by the Department of Energy.
- Obtain, review, and apply any State-specific or sector-specific growth factors submitted by stakeholders.
- Obtain information regarding sources that have shut down after 2002 and work with the states to determine if these sources should be removed from the future year inventory.
- Obtain, review, and apply control assumptions that are expected to be in place by 2009.

Controls Applied to the Non-EGU Inventory

1-hour Ozone SIP

Information about control programs for the 1-hour ozone nonattainment areas came from the report by E.H. Pechan and Associates entitled *VOC and NO_x Control Measures Adopted by States and Nonattainment Areas for 1999 NEI Base Case Emissions Projection Calculations*. The report identified and compiled a listing of the VOC and NO_x control measure programs expected to be implemented after 1999, as well as an estimate of their influence on projected emissions. Five nonattainment areas in the VISTAS region were included: Atlanta, Birmingham, metro Washington DC (including several counties in Virginia), Louisville, and northern Kentucky.

Emission reductions requirements from NO_x Reasonably Available Control Technology (RACT) in 1-hour Ozone SIP areas were implemented prior to 1999. These reductions should already be accounted for in the VISTAS 2002 inventory since the 2002 inventory was based on 2002 actual emissions submitted by the States.

NO_x SIP Call

For non-EGU sources, Phase I of the NO_x SIP call applies to large industrial boilers and turbines, and cement kilns. States in the VISTAS region affected by the NO_x SIP call have developed rules for the control of NO_x emissions that have been approved by the USEPA. The VISTAS contractor has reviewed the available state rules and guidance documents to determine the affected sources and ozone season allowances.

For the sources within North Carolina, the NCDAQ has decided to use the 2007 emission allowances for the 2009 future year inventory. The allowances are given in terms of tons per ozone season (the five month period from May to September). To calculate annual emissions, the capped allowances were multiplied by a factor of 12/5.

The Phase II rule applies to large internal combustion engines, which are primarily used in pipeline transmission service at compressor stations. The NCDAQ has established emissions caps for three facilities affected by the Phase II NO_x SIP call rule and will apply these caps to the future year inventory.

For the other states in the VISTAS region, affected units were identified using the same methodology as was used by the USEPA in the proposed Phase II rule (i.e., a large internal combustion engine is one that emitted, on average, more than 1 ton per day during 2002). The final rule reflects a control level of 82 percent for natural gas-fired internal combustion engines and 90 percent for diesel or dual fuel categories. Therefore, these control levels were applied to the identified sources.

Maximum Achievable Control Technology Regulations

The USEPA anticipates reductions in particulate matter and SO_2 as a result of the Industrial Boiler/Process Heater Maximum Achievable Control Technology (MACT) standard. The methods used to account for these reductions are the same as those used for the Interstate Air Quality Transport Rule. Since the attainment demonstration is utilizing one atmosphere modeling, the reductions for these pollutants were accounted for.

MACT requirements were also applied, as documented in the USEPA report entitled *Control Packet Development and Data Sources,* dated July 14, 2004. The point source MACTs and associated emission reductions were designed from Federal Register notices and discussions with the USEPA's Emission Standards Division staff. Emission reductions will be applied only for MACT standards with an initial compliance date of 2002 or greater, since effects from MACT with earlier compliance dates should already be accounted for in the 2002 base year inventory.

The future year base inventory does not include the NO_x co-benefit effects of the Gas Turbines or stationary Reciprocating Internal Combustion Engines MACT regulations, which the USEPA estimates to be small compared to the overall inventory.

Petroleum Refinery Initiative

Three refineries in the VISTAS region are affected by two October 2003 Clean Air Act settlements under the USEPA Petroleum Refinery Initiative. The refineries are: (1) the Chevron refinery in Pascagoula, Mississippi; (2) the Ergon refinery in Vicksburg, Mississippi; and (3) the Ergon refinery in Newell, West Virginia. Although these sources are not within North Carolina or South Carolina, the expected emission reductions will be accounted for in the 2009 modeling.

NO_x RACT in 8-hour Ozone SIP

The NCDAQ will make every effort to include NO_x RACT controls for 8-hour ozone nonattainment areas in the VISTAS region. However, since cost is a factor of consideration in a RACT determination, it may not be known at the time of the final modeling which sources will be subject to actual controls.

Clean Air Interstate Rule

As stated in the preamble to the CAIR rule, the rule would not require or assume additional emission reductions from non-EGU boilers and turbines.

6.2. Stationary Area Source Emissions

Stationary area sources include sources whose emissions are relatively small but due to the large number of these sources, the collective emissions could be significant (i.e., combustion of fuels for heating, structure fires, service stations, etc.). Emissions are estimated by multiplying an emission factor by some known indicator of collective activity, such as fuel usage, number of household or population. Thus, a variety of activity level data is collected, including, United States Census economic data, forestry and agriculture agency data, and other data sources. Stationary area source emissions are estimated on the county level.

Actual Base Year Inventory

A portion of the area source 2002 base year inventory for North Carolina was developed by the NCDAQ and provided to the VISTAS contractor. The remaining portion of the area source inventory was calculated by the VISTAS contractor. The sources estimated by the contractor included emissions from animal husbandry, wildland fires, and particulate matter from paved and unpaved roads. For the other states within the modeling domain, the state supplied data or the CERR data was used.

Area source categories estimated by the NCDAQ were identified from a list in the USEPA guidance document EPA-450/4-91-016, *Procedures for the Preparation of Emission Inventories of Carbon Monoxide and Precursors of Ozone*, and from the Emission Inventory Improvement Program (EIIP) technical reports.

In general, emission factor estimation approaches were used to calculate area source emissions. Emission factors may be grouped as per capita emission factors; commodity consumption-related emission factors; and level-of-activity based emission factors. The emission factors were obtained from the *Procedures for the Preparation of Emission Inventories of Carbon Monoxide and Precursors of Ozone*, from the EIIP technical reports, or the USEPA's *AP-42, Compilation of Air Pollutant Emission Factors, Fifth Edition*.

The emissions from area sources were estimated by multiplying an emission factor by the appropriate indicator of collective activity for each source category within the inventory area. An indicator is any parameter associated with the activity level of a source that can be correlated with the air pollutant emissions from that source, such as fuel usage, number of households, or population. The values of these indicators are gathered from various sources (government reports, census, trade groups, employment data, direct surveys, etc.) as appropriate.

For the animal husbandry and fertilizer application emissions, the Carnegie Mellon University ammonia model was used. For paved and unpaved roads particulate matter emissions, emissions developed by the USEPA as part of their 2002 National Emissions Inventory development effort was used.

Windblown dust and sea salt emissions were not included in the inventory. These source categories are insignificant sources of particulate matter in North Carolina and therefore, do not significantly impact the $PM_{2.5}$ nonattainment issues and would not affect the $PM_{2.5}$ attainment modeling demonstration.

For wildland fires, i.e., wildfires and prescribed burns, monthly estimates of fire emissions, which include burn acreage and biomass loading information will be used. Depending on the completeness and quality of the data, attempts will be made to calculate spatial and temporal distributions of the fire emissions, rather than relying on standard distribution profiles. Data will be obtained through consultation with stakeholders that participate in the VISTAS Fire Special Interest Work Group. The fire data will be split into two groups, small fires estimated on a county level and treated as an area source; and large fires that will be treated as a point source.

Typical Base Year Inventory

The actual base year inventory will serve as the typical base year inventory for all area source categories except for wildland fires. For this source category, development of a typical year fire inventory provided the capability of using a comparable dataset for both the base year and future years. Thus, fire emissions would remain the same for air quality modeling in both the base and any future years. The VISTAS Fire Special Interest Work Group was consulted and decided to use State level ratios of acres over a longer term record (three or more years) developed for each fire type relative to 2002. The 2002 acreage was then scaled up or down based on these ratios to develop a typical year inventory.

Future Year Base Inventory

The VISTAS contractor generated the future base year emissions inventory used in the attainment demonstration modeling. The general approach used to calculate the future base year emissions for stationary area sources was as follows:

- Use the final 2002 VISTAS base year inventory as the starting point for the future base year inventory.
- Obtain any State specific growth factors and/or future controls from the States to use in developing the projections.
- Back calculate uncontrolled emissions for the 2002 base year inventory based on existing controls reported for the 2002 base year inventory.
- Controls (including control efficiency, rule effectiveness and rule penetration) provided by the States or originally developed for use in estimating projected emissions for the USEPA's Heavy Duty Diesel rulemaking emission projections and used in the CAIR projections were then used to calculate controlled emissions. State submitted controls had precedence over the USEPA developed controls.
- Growth factors supplied from the States or the USEPA's CAIR emission projections were then applied to project the controlled emissions to the appropriate year. In some cases, the USEPA's Economic Growth and Analysis System Version 5 growth factors were used if no growth factor was available from either the States or the CAIR growth factor files.

6.3. Non-Road Mobile Source Emissions

Non-road mobile sources are equipment that can move but do not use the roadways, such as construction equipment, aircraft, railroad locomotives, lawn and garden equipment, etc. For the non-road mobile source inventory, the list of sources to inventory came from the USEPA's NONROAD2005 model and the USEPA guidance document, *Procedures for Emission Inventory Preparation Volume IV: Mobile Sources*. For the majority of the non-road mobile sources, the emissions can be estimated using the USEPA's NONROAD model. For the three source categories not included in the NONROAD model, i.e., aircraft engines, railroad locomotives and commercial marine, more traditional methods of estimating the emissions were used.

2002 Base Year Inventory

For the non-road mobile sources, the same inventory will be used for both the actual and typical base year emissions inventories. All non-road mobile source emissions, except for aircraft engines, commercial marine vessels and railroad locomotives, were estimated using the USEPA NONROAD2005 model. This model predicts the emissions for non-road equipment based upon the year inputted into the model.

For railroad locomotive emissions, emission factors were supplied by the *Procedures for Emission Inventory Preparation Volume IV: Mobile Sources* document, which were then multiplied by a variety of different activity levels (i.e., gallons of fuel per county for railroad locomotive engines). Refinements could be made using information from *Development of*

Railroad Emission Inventory Methodologies (SR2004-06-02) from the Southeastern States Air Resource Managers, Inc.

Aircraft emissions at airports were calculated by VISTAS contractors using landing and take off data from Federal data sources. These will be reviewed and refined as appropriate for the Charlotte, Greensboro, and Raleigh-Durham airports. Emissions are calculated using the Federal Aviation Administration's (FAA's) Emissions and Dispersion Modeling System version 4.2, when there is sufficient detail to employ it.

Commercial marine emissions are estimated by procedures described in *Commercial Marine Activity for Deep Sea Ports in the United States (EPA420-R-99-020)*.

Future Base Year Inventory

For the source categories estimated using the USEPA NONROAD model, the model was used to create a future base year inventory. The NONROAD model takes into consideration rules that are in effect that could impact the emissions from these source categories. For the four largest airports in North Carolina, the FAA's Terminal Area Forecast will be used to project growth in aircraft emissions.

For the commercial marine, railroad locomotives and the remaining airport emissions, the VISTAS contractor will project the future base year emissions using the following guidelines:

- Use the final 2002 VISTAS inventory as the starting point for the future base year inventory.
- Detailed inventory data (both before and after controls) for 1996 and 2010 will be obtained from the USEPA's Clean Air Interstate Rule Technical Support Document. Straight-line interpolations between 1996 and 2010 will be used to create a combined growth and control factor. This is done at the State-County-SCC-Pollutant level of detail.
- Obtain, review and apply any State-specific growth factors submitted.
- Apply adjustments to account for additional emission reductions do the low sulfur non-road diesel fuels.

6.4. On-Road Mobile Source Emissions

Highway mobile sources are considered those vehicles that travel on the roadways and comprise over 30 percent of the NO_x emissions in North Carolina, and 42 percent of the NO_x emissions in South Carolina. Emissions from motor vehicles occur throughout the day while the vehicle is in motion, at idle, parked, and during refueling. Each of these emissions sources needs to be estimated in order to properly reflect the total emissions from this source category. In its simplest terms emissions from highway mobile sources are calculated by multiplying an activity level, in this case daily vehicle miles traveled (VMT) as provided by the North Carolina Department of Transportation (NCDOT), by an emission factor.

The USEPA developed the MOBILE model to estimate emission factors based on information on the way vehicles are driven in a particular area. The newest version of the MOBILE model, MOBILE6.2, will be used to develop the on-road mobile source emissions estimates for carbon monoxide (CO), NO_x, particulate matter, and VOC emissions. Key inputs for the MOBILE model include information on the age of vehicles on the roads, the average speed of those vehicles, what types of road those vehicles are traveling on, and any control programs (e.g., emissions inspection programs). Inputs are combined with gridded, day-specific temperature data to calculate the gridded, temporalized emission estimates. Of note, whereas the on-network emissions estimates are spatially allocated based on link location and subsequently summed to the grid cell level, the off-network emissions estimates are spatially allocated based on a combination of the Federal Highway Administration version 2.0 highway networks and population. For the North Carolina 36/12-km modeling, no link-based data will be used. The MOBILE6 emissions factors are based on day-specific temperatures predicted by the meteorological model.

6.4.1. Speed Assumptions

Emissions from motor vehicles vary with the manner in which the vehicle is operated. Vehicles traveling at 65 miles per hour (mph) emit a very different mix of pollutants than the car that is idling at a stoplight. The NCDAQ will collect hourly speeds per functional class for this modeling effort. Information from Travel Demand Models will be used where available.

6.4.2. Vehicle Age Distribution

The North Carolina vehicle age distribution comes from the NCDOT annual registration data. Both statewide and area specific registration data is provided. The only areas with "area specific" registration data include the Charlotte/Gastonia, Raleigh/Durham and Greensboro/ Winston-Salem areas. The latest available age distribution at the time of the modeling will be used.

6.4.3. Vehicle Mix Assumptions

The North Carolina statewide vehicle mix will be developed by the NCDAQ using the latest available, at the time of the modeling, Highway Performance Maintenance System count data. The raw data is converted into MOBILE6.2 format following the method outlined in the August 2004 guidance document *EPA420-R-04-013, Technical Guidance on the Use of MOBILE6.2 for Emissions Inventory Preparation*. For the Hickory and Triad nonattainment areas, local vehicle count data will be used to generate the vehicle mix for all road types except for urban and rural interstates. Local data is not available for the interstates; therefore, the State-wide mix data will be used.

Version 2 of the SMOKE model uses the MOBILE5 eight vehicle classification format for the vehicle mix. Therefore, the current vehicle mix format used by the NCDAQ had to be converted from the sixteen MOBILE6 vehicle classification format to correlate to the MOBILE5 eight vehicle classification system. This was done using the guidance provided by the USEPA.

6.4.4. Temperature Assumptions

MOBILE6 in the SMOKE emissions model uses the gridded (modeled) meteorology data to calculate temperature. Spatial and temporal temperature averaging will be implemented to minimize the SMOKE (mobile) run times.

6.4.5. Vehicle Inspection and Maintenance Program Assumptions

In the early 1990's, North Carolina adopted emissions inspection requirements for vehicles in nine urban counties. This program tests emissions at idle for 1975 and newer gasoline powered light and heavy duty vehicles. The program is a basic, decentralized tailpipe test for Hydrocarbons and CO only.

In 2002, North Carolina implemented a new vehicle emissions inspection program referred to as onboard diagnostics (OBDII). This program covers all light-duty gasoline powered vehicles that are model year 1996 and newer. The program was implemented in the original nine tailpipe test counties and expanded to a total of forty-eight counties by January 1, 2006. In addition, the idle test will be phased-out in 2006 in the original nine counties. In order to accurately reflect these OBDII tests, two separate programs must be incorporated into the 2002 input files. The implementation dates of each program are also included in the input files.

6.4.6. RVP Assumptions

Reid Vapor Pressure (RVP) reflects a gasoline's volatility. North Carolina has adopted the Phase II RVP of 7.8 psi during June-September as a control measure for the following counties: Davidson, Durham, Forsyth, Gaston, Guilford, Mecklenburg, Wake, Granville, and Davie. Lower RVP leads to lower VOC emissions from gasoline handling and lowers vapor losses from motor vehicles. The remaining areas have a RVP of 9.0 psi during June-September. For remaining months, RVPs are as follows:

- October RVP = 13.5 psi statewide
- November RVP = 13.5 psi statewide
- December RVP = 15 psi statewide
- January RVP = 15 psi statewide
- February RVP = 13.5 psi statewide
- March RVP = 13.5 psi statewide
- April RVP = 13.5 psi statewide
- May RVP = 9.0 psi statewide

6.4.7. VMT Assumptions

Mobile source emissions are calculated by multiplying emission factors by daily VMT. In this modeling exercise, the NCDAQ will use VMT from Travel Demand Models where available. For all other areas the VMT data will be provided by the NCDOT.

6.5. Biogenic Source Emissions

A revised version of a commonly used biogenic emissions model, the Biogenic Emissions Inventory System, has recently been developed and tested by the USEPA over two separate modeling domains/episodes. This version of the model (BEIS-3, v0.9) contains several changes over BEIS-2, including the following:

- Vegetation input data -- are now based on a 1-km Biogenic Emissions Landuse Database (BELD3) vegetation data base,
- Emission factors – many updates including some recent North American Research Strategy for Tropospheric Ozone (NARSTO) modifications,
- Environmental algorithm -- includes a sunlit/shaded leaf solar radiation model.

A series of sensitivity modeling simulations has been completed and concluded that the more recent BEIS-3 methodology will impact base case model ozone predictions in most parts of the United States. The preliminary tests have also shown that the newer biogenic emissions do not appear to have a large effect on: 1) the control signal response, 2) relative reduction factors resulting from a projected emissions change, or 3) overall regional model performance in the eastern United States.

For this particular application of BEIS-3, version 0.9 as currently incorporated in the SMOKE processor will be used. This means that: 1) soil nitric oxide (NO) emissions shall be prepared without the input of specific soil moisture and precipitation data and 2) methanol emissions will not be modeled explicitly. Otherwise, the modeling should be identical to a BEIS-3 (v1.0) application.

The BELD-3 landuse data on a Lambert conformal grid at 1-km resolution have already been developed, are available, and will be used to estimate biogenic emissions in this study. The BEIS model also requires as input hourly, gridded temperature and solar radiation data to estimate biogenic emissions, and these data will be derived from the MM5 predictions.

6.6. Development of Modeling Inventories

The SMOKE emissions model will be used to create the air quality model ready files. The chemical speciation method used is the CB4 mechanism. The gridding surrogates are based off the 2000 census data and are the most up to date available. The temporal profiles used to disaggregate the annual emissions to the appropriate month, day and hour are the latest available profiles provided with the SMOKE model with the exception of the EGU profiles, which will be developed based on CEM data.

For each model-ready emissions inventory, separate air quality model-ready files will be created for the EGU point sources, non-EGU point sources, area sources, dust, low-level fires, elevated fires, non-road mobile sources, on-road mobile sources, and biogenic emissions.

7.0 Quality Assurance Plan

This section discusses the QA procedures that will be used in the SIP modeling. The QA procedures listed here describe the combined efforts to be employed by VISTAS and the NCDAQ. The VISTAS contractors will perform QA on modeling inputs and outputs for the modeling region as a whole. The NCDAQ will perform QA on their respective emission inventories, as well as look at near state data for reasonableness. Additionally, the NCDAQ will review the modeling outputs for reasonableness.

7.1. Quality Assurance Objectives

In December 2002, the USEPA published extensive guidance on developing a Quality Assurance Project Plan (QAPP) for modeling studies (EPA, 2002). The objective of a QAPP is to ensure that a modeling study is scientifically sound, robust, and defensible. The new USEPA guidance suggests that a QAPP should include the following elements:

- A systematic planning process including identification of assessments and related performance criteria
- Peer reviewed theory and equations
- A carefully designed life-cycle development process that minimizes errors
- Clear documentation of assumptions, theory, and parameterization that is detailed enough so others can fully understand the model output
- Input data and parameters that are accurate and appropriate for the problem
- Output data that can be used to help inform decision-making
- Documentation of any changes from the original quality assurance plan

Moreover, the USEPA guidance specifies that different levels of QAPP may be required depending on the intended application of the model, with a modeling study designed for regulatory purposes requiring the highest level of quality assurance.

The QAPP also provides a valuable resource for project management. It can be used to document data sources and assumptions used in the modeling study, and it can be used to guide project personnel through the data processing and model application process to ensure that choices are consistent with the project objectives.

The guidance document also addresses model development, coding and selection of models, and model performance requirements. VISTAS/NCDAQ modeling are using an existing USEPA sponsored model hence our QAPP will focus primarily on documenting data sources and QA of data processing performed by the model team. The QA objectives for specific aspects of the project are discussed below, and these will be incorporated into a QAPP that conforms to the USEPA guidance document for modeling studies.

7.2. Emissions Model Inputs and Outputs

Emissions QA and Quality Control (QC) are the most critical steps in performing air quality modeling studies. Emissions processing can be time consuming and involves complex manipulation of many different types of large datasets. If errors are made and rigorous QA measures are not in place, these errors may remain undetected, resulting in delays and wasted time and resources.

7.2.1. VISTAS QA Effort

As part of the VISTAS QA effort, an "Emissions Gatekeeper" function will be implemented. The role of this Gatekeeper is to perform quality assurance activities on the following emissions inventory data:

- Emissions inventory data obtained from the VISTAS emissions inventory contractors

- The emission inventory to be used for modeling outside of the states in the VISTAS region.

Specifically, the Emissions Gatekeeper will review the content and format of the provided emission inventories, ensuring an appropriate appraisal of the emissions data and estimates for the VISTAS States. Other tasks will include any additional translation from mass emissions files into the emissions modeling input file structure necessary for modeling. The VISTAS Study Team will supplement these activities with QA checks on the intermediate and model output files using internal and public domain visualization and diagnostic packages.

This multistep emissions QA/QC approach includes the initial emissions QA/QC by the Emissions Gatekeeper described above, as well as QA/QC by the Emissions Modeler during the processing of emissions, and then additional QA/QC by the air quality modeler of the processed model ready emission files. This multistep process, with three separate groups involved in the QA/QC of the emissions, is much more likely to catch any errors prior to the air quality model simulations.

7.2.2. Emissions Modeling QA/QC

Modeling QA involves performing data quality checks, assuring simulation accuracy, and recognizing and identifying problems as they happen; it is the process of looking for glaring faults in the model input and output data (I/O) and determining whether the input data are producing the desired results. Scrutiny of the I/O using standard statistical analyses can reveal problems in the data and/or the model setup. Using a standard approach for analyzing emissions model I/O establishes reference points to use when scrutinizing the data. Seeking these indicators of correct model performance allows QA personnel to determine the accuracy of the simulations and whether faults in the data or model configuration exist.

QA documentation will include records of model configuration, details about data files, simulation records, and final report generation. After finishing each QA step, the modeler will record the result and his/her initials on a QA checklist.

Data formats will be confirmed using the SMOKE manual to check text files and using PAVE to check binary netCDF files, such as the meteorology inputs. Sanity checks look for glaring errors in the file contents and ensure that the data make sense in the context of how they will be used and relative to similar or reference datasets.

Lead modelers will oversee the entire modeling process, perform the majority of the SMOKE modeling, and receive and archive input and output data. Secondary modelers will perform some of the SMOKE modeling, organize the SMOKE QA reports into emissions summaries for data QA and reporting, and will generate custom QA summaries and reports for troubleshooting any problems encountered during the modeling process.

Outside reviewers will be solicited from outside the emissions modeling team on a volunteer basis to conduct periodic reviews/audits of the data and modeling process. Outside reviewers will consist of peers, co-workers not working directly on the inventory in question, state inventory contacts and stakeholders.

7.2.3. SMOKE Log Files

Each of the programs that make up SMOKE produces a log at run time. Stored in a single directory for each unique simulation, the logs contain information about the configuration of SMOKE, the names and locations of the input and output files used in the simulation, and any warnings, notes, or errors (collectively called "flags") that occurred during model execution. Generated as text files, the logs are named according to the program that created them and the emissions source modeled by the simulation, and the names include identifiers that distinguish the simulation from all others. The logs are usually the first source of information consulted in determining whether a simulation completed as expected or for troubleshooting suspected problems.

7.2.4. SMOKE QA Reports

Two types of QA reports are generated by SMOKE. One set is created by the program *Smkmerge* and the other by the program *Smkreport*. While both programs allow users to configure the content of the reports, *Smkreport* is a more powerful reporting program that was designed specifically as a QA tool. Controlled by configuration files, *Smkreport* can create text reports at every step in the emissions generation process. In addition to creating reports from information drawn from the intermediate SMOKE data matrices (e.g., the temporal matrix), *Smkreport* can summarize the amount of emissions assigned to different temporal, spatial, and chemical profiles; normalize emissions by population; and report the amount of emissions allocated to each vertical layer per model-hour. *Smkreport* also allows the targeted reporting of emissions at specific sources, plants, grid cells, or subdomains.

The program *Smkmerge* creates either state- or county-level reports at each of the major steps in the emissions generation process (spatial allocation, temporal allocation, chemical allocation or speciation, and merging). Although *Smkmerge* cannot create as many different report types as *Smkreport*, *Smkmerge* does have the ability to report biogenic emissions totals, whereas *Smkreport* can create reports only for anthropogenic emissions sources.

7.2.5. Visualization Tools

Visualization is an important part of the QA/QC procedure. Viewing bar charts and pie charts of the data verifies that more populous urban counties have greater emissions then the rural counties. Additionally, the PAVE visualization tool is used to graphically view the data to make sure that the data appears reasonable both spatially and temporally.

Visualization tools will be used to assist in the QA process for the emissions data both before and after being processed through the SMOKE emissions model. The air quality data will also employ visualization tools to view the modeling results to ensure that the modeling results look reasonable.

7.2.6. Document Tracking

In order to keep track of the details of modeling, certain notes and files will be maintained. Notes will be kept of files produced on desktop computers as to origin and purpose. These notes may be maintained in a logbook or by using the file properties summary tag available for files in the Windows operating system. Files in the workstation will be similarly tracked. It may be useful to maintain a log within directories for this purpose.

7.3. Meteorological Model Outputs

As part of the VISTAS QA effort, a "Meteorological Gatekeeper" will be tasked with providing an independent review and quality assurance of the meteorological modeling and related datasets developed by the VISTAS meteorological modeling contractor (BAMS) and used subsequently by the emissions and air quality modeling teams. This Gatekeeper QA review ensures that any potential problems with the datasets (should they exist) are identified and corrected in a timely manner. In the case of meteorology, the Gatekeeper's independent QA analysis of the MM5 meteorological datasets serves to provide direct assistance to the emissions and air quality modeling team as it undertakes to ratify the SMOKE model outputs and to diagnose CMAQ model performance and sensitivity analyses.

In addition to having personal responsibility for the quality and chain of custody of the meteorological datasets supplied by other VISTAS contractors, the Meteorological Gatekeeper will be responsible for ensuring and maintaining the integrity of the data files uploaded to the project website. This website, hosted by UCR (University California – Riverside), serves as the repository of data for the ENVIRON/UCR/Alpine modeling centers and for the VISTAS Technical Analysis Workgroup participants. In performing the Gatekeeper quality assurance activity, one of the first steps is to conduct an independent operational evaluation on the MM5 model results at 36-km and 12-km grid scale. This evaluation covers surface and aloft wind direction, temperature, mixing ratio, precipitation, and PBL depths on a continental scale (36-km) and subregional scale (12-km) basis.

The Gatekeeper will also perform supplemental, ad hoc analysis of pertinent MM5 fields (e.g., PBL depths) where that might be useful to the emissions and air quality modeling teams. Another task of the Gatekeeper will be to exercise MCIP version 2.3 to read the MM5 outputs from BAMS and produce binary input files for the CCTM to provide the complete set of parameters necessary in the emissions processing and air quality modeling.

In summary, the quality assurance plan for the meteorological data will include the following elements:

- Upon receiving the MM5 and MCIP 2.3 output files from BAMS, the NCDAQ will verify the integrity of the file transfer (i.e., no missing and/or corrupted files).

- Since the CMAQ modeling domain is a subset of the MM5 domain, the NCDAQ will verify that the modeling domain and vertical layer structures in the MCIP files are identical to the CMAQ modeling domain.
- Several days of the MM5 output will be selected and the meteorological modeling team will reprocess the MM5 files with MCIP v2.3 using the predetermined MCIP options. The MCIP files will then be compared with those provided by BAMS to verify that identical results from the MCIP processing were obtained.
- Horizontal and vertical plots of temperature, pressure, precipitation, modeled flow patterns, PBL heights, etc. will be created to assess whether the MCIP output fields are reasonable.
- The VISTAS 2002 MM5 simulation will be evaluated using the same surface observations, subdomains and procedures as used to evaluate the Western Regional Air Partnership 2002 MM5 simulation as an independent QA and evaluation of the database.
- Plots constructed by the VISTAS Gatekeeper will be made available on the VISTAS website for viewing and download (http://pah.cert.ucr.edu/vistas/vistas2/index.shtml).

7.4. Air Quality Model Inputs and Outputs

Key aspects of QA for the CMAQ input and output data include the following:

- Verification that correct configuration and science options are used in compiling and running each model of the CMAQ modeling system, where these include the MCIP, JPROC, ICON, BCON and the CCTM.
- Verification that correct input datasets are used when running each model.
- Evaluation of CCTM results to verify that model output is reasonable and consistent with general expectations.
- Processing of ambient monitoring data for use in the model performance evaluation.
- Evaluation of the CCTM results against concurrent observations.
- Backup and archiving of critical model input data.

The most critical element in the QA plan for CMAQ simulations is the QA/QC of the meteorological and emissions input files. The major QA issue specifically associated with the air quality model simulations is verification that the correct science options were specified in the model itself and that the correct input files were used when running the model. For the CMAQ model, a system of naming conventions was employed which uses environment variables in the compile and run scripts that guarantee that correct inputs and science options are used. A redundant naming system is also used so that the name of key science options or inputs is included in the name of CMAQ executable program, in the name of the CMAQ output files, and in the name of the directory in which the files are located. This is accomplished by using the environment variables in the scripts to specify the names and locations of key input files. For example, if a model simulation is performed using the CB4 mechanism, all compile and run scripts contain the variable definition "$MECH = CB4," and this variable is hard coded into the script for the executable name, the output file name, and the output directory name. This procedure produces long file/directory names but it effectively prevents mistakes or makes mistakes readily apparent if they do occur.

A second key QA procedure is to never "recycle" run scripts (i.e., the original runs scripts and directory structure that were used in performing a model simulation). For example, if a simulation is performed with the SAPRC mechanism, instead of editing the original scripts to specify "$MECH = SAPRC," a parallel directory structure with a new set of scripts to perform the SAPRC simulations will be created. This provides a permanent archive of the scripts that were used in performing model simulations. In addition, output from the model simulation will be directed to a log file that provides a record of input file names, warning messages, etc., that will be archived.

Post-processing QA of the CMAQ output files similar to that described for the emissions processing will be performed. Animated graphics interchange format (GIF) files using PAVE will be generated to search for unexpected patterns in the CMAQ output files. In the case of model sensitivity studies, the animated GIFs will be prepared as difference plots for the sensitivity case minus the base case. Often, errors in the emissions inputs can be discovered by viewing the animated GIFs. Finally, 24-hour average plots for each day of the CMAQ simulations will be produced. This provides a summary that can be useful for more quickly comparing various model simulations.

8.0 Model Performance Evaluation

The USEPA's April 2007 guidance document *Guidance on the Use of Models and Other Analyses for Demonstrating Attainment of the Air Quality Goals for Ozone, $PM_{2.5}$ and Regional Haze* suggests that model performance be evaluated based on two components:

- How well the model is able to replicate observed concentrations of $PM_{2.5}$ components, ozone and/or precursors (surface and aloft), and
- How accurately the model characterizes the sensitivity of changes in ozone and/or $PM_{2.5}$ to changes in emissions.

Each component suggests a different type of evaluation procedure, with the first being "operational evaluation," and the second being "diagnostic evaluation." Since the attainment test is a relative test, it is not as necessary to exactly duplicate ozone concentrations. As a result, there is now more emphasis placed on the diagnostic model evaluation.

This section outlines the method used to evaluate model performance. Working with the knowledge that many states involved with the VISTAS regional haze work would want to apply some of the work to their individual SIPs for 8-hour ozone and $PM_{2.5}$, plans were put in place to perform exhaustive analysis of all atmospheric constituents, including ozone. The NCDAQ intends to build off the modeling efforts with VISTAS; therefore, the model performance evaluation will be an extension of VISTAS efforts.

8.1. Model Evaluation Tools (Operational Evaluation)

8.1.1. Statistical Performance Metrics

In compliance with the aforementioned USEPA guidance (EPA, 2007), VISTAS will compile a suite of metrics for use in evaluating model performance. The standard set of statistical performance measures suggested by the USEPA for evaluating $PM_{2.5}$ models includes: normalized bias, normalized gross (unsigned) error, fractional bias, fractional gross error, and fractional bias in standard deviations. Several other measures will be included in the final report to fulfill the requirements in the 8-hour ozone guidance (addition of average peak prediction accuracy), and to better accommodate other modeling groups with their comparison of modeling efforts. A list of metrics for calculation on a routine basis using the UCR analysis package is listed in Table 8.1-1. The metrics calculated in conjunction with VISTAS will include the examination of various atmospheric constituents, including the major components of $PM_{2.5}$.

Typically, the statistical metrics are calculated at each monitoring site across the full computational domain for all simulation days. During the VISTAS CMAQ evaluation, the gas-phase and aerosol statistical measures shown in Table 8.1-1 will be computed for the full 36-km and 12-km domains, as well as for the individual RPOs and on other subdomains as appropriate. Temporally, the statistical measures will be computed for the appropriate averaging times: 1 hr for ozone, and gas-phase precursors such as NO, nitrogen dioxide (NO_2), CO, SO_2, 8-hour for ozone, and 24-hour for sulfate, nitrate, $PM_{2.5}$, and other aerosol species. These results will then be averaged over annual, monthly, and seasonal periods for display, further analysis, and reporting. Should it become necessary as part of model performance diagnosis, the statistics will be aggregated in other ways, e.g., (a) day vs. night, (b) weekday vs. weekend, (c) precipitation vs. non-precipitation days, (d) month of the year, and (e) the 20% haziest/cleanest days, in order to help elucidate model performance problems. For the purposes of the Hickory/Triad $PM_{2.5}$ SIP, only the statistics for $PM_{2.5}$ and its component species will be reported. The statistics for the pollutants and precursors will be reviewed internally for reasonableness.

Table 8.1-1: Statistical Metrics

Statistical Measure	Shorthand Notation	Mathematical Expression	Notes
Accuracy of Paired Peak	A_p	$\frac{P - O_{peak}}{O_{peak}}$	
Coefficient of Determination	r^2	$\frac{\left[\sum_{i=1}^{N}\left(P_i - \overline{P}\right)\left(O_i - \overline{O}\right)\right]^2}{\sum_{i=1}^{N}(P_i - \overline{P})^2 \sum_{i=1}^{N}(O_i - \overline{O})^2}$	P_i= prediction at time and location i; O_i = observation at time and location i; $\overline{P}$ = arithmetic average of P_i, i = 1, 2, . . ., N; $\overline{O}$ = arithmetic average of O_i, i = 1, 2, . . ., N;
Normalized Mean Error	NME	$\frac{\sum_{i=1}^{N}\left\|P_i - O_i\right\|}{\sum_{i=1}^{N}O_i}$	Reported as %
Root Mean Square Error	RMSE	$\left[\frac{1}{N}\sum_{i=1}^{N}(P_i - O_i)^2\right]^{\frac{1}{2}}$	Reported as %
Fractional Gross Error	F_E	$\frac{2}{N}\sum_{i=1}^{N}\left\|\frac{P_i - O_i}{P_i + O_i}\right\|$	Reported as %
Mean Absolute Gross Error	MAGE	$\frac{1}{N}\sum_{i=1}^{N}\left\|P_i - O_i\right\|$	
Mean Normalized Gross Error	MNGE	$\frac{1}{N}\sum_{i=1}^{N}\frac{\left\|P_i - O_i\right\|}{O_i}$	Reported as %
Mean Biased	MB	$\frac{1}{N}\sum_{i=1}^{N}(P_i - O_i)$	Reported as concentration
Mean Normalized Bias	MNB	$\frac{1}{N}\sum_{i=1}^{N}\frac{(P_i - O_i)}{O_i}$	Reported as %
Mean Fractionalized Bias (Fractional Bias)	MFB	$\frac{2}{N}\sum_{i=1}^{N}\left(\frac{P_i - O_i}{P_i + O_i}\right)$	Reported as %

Table 8.1-1: Statistical Metrics (Continued)

Statistical Measure	Shorthand Notation	Mathematical Expression	Notes
Normalized Mean Bias	NMB	$\frac{\sum_{i=1}^{N}(P_i - O_i)}{\sum_{i=1}^{N} O_i}$	Reported as %
Bias Factor	BF	$\frac{1}{N}\sum_{i=1}^{N}\left(\frac{P_i}{O_i}\right)$	Reported as BF:1 or 1:BF or in fractional notation (BF/1 or 1/BF)

8.1.2. Graphical Representations

The core operational air quality model evaluation will utilize numerous graphical displays to facilitate quantitative and qualitative comparisons between CMAQ predictions and measurements. Together with the statistical metrics listed in Table 8.1-1, the graphical procedures are intended to help: (a) identify obviously flawed model simulations, (b) guide the implementation of any performance improvements in the 2002 model input files in a logical, defensible manner, and (c) to help elucidate the similarities and differences between the alternative CMAQ simulations. These graphical tools are intended to depict the model's ability to predict the observed gaseous species, such as ozone, and fine particulate species concentrations. The core graphical displays to be considered for use in model performance evaluation include the following:

- Spatial mean concentration time series plots
- Time series plots at monitoring locations
- Ground-level gas-phase and particulate concentration maps (i.e., tile plots)
- Concentration scatter plots stratified by station, by time, and by network
- Soccer and bugle plots
- Histogram plots of the statistical metrics, stratified by day, by pollutant, by subregion (e.g., 12-km vs. 36-km, by RPO), and by monitoring network
- Quantile - Quantile (Q-Q) plots
- Animations of predicted hourly pollutant concentrations

These graphical displays will be generated, where appropriate, for the full annual cycle as well as for monthly and seasonal periods.

8.2. Model Performance Testing (Diagnostic Evaluation)

Rarely does a modeling team find that the first simulation satisfactorily meets all (or even most) model performance expectations. Based on experience, initial simulations that "look very good" usually do so as the result of compensating errors. The norm is to engage in a logical, documented process of model performance improvement wherein a variety of diagnostic probing tools and sensitivity testing methods are used to identify, analyze, and then attempt to remove the causes of inadequate model performance. This is invariably the most technically-challenging and time consuming phase of a modeling study. The annual CMAQ model base case simulations are expected to present some performance challenges that may necessitate focused diagnostic and sensitivity testing in order for them to be resolved. It is hoped that these diagnostic and/or sensitivity tests can be adequately carried out within the resources and schedule. Where practical, diagnostic or sensitivity analyses, if needed, could be performed on selected episodes within the annual cycle, thereby avoiding the time-consuming task of running CMAQ for the full 2002 period. Below, the types of diagnostic and sensitivity testing methods that might be employed in diagnosing inadequate model performance and devising appropriate methods for improving the model response are identified.

8.2.1. Traditional Sensitivity Testing

Model sensitivity experiments are useful in three distinct phases, or "levels", of an air quality modeling study and all will be used as appropriate. These levels are:

- **Level I**: Model algorithm evaluation and configuration testing
- **Level II**: Model performance testing, uncertainty analysis and compensatory error diagnosis
- **Level III:** Investigation of model output response (e.g., ozone, aerosol, deposition) to changes in precursors as part of emissions control scenario analyses.

The Level I and Level II cover the aspect of operational evaluation, while Level III covers diagnostic evaluation.

The Level I sensitivity tests with CMAQ have already been completed in the initial VISTAS configuration and diagnostic analyses. However, given that open community nature of CMAQ and the frequent science updates to the model and supporting databases, it is possible that some additional configuration sensitivity testing will be necessary.

Potential Level II sensitivity analyses might be helpful in accomplishing the following tasks:

- To reveal internal inconsistencies in the model
- To provide a basis for compensatory error analysis
- To reveal the parameters (or inputs) that dominate (or do not dominate) the model's operation
- To reveal propagation of errors through the model
- To provide guidance for model refinement and data collection programs

The merits of performing Level II sensitivity testing will depend upon whether performance problems are encountered. In addition, the number of tests possible, should performance difficulties arise, will be limited by the available schedule and resources. From past experience with CMAQ and other models, it is possible to identify examples of sensitivity runs that could be useful in model performance improvement exercises with the annual 2002 CMAQ simulation. These include:

- Modified biogenic emissions estimates
- Modified on-road motor vehicle emissions
- Modified air quality model vertical grid structure
- Modified boundary conditions
- Modified fire emissions
- Modified EGU emissions
- Modified ammonia emission estimates
- Modified aerosol/Nitric Pentoxide/Nitric acid (HNO_3) chemistry
- Modified ammonia and HNO_3 deposition velocities

Note that in a few cases [e.g., vertical grid structure, ammonium (NH_4) emissions estimates], some sensitivity experimentation has already been carried out by VISTAS. To the extent that this information can help guide the future diagnostics analyses, this earlier work will be used.

Level III sensitivity analyses have two main purposes. First, they facilitate the emissions control scenario identification and evaluation processes. Currently, four complimentary sensitivity "tools" can be used in regional photochemical models depending upon the platform being used. These methods include: (a) traditional or "brute force" testing, (b) Decoupled Direct Method, (c) Ozone Source Apportionment Technology and Particulate Matter Source Apportionment Technology, and (d) Process Analysis. Each method has its strong points and they will be employed where needed. The second purpose of Level III sensitivity analyses is to help quantify the estimated reliability of the air quality model in simulating the atmosphere's response to significant emissions changes.

Examples of Level III monthly or annual sensitivity runs for Phase II might include:

- Ozone, sulfate, nitrate, ammonium and other aerosol sensitivities to SO_2 emissions
- Ozone, sulfate, nitrate, ammonium and other aerosol sensitivities to elevated point source NO_x emissions
- Ozone, sulfate, nitrate, ammonium and other aerosol sensitivities to ground level NO_x emissions
- Sulfate, nitrate, ammonium and other aerosol sensitivities to ammonia

The need to perform sensitivity experimentation (Levels I, II, or III) will depend on the outcome of operational performance evaluations. If such a need arises, the ability to actually carry out selected sensitivity and/or diagnostic experiments will hinge on the availability resources and sufficient time to carry out the analyses. Clearly, selection of the specific analysis method will depend upon the nature of the technical question(s) being addressed at the time.

8.3. Air Quality and Ozone Column Data

Data from ambient monitoring networks for both gas and aerosol species are used in the model performance evaluation. Table 8.3-1 summarizes ambient monitoring networks used to collect data for Air Quality model performance evaluation. Data have been compiled for all networks listed except the Photochemical Assessment Monitoring Stations (PAMS) and particulate matter Super-sites.

Additional data used in the air quality modeling include the Total Ozone Mapping Spectrometer (TOMS). TOMS data provides ozone column data, is available for 24-hour average, and is obtained from http://toms.gsfc.nasa.gov/eptoms/ep.html. The TOMS data is used in the CMAQ radiation model to calculate photolysis rates.

Table 8.3-1: Overview of Ambient Data Monitoring Networks.

Monitoring Network	Chemical Species Measured	Sampling Period	Data Availability/Source
The Interagency Monitoring of Protected Visual Environments (**IMPROVE**)	Speciated $PM_{2.5}$ and PM_{10} (see species mappings)	1 in 3 days; 24 hr average	http://vista.cira.colostate.edu/improve/Data/IMPROVE/improve_data.htm
Clean Air Status and Trends Network (**CASTNET**)	Speciated $PM_{2.5}$, Ozone (see species mappings)	Approximately 1-week average	http://www.epa.gov/castnet/data.html
National Atmospheric Deposition Program (**NADP**)	Wet deposition (hydrogen (acidity as pH), sulfate, nitrate, ammonium, chloride, and base cations (such as calcium, magnesium, potassium and sodium)), Mercury	1-week average	http://nadp.sws.uiuc.edu/
Air Quality System (**AQS**) Aka Aerometric Information Retrieval System (**AIRS**)	CO, NO_2, O_3, SO_2, $PM_{2.5}$, PM_{10}, Pb	Typically hourly average	http://www.epa.gov/air/data/
Speciation Trends Network (STN)	Speciated PM	24-hour average	http://www.epa.gov/ttn/amtic/amticpm.html
Southeastern Aerosol Research and Characterization (**SEARCH**)	24-hr $PM_{2.5}$ (FRM Mass, OC, BC, SO_4, NO_3, NH_4, Elem.); 24-hr PM coarse (SO_4, NO_3, NH_4, elements); Hourly $PM_{2.5}$ (Mass, SO_4, NO_3, NH_4, EC, TC); and Hourly gases (O_3, NO, NO_2, NO_y, HNO_3, SO_2, CO)	Hourly or 24hour average, depending on parameter.	Electric Power Research Institute (EPRI), Southern Company, and other companies. http://www.atmospheric-research.com
USEPA Particulate Matter Supersites	Speciated $PM_{2.5}$		http://www.epa.gov/ttn/amtic/supersites.html
Photochemical Assessment Monitoring Stations (**PAMS**)	Varies for each of 4 station types.		http://www.epa.gov/ttn/amtic/pamsmain.html
National Park Service Gaseous Pollutant Monitoring Network	Acid deposition (Dry; SO_4, NO_3, HNO_3, NH_4, SO_2), O_3, meteorological data	Hourly	http://www2.nature.nps.gov/ard/gas/netdata1.htm

9.0 Control Strategy

It is important to remember that photochemical models are tools; they do not make decisions. The results from photochemical models are one of several pieces of information that decision-makers must consider when adopting control strategies. To ensure that the modeling analyses provide information that meets the needs of the decision makers, it is imperative that the air quality modelers and decision makers agree upon the type and amount of information that is needed to meet the study objectives. This section outlines the process behind developing and evaluating emission control strategies to be employed for the $PM_{2.5}$ attainment demonstration.

9.1. Control Strategy Design

9.1.1. Emission Sensitivity Test

To begin the process of control strategy design a series of simulations using across-the-board reductions of direct $PM_{2.5}$ emissions and $PM_{2.5}$ precursors can be run. The purpose of these simulations is to evaluate the relative effectiveness of various pollutant reductions to help tailor effective control strategy measures.

Errors in emission estimates can lead to errors in control decisions. Important sources in future year inventories can be simulated at the lower and upper bounds of their estimated accuracy. In doing this, the NCDAQ can find out if changes, within the known accuracy of the emission estimates, can lead to different decisions for control strategies. Once the future year inventories are assembled, the sources with the highest uncertainty can be identified. These sources could include biogenic emissions, motor vehicle exhaust, and gasoline evaporation. VOC speciation profiles can also be included in these sensitivity tests.

9.1.2. Isopleth Construction

From the emissions sensitivity tests, isopleths relating uniform reductions of $PM_{2.5}$ precursor emissions to $PM_{2.5}$ formation can be constructed. These isopleths can give some insight into emission reduction goals, but are not designed to evaluate specific control strategies. They do not simulate real controls that change temporal and spatial distributions as well as the organic mix of species. With these limitations in mind, the isopleths can help design the control measures that may reduce levels close to ambient standards. If resources are available, a series of simulations covering a range of actual control measures will be run. These simulations can be used to design appropriate and defensible control strategies. In addition, isopleths of population exposure can be prepared and used to assess proposed control measures in an integrated manner.

9.1.3. Ranking Control Strategies

Control strategies should be implemented in an ordered fashion that reduces both $PM_{2.5}$ concentrations and population exposure. Emission controls that affect multiple pollutants should be sorted separately from single pollutant controls. Estimates of control levels that are expected in future years should be made. An attempt to reduce population exposure to a minimum each year while reducing $PM_{2.5}$, can be made by looking at all potentially available controls.

9.2. Control Strategy Evaluation

Selection of candidate control strategies will take into consideration the results of the combination of analyses described in the previous sections. Once candidate control strategies are identified, the strategies may be simulated. If needed, an analysis will be performed to investigate the predicted impact of each strategy on air quality and population exposure. The results of these analyses will be summarized both in tabular and graphical form to allow systematic comparison and contrast of all strategies.

To assist decision makers in fully understanding the impact of proposed control strategies, the following products may be prepared as a part of the control strategy evaluation:

1. Total $PM_{2.5}$ Spatial Plots
2. Difference Plots
3. Population Exposure Tables and Histograms
4. Change in predicted future design values

Each of these products will compare future year base simulations with one or more control simulations. An attempt should be made to minimize population exposure as controls are introduced. To assist in this effort, population exposure and $PM_{2.5}$ statistics can be organized by future year and control strategy. Upon completion of this evaluation, a final control strategy will be selected for detailed evaluation.

9.3. Identification of Control Strategy Scenarios

A designated subcommittee will select the control strategy scenarios to be modeled for demonstrating attainment. The control strategy selection process will follow the current the USEPA guidance, and will incorporate our present understanding of $PM_{2.5}$ formation on an urban and regional scale.

Mandated controls will be modeled first (inspection and maintenance programs, NO_x SIP Call, North Carolina's Clean Smokestacks Act legislation, federal engine standards, federal fuel standards, etc.). If attainment of the annual $PM_{2.5}$ NAAQS is not shown, additional alternative control strategies identified by the preceding steps, will be modeled until attainment is reached.

A "frozen" future year dataset will be available for use in testing alternative control strategies. This will consist of a set of model input and output files for each episode. Anyone with access to the model (e.g., power companies and universities) can use these files as long as they do not change future base case emission inventories, meteorology, growth factors, or mandated controls. Alternative controls can be modeled in addition to controls strategies modeled by the states.

10.0 Demonstration of Attainment

This section summarizes the procedures that will be used to demonstrate attainment of the annual $PM_{2.5}$ NAAQS. An attainment demonstration consists of (a) analyses which estimate whether selected emissions reductions will result in ambient concentrations that meet the NAAQS, and (b) an identified set of measures that will result in the required emissions reductions. Determining necessary emission reductions may be done by relying exclusively on results obtained with air quality models. These include the outcomes of the modeled attainment test plus a screening test to estimate whether a proposed emission reduction suffices to meet the NAAQS.

10.1. $PM_{2.5}$ Model Attainment Test

The $PM_{2.5}$ model attainment test is similar to the ozone model attainment test, in that both test use the model estimate in a relative sense using relative response factors (RRFs). A RRF is calculated for each constituent of $PM_{2.5}$ and is then used to calculate the projected $PM_{2.5}$ concentration for the future modeling year. Since the attainment test for $PM_{2.5}$ utilizes both total $PM_{2.5}$ and the individual component species, the test is referred to the Speciated Model Attainment Test (SMAT). In its entirety, SMAT consists of four basic steps.

First, the observed quarterly mean $PM_{2.5}$ and quarterly mean composition for each monitor is calculated. This is achieved by multiplying the monitored quarterly mean concentration of $PM_{2.5}$ from FRM monitors by the monitored fractional composition of $PM_{2.5}$ species for each quarter (e.g., (20% sulfate) x (15.0 $\mu g/m^3$ PM2.5 mass) = 3.0 $\mu g/m^3$ sulfate mass).

The monitored quarterly mean concentration of $PM_{2.5}$ from FRM monitors are the 5 year baseline design values (DVB) that are the result of averaging the 3 current design values (DVC) that straddle the modeling base year. The fractional composition of $PM_{2.5}$ species is derived from STN monitoring site data that has been processed by the "sulfate, adjusted nitrate, derived water, inferred carbonaceous material balance approach", or SANDWICH method, so STN and FRM masses are equivalent. The mean composition derived from the SANWICH method includes the percent of $PM_{2.5}$ that can be attributed to SO_4, NO_3, OC, EC, other primary inorganic particulates (or crustal materials), NH_4, and particle bound water (PBW).

The second step is to use model results to derive component specific RRF for each monitor for each quarter.

$$(RRF)_{ij} = ([C_{j,\,projected}]/[C_{j,\,current}])_i \qquad \textit{Equation 10.1-1}$$

Where:

$C_{j,\,current}$ is the quarterly mean concentration predicted at or near the monitoring site with emissions characteristic of the period used to calculate the baseline design value for annual $PM_{2.5}$.

$C_{j,\,projected}$ is the future year quarterly mean concentration predicted at or near the monitoring site.

For the third step, the component specific RRFs are applied to the observed air quality concentrations to projected quarterly species estimate. For each quarter, the current quarterly mean component concentration (step 1) are multiplied by the component-specific RRF obtained in step 2. This leads to an estimated future quarterly mean concentration for each component.

The fourth step sums the quarterly components to get a quarterly mean PM2.5 value. These quarterly mean values are then averaged to produce a future year annual average PM2.5 estimate, or future design value (DVF), for each FRM monitoring site. This final value is then compared to the NAAQS (15.0 $\mu g/m^3$) to determine if attainment is reached. An example calculation for site "X" is presented in Example 10.1 to further demonstrate the procedure for the $PM_{2.5}$ nonattainment test.

Example 10.1:

Step 1: Site X has the following observed quarterly mean $PM_{2.5}$ mass for the four quarters in the 2000-2004 period:

Table 10.1 –1: Observed Quarterly PM2.5 Concentrations for Site X

Quarter	2000	2001	2002	2003	2004
1	16.14	15.30	13.25	12.94	13.10
2	16.58	16.61	14.32	16.08	14.92
3	18.90	18.83	21.12	19.34	19.60
4	18.89	13.16	12.73	11.81	12.39

This data yields the following 3-year DVCs, and 5-year DVB:

Table 10.1-2: 3year DVC and 5 year DVB for Site X

Quarter	2000-2002 3-YR DVC	2001-2003 3-YR DVC	2002-2004 3-YR DVC	2000-2004 5-YR DVB
1	14.90	13.83	13.10	13.94
2	15.84	15.67	15.11	15.54
3	19.62	19.76	20.02	19.80
4	14.93	12.57	12.31	13.27

Based on a collocated STN site, the quarterly speciation profile for site X is:

Table 10.1-3: Quarterly Component Fraction at Site X

Quarter	Fraction Crustal	Fraction EC	Fraction OC	Fraction SO4	Fraction NO3	Fraction NH4	Fraction H2O
1	2.43%	5.96%	46.88%	24.94%	4.79%	8.37%	6.63%
2	4.13%	3.69%	36.73%	34.88%	0.07%	10.33%	10.16%
3	2.86%	2.52%	33.08%	39.29%	0.05%	11.30%	10.90%
4	2.04%	4.82%	48.63%	24.12%	4.17%	8.83%	7.38%

Multiplying the 5-year quarterly DVB by the quarterly speciation profile yields the following quarterly mean composition:

Table 10.1-4: Quarterly Mean Composition for Site X

Quarter	FRM Mass	Blank Mass	Non-Blank Mass	Crustal	EC	OC	SO4	NO3	NH4	PBW
1	13.94	0.50	13.44	0.33	0.80	6.30	3.35	0.64	1.12	0.89
2	15.54	0.50	15.04	0.62	0.56	5.52	5.25	0.01	1.55	1.53
3	19.80	0.50	19.30	0.55	0.49	6.38	7.58	0.01	2.18	2.10
4	13.27	0.50	12.77	0.26	0.62	6.21	3.08	0.53	1.13	0.94

Step 2: Modeling produced the following RRFs for Crustal, EC, OC, SO_4, and NO_3 component of PM2.5 near site X:

Table 10.1-5: RRFs for Site X

Quarter	Crustal	EC	OC	SO4	NO3
1	0.9987	0.7752	0.8814	0.8856	0.9417
2	1.1504	0.7894	0.9516	0.7614	0.7045
3	1.2178	0.8145	0.9629	0.6326	0.6050
4	1.0373	0.7436	0.8966	0.8096	0.8672

Step 3: The quarterly mean RRFs from table 10.1-5 are multiplied by the weighted quarterly average species concentrations from table 10.1-4 to derive future year concentrations. The future year ammonium concentrations are calculated from the sulfate, nitrate, and (current year) degree of neutralization (DON) values. Assuming that the DON is unchanged from the current year, the ammonium is calculated using the following formula:

$NH4_{future} = DON * SO4_{future} + 0.29*NO3_{future}$ *Equation 10.1-2*

In the example above, assuming the base year DON is:

Table 10.1-6: DON for Each Quarter for Site X

Quarter	DON
1	0.280
2	0.296
3	0.287
4	0.316

then the Quarter 1 $Ammonium_{Future} = 0.280 * 3.35 + 0.29 * 0.64 = 1.007$ µg/m3, etc.

The $NH4_{future}$, $SO4_{future,}$ and $NO3_{future}$ concentrations can then be used to develop a polynomial equation to predict future year particle bound water concentration. This step yields estimated future quarterly component concentrations of:

Table 10.1-7: Future Quarterly Component Concentrations for Site X

Quarter	Crustal	EC	OC	SO4	NO3	NH4	PBW
1	0.326	0.621	5.553	2.969	0.606	1.007	0.792
2	0.714	0.438	5.256	3.994	0.008	1.183	1.161
3	0.673	0.397	6.148	4.797	0.006	1.379	1.335
4	0.271	0.458	5.567	2.493	0.462	0.921	0.764

Step 4: These quarterly components are then added to get a quarterly mean PM2.5 value.

Table 10.1-8: Future Quarterly Component Concentrations and Quarterly Mean PM2.5 Concentrations (SUM) for Site X

Quarter	Crustal	EC	OC	SO4	NO3	NH4	PBW	SUM
1	0.326	0.621	5.553	2.969	0.606	1.007	0.792	12.083
2	0.714	0.438	5.256	3.994	0.008	1.183	1.161	13.593
3	0.673	0.397	6.148	4.797	0.006	1.379	1.335	16.399
4	0.271	0.458	5.567	2.493	0.462	0.921	0.764	14.172

These quarterly sums are then average to produce a future year annual average PM2.5 estimate, or DVF, of 13.08 $\mu g/m^3$ for monitoring site X. This DVF at site X is less than 15 $\mu g/m^3$; therefore, the site passes the attainment test.

10.2. Screening Test

Per the USEPA Guidance, the states will perform an analysis of unmonitored areas to determine if attainment of the annual $PM_{2.5}$ standard is expected in these areas. The USEPA is working on developing the Model Attainment Test Software (MATS) to perform the unmonitored area analysis, or screening test. This tool will allow for spatial interpolation of baseline monitoring data, which will provide modeling current design values for an entire area and not just at monitoring sites. This field is then paired with the modeling results in MATS to produce DVFs for an entire geographic area. This final gradient adjusted spatial field can then be examined for any unmonitored areas that area predicted not to meet the $PM_{2.5}$ NAAQS. The NCDAQ will implement this tool, should it be available in time to contribute to a timely SIP submittal. Should a peer reviewed MATS release be delayed, and is unavailable at the time of SIP submittal NCDAQ will examine the modeling data and current monitoring network to determine if any additional violations are suggested and is the logical course of action that should be taken.

10.3. Corroborative Analysis

After the completion of the attainment test, the USEPA $PM_{2.5}$ modeling guidance suggests additional measures should be taken to further support or refutes the attainment test results. This corroboratory evidence is referred to as supplemental analysis when used to further support an attainment demonstration. A weight of evidence determination can be used to conclude that attainment is likely, especially when the predicted future design values are between 14.5 and 15.5 $\mu g/m^3$. Analysis can include a wide variety of tests and analyses, including the application and results of air quality models, observed air quality trends and estimated emissions trends, and the outcome of observational models.

Should the area, clearly demonstrate attainment (DVF $< 14.5\ \mu g/m^3$), then basic supplemental analysis will be performed to further support the test's findings. If either the attainment or screening tests are greater than 15.5 $\mu g/m^3$, it is doubtful that the more qualitative arguments made in a weight of evidence determination can be sufficiently convincing to conclude that the NAAQS for $PM_{2.5}$ will be attained.

For DVFs between 14.5 and 15.5 µg/m^3, a weight of evidence determination will be preformed to supplement the conclusion that the area is expected to attain the NAAQS. The end product of a weight of evidence determination is a document which describes analyses performed, data used, key assumptions and outcomes of each analysis, and why the State believes that the evidence, viewed as a whole, supports a conclusion that the area will attain the annual NAAQS for $PM_{2.5}$.

1.0 INTRODUCTION

This report constitutes the first draft of the Air Quality Modeling Protocol for the Association for Southeastern Integrated Planning (ASIP) to address the regional component of emissions and air quality modeling of 8-hour ozone and $PM_{2.5}$ nonattainment in the Southeastern United States. The ASIP emissions and air quality modeling activities are being carried out by the contractor team of ENVIRON International Corporation and Alpine Geophysics, LLC. Southeastern States may use the regional emissions and air quality modeling from ASIP and also may conduct more refined ozone and $PM_{2.5}$ modeling of their own nonattainment areas. Previously, the ASIP team has prepared a Quality Assurance Project Plan (QAPP) that details the extensive quality assurance (QA) and quality control (QC) activities being performed as part of ASIP (Morris and Stella, 2005).

1.1 SESARM Organization

Southeastern States Air Resource Managers, Inc., commonly known as SESARM, is a Georgia corporation organized and operated under the provisions of the Official Code of Georgia Annotated, Title 14, Chapter 3, also known as the Georgia Nonprofit Corporation Code. SESARM qualifies as a charitable, tax-exempt, nonprofit corporation as provided in the United States Code, Title 26, Subtitle A, Chapter 1, Subchapter F, Part 1, Section 501(c)(3). SESARM does not engage in for-profit activities nor does it use federal funds to influence legislation. SESARM was incorporated February 24, 1997. Its tax-exempt status was most recently re-confirmed in correspondence from the United States Internal Revenue Service dated December 12, 2001.

SESARM directly represents the eight southeastern state air pollution control agencies located within Region 4 of the United States Environmental Protection Agency (EPA). The member states are Alabama, Florida, Georgia, Kentucky, Mississippi, North Carolina, South Carolina, and Tennessee. The Board of Directors of SESARM consists of the air pollution control agency director from each state air pollution control agency.

SESARM's Articles of Incorporation describe its purposes as being to enhance communication and thus promote more effective air pollution management in the Southeast, improve the effectiveness of its members in meeting national and regional air pollution goals, conduct and facilitate research and training necessary to meet its purposes, evaluate air quality issues, recommend actions to resolve air quality problems, and develop steps to accomplish air quality improvements.

When EPA promulgated regional haze regulations on July 1, 1999, it established requirements that states and tribes submit implementation plans to demonstrate reasonable progress towards the ultimate visibility goals of the rule. The first demonstration of reasonable progress is to be made for the year 2018 in state implementation plans due December 2007. EPA also offered an optional approach that groups of states might collaborate in regional analyses of the haze problem. This option showed promise in allowing more cost-effective analyses and the southeastern states opted to follow this option. Southeastern States Air Resource Managers Inc.

(SESARM) accepted responsibility for regional planning organization work tasks on behalf it its member agencies pursuant to this option.

The member agencies of SESARM determined that it was appropriate to expand the collaborative effort for the regional haze program beyond their member boundaries and invited Virginia and West Virginia to join the group. A memorandum of agreement was arranged among the agencies and executed on August 22, 2001. The effort was named the Visibility Improvement State and Tribal Association of the Southeast (VISTAS). Since that time, the agencies have worked together to organize their efforts, develop work task lists and schedules, procure professional services, and support administrative operations. Bylaws were developed and agreed upon by the participating members. An organizational structure was created including an oversight committee, an operations committee, and various work groups. This early planning has served the project well and much progress has been made.

1.2 ASIP Project Background

On December 17, 2004, EPA made fine particle ($PM_{2.5}$) nonattainment determinations for at least one area in seven of the states participating in the VISTAS regional haze project. They are Alabama, Georgia, North Carolina, Kentucky, Tennessee, Virginia, and West Virginia. In addition, South Carolina has one three-county area that was designated as unclassifiable in the same action. EPA's Clean Air Interstate Rule (CAIR) modeling indicated that certain nonattainment areas may still be in nonattainment after full implementation of CAIR. These areas include Jefferson County, Alabama and Clayton and Fulton Counties in Georgia.

The $PM_{2.5}$ compliance date is April 2010 unless a state demonstrates that more time is necessary in which case up to five additional years may be granted. The nonattainment designations triggered the requirement for development of state implementation plans (SIPs) that will be due in April 2008. The draft guidance from EPA indicates that a significant requirement of $PM_{2.5}$ SIPs will be attainment demonstrations using, at least in part, modeling analyses to define effective emissions control strategies and confirm that attainment can be achieved after implementation of the strategies. 2009 is the modeling year for the $PM_{2.5}$ attainment demonstration and also is an interim analysis year for the VISTAS regional haze demonstration.

In April of 2004, EPA determined areas that were not meeting the 8-hour ozone standard. States having one or more 8-hour ozone nonattainment areas in the Southeast are Alabama, Georgia, Kentucky, North Carolina, South Carolina, Tennessee, Virginia, and West Virginia. EPA will require attainment of the 8-hour ozone standard in basic nonattainment areas by June 15, 2009 and in moderate nonattainment areas by June 15, 2010. This will require states with basic 8-hour ozone nonattainment areas to model 2008 as the SIP modeling demonstration year while moderate nonattainment areas will require 2009 as the modeling year. Given that North Carolina and Virginia have two year SIP approval processes, there is an immediate need to complete an analysis of ozone attainment using air quality modeling.

The states participating in the VISTAS project (the SESARM EPA Region 4 states plus Virginia and West Virginia from Region 3) have concluded that a collaborative process will be the most efficient approach for the collective states to develop information upon which to base the $PM_{2.5}$ and 8-hour ozone attainment demonstrations. The local air regulatory agencies for Jefferson County, AL, Jefferson County, KY, Mecklenburg County, NC, Forsythe County, NC, Knox County, TN, and Shelby County, TN have also become signatory parties to this collaborative effort. SESARM will coordinate among participating agencies and oversee the performance of the inventory and modeling tasks in parallel with the VISTAS regional haze project tasks.

The name of this collaborative effort is the Association for Southeastern Integrated Planning (ASIP). SESARM was awarded a grant from EPA on February 8, 2005 to conduct what was originally called the fine particle SIP development support project but is now known as ASIP.

1.3 Purpose of the ASIP Modeling Protocol

The ASIP Modeling Protocol sets forth the procedures, data sources and modeling approach to be used in performing the ASIP 8-hour ozone and $PM_{2.5}$ modeling for the Southeastern United States that will be the basis of the regional modeling component for the Southeastern States 8-hour ozone and $PM_{2.5}$ State Implementation Plans (SIPs) due June 2007 and April 2008 respectively. The procedures will be reviewed by States, Federal Agencies, Stakeholders and others so that a full and complete understanding of the modeling approach will be understood by all. States, Agencies and Stakeholders and invited to comment on the procedures outlined in the Modeling Protocol and will warranted the procedures will be refined to address comments.

1.4 Problem Definition

Figures 1-1 and 1-2 display the 8-hour ozone and $PM_{2.5}$ nonattainment areas designed by EPA in April and December 2004, respectively. Of the 10 States in the VISTAS region, 8 include counties that have been designed as nonattainment of the 8-hour ozone standard (Alabama, Georgia, Kentucky, North Carolina, South Carolina, Tennessee, Virginia, and West Virginia). Similarly, seven of the VISTAS states have counties that are designated as nonattainment for $PM_{2.5}$ (Alabama, Georgia, North Carolina, Kentucky, Tennessee, Virginia, and West Virginia). Of the 10 VISTAS states only Florida and Mississippi do not have any 8-hour ozone and $PM_{2.5}$ nonattainment areas, South Carolina includes 8-hour ozone nonattainment counties (near Charlotte) but no $PM_{2.5}$ nonattainment areas.

The states need to submit the 8-hour ozone State Implementation Plans (SIPs) to EPA by June 2007; the $PM_{2.5}$ SIPs are due by April 2008. Some of the states involved in the ASIP ozone/PM modeling have two-year legislative review processes. Thus, the definition of the SIP control plans is needed in early 2006. Consequently, the ASIP regional ozone and PM modeling has an aggressive schedule.

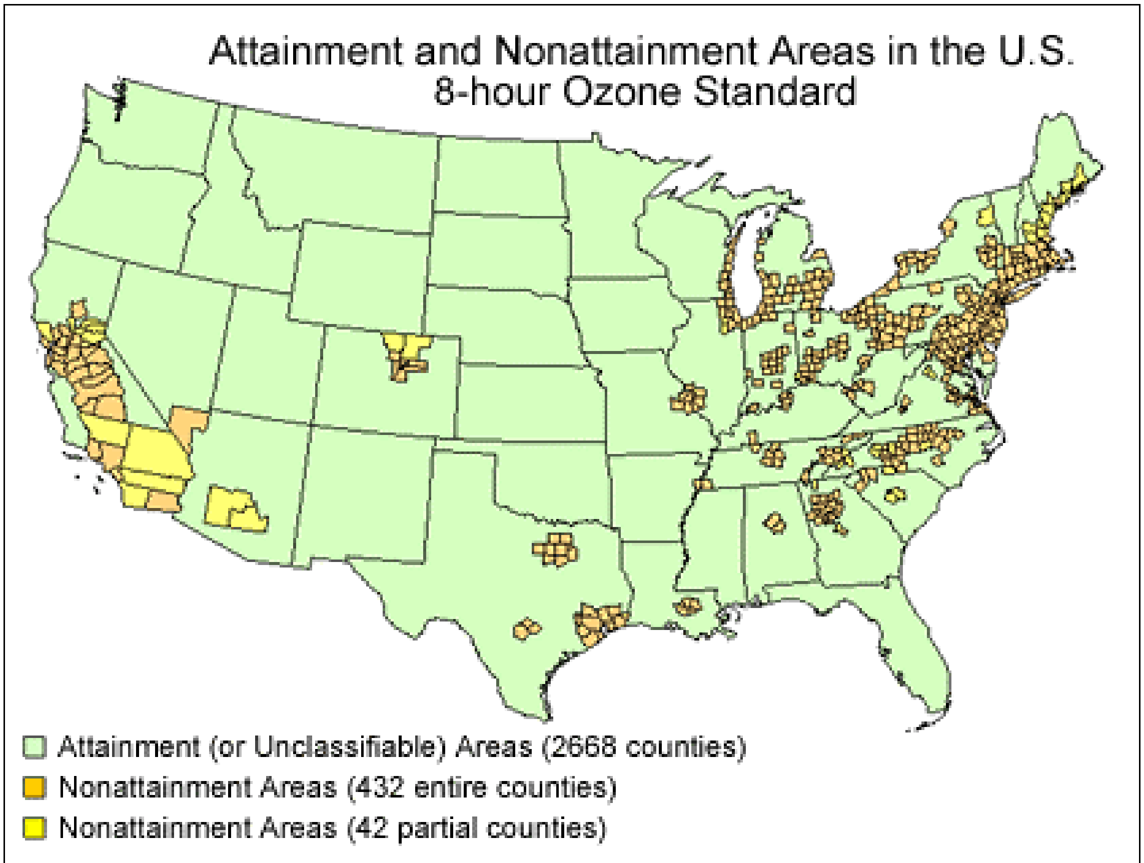

Figure 1-1. 8-hour ozone nonattainment counties in the US designated by EPA in April 2004.

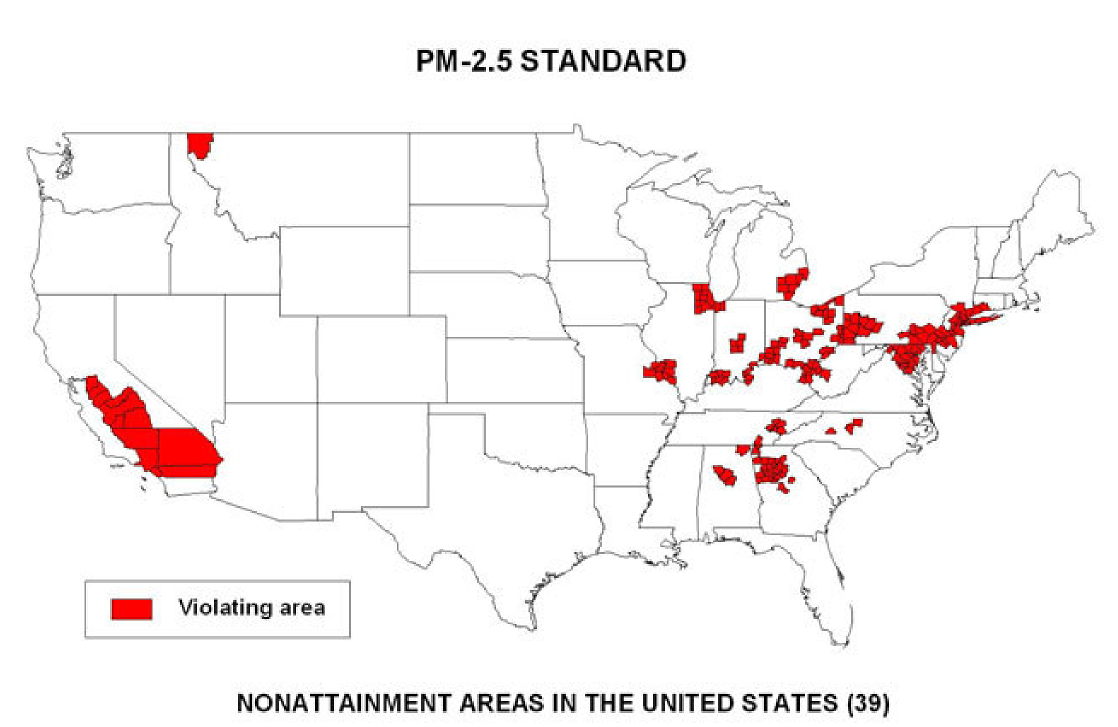

Figure 1-2. $PM_{2.5}$ nonattainment counties designed by EPA in December 2004.

1.5 Background

The Association for Southeastern Integrated Planning (ASIP) Emissions and Air Quality Modeling Team is operating regional scale, three-dimensional air quality models for ozone and fine particulate matter ($PM_{2.5}$) that simulate the emissions, chemical transformations, and transport of gaseous and particulate matter (PM) species in the eastern United States. A key element of this work includes the integration of emissions inventories and models with regional transport models. The general services provided by the ASIP Emissions and Air Quality Modeling Team include, but are not limited to:

- Emissions processing and modeling;
- Air quality modeling simulations;
- Analysis, display, and reporting of modeling results; and
- Storage/quality assurance of the modeling input and output files.

The ASIP regional emissions and air quality modeling is leveraging the modeling databases developed by VISTAS to provide the technical basis for the regional haze SIPs due in December 2007. Regional haze is caused by primary and secondary fine particles and is simulated using "one-atmosphere" regional photochemical grid models. Such models also simulate regional ozone and fine PM so can also be used to address the ASIP 8-hour ozone and $PM_{2.5}$ issues. VISTAS initiated their regional haze modeling in 2003 using a two-phase approach.

1.5.1 VISTAS Two-Phased Approach

The VISTAS Emissions and Air Quality Modeling activities are being performed in two Phases. Phase I, which occurred primarily during the 2003 calendar year, consisted of emissions and regional haze modeling for three episodes to identify the optimal model configuration(s) for simulating regional haze, ozone and fine PM in the southeastern US. Phase II, initiated in 2004, consists of operating the emissions and air quality models for the 2002 calendar year to develop the regional haze modeling databases needed to address the requirements of the Section 308 RHR SIPs and TIPs. The ASIP regional ozone and $PM_{2.5}$ modeling is building off the VISTAS Phase II 2002 36/12 km annual modeling activities.

1.5.1.1 VISTAS Phase I

The objective of VISTAS Phase I was to determine the optimal modeling configuration for use in the subsequent Phase II visibility assessment. Accordingly, Phase I entailed a comprehensive literature review of recent relevant visibility studies using various photochemical/aerosol modeling platforms in order to assess and identify model configurations, data bases, and model testing methodologies that were appropriate for use in conducting the VISTAS Phase I emissions and PM modeling assessment. Key elements of Phase I included:

- Review all relevant air quality model simulations that have been completed related to regional haze and $PM_{2.5}$ modeling and document the relevant sensitivity analyses, model configuration testing, and performance evaluations that have been performed (ENVIRON, 2003b);

- Review the current science in regional emissions modeling (e.g., EPS, EMS and SMOKE) and PM air quality modeling (e.g., CMAQ, CMAQ-MADRID, CMAQ-AIM, REMSAD, UAM-V/PM, CAMx4 and PMCAMx) to determine the most appropriate model(s) for use by VISTAS (ENVIRON, 2003b);

- Review available ambient data for evaluating one-atmosphere PM/ozone models (ENVIRON, 2003c);

- Develop and implement a plan or Modeling Protocol for testing and evaluating alternative science configurations of the recommended Phase I model(s) and document the results (ENVIRON, 2003a); and

- Prepare a Task 6 Modeling Protocol prescribing the model set-up, data base development, performance testing, and control strategy evaluation procedures to be implemented in VISTAS Phase II (ENVIRON, 2004a).

VISTAS formed three standing workgroups to plan and direct the project. These included: (a) the Technical Analysis (emissions and modeling) Workgroup; (b) the Data (monitoring) Workgroup; and (c) the Planning Workgroup. Under Phase I, the VISTAS Technical Analysis Workgroup (TAWG) managed the comprehensive model configuration testing program aimed, as noted above, at evaluating the capabilities of current state-of-science regional emissions, prognostic meteorological and PM/visibility models. The resultant modeling system (models and databases) identified and tested in Phase I were intended to be applied in Phase II following the procedures set forth in the Phase II Modeling Protocol (ENVIRON, 2004a).

For the meteorological component of the Phase I modeling, SESARM contracted with Baron Advanced Meteorological Systems (BAMS) to apply the PSU/NCAR Mesoscale Model (MM5) in multiple configurations and to evaluate its performance against surface and aloft meteorological observations (Olerud, 2003a-d). The emissions modeling component of VISTAS Phase I was carried out by the research team of ENVIRON/Alpine/UCR with staff at Alpine Geophysics taking the lead role in setting up, testing, and applying the emissions modeling system. The air quality modeling component was performed by the team at the ENVIRON/Alpine/UCR modeling centers. A dominant theme during Phase I was the exchange of modeling codes, databases, and evaluation software between the three modeling centers as the air quality modeling was carried out.

1.5.1.2 VISTAS Phase II

The VISTAS Phase II modeling is performing annual PM/regional haze simulations for the 2002 calendar year. Detailed performance testing has been completed. The modeling system has been demonstrated using several inventory versions for the base year (2002) and future years (2009 and 2018). These results are posted to the VISTAS modeling website managed by University of California at Riverside (http://pah.cert.ucr.edu/vistas/vistas2/). Beginning in winter 2005-2006, the modeling system will be exercised with a variety of emissions control scenarios enabling VISTAS to assess the effects of future year emission control strategies on visibility and other air quality issues. The modeling system will also allow VISTAS to track reasonable progress toward regional haze goals. More specifically, the VISTAS Phase II program will focus on the use of the CMAQ modeling system for calendar year 2002 over the same 36/12 km horizontal grid system used in Phase I. A potentially large number of annual (and episodic) model simulations has been or will be performed; the list below reflects current plans:

- **2002 Annual Run.** The initial annual model simulations and performance evaluations using the 2002 inventory for VISTAS and non-VISTAS states, Canada and Mexico. Multiple iterations of the 2002 annual simulation have been required to confirm the appropriateness of the model science configuration(s) recommended by the Phase I work, to evaluate updates to the model and model inputs (especially emissions inventory versions) and to refine model performance.

- **2002 Annual Run with "Typical Year" EGU/Fire Inventory.** An annual 2002 simulation representing the 2000-2004 baseline period for EGU and fire emissions and using 2002 revised inventory for all other source sectors. The primary objective of this inventory is to provide the base line modeled air quality condition against which future year modeling runs will be compared to develop relative reduction factors for each pollutant species.

- **2018 Future Year Annual Runs.** 2018 future year emission inventory simulations using the 2002 calendar year meteorological conditions involving a base case inventory of typical EGU and fire emissions. Initially a 2018 On-the-Books (OTB) base case scenario, which consisted of all promulgated regional controls measures as of the beginning of 2005, and a 2018 On-the-Way (OTW) scenario that consisted of OTB plus regional SOx and NOx controls expected to be part of the Clean Air Interstate Rule (CAIR) and Clean Air Mercury Rule (CAMR) were modeled. After the final CAIR was released in June 2005, the 2018 OTB scenario was dropped. The Integrated Planning Model (IPM) was used to project future EGU emissions; all other inventories were forecasted to 2018 using growth and control factors documented by MACTEC (2005).

- **2009 Intermediate Future Year Annual Runs.** Simulations for the 2009 future-year were performed to provide estimates of visibility improvements at Class I areas for an intermediate future year.

- **Future Year Emission Control Strategies.** Prescription of the future year emissions control strategies to be performed in 2006 will be defined after the foregoing simulations and analyses have been completed. Currently, a 2018 CAIR plus BART control strategy is being developed.

Closely integrated with the annual meteorological, emissions and air quality modeling will be ongoing project management, technical review, and quality assurance activities performed under the guidance of the VISTAS Contracting Officer and the TAWG. The modeling team members will participate with VISTAS management in regular monthly conference calls, as well as ad hoc topical conference calls as needed, and will attend periodic meetings with the TAWG members throughout Phase II.

Complementing the data acquisition, modeling input development activities, and project management activities, four other Phase II activities will be performed, consistent with the VISTAS Quality Assurance Project Plan (QAPP) (ENVIRON, Alpine and UCR, 2004).

1.6 ASIP Modeling Approach

The ASIP regional ozone and PM modeling builds off of the VISTAS Phase II 2002 annual modeling and uses many of the same QA/QC procedures.

1.6.1 Data Gatekeepers

The ASIP and VISTAS emissions and air quality modeling team receive emissions, meteorological and air quality data from other contractors or other sources. As a first line of QA, we have defined a Gatekeeper function to assure the data have been received correctly, the quality of the data has been evaluated, and that the data received have been documented. The same Gatekeeper QA approach will be used in the ASIP ozone and $PM_{2.5}$ modeling. Separate air quality, meteorological and emissions Gatekeepers have been identified whose roles are defined below. In addition, a Data Management Gatekeeper has been defined who will post data, reports and results to the project website and archive all key data generated in the project.

- **Air Quality Data Gatekeeper**. As necessary, obtain air quality data as appropriate for model input development and model performance evaluation and assure that the quality of all air quality data obtained is consistent with the approved QAPP. Provide documentation of evaluation and generate IC/BC inputs for CMAQ for all modeling runs.

- **Meteorological Gatekeeper**. As necessary, obtain meteorological data, as MM5 or MCIP files, as appropriate for annual 2002 modeling runs and other episode periods and perform data quality checks as approved in the QAPP, together with appropriate documentation of model performance evaluation activities.

- **Emissions Gatekeeper.** Obtain emissions inventory data necessary to support annual 2002 and future year modeling and recommend sources of emissions data to be used for Canada and Mexico. Assure quality of all emissions data received is consistent with the approved QAPP, and develop all emissions modeling files to support modeling runs for 2002 and future years. Develop the chemical speciation files and temporal and spatial allocation files necessary to convert annual inventories into hourly and daily emissions modeling files, as appropriate. Develop all emissions modeling files for non-VISTAS states to support modeling runs for future year base case and emissions strategies.

- **Data Management Gatekeeper**: Maintain the ASIP results and other documents as requested by the ASIP group to support all 8-hour ozone and $PM_{2.5}$ modeling tasks. This includes, for example, the storage of model inputs and outputs for annual runs and the transfer (via USB/firewire portable disk or alternative media) of electronic files to ASIP states, EPA, other contractors, and stakeholders.

1.6.2 Emissions QA/QC

Emissions Quality Assurance (QA) and Quality Control (QC) are the single most critical steps in performing air quality modeling studies. Because emissions processing is tedious, time consuming and involves complex manipulation of many different types of large data sets, errors are frequently made in emissions processing and, if rigorous QA measures are not in place, these errors may remain undetected. In ASIP we will continue with the multistep emissions QA/QC approach applied in the VISTAS Phase I and II modeling. This includes the initial emissions QA/QC by the Emissions Gatekeeper described above, as well as QA/QC by the Emissions Modeler during the processing of emissions and then additional QA/QC by the Air Quality Modeler of the processed model ready emission files. This multistep process with three separate groups involved in the QA/QC of the emissions is intended to detect and correct errors prior to the air quality model simulations.

Emissions QA/QC performed as part of the emissions modeling includes:

EMS and EPA Input Screening Error Checking Algorithms: Although the SMOKE emissions model will be used for emissions processing, some of the more advanced EMS input error checking algorithms will be used to screen the data and identify potential emission input errors. Additionally, EPA has issued revised stack QA and augmentation procedures memorandum that will be used to identify and augment any outlying stacks.

SMOKE Error Messages: SMOKE provides various cautionary or warning messages during the emissions processing. We will redirect the SMOKE output to log files and review the log files for serious error messages. An archive of the log files will be maintained so that the error messages can be reviewed at a later date if necessary.

SMOKE Emissions Summaries: We will use QA functions built into the SMOKE processing system to provide summaries of processed emissions as daily totals according to species, source category and county and state boundaries. These summaries will then be compared with summary data prepared for the pre-processed emissions, e.g., state and county totals for emissions from the augmented emissions data.

Once the CMAQ-ready emission inputs have been prepared, we will perform additional emissions QA/QC as follows:

Spatial Summary: We will sum the emissions for all layers and for all 24 hours that is used to prepare a PAVE plot showing the daily total emissions spatial distribution. For a 20 day simulation this produces approximately 20 days x 20 species x 5 emissions categories = 2,000 plots. In our base case simulations these plots will be presented as tons per day. The objective of this step is to identify errors in spatial distribution of emissions.

Vertical Profile: For point sources the emissions total for each layer will be summed and plotted to show the vertical distribution of emissions. These plots show the emissions on the x-axis for each model layer on the y-axis. The objective of this step is to identify possible errors in vertical distribution of emissions.

Short Term Temporal Summary: The total domain emissions for each hour will be accumulated and time series plots prepared that display the diurnal variation in total hourly emissions. The objective of this step is to identify errors in temporal profiles.

Long Term Temporal Summary: The total domain emissions for each day will be accumulated and displayed as time series plots that show the daily total emissions across the domain as a function of time. The objective of this step is to identify particular days for which emissions appear to be inconsistent with other days for no reason (e.g., not a weekend) and compare against the general trend.

Control Strategy Spatial Displays: Spatial summary plots of the daily total emissions differences between a control strategy and base case emissions scenarios will be generated. These plots can be used to immediately identify a problem in a control strategy. For example, if a state's SO_2 control strategy is being analyzed and there are changes in emissions for other pollutants or for SO_2 outside of the state under study problems in emissions processing can be identified prior to the air quality model simulation.

1.6.3 Meteorology QA/QC

The meteorological modeling contractor (BAMS) had primary responsibility in the QA/QC of the MM5 meteorological fields. ASIP will rely on the QA/QC conducted by the VISTAS emissions and air quality modeling team as part of Phase II modeling to assure that the data has transferred correctly, to obtain an assessment of the quality of the data and to assist in the interpretation of the air quality modeling results.

The VISTAS Phase II Meteorological Gatekeeper performed the following activities that serve to QA/QC the meteorological fields used in the ASIP modeling:

- Analyzed the MM5 data to assure it had been transferred correctly.
- Evaluated the MM5 using METSTAT and the surface meteorological network.
- Evaluated upper-air MM5 meteorological estimates by comparing them to upper-air observations and satellite images.
- Compared the VISTAS 2002 MM5 simulation with the one generated by WRAP.
- Generated the CMAQ-ready meteorological inputs using the MCIP2.2 processor.

The CMAQ meteorological input files were updated to MCIP version 3.0 in late 2005.

1.6.4 Air Quality Modeling QA/QC

- Key aspects of QA/QC for the ASIP CMAQ modeling input and output data include the following:
- Verification that correct configuration and science options are used in compiling and running each model in the CMAQ modeling system, where these include the MCIP, JPROC, ICON, BCOM and the CCTM.
- Verification that correct input data sets are used when running each model.
- Evaluation of CMAQ results to verify that model output is reasonable and consistent with general expectations.
- Backup and archiving of critical model input data.

The most critical element for ASIP CMAQ simulations is the QA/QC of the emissions input files, which is discussed above. The major QA issue specifically associated with the air quality model simulations is verification that the correct science options were specified in the model itself and that the correct input files were used when running the model. For the CMAQ model we employ a system of naming conventions using environment variables in the compile and run scripts that guarantee that correct inputs and science options are used. We also employ a redundant naming system so that the names of key science options or inputs are included in the name of the CMAQ executable program, in the name of the CMAQ output files, and in the name of the directory in which the files are located. This is accomplished by using the environment variables in the scripts to specify the names and locations of key input files.

A second key QA procedure is to never "recycle" run scripts, i.e., we always preserve the original runs scripts and directory structure that were used in performing a model simulation.

We will also perform a post-processing QA of the CMAQ output files similar to that described for the emissions processing. We will generate animated gif files using PAVE that can be viewed to search for unexpected patterns in the CMAQ output files. In the case of model sensitivity studies, the animated gifs will be prepared as difference plots for the sensitivity case minus the base case. Often, errors in the emissions inputs can be discovered by viewing the animated GIFs. Finally, we will produce 24 hour average plots for each day of the CMAQ simulations. This provides a summary that can be useful for quickly comparing various model simulations.

1.6.5 Overview of Data Flow and Quality Assurance Process

Figure 1-3 displays an overview of the data flow and quality assurance process in the ASIP Emissions and Air Quality Modeling study. The ASIP Modeling Team receives different types of data from various contractors and other sources that have performed their own Quality Assurance (QA) and Quality Control (QC). Whenever data are received by the Modeling Team, it is first subjected to a QA check by a Gatekeeper who assesses the accuracy and quality of the data and prepares a summary presentation on the QA check. Figure 1-3a lists the Gatekeepers in the Modeling Team for emissions, boundary conditions, meteorological, ozone column (TOMS) and air quality data. If the Gatekeeper identifies any problems with the data, the provider of the data is contacted and asked to correct the data. Once the Gatekeeper has conducted a QA check of the data it is passed on to the modeler who performs their QA of the data. The data are then used in the modeling and resultant output (e.g., model-ready emissions or meteorological files) are then subjected to another round of QA to assure the integrity of the data is retained.

Once the model-ready inputs have been developed and subjected to QA/QC, the CMAQ model is applied using Base Case emissions and the modeling results subjected to a model performance evaluation. The model performance evaluation (MPE) represents an extensive QA effort and is the most time consuming component of the study. EPA has developed draft guidance for evaluating regional PM and haze models that includes performance goals (EPA, 2001). In addition, the Modeling team has adapted EPA MPE approaches and goals for 1-hour (EPA, 1991) and 8-hour (EPA, 1999; 2005b) ozone modeling. The MPE/QA process is being performed under VISTAS since VISTAS and ASIP share the same modeling platform database and approach. The MPE/QA approach is using as many different tools and analysis as possible in order to fully understand the accuracy and reliability of the model simulation. As seen in Figure 1-3b, the MPE process in VISTAS/ASIP is a multistep process using several different techniques:

UCR Analysis Tools: The University of California at Riverside (UCR) Analysis Tools were used extensively in VISTAS and are run on a Linux platform separately for each network. Graphics are automatically generated using gnuplot and the software generates the following:

- Tabular statistical measures;
- Time Series Plots; and
- Scatter Plots by allsite_allday, allday_onesite and allsite_oneday.

MAPS Analysis Tools: Alpine Geophysics (Alpine) has a MAPS Analysis Tool that also runs under Linux and is based on Fortran and NCAR Graphics. It was originally developed for evaluating ozone models and has been extended to treat PM species as well. In addition to calculating similar statistics, scatter plots and time series plots as the UCR Analysis Tools, it also can generate spatially averaged time series plots of concentrations, bias and error, performs analysis of peak concentrations and includes a Flying Data Grabber (FDB) for comparing modeling results with aircraft data.

ENVIRON Analysis Tools: ENVIRON has developed specialized evaluation tools to analyze ozone and PM model performance for urban-scale modeling and comparison against EPA model performance goals.

GA DNR Analysis Plots: Dr. James Boylan of the Georgia Department of Natural Resources has extended the concept in EPA's draft PM fine particulate and regional haze modeling guidance that model performance for species that make up a major contribution to visibility impairment be subjected to more stringent goals than species that are minor contributors by developing concentration-dependent performance goals and "Bugle Plots" to display them.

The evaluation of the VISTAS/ASIP 2002 CMAQ Base Case simulation used each of the analysis tools listed above demonstrating their descriptive and complimentary nature.

The issue of model performance goals for PM species is an area of ongoing research and debate. For ozone modeling, EPA has established performance goals for 1-hour ozone normalized mean bias and gross error of ≤±15% and ≤35%, respectively (EPA, 1991). EPA's draft fine particulate modeling guidance notes that performance goals for ozone should be viewed as upper bounds of model performance, which PM models may not be able to always achieve and we should demand better model performance for PM components that make up a larger fraction of the PM mass than those that are minor contributors (EPA, 2001). Measuring PM species is not as precise as ozone monitoring. In fact, the differences in measurement techniques for some species likely exceed the more stringent performance goals, such as those for ozone. For example, recent comparisons of the PM species measurements using the IMPROVE and STN measurement technologies found differences of approximately ±20% (SO_4) to ±50% (EC) (Solomon et al., 2004).

In the VISTAS/ASIP 2002 CMAQ Base Case modeling, we have adopted three levels of model performance goals for bias and gross error as listed in Table 1-1 that are used to help evaluate model performance. Note that we are not suggesting that these performance goals be generally adopted or that they are the most appropriate goals to use. Rather, we are just using them to frame and put the PM model performance into context and to facilitate model performance intercomparison across episodes, species, models and sensitivity tests.

As noted in EPA's draft PM modeling guidance, less abundant PM species should have less stringent performance goals. Accordingly, we are also using performance goals that are a continuous function of average observed concentrations proposed by Dr. James Boylan at the Georgia Department of Natural Resources that have the following features:

- Asymptotically approaching proposed performance goals or criteria when the mean of the observed concentrations are greater than 2.5 ug/m^3.

- Approaching 200% error and ±200% bias when the mean of the observed concentrations are extremely small.

Dr. Boylan uses bias/error goals and criteria of ±30%/50% and ±60%/75% and plots bias and error as a function of average observed concentrations. As the mean observed concentration approaches zero the bias performance goal and criteria flare out to ±200% creating a horn shape, hence the name "Bugle Plots".

Table 1-1. Model performance goals to help interpret modeling results.

Fractional Bias	Fractional Error	Comment
≤±15%	≤35%	Ozone model performance goal for which PM model performance would be considered good.
≤±30%	≤50%	A level of model performance that we would hope each PM species could meet

≤±60%	≤75%	At or above this level of performance indicates fundamental problems with the modeling system.

1.7 Project Management

1.7.1 Project Organization

The ASIP ozone and PM modeling project is conducted by ENVIRON International Corporation (ENVIRON) and Alpine Geophysics, LLC (Alpine), with input from SESARM and the ASIP States. Organizational commitment is an essential element for developing and implementing a successful research project. Ralph Morris of ENVIRON would be the ASIP Emissions and Air Quality Modeling Project Manager (PM). The ASIP Modeling Team has two Co-Principal Investigators that coordinate activities at each of the modeling centers, Ralph Morris of ENVIRON and Gregory Stella of Alpine. The PM and two Co-PIs are kept apprised of all project activities, from identifying the need to develop sound experimental and project designs to delivering reports. Commitments to research and project activities, such as those described in this QAPP are made only after the activities are thoroughly reviewed and approved by the PM and Co-PIs and SESARM and the ASIP States. Figure 1-4 presents the organizational chart that shows the lines of responsibility and information flow for activities under this project. Table 1-2 lists the project responsibilities for participants in the ASIP Emissions and Air Quality Modeling study, with more details on their roles provided next.

1.8 ASIP Project Manager and Co-Principal Investigator

Mr. Ralph Morris of ENVIRON is the Project Manager (PM) and Co-Principal Investigator (Co-PI) for the Association for Southeastern Integrated Planning (ASIP) Emissions and Air Quality Modeling Team. He provides overall direction to the project and establishes a policy relationship with the sponsor, ensuring that all issues of importance to the ASIP group are addressed. The PM is responsible for the overall conduct of the project, experimental design, reporting of the results, and interacting with the client, consultants, and project staff. The specific responsibilities of the PM include, but are not necessarily limited to, the following:

- Directs and coordinates the activities of the project team and computer facilities to conduct the test program
- Ensures that this QAPP and the Modeling Protocol are followed during the course of the project
- Guides the overall approach for performing modeling evaluations
- Keeps current on project status and delivers progress reports
- Conducts initial modeling or analysis of experiments to determine if inconsistencies or unexpected results suggest possible experimental or measurement problems
- Evaluates overall data quality, characterization results, and overall system performance with regard to meeting project objectives
- Reviews and delivers modeling and assessment reports
- Interacts with external scientific reviewers, collaborators and other external groups in their area of expertise in the development of study priorities, reporting of results, and obtaining external input
- Oversees the project team in responding to any issues raised in assessment reports and initiates corrective actions as necessary
- Serve as ENVIRON's primary point of contact for contract issues
- Establishes a project budget and monitors the effort to ensure that budget is not exceeded
- Establishes a Subcontract with Alpine Geophysics, LLC to perform the work, and adhere to the terms and conditions of that contract
- Assists in the performance of the modeling program in accordance with its contract and the Work Plan
- Provides information to assist the ASIP group in achieving its goals as stated in its Work Plan and Strategic Plan
- Develops individual test protocols and reports as directed
- Analyzes modeling data and provides assessment reports
- Supports the Principal Investigator and ASIP in responding to any issues raised in assessment reports

1.8.1 ENVIRON and Alpine Geophysics Co-Principal Investigators

The two Co-Principal Investigators of Ralph Morris and Gregory Stella perform the following functions:

- Direct and coordinate the day-to-day project activities of the project team and computer facilities to conduct the test program

- Ensure that this QAPP and Modeling Protocol are followed during the course of the project
- Manage the activities in each of the two modeling centers
- Direct personnel working on this project
- Guide the approach for performing modeling evaluations following the direction of the Project Manager
- Keep current on project status and deliver information to Project Manager for progress reports
- Conduct initial modeling or analysis of experiments to determine if inconsistencies or unexpected results suggest possible experimental or measurement problems
- Evaluate overall data quality, characterization results, and overall system performance with regard to meeting project objectives
- Review and deliver data and sections for integration into modeling and assessment reports
- With the Project Manager, interact with external scientific reviewers, collaborators and other external groups in their area of expertise in the development of study priorities, reporting of results, and obtaining external input
- Oversee the project team in each modeling center responding to any issues raised in assessment reports and initiate corrective actions as necessary with the Project Manager
- Monitor the effort to ensure that budget is not exceeded
- Assist in the performance of the modeling program in accordance with its contract and the Work Plan
- Develop individual test protocols and report as directed
- Analyze modeling data and provide assessment reports

1.8.2 ASIP Contracting Officer

The ASIP Contracting Officer (Patricia Brewer) serves as the primary contact between the Emissions and Air Quality Modeling Team and ASIP and performs the following functions:

- Provides day-to-day oversight of the ASIP Emissions and Air Quality Modeling Team activities
- Works with the Project Manager, Co-Principal Investigators, SESARM, ASIP States, collaborators, Stakeholders, etc. to define scope of work and to assure that the interests and concerns of all of the ASIP participants are appropriately represented as project priorities are developed or modified due to external input
- Assists in organizing and conducting meetings, conference calls, and workshops where this and related projects are discussed
- Reviews work products

1.8.3 ASIP Technical Contact

The ASIP Technical Contact (James Boylan) for the Emissions and Air Quality Modeling Team works with the ASIP Contacting Officer in the day-to-day oversight and management of the modeling analysis:

- Provides day-to-day oversight of ASIP Emissions and Air Quality Modeling Team activities
- Works with the ASIP Contracting Officer, Project Manager, and Co-Principal Investigators to assure that the study is being carried out in a technically correct fashion following the QAPP and Modeling Protocol
- Prepares and gives presentations to VISTAS groups on the activities of the Modeling team.
- Reviews work products.

1.8.4 ASIP States

The primary purpose of the ASIP Emissions and Air Quality Modeling work is to develop the regional modeling component for 8-hour ozone and $PM_{2.5}$ State Implementation Plans (SIPs) being developed by several southeastern U.S. states that are due June 2007 and April 2008, respectively. Most of the ten VISTAS states also participate in ASIP. Alabama, Georgia, North Carolina, Kentucky, Tennessee, Virginia, and West Virginia have $PM_{2.5}$ non-attainment areas and Alabama, Georgia, Kentucky, North Carolina, South Carolina, Tennessee, Virginia, and West Virginia have 8-hour ozone non-attainment areas. The ASIP states will oversee the regional emissions inventory development and ozone and fine particulate modeling that will be required for the State Implementation Plans (SIP's). Emissions Inventory efforts include the development of 2002 base case emissions inventories and future year forecasts to be utilized in the ASIP modeling efforts. Modeling efforts will include identification, evaluation, and application of air quality modeling tools to quantify the effects of emission management options upon air quality in 8-hour ozone and $PM_{2.5}$ nonattainment areas in the southeastern United States. Specific activities of the ASIP States include:

- Oversee the activities of the ASIP Emissions and Air Quality Modeling Team through the Contracting Officer, conference calls, and periodic in-person meetings and workshops
- Provides the Contracting Officer, technical Contact, Project Manager and Co-Principal Investigators input on the research plans and their ability to meet the needs of the various stakeholders relevant to the overall objectives of the project
- Provides input as needed to assure that the project has effective and appropriate peer review
- Makes the Project Manager and Co-Principal Investigators aware of other projects that may be of relevance to this project
- Reviews the Modeling Protocol and QAPP and conducts critical project reviews

1.9 Communications Plan

The ASIP Emissions and Air Quality Modeling Team members, other ASIP Contractors and ASIP representatives are linked by e-mail correspondence, and also use this as a means to communicate and exchange data, either as e-mail attachments, website or by network-accessible files. A considerable amount of information is exchanged by e-mail within this project. The ASIP Modeling Team will use the same four listservs as used by VISTAS to distribute information to different groups as indicated in Table 1-3.

Table 1-3. VISTAS listservs that will be used to distribute information by the ASIP Emissions and Air Quality Modeling Team and other ASIP participants.

Listserv	Purpose
Vistas-all@cert.ucr.edu	Contacts all participants including Modeling Team, VISTAS TAWG and Stakeholders
Vistas-modeling@cert.ucr.edu	Contacts Modeling team and VISTAS TAWG Modeling Contacts
Vistas-emissions@cert.ucr.edu	Contacts emissions staff in the Modeling team and emissions people in the VISTAS TAWG
Vistas-met@cert.ucr.edu	Contacts meteorology staff in the Modeling team and meteorology people in the VISTAS TAWG

The Modeling Team members and ASIP States and Contracting Officer hold periodic conference calls and meetings to report results, discuss project status, and modify work plans as necessary. Unscheduled meetings or conference calls are also held concerning specific issues as the needs arise. In addition, periodic project meetings and conference calls are held. In these meetings detailed technical information is exchanged, project status is discussed, and project direction is assessed.

Written progress reports on the ASIP Emissions and Air Quality Modeling Team activities are submitted to the ASIP Contracting Officer on a monthly basis. These reports summarize project progress, results to date, problems encountered and necessary action items, and plans for the upcoming reporting period.

2.0 MODEL SELECTION

This chapter introduces the regional meteorological, emissions and air quality models to be used in the 8-hour ozone and $PM_{2.5}$ regional modeling for ASIP. The specific science configurations for each modeling system are identified and discussed briefly, where necessary. The configurations of each modeling system have been selected as the culmination of the regional modeling performed as part of the closely related VISTAS regional haze modeling efforts.

2.1 Recommended Models

Based on the findings in the VISTAS Phase I and II modeling activities, ASIP selected the following models for use in modeling 8-hour ozone and particulate matter (PM) of size of 2.5 microns or less ($PM_{2.5}$):

- **MM5:** The Pennsylvania State University/National Center for Atmospheric Research (PSU/NCAR) Mesoscale Meteorological Model (MM5) is a nonhydrostatic, prognostic meteorological model routinely used for urban- and regional-scale photochemical, fine particulate, and regional haze regulatory modeling studies.

- **SMOKE**: The Sparse Matrix Operator Kernel Emissions (SMOKE) modeling system is an emissions modeling system that generates hourly gridded speciated emission inputs of mobile, nonroad, area, point, fire and biogenic emission sources for photochemical grid models.

- **CMAQ:** EPA's Models-3/Community Multiscale Air Quality (CMAQ) modeling system is a 'One-Atmosphere' photochemical grid model capable of addressing ozone, particulate matter (PM), visibility and acid deposition at regional scale for periods up to one year.

Application of the MM5 for the 2002 annual period and the ASIP 36/12 km domains was performed by BAMS under contract to SESARM as part of the VISTAS Phase II activities. Details of the model application and evaluation procedures being carried out by BAMS may be found at http://www.baronams.com/projects/VISTAS/. For completeness, in this chapter we describe the three regional modeling systems and their intended use in the ASIP 2002 annual modeling.

2.2 MM5 Mesoscale Prognostic Model

Over the past decade, researchers at the Pennsylvania State University (PSU) and the National Center for Atmospheric Research (PSU/NCAR) have collaborated in the refinement and extension of the PSU Mesoscale Meteorological Model leading to the current version of the system, MM5 (Ver 3.6, MPP). Originally developed in the 1970s at PSU and first documented by Anthes and Warner (1978), the MM5 modeling system maintains its status as a state-of-the-science model through enhancements provided by a broad user community (e.g., Chen and

Dudhia, 2001; Stauffer and Seaman, 1990, 1991; Xiu and Pleim, 2000). The MM5 modeling system is routinely employed in forecasting projects as well as refined investigations of severe weather. Utilization of MM5 within air quality applications is also a common practice. In recent years, the MM5 modeling system has been successfully applied in continental scale annual simulations for the years 1996 (Olerud et al., 2000), 2001 (McNally and Tesche, 2003), and 2002 (Johnson, 2003). Due to its ongoing scientific development worldwide, extensive historical applications, broad user community support, public availability, and established performance record compared with other applications-oriented prognostic models, ASIP/VISTAS selected the MM5 as the preferred meteorological model. This section provides an overview of the MM5 and its data input requirements.

2.2.1 MM5 Overview

The non-hydrostatic MM5 model (Dudhia, 1993; Grell et al., 1994) is a three-dimensional, limited-area, primitive equation, prognostic model that has been used widely in regional air quality model applications (Seaman, 2000). The basic model has been under continuous development, improvement, testing and open peer-review for more than 20 years (Anthes and Warner, 1978; Anthes et al., 1987) and has been used world-wide by hundreds of scientists for a variety of mesoscale studies, including cyclogenesis, polar lows, cold-air damming, coastal fronts, severe thunderstorms, tropical storms, subtropical easterly jets, mesoscale convective complexes, desert mixed layers, urban-scale modeling, air quality studies, frontal weather, lake-effect snows, sea-breezes, orographically induced flows, and operational mesoscale forecasting.

MM5 is based on the prognostic equations for three-dimensional wind components (u, v, and w), temperature (T), water vapor mixing ratio (q_v), and the perturbation pressure (p'). Use of a constant reference-state pressure increases the accuracy of the calculations in the vicinity of steep terrain. The model uses an efficient semi-implicit temporal integration scheme and has a nested-grid capability that can use up to ten different domains of arbitrary horizontal and vertical resolution. The interfaces of the nested grids can be either one-way or two-way interactive. The model is also capable of using a hydrostatic option, if desired, for coarse-grid applications.

MM5 uses a terrain-following non-dimensionalized pressure, or "sigma", vertical coordinate similar to that used in many operational and research models. In the non-hydrostatic MM5 (Dudhia, 1993), the sigma levels are defined according to the initial hydrostatically-balanced reference state so that the sigma levels are also time-invariant. The gridded meteorological fields produced by MM5 are directly compatible with the input requirements of 'one atmosphere' air-quality models using this coordinate (e.g., CMAQ). MM5 fields can be easily used in other regional air quality models with different coordinate systems (e.g., CAMx) by performing a vertical interpolation, followed by a mass-conservation re-adjustment.

Distinct planetary boundary layer (PBL) parameterizations are available for air-quality applications, both of which represent sub-grid-scale turbulent fluxes of heat, moisture and momentum. These parameterizations employ various surface energy budget equations to estimate ground temperature (T_g), based on the insolation, atmospheric path length, water vapor, cloud cover and longwave radiation. The surface physical properties of albedo, roughness length, moisture availability, emissivity and thermal inertia are defined as functions of land-use for numerous categories via a look-up table. One scheme uses a first-order eddy diffusivity formulation for stable and neutral environments and a modified first-order scheme for unstable regimes. The other uses a prognostic equation for the second-order turbulent kinetic energy, while diagnosing the other key boundary layer terms.

Initial and lateral boundary conditions are specified from mesoscale three-dimensional analyses performed at 12-hour intervals on the outermost grid mesh selected by the user. Additional surface fields are analyzed at three-hour intervals. A Cressman-based technique is used to analyze standard surface and radiosonde observations, using the National Meteorological Center's (NMC) spectral analysis as a first guess. The lateral boundary data are introduced into MM5 using a relaxation technique applied in the outermost five rows and columns of the most coarse grid domain.

A major feature of the MM5 is its use of state-of-science methods for Four Dimensional Data Assimilation (FDDA). The theory underlying this approach and details on how it has been applied in a variety of applications throughout the country are described in depth elsewhere (Stauffer and Seaman, 1990, 1991; Seaman et al., 1992, 1997).

Results of detailed performance evaluations of the MM5 modeling system in regulatory air quality application studies have been widely reported in the literature (e.g., Emery et al., 1999; Tesche et al., 2000, 2003) and many have involved comparisons with other prognostic models such as RAMS and SAIMM. The MM5 enjoys a far richer application history in regulatory modeling studies compared with RAMS or other models. Furthermore, in evaluations of these models in over 60 recent regional scale air quality application studies since 1995, we have generally found that MM5 model tends to produce somewhat better photochemical model inputs than alternative models. For these and other reasons set forth in the MM5 modeling protocol developed by BAMS (Olerud and Sims, 2003), MM5 was selected as the meteorological modeling system for the ASIP/VISTAS study.

2.2.2 MM5 Configuration for ASIP and VISTAS Phase II Modeling

Based on the extensive sensitivity testing carried out by Olerud and Sims (2003) as part of VISTAS, the MM5 (Ver 3.6, MMP) configuration to be used by BAMS modelers in the VISTAS Phase II modeling that will also be used by ASIP will consist of the following (see Table 2-3 for more details):

> Nested 36/12 km grids, with 34 vertical layers;
> Two way nesting, no feedback;
> Initialization and boundary conditions from Eta analysis fields;
> Pleim-Xiu (P-X) soil model;
> Asymmetric Convective Mixing (ACM) PBL model;
> Kain-Fritsch 2 cumulus parameterization;
> Mixed phase (Reisner 1) cloud microphysics;
> Raptid Radiative Transfer Model (RRTM) radiation;
> Snow effect turned on;
> ETA model sea surface temperature;
> 24-category USGS vegetation data sets;

> Thermal roughness by the Garratt method; and
> Standard FDDA analysis nudging on 36 km and 12 km grid nests.

2.3 SMOKE Emissions Modeling System

2.3.1 SMOKE Overview

The Sparse Matrix Operator Kernel Emissions (SMOKE) Emissions Processing System Prototype was originally developed at MCNC (Coats, 1995; Houyoux and Vukovich, 1999). As with most 'emissions models', SMOKE is principally an *emission processing system* and not a true *emissions modeling system* in which emissions estimates are simulated from 'first principles'. This means that, with the exception of mobile and biogenic sources, its purpose is to provide an efficient, modern tool for converting emissions inventory data into the formatted emission files required by an air quality simulation model. For mobile sources, SMOKE actually simulates emissions rates based on input mobile-source activity data, emission factors and in some cases, outputs from transportation travel-demand models.

SMOKE was originally designed to allow emissions data processing methods to utilize emergent high-performance-computing (HPC) as applied to sparse-matrix algorithms. Indeed, SMOKE is the fastest emissions processing tool currently available to the air quality modeling community. The sparse matrix approach utilized throughout SMOKE permits both rapid and flexible processing of emissions data. The processing is rapid because SMOKE utilizes a series of matrix calculations instead of less efficient algorithms used in previous systems. The processing is flexible because the processing steps of temporal projection, controls, chemical speciation, temporal allocation, and spatial allocation have been separated into independent operations wherever possible. The results from these steps are merged together at a final stage of processing.

SMOKE supports area, mobile, fire and point source emission processing and also includes biogenic emissions modeling through a rewrite of the Biogenic Emission Inventory System, Version 3 (BEIS3) (see, http://www.epa.gov/ttn/chief/software.html#pcbeis). SMOKE has been available since 1996, and it has been used for emissions processing in a number of regional air quality modeling applications. In 1998 and 1999, SMOKE was redesigned and improved with the support of the U.S. Environmental Protection Agency (EPA), for use with EPA's Models-3/CMAQ (http://www.epa.gov/asmdnerl/models3). The primary purposes of the SMOKE redesign were support of: (a) emissions processing with user-selected chemical mechanisms and (b) emissions processing for reactivity assessments.

SMOKE contains a number of major features that make it an attractive component of the VISTAS modeling system (Seppanen, 2003). The model supports a variety of input formats from other emissions processing systems and models including the Inventory Data Analyzer (IDA), Emissions Modeling System—2003 (EMS-2003), and the Emissions Preprocessor System 2.x (EPS2.x). It supports both gridded and county total land use scheme for biogenic emissions modeling. Although not necessary in ASIP, SMOKE can accommodate emissions files from up to 10 countries and any pollutant can be processed by the system.

Recent *computational improvements* to SMOKE include: (a) enhanced disk space requirements compared with other emissions processing software, (b) run-time memory allocation, eliminating any need to recompile the programs for different inventories, grids, or chemical mechanisms, and (c) updated I/O API libraries. A number of *science features* have been incorporated into the version 2.0 of SMOKE including: (a) any chemical mechanism can be used to partition pollutants to model species, as long as the appropriate input data are supplied, (b) integration with the MOBILE6.2 on-road mobile source emissions model including link based processing, (c) support of plume-in-grid (PiG) processing, (d) integration of the BEIS3 emissions factors in SMOKE.

Notable features of SMOKE from an *applications* standpoint include: (a) improved control strategy input formats and designs, (b) control strategies can include changes in the reactivity of emitted pollutants, a useful capability, for example, when a solvent is changed in an industrial process, (c) no third party software is required to run SMOKE, although some input file preparation may require other software, (d) fewer SMOKE programs than the SMOKE prototype because programs were combined where possible to be used for multiple source categories, (e) integration with Models-3 file formats and settings, (f) improved data file formats, (g) support of various air quality model emissions input formats (e.g., CMAQ, MAQSIP, UAM-IV, UAM-V, REMSAD and CAMx), (h) enhanced quality assurance pre- and post-processing, (h) fully integrated with Models-3, which will provide the SMOKE Tool for SMOKE input file preparation, (i) enhanced treatment of growth and control factors, (j) improved emissions reporting and QA capabilities, and (k) improved temporal allocation.

Continuing model development activities with SMOKE now occur out of the University of North Carolina (UNC) Carolina Environmental Program (CEP). SMOKE beta Version 1.5b was released 17 March 2003 and this is the version employed in the VISTAS Phase I modeling. Several patches to the model were provided during the summer of 2003, and SMOKE Version 2.0 was released on 30 Sept '03. In 2004 SMOKE Version 2.1 was released that contained further improvements and enhancements. The VISTAS/ASIP modeling adopted SMOKE Version. 2.1 at that time. In September 2005 SMOKE Version 2.2 was released by the Community Modeling and Analysis (CMAS) center's Model Clearinghouse at http://www.cmascenter.org/modelclear.shtml. At that time ASIP/VISTAS had expended considerable effort in setting up and performing emissions modeling using SMOKE Version 2.1. Additionally, the upgrades identified in Version 2.2 were options that ASIP/VISTAS had circumvented using existing file code and formats and switching to this latest version was felt could jeopardize the modeling schedule. Consequently, ASIP elected to continue emissions modeling using SMOKE Version 2.1. The SMOKE user's guide is available online at the main SMOKE website, http://www.cep.unc.edu/empd/products/smoke.

2.3.2 SMOKE Configuration for ASIP Modeling

As an emissions processing system, SMOKE has far fewer 'science configuration' options compared with the MM5 and CMAQ models. For a thorough characterization of the methods that will be used to exercise the SMOKE system for the annual 2002 emissions processing, see Section 5.2, "Development of Emissions Model Inputs and Resultant Inventories". Table 2-4 summarizes the version of the SMOKE system to be used and the sources of data to be employed in constructing the required modeling inventories.

2.4 CMAQ Modeling System

2.4.1 CMAQ Overview

For more than a decade, EPA has been developing the Models-3 Community Multiscale Air Quality (CMAQ) modeling system with the overarching aim of producing a 'One-Atmosphere' air quality modeling system capable of addressing ozone, particulate matter (PM), visibility and acid deposition within a common platform (Dennis, et al., 1996; Byun et al., 1998a; Byun and Ching, 1999, Pleim et al., 2003). The original justification for the Models-3 development emerged from the challenges posed by the 1990 Clean Air Act Amendments and EPA's desire to develop an advanced modeling framework for 'holistic' environmental modeling utilizing state-of-science representations of atmospheric processes in a high performance computing environment (Ching, et al., 1998). EPA completed the initial stage of development with Models-3 and released the Community Multi-Scale Air Quality model (CMAQ) in mid-1999 as the initial operating science model under the Models-3 framework (Byun et al., 1998b). Since the initial CMAQ release in 1999, there have typically been annual[GMS1]

CMAQ consists of a core Chemical Transport Model (CTM) and several pre-processors including the Meteorological-Chemistry Interface Processor (MCIP), initial and boundary conditions processors (ICON and BCON) and a photolysis rates processor (JPROC). EPA is continuing to improve and develop new modules for the CMAQ model and typically provides a new release each year. In the past EPA has also provides patches for CMAQ as errors are discovered and corrected. EPA has funded the Community Modeling and Analysis Systems (CMAS) center to support the coordination, update and distribution of the Models-3 system.

A number of features in CMAQ's theoretical formulation and technical implementation make the model well-suited for annual PM and 8-hour ozone modeling. In CMAQ, the modal approach has been adapted to dynamically represent the PM size distribution using three log-normal modes (2 fine and 1 coarse). Transfer of mass between the aerosol and gas phases is assumed to be in equilibrium and all secondary aerosol (sulfate, nitrate, SOA) is assumed to be in the fine modes. The thermodynamics of inorganic aerosol composition are treated using the ISORROPIA module. Aerosol composition is coupled to mass transfer between the aerosol and gas phases. For aqueous phase chemistry, the RADM model is currently employed. This scheme includes oxidation of SO_2 to sulfate by ozone, hydrogen peroxide, oxygen catalyzed by metals and radicals. The impact of clouds on the PM size distribution is treated empirically. For wet deposition processes, CMAQ uses the RADM/RPM approach. Particle dry deposition is included as well. CMAQ contains three options for treating secondary organic aerosol (SOA), latest being the Secondary Organic Aerosol Model (SORGAM) that was updated in August 2003 to be an reversible semi-volatile scheme whereby VOCs can be converted to condensable gases that can then form SOA and then evaporate back into condensable gases depending on atmospheric conditions. Gas-phase chemistry can be treated by the CB4, RADM or SAPRC chemical mechanisms.

Pleim et al., (2003) describe the features implemented in CMAQ Version 4.3 (released August 2003). Many of these features are mentioned above; others pertain to details in the model's chemistry, transport, computer implementation, and model operation. In September 2004 CMAQ Version 4.4 was released that included updates and enhancements (Pleim, 2004). CMAQ Versions 4.3 and 4.4 were used for much of the VISTAS Phase I and II testing and model performance evaluation. In October 2005 CMAQ Version 4.5 was released (Pleim, 2005) which has been adopted for the ASIP and VISTAS modeling.

The VISTAS model evaluation indicated fairly good performance for sulfate, winter overestimation bias and summer underestimation bias for nitrate and reasonably good performance for Elemental Carbon (EC), albeit with lots of scatter and low correlation. However, Organic Carbon (OC) was underestimated with the summer OC underestimation bias being quite severe. As OC is typically the second most important PM component contribution to visibility impairment and is the most or second most important component contributing to $PM_{2.5}$ violations in the southeastern US, VISTAS and ASIP were concerned with the large OC underestimation tendency. After an intense focused analysis of the issue, VISTAS identified processes important to the formation of Secondary Organic Aerosols (SOA) that were not included in the CMAQ SOA module that may be important to OC in the Southeastern US (Morris et al., 2005). Consequently, VISTAS enhanced the CMAQ SOA module by adding several new processes. This enhancement, called SOAmods described below, was implemented in CMAQ Version 4.4 and exhibited much improved OC model performance over the standard CMAQ SOA treatment (Morris et al., 2005b).

In October 2005, the new Version 4.5 of CMAQ was released (Pleim, 2005). CMAQ Version 4.5 included several enhancements and corrections, including a correction to the CMAQ mass conservation scheme. Given the importance of mass conservation in air quality modeling, ASIP and VISTAS have adopted an enhanced version of CMAQ Version 4.5 for their modeling and transferred the SOAmods enhancement to it.

2.4.3 CMAQ Version 4.5

CMAQ Version 4.5 has several corrections, updates and enhancements over earlier versions of the model:

1) Aerosols
   - Added sea salt (fine equilibrium; non-interactive coarse mode) -- aero4
   - Updated aerosol dry deposition algorithm
   - Updated mechanism include files to remove any aerosol species with zero concentrations for aero4
   - Updated ISORROPIA to v1.5 (25 Oct 2003) and fixed some discontinuities
   - Added diagnostic variables to calculate PM2.5 concentrations
   - Corrected bug in mode merging to reduce mode crossover
   - Modified SO4 used in ISORROPIA call
   - Corrected inconsistency in MINL2SG (aerodepv)
   - Corrected the EMSULF (H2SO4 emissions) unit conversion bug

2) Chemistry
   - Added CB4/chlorine chemistry and associated EBI solver
   - Added CB4/air toxics and SAPRC99/air toxics chemistry and associated EBI solvers
   - Added degradation algorithm to the generalized solvers
   - Corrected treatment of convergence failures in EBI solvers

- No longer support the RADM2 mechanism

3) P-in-G
   - Improved calculation of plume centerline
   - Fixed bug in the aerosol species array subscripting
   - Corrected error in non-reactive species NH3 fluxes and dry deposition

4) PBL modeling
   - Updated to use PURB (% urban) for setting minimum Kz

5) Clouds
   - Added new sub-grid cloud mixing algorithm/module (based on ACM)
   - Added new cloud diagnostic variables
   - Corrected the interpolation times for resolved clouds (to time-step midpoint) and for subgrid clouds (to half hour)

6) Advection
   - Added new mass continuity scheme

7) Other
   - Added dynamic vertical layer allocation
   - Added primary carbon source apportionment capability
   - Added sulfate tracking capability

Thus, even though VISTAS Phase I and II modeling testing and evaluation and initial ASIP runs were performed using CMAQ Versions 4.3 and 4.4 and considerable effort has been committed to these earlier versions of CMAQ, the CMAQ Version 4.5 model updates were significant enough that VISTAS and ASIP decided to switch over to the new version (Ver 4.5) of CMAQ.

In the VISTAS testing and evaluation of the CMAQ V4.3 and V4.4, the model performance for Organic Carbon (OC) was characterized by a systematic under-prediction bias that was particularly severe in the summer. As OC is one of the two most important PM components for $PM_{2.5}$ exceedances and visibility degradation in the Southeastern US (SO4 being the other), VISTAS/ASIP were concerned with this underestimation tendency. Thus, VISTAS performed research in this area and identified several missing processes related to Secondary Organic Aerosol (SOA) formation in the CMAQ model. In particular, CMAQ failed to account for SOA from several biogenic emission sources such as sesquiterpenes and isoprene. Consequently, VISTAS enhanced the CMAQ SOA module to treat these missing processes that resulted in improved OC performance (Morris et al., 2006). This SOAmods enhancement is discussed next.

2.4.4 SOAmods Enhancement

The formulation of the CMAQ SOA module is described in Binkowski and Roselle (2003). SOA is formed primarily from aromatic VOCs and biogenic terpenes. The biogenic

SOA precursors were modeled with the Biogenic Emissions Information System – Version 3 (BEIS3) model (Pierce et al., 2002). BEIS3 generates three biogenic VOC species: isoprene (ISOP), monoterpenes (TERP) and other biogenic VOC (OVOC). For this study, the Carbon Bond IV photochemical mechanism was used (Gery et al., 1987) that represents VOC compounds based on their carbon bond structure. The BEIS3 ISOP, TERP and OVOC species are speciated into the CB4 species for photochemical modeling in CMAQ and CAMx as follows (molar speciation):

- ISOP = ISOP (isoprene is an explicit species)
- ALD2 = 1.5 x TERP
- OLE = 0.5 x TERP
- PAR = 6.0 x TERP
- NR = 0.5 x OVOC
- OLE = 0.5 x OVOC
- PAR = 8.5 x OVOC
- TERPB = TERP

Here, ALD2, OLE, PAR and NR are the CB4 chemical mechanism representations of the biogenic VOC emissions as high molecular weight aldehydes, olefinic carbon bond, paraffin carbon bond and non-reactive functional groups. In CMAQ, the TERPB species is specified in the emissions inputs, along with its CB4 representation of ALD2, OLE and PAR, but does not participate in the photochemical mechanism and is only used in the SOA formation module. The TERPB species forms a SGTOT species based on oxidation parameters extracted from the photochemical module. SGTOT consists of the combined gaseous condensable gas (CG) plus particle SOA that are assumed to be in equilibrium. CMAQ transports the SGTOT species and splits it to a CG gaseous and particle SOA for output.

The CMAQ TERB SOA formation rate is based on a fit to smog chamber data collected at the California Institute of Technology for several biogenic monoterpene species (Binkowski and Roselle, 2003). A review of recent literature of biogenic SOA measurements identified several processes that may be important to biogenic SOA formation that are not treated by the BEIS3 biogenic emissions and the CMAQ SOA module:

Polymerization: Recent measurements indicate that some SOA species may polymerize, resulting in species that are no longer volatile and cannot evaporate back to a CG. In this case, the equilibrium assumption between the CG and SOA will understate the amount of particle SOA present in the atmosphere (Kalberer et al., 2004; Jang et al., 2002).

Sesquiterpenes: Sesquiterpenes are not accounted for in the BEIS3/CMAQ SOA modeling system (Guenther et al., 2000; Vizuete et al., 2004).

Isoprene: More recent evidence suggests that isoprene can also form particle SOA compounds that are not accounted for in CMAQ (Claeys et al., 2004; Matsunaga et al., 2003; 2005).

Acid Catalyzation: Recent literature also suggests that some SOA formation may have acid catalyzed reactions (Claeys et al., 2004; Jang et al., 2005).

Heterogeneous Reactions: Recent evidence suggests that some SOA formation may occur during heterogeneous aqueous-phase chemical reactions (Yu et al., 2005).

A prototype module was added to CMAQ that accounted for the first three processes listed above. The last two processes were not included in this work because there are not enough quantitative experimental data yet to establish a parameterization. Modules were added to the CMAQ SOA module under the following constraints:

- The existing CMAQ SOA module for monoterpenes would remain unchanged;
- The same CMAQ model inputs would be used; and
- The basic CMAQ model formulation would remain unchanged, modules would be added to account for polymerization and SOA from sesquiterpenes and isoprene.

Figure 2-1 displays how the prototype representation of new processes to represent SOA polymerization and SOA formation from sesquiterpenes and isoprene were added to the CMAQ SOA module using the existing CMAQ structure and inputs. The new components of the SOA module are indicated in bold italic, whereas the existing CMAQ SOA components (Binkowski and Roselle, 2002) use a regular font. There are several parameters that must be defined in the new elements of the enhanced SOA module: emission factors (EF), canopy escape efficiencies for gases (EEG) and aerosols (EEA) and SOA yields (Y). Based on an analysis of recent measurements, primarily from a recent biogenic emissions field study in Duke Forest, North Carolina (Stroud et al., 2005; Matsunaga et al., 2005), a range of values for the factors in Figure 2-1 were developed as shown in Table 2-1. For the initial prototype of the enhanced SOA module, we selected the mid-point of the range values for the factors from the measurements (Table 2-1). No attempt was made to optimize the parameters in Table 2-1 for OC/TCM model performance.

The emission factors, EF1 and EF2, relate the monoterpene emissions estimated by BEIS3 to emissions of monoterpenes, EF1 (e.g., α-pinene), and sesquiterpenes (EF2). Table 2-1 displays the range of EF1 and EF2 factors based on recent field study data (Stroud et al., 2005). Using the midpoint of the range results in emission factors of 0.7 for EF1 and 0.4 for EF2. EF1 is assigned a value of 0.7 based on field observations that indicate that the BEIS3 terpene emission factors are likely overestimated due to a tendency of earlier measurements approaches to artificially increase the emissions due to disturbance when leaves were enclosed in the measurement system. As an initial approach for including sesquiterpene emissions, we have assigned EF2 a value of 0.4 based on the ratio of the observed sesquiterpene emission from the Duke Forest field study (Stroud et al, 2005) to the BEIS3 monoterpene emission estimate. The net result is that BEIS3 TERP emissions are increased by 10% and split 64% as monoterpenes and 36% as sesquiterpenes. The CG yields from the sesquiterpenes are assumed to partly condense into a non-volatile SOA particle that is modeled in CMAQ using the new secondary organic carbon species (SOC2) species and only some of the gas and aerosol species associated with sesquiterpenes are assumed to escape from the canopy using the mid-range of the Escape Efficiencies (EE) estimated by Stroud et al. (2005). The fraction of BEIS3 TERP emissions that are assumed to be monoterpenes (i.e., 64% of the emissions) are treated with the standard CMAQ two-product SOA module (Binkowski and Roselle, 2003) assuming equilibrium between the CG and SOA with the SOA output in the standard AORGB species (Binkowski and Roselle, 2003).

The isoprene SOA formation pathway forms a CG using the mid-point yield rate based on the range of recent measurements (Stroud et al., 2005) and a CG/SOA partitioning rate based on the mid-point of measurements from Matsunaga et al. (2003, 2005) (Table 2-1). The isoprene SOA is assumed to be volatile and is modeled as a new secondary organic carbon species in CMAQ SOAmods (SOC3). Finally, all SOA species, with the exception of the already non-volatile SOC1 (polymerized SOA) and SOC2 (sesquiterpene product) species, are assumed to partially polymerize into non-volatile particles that are stored in the SOC1 species. The polymerization rate is based on the results of Kalberer et al (2004) who found that 50% of the SOA polymerized in 20 hours.

Several levels of Quality Assurance and Quality Control of the enhanced SOAmods module in the CMAQ model were conducted as follows.

QA/QC of SOAmods Coding: The SOAmods implementation was conducted at ENVIRON. Staff at the University of California at Riverside performed independent QA/QC of the SOAmods code implementation and independent testing and evaluation.

QA of SOAmods Formulation: The new processes being added to the CMAQ SOA module was discussed with researchers at EPA's Office of Research and Development (ORD). Although they have not completed all the laboratory tests, the inclusion of SOA from sesquiterpene and isoprene has been observed and are supported.

Peer Review of SOAmods: The formulation of the SOAmods enhancement to the CMAQ SOA module was documented and comments were received by several parties. The results were also written up and submitted to *Atmospheric Environment* where it was subjected to peer review and is awaiting publication (Morris et al., 2006).

Model Performance Evaluation of SOAmods: The final level of QA of the SOAmods was comparisons of CMAQ V4.4 model performance with and without including the SOAmods enhancement. Table 2-2 displays fractional bias error for Organic Carbon (OC) IMPROVE and STN monitoring sites in the VISTAS, MRPO, MANE-VU and CENRAP states using the standard CMAQ Version 4.4 (V4.4) and then CMAQ V4.4 with the SOAmods enhancement. Whereas the standard CMAQ V4.4 underestimates OC across IMPROVE sites of from –76% (MRPO) to –102% (VISTAS), with the SOAmods enhancement the fractional biases centered on zero and ranges from –14% to +8%. Similar results are seen for OC fractional bias across the more urban STN sites where the CMAQ V4.4 exhibits an underestimation bias of –67% to –105%, when using SOAmods the under-prediction bias is –27% to –44%. Note that the continued underestimation of OC across the urban STN sites is likely due to missing primary OC emissions and uncertainties in the STN OC measurements.

With the release of CMAQ Versions 4.5 in October 2005, the SOAmods enhancement was added to the AERO3 aerosol module in CMAQ Version 4.5 that was compared against the standard CMAQ Versions 4.5 and SOAmods was found to produce similar improvements in OC model performance as seen with CMAQ Versions 4.4. ASIP and VISTAS are now proceeding with their regional haze and 8-hour ozone/$PM_{2.5}$ modeling using the CMAQ Versions 4.5 SOAmods.

2.4.5 CMAQ Configuration for ASIP Modeling

The configuration of CMAQ used in the ASIP modeling is based on the extensive testing and evaluation of several versions and configurations of CMAQ performance as part of Phase I and II of the VISTAS modeling (Morris et al., 2004a,b; Morris et al., 2005a). As part of VISTAS, the science team has tested and evaluated CMAQ versions 4.3, 4.4beta, 4.4 and 4.5. When the CMAQ treatment of SOA was found to be incomplete, it was enhanced with the SOAmods update, first in CMAQ Version 4.4 and then in CMAQ Version 4.5. In this section we identify the main science options we recommend for 8-hour ozone and $PM_{2.5}$ modeling with CMAQ. In particular, we propose to run CMAQ Version 4.5 with the SOAmods enhancement and the configuration as shown in Table 2-5. The model would be set up and exercised on the same nested 36/12 km grid domain used in VISTAS, employing one-way grid nesting. That is, boundary conditions for the 12 km grid simulation are extracted from the 36 km run using the CMAQ BCON processor. A total of 19 vertical layers would be implemented, extending up to a region top of 100 mb (approximately 15 km AGL).

The PPM horizontal advection solver will be used along with the spatially varying (Smagorinsky) horizontal diffusion approach and K-theory for vertical diffusion. The new Yamertino vertical transport scheme of CMAQ Version 4.5 will be used to correct the mass conservation problems in past versions of the model. MM5 meteorological output based on the Pleim-Xiu Land-Surface Model (LSM) and the ACM planetary boundary layer (PBL) scheme will be used (see Table 2-3) and the recently updated CMAQ Meteorological-Chemistry Interface Processor (MCIP3.0) would process the MM5 data using the "pass through" option. The CB4 gas-phase, RADM aqueous-phase, and AERO4/ISORROPIA aerosol chemistry schemes are recommended for use in the CMAQ 2002 modeling. Treatment of reversible secondary organic aerosols would be simulated by the SORGAM implementation in CMAQ with the SOAmods enhancement described above.

2.5 Model Limitations

All mathematical models possess inherent limitations owing to the necessary simplifications and approximations made in formulating the governing equations, implementing them for numerical solution on fast computers, and in supplying them with input data sets and parameters that are themselves approximations of the full state of the atmosphere and emissions processes. Below, we list the more important limitations of the various modeling systems to be employed in ASIP and VISTAS modeling.

2.5.1 MM5

Four different configurations of the MM5 Land Soil Model (LSM) and Planetary Boundary Layer (PBL) were evaluated as part of the 2002 meteorological modeling. Depending on the meteorological variable (e.g., winds, temperature, moisture) and location (e.g., mountains, coastal, east, west) different LSM_PBL configurations performed better. The Pleim-Xiu Asymmetric Convective Mixing PX_ACM LSM_PBL configuration was selected because it consistency was near the top performing configuration in the VISTAS region across variables and locations and was never the worst performing configuration. However, there are numerous limitations in the MM5 with the LSM and PBL treatment being some of the most important. The MM5 PX_ACM frequently predicts very low PBL heights that can appear as "holes" in the spatial distribution of PBL heights that don't appear physically realistic and may affect air quality modeling. Although the MM5 PX_ACM configuration model performance in the VISTAS region mostly met performance benchmarks, the performance was much worst in the western U.S. In addition, there is a stochastic component of real world meteorology that is not captured by MM5. For example, for some ozone episodes stagnation is an important attribute that MM5 fails to simulate well as it tries to organize the flow fields. The MM5 model represents approximately 20 years of development by various researchers and is showing its age. The many limitations in MM5 have spawned the development of a new meteorological model, the Weather Research Forecast (WRF) model. However, the WRF model will not be used or tested in the VISTAS/ASIP modeling.

2.5.2 SMOKE

In the VISTAS Phase I study a number of undocumented features of the SMOKE 1.5b version necessitated re-runs of the emissions processing software to overcome errors and/or ambiguities in source documentation and QA reporting. Although there were fewer problems with the SMOKE Version 2.0 and 2.1 releases, problems were encountered that were not well documented that necessitated reruns of the model. In October 2005 Version 2.2 of SMOKE was released. However, for reasons discussed earlier, ASIP elected to keep using Version 2.1 and not transition to the new SMOKE Version 2.2. VISTAS has fully set up and evaluated SMOKE Version 2.1, including identification of problems in the modeling that have been corrected. Switching to the new Version 2.2 could not only cause a serious set back in the ASIP modeling schedule, it may result in picking up additional new undocumented errors in the new modeling system that could require rerunning scenarios. Should problems arise or issues be encountered which would require additional SMOKE runs or potential SMOKE modifications or alternate modeling methods, we will immediately notify ASIP and make recommendations for resolving the issues. Upon receipt of technical direction from ASIP, appropriate corrective action will be taken.

Features are continuing to be developed in the SMOKE emissions model. As it is not as mature as some other emission models (e.g., EMS, EPS, etc.) it does not include as many features. We will keep abreast of SMOKE development activities to identify new features that will assist in the ASIP emissions modeling.

2.5.3 CMAQ

Like all air quality models, a major limitation of CMAQ is the emissions, meteorological and IC/BC inputs. Key science limitations in the model itself include the nitrate formation and Secondary Organic Aerosol (SOA) chemistry. The VISTAS testing found the CMAQ nitrate performance suspect with winter overestimations and summer underestimations. Improvements in the ammonia emissions inventory and model formulation have improved this performance attribute, especially the winter overestimation bias. Deficiencies in the CMAQ SOA module have been partly corrected with the SOAmods enhancement. However, the current SOAmods formulation is based on very little data and more refined SOA enhancements are needed. Lack of any two-way grid nesting limits the ability of the model to properly resolve point source plumes or urban photochemistry a without a prohibitive number of grid cells. Another limitation of CMAQ is the computational requirements, including the need of excessive disk space.

2.6 Model Input Requirements

Each of the ASIP/VISTAS modeling system components has significant data base requirements. These data needs fall into two categories: those required for model setup and operation, and those required for model evaluation testing. Below, we identify the main input data base requirements for the meteorological, emissions, and air quality models.

2.6.1 MM5

The databases required to set up, exercise, and evaluate the MM5 model for the annual 2002 episode consist of various fixed and variable inputs.

- Topography: High resolution (e.g., 30 sec to 5 min) topographic information derived from the Geophysical Data Center global data sets from the National Center for Atmospheric Research (NCAR) terrain databases are available for prescribing terrain elevations throughout the 36 km and 12 km grid domain.

- Vegetation Type and Land Use: Vegetation type and land use information on the 36 km grid may be developed using the NCAR/PSU 10 min. (~18.5 km) databases while for the 12 km grids, the United States Geological Survey (USGS) data are available.

- Atmospheric Data: Initial and boundary conditions to the MM5 may be developed from operationally analyzed fields derived from the National Center for Environmental Predictions (NCEP) ETA (40 km resolution) following the procedures outlined by Stauffer and Seaman (1990). These 3-hr synoptic-scale initialization data the horizontal wind components (u and v), temperature (T), and relative humidity (RH) at the standard pressure levels, plus sea-level pressure (SLP) and ground temperature (T_g). Here, T_g represents surface temperature over land and sea-surface temperature over water.

- Water Temperature: Water temperatures required on both 36 km and 12 km grids can be derived from the ETA skin temperature variable. These temperatures are bi-linearly interpolated to each model domain and, where necessary, filtered to smooth out irregularities.

- Clouds and Precipitation: While the non-hydrostatic MM5 treats cloud formation and precipitation directly through explicit resolved-scale and parameterized sub-grid scale processes, the model does not require precipitation or cloud input. The potential for precipitation and cloud formation enters through the thermodynamic and cloud processes formulations in the model. The only precipitation-related input required is the initial mixing ratio field that is developed from the NWS and NMC data sets previously discussed.

- Multi-Scale FDDA: The standard "multi-scale" data assimilation strategy to be used on the 36 km and 12 km grids will objectively analyzed three-dimensional fields produced every 3-hr from the NWS rawinsonde wind, temperature, and mixing ratio data, and similar analyses generated every three hours from the available NWS surface data.

2.6.2 SMOKE

The databases required to set up and operate SMOKE for the ASIP 2002 annual simulation are as follows:

- Area Source emissions in IDA format
- Fugitive Dust Source emissions in IDA format
- Nonroad source emissions in IDA format
- Non-EGU Stationary Point Source emissions in IDA format
- EGU Stationary Point Source emissions in IDA format
- CEM-Based EGU Emissions, hour specific for 2002
- Prescribed, Agricultural, and Wildfire Emissions, day specific for 2002
- Onroad Motor Vehicle VMT and activity data
- MOBILE6.2 input parameters

Also required for annual modeling are data files specific for:

- Temporal allocation
- Spatial allocation
- Speciation

Chapter 5 discusses the data input requirements and data sources in detail.

2.6.3 CMAQ

As described in more detail in Chapter 5, the CMAQ Chemical Transport Model (CTM) requires the following inputs:

- Three-dimensional hourly meteorological fields that will be generated by the CMAQ MCIP3.0 processing of the BAMS MM5 output;
- Three-dimensional hourly emissions generated by SMOKE;
- Initial conditions and boundary conditions (IC/BC);
- Topographic information;
- Land use categories; and
- Photolysis rates generated by the CMAQ JPROC processor.

Table 2-1. Parameters use in enhanced SOA module (see Figure 2-1).

Parameter	Mid-Point	Range
EF1	0.7	0.4 ~ 1.0
EF2	0.4	0.2 ~ 0.6
EEG1	0.325	0.2 ~ 0.45
EEA1	0.2	0.05 ~ 0.35
Y2	0.875	0.75 ~ 1.0
Y1	0.11	0.06 ~ 0.16
P1	0.45	0.15 ~ 0.75

EF1 = emission factor of monoterpenes to the TERP emissions estimated by BEIS3
EF2 = emission factor of sesquiterpenes relative to the TERP emissions estimated by BEIS3
EEG1 = escape efficiency of gas phase precursor of sesquiterpenes from canopy
EEA1 = escape efficiency of SOA from sesquiterpenes from canopy
Y1 = SOA yield of oxidated isoprenes
Y2 = SOA yield of sesquiterpenes

Table 2-2. Comparison of fractional bias performance metric for Organic Carbon (OC) using the standard CMAQ Version 4.4 (V4.4) and CMAQ V4.4 with the SOAmods enhancement.

July 2002 Fractional Bias	IMPROVE OC		STN OC	
	V4.4	SOAmods	V4.4	SOAmods
Southeastern U.S.	-102%	-2%	-105%	-32%
Midwestern U.S.	-76%	+12%	-67%	-24%
Northeast U.S.	-82%	-14%	-95%	-44%
Central U.S.	-98%	+8%	-81%	-27%

3.0 EPISODE SELECTION

This chapter provides a brief overview of the process followed by the ASIP in determining the most appropriate period(s) for $PM_{2.5}$ and 8-hour ozone modeling to be used in the Southeastern States $PM_{2.5}$ and 8-hour ozone attainment demonstrations for their State Implementation Plans (SIPs). As discussed in more detail below, one criteria in selecting modeling periods for attainment demonstration modeling is the selection of modeling periods for which databases already exist, if appropriate. This was a major criteria for the ASIP 8-hour ozone and $PM_{2.5}$ modeling that relied heavily on the VISTAS modeling databases. Thus, the ASIP episode selection was based on the analysis by the VISTAS Technical Analysis Work Group (TAWG) selection of the 2002 annual period for regional haze modeling. ASIP reviewed the 2002 annual period and also found it suitable for $PM_{2.5}$ and 8-hour ozone modeling. While ASIP and the VISTAS TAWG plan to prepare a formal report documenting these activities, this work was not available at the time of this writing. However, much of the technical work underpinning the ASIP/VISTAS episode selection process has been published and peer-reviewed over the later stages of the VISTAS work efforts and it is this body of information that we have distilled in preparing the brief episode selection summary that follows.

3.1 Overview of EPA Guidance

EPA's current draft guidance on $PM_{2.5}$/Regional Haze modeling (EPA, 2001) and final guidance for 8-hour ozone modeling (EPA, 2005) identifies specific goals to consider when selecting one or more episodes for use in demonstrating attainment of the $PM_{2.5}$ and 8-hour ozone NAAQS. There is much in common with selecting episodes for annual and episodic $PM_{2.5}$ and 8-hour ozone attainment demonstrations, as well as regional haze, EPA's guidance addresses all three in a consistent fashion in their guidance documents (EPA, 2001; 2005). As an update to the draft $PM_{2.5}$ and regional haze modeling guidance, EPA has published an updated summary of $PM_{2.5}$ and Regional Haze Modeling Guidance (Timin, 2002) that serves, in some respects, as in interim placeholder until the final guidance is issued as part of the PM2.5/regional haze NAAQS implementation process that is expected during 2006.

EPA recommends that episode selection derive from three principal criteria:

- A variety of meteorological conditions that lead to exeedances of the $PM_{2.5}$ and 8-hour ozone NAAQS should be covered;
- To the extent possible, the modeling data base should include days for which extensive data bases (i.e. beyond routine aerometric and emissions monitoring) are available; and
- Sufficient days should be available such that relative reduction factors (RRFs) can be based on several days ($\geq$ 15 days, with at least 5 days being essentially mandatory).

For regional haze and annual $PM_{2.5}$ modeling, the guidance goes further by suggesting that the preferred approach is to model a full, *representative* year (EPA, 2001, pg. 188). EPA also lists several 'other considerations' to bear in mind when choosing potential PM/regional haze and 8-hour ozone modeling episodes including: (a) choose periods which have already been modeled; (b) choose periods which are drawn from the years upon which the current design values are based; (c) include weekend days among those chosen; and (d) choose modeling periods that meet as many episode selection criteria as possible in the maximum number of nonattainment areas as possible.

ASIP and VISTAS adopted a logical, stepwise approach in implementing the EPA guidance in order to identify the most preferable, representative year for $PM_{2.5}$, regional haze and 8-hour modeling. These steps are summarized briefly in this chapter.

3.2 Episode Selection Methodology

The episode selection methodology entailed coordinated investigations by ASIP and VISTAS contractors and members of the VISTAS Technical Analysis Workgroup (TAWG). To begin, Olerud (2003b) identified important meteorological characteristics and data sets in the Southeastern U. S. directly relevant to the evaluation of candidate annual modeling episodes. A separate detailed aerometric analysis and pattern recognition study was carried out by ICF (Douglas et al., 2003) to characterize the extent to which days from January-March 2002 and January-March 2003 represent the type of meteorological conditions that are most frequently associated with high and low values of a haze index and $PM_{2.5}$ concentrations. Using the standard Classification and Regression Tree (CART) analysis software, these researchers characterized each of the days within these two three-month periods relative to haze and $PM_{2.5}$ observations as well as other relevant meteorological factors. This work was based on previous episode characterization work carried out in support of the SEARCH and MARAMA research projects (Douglas et al., 2003). The analysis was also supported by climate summaries provided by the North Carolina Division of Air Quality (NCDAQ).

In parallel with the CART episode characterization analyses, collaborative investigations by ASIP and VISTAS TAWG participants (e.g., NCDAQ, Georgia DNR, FL DEP) intensively studied the availability of $PM_{2.5}$ ozone, meteorological, and emissions data and representativeness of alternative Baseline modeling periods from a regulatory standpoint (Boylan et al., Brewer et al., 2003). Daily average speciated $PM_{2.5}$ monitoring data in the Southeastern US were review intensively, by site and by monitoring network (e.g., IMPROVE, SEARCH, STN, FRM). 8-hour ozone data for the nonattainment areas were also analyzed. In addition to analyzing data representativeness, consideration was given to the timeliness with which new data could be obtained for the ASIP and VISTAS modeling. Also, data availability from parallel meteorological and emissions database acquisition efforts was considered both for the Southeastern US states as well as for other states and countries in the 36 km domain.

To assess the representativeness of the five year baseline 2000-2004 period that is used in the 8-hour ozone, PM2.5 and regional haze projections (see Chapter 8), temperature and precipitation records were examined over the 108 yr period of record and additional high-resolution meteorological analyses were considered (e.g., CART analyses for SEARCH and MARAMA sites). For each PM2.5 monitoring site in the VISTAS domain, and for each component of PM 2.5, monthly means and deviations (from the monthly mean) were calculated for the months within the 2002-2003 period of record. Daily, monthly, and annual trends of PM 2.5 concentrations across the three year period were subsequently analyzed (Boylan et al., 2003). Equally as important, the methodologies and decisions underpinning the episode selection processes carried out by other RPOs were also considered (several had already chosen CY-2002 as the modeling year).

3.3 Selection of CY 2002 For ASIP and VISTAS

After a lengthy process of integrated studies, the episode selection process culminated in the selection of calendar year (CY) 2002 (1 January through 31 December) as the most current, representative, and pragmatic choice for VISTAS regional haze and ASIP 8-hour ozone and $PM_{2.5}$ modeling. All of the EPA criteria for 8-hour ozone, $PM_{2.5}$ and PM/regional haze episode selection were directly considered in this process together with many other pragmatic considerations (e.g., timing of new emissions or aerometric data deliveries by EPA or the states to the modeling teams).

4.0 MODELING DOMAINS AND DATA AVAILABILITY

This chapter summarizes the model domain definitions including the model domain, resolution, map projections and nesting schemes for high resolution sub-domains.

4.1 Horizontal Modeling Domain

The ASIP horizontal domains for each of the models will be identical to those used in the VISTAS Phase I and II modeling. As in VISTAS, as well as the CENRAP and WRAP RPOs, a coarse grid continental United States (US) domain with a 36 km horizontal grid resolution will be used (the Inter-RPO domain). The CMAQ domain is nested in the MM5 domain. The selection of the MM5 domain is described in the VISTAS MM5 modeling protocol (Olerud, 2003). Figure 4-1 shows the MM5 horizontal domain as the outer most, blue grid. Also shown in Figure 4-1 is the CMAQ 36 km domain nested in the MM5 domain. To achieve finer spatial resolution in the Southeastern US States are also using a one-way nested high resolution grid with a 12 km grid resolution. Figure 4-2 shows the 36 km CMAQ continental grid and the high resolution, nested 12-km grid in the VISTAS states. Figure 4-3 shows in more detail the 12 km grid for the Southeaster US region that is the focus of ASIP and VISTAS.

Both MM5 and CMAQ employ the Regional Planning Organization (RPO) unified grid definition for the 36 km continental domain. The RPO unified grid consists of a Lambert-Conformal map projection using the map projections parameters listed in Table 4-1.

Table 4-1. RPO Unified Grid Definition.

PARAMETER	VALUE
projection	Lambert-conformal
alpha	33 degrees
beta	45 degrees
x center	97 degrees
y center	40 degrees

The MM5 36 km grid includes 164 cells in the east-west dimension and by 128 cells in the north-south dimension. The CMAQ 36 km grid includes 148 cells in the east-west dimension and 112 cells in the north-south dimension. Because the MM5 model is also nested in the Eta model, there is a possibility of boundary effects near the MM5 boundary that occur as the Eta meteorological variables are being simulated by MM5 and must come into dynamic balance with MM5's algorithms. Thus, a larger MM5 domain was selected to provide a buffer of 8 to 9 grid cells around each boundary of the CMAQ 36 km domain. This is designed to eliminate any errors in the meteorology from boundary effects in the MM5 simulation at the interface of the MM5 and Eta models. The buffer region used here exceeds the EPA suggestion of at least 5 grid cell buffer at each boundary.

Table 4-2 lists the number of rows and columns and the definition of the X and Y origin (i.e., the southwest corner) for the 36 km and 12 km grids for both MM5 and CMAQ. Note that the CMAQ grid is rotated 90 degrees relative to the MM5 grid, so rows and columns are reversed. In Table 4-2 "Dot" refers to the grid mesh defined at the vertices of the grid cells while "cross" refers to the grid mesh defined by the grid cell centers. Thus, the dimension of the dot mesh is equal to the cross mesh plus one. Finally, we note that the grid definition for the CMAQ Meteorology Chemistry Interface Processor (MCIP) and CMAQ Chemical Transport Model (CCTM) are identical.

Table 4-2. Grid Definitions For MM5 and CMAQ.

MODEL	COLUMNS DOT(CROSS)	ROWS DOT(CROSS)	XORIGIN	YORIGIN
MM5 36km	129 (128)	165 (164)	-2952000	-2304000
CMAQ 36km	149 (148)	113 (112)	-2736000	-2088000
MM5 12km	190 (189)	181 (180)	7200	-1656000
CMAQ 12km	169 (168)	178 (177)	108000	-1620000

4.2 Vertical Modeling Domain

The CMAQ vertical structure is primarily defined by the vertical grid used in the MM5 modeling. The MM5 model employed a terrain following coordinate system defined by pressure, using 34 layers that extend from the surface to the 100 mb. Table 4-3 lists the layer definitions for both MM5 and for CMAQ. A layer averaging scheme is adopted for CMAQ to reduce the computational cost of the CMAQ simulations. The effects of layer averaging were evaluated in the VISTAS Phase I modeling effort and found to have a relatively minor effect on the model performance metrics when both the 34 layer and a 19 layer CMAQ models were compared to ambient monitoring data.

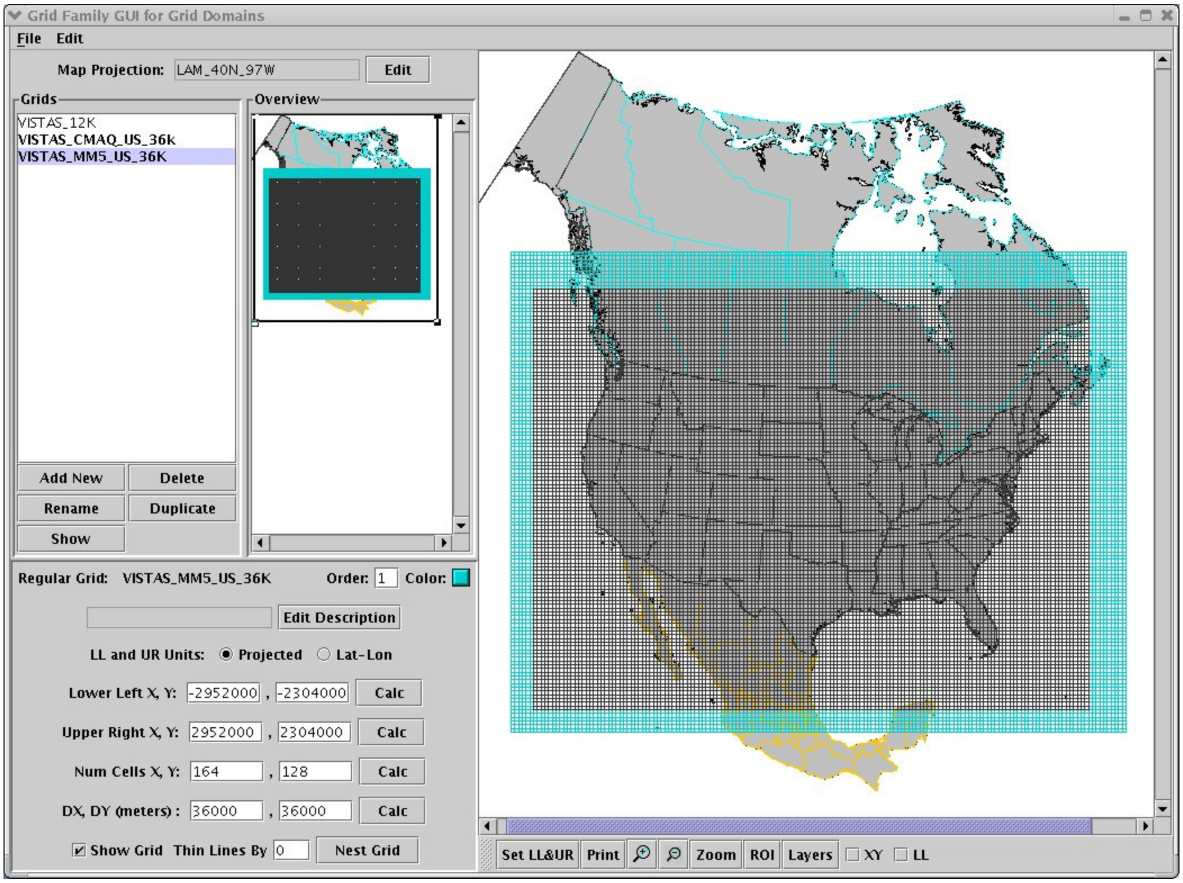

Figure 4-1. Nesting of 36-km CMAQ Grid in the MM5 36-km Grid.

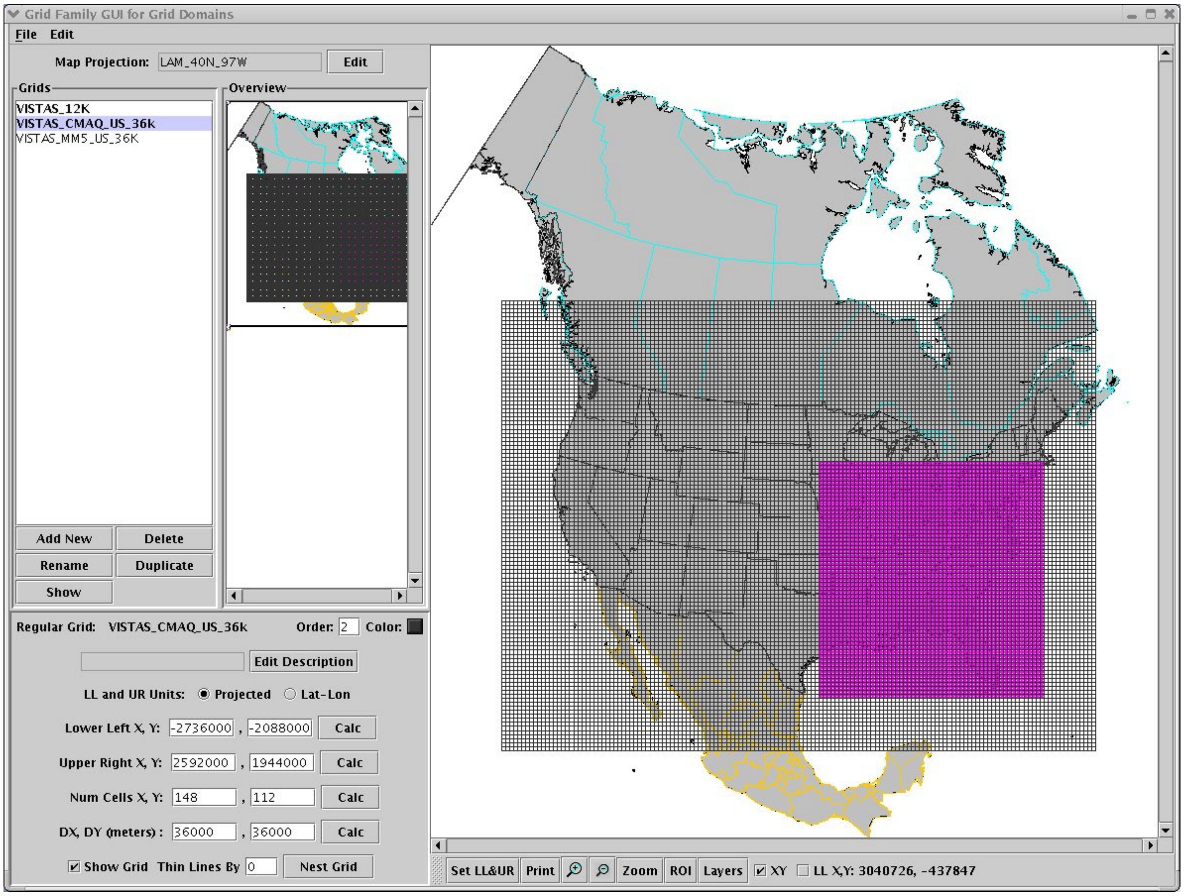

Figure 4-2. Nesting of 12-km Grid in the CMAQ 36-km Grid.

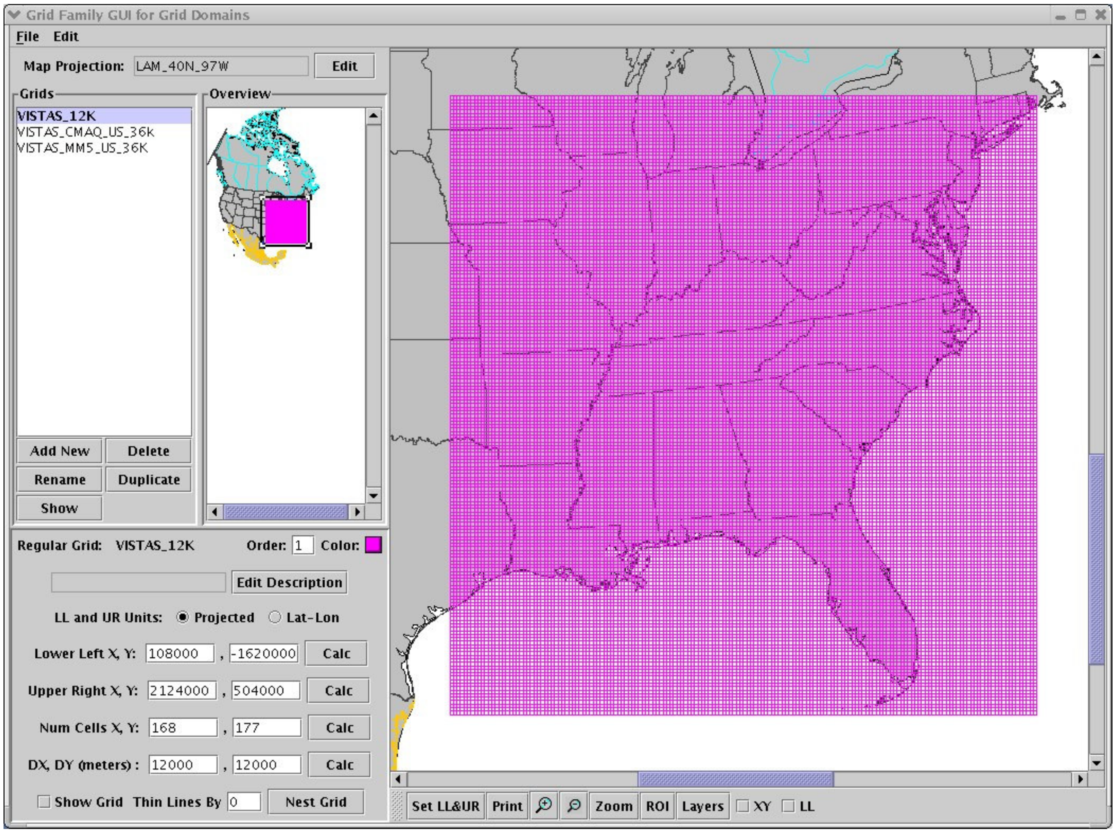

Figure 4-3. Domain Definition for High Resolution 12-km Grid.

Table 4-3. Vertical Layer Definition For MM5 Simulations (Left Most Columns), And Approach For Reducing CMAQ Layers By Collapsing Multiple MM5 Layers (Right Columns).

4.3 Data Availability

The CMAQ modeling system requires emissions, meteorological, initial and boundary condition (IC/BC) and ozone column data for defining the inputs to operate the CMAQ Chemical Transport Model and air quality data with which to evaluate the CMAQ CTM concentrations and deposition estimates.

4.3.1 Emissions Data

The base year emissions inventory for Phase II of the VISTAS modeling will be the basis for the ASIP modeling. These data are founded on 2002 Consolidated Emission Reporting Rule (CERR) inventories submitted to VISTAS by participating state or local agencies and compiled by VISTAS emission inventory contractors in NEI Input Format (NIF) 3.0. These emissions were reviewed by VISTAS stakeholders and considered complete in January of 2004, with minor modifications submitted since that time. Non-VISTAS state emissions will be based on inventories obtained by the Study Team from the other RPOs or EPA and determined to be representative of the 2002 episode year. Mexican and Canadian emissions will be based on the latest available inventories obtainable by the Study Team in formats lending themselves to emissions modeling. For purposes of air quality model validation, actual 2002 calendar year emissions for EGU and fire activity will be used. For strategy and future year emission runs, “typical year” emissions for these categories will be processed for 2002 and the future years.

A final revised 2002 VISTAS state emission inventory is expected in February 2006 and will be used in the final model performance demonstration and configuration expected to begin in spring 2006. Non-VISTAS state emissions are expected to be based on RPO updated base year emissions augmented with additional data provided by RPO, State, and international sources. As in the initial revised modeling, actual 2002 calendar year emissions will be modeled for EGU and fires for base case model performance evaluation, while “typical year” emissions for these categories for 2002 and the future years will be processed during the strategy runs.

All emissions will be converted to Inventory Data Analyzer (IDA) formatted versions and the data will be processed for air quality modeling using Version 2.1 of the Sparse Matrix Operating Kernel Emissions (SMOKE) model. Included in these runs will be the temporal and speciation profiles and cross-reference data provided with the version 2.1 release of the model augmented with any recommended and approved emission profile data provided by the emissions inventory contractor, obtained from EPA, or prepared by the Study Team prior to initial emissions modeling. Spatial allocation of the emissions will be based on profiles and spatial allocation factors developed for the National RPO grid. Additional description of emissions processing is described in Chapter 5 and emissions QA is described in Chapter 6.

4.3.2 Air Quality

Data from ambient monitoring networks for both gas and aerosol species are used in the model performance evaluation. Ambient monitoring data are described in detail in the report: “Review and Assessment of Available Ambient Air Quality Data to Support Modeling and Modeling Performance Evaluation for the Three VISTAS Phase I Episodes” (ENVIRON, UCR and Alpine 2003) so are not repeated here. Table 4-4 summarizes ambient monitoring networks. Data have been compiled for all networks except the PAMS and PM Supersites.

Of particular note for the ASIP 8-hour ozone and $PM_{2.5}$ attainment demonstration modeling are the locations of the key ozone monitors and key FRM monitors where ozone and PM has been determined to be in nonattainment. Also important are the STN speciated PM monitor that is associated with each FRM PM monitor. ASIP is currently formulating its strategy on how the $PM_{2.5}$ attainment demonstration will be performed using associated FRM and STN PM monitoring sites.

Table 4-4. Overview of Ambient Data Monitoring Networks.

Monitoring Network	Chemical Species Measured	Sampling Period	Data Availability/Source
The Interagency Monitoring of Protected Visual Environments (**IMPROVE**)	Speciated PM25 and PM10 (see species mappings)	1 in 3 days; 24 hr average	http://vista.cira.colostate.edu/improve/Data/IMPROVE/improve_data.htm
Clean Air Status and Trends Network (**CASTNET**)	Speciated PM25, Ozone (see species mappings)	Approximately 1-week average	http://www.epa.gov/castnet/data.html
National Atmospheric Deposition Program (**NADP**)	Wet deposition (hydrogen (acidity as pH), sulfate, nitrate, ammonium, chloride, and base cations (such as calcium, magnesium, potassium and sodium)), Mercury	1-week average	http://nadp.sws.uiuc.edu/
Air Quality System (**AQS**) Aka Aerometric Information Retrieval System (**AIRS**)	CO, NO2, O3, SO2, PM25, PM10, Pb	Typically hourly average	http://www.epa.gov/air/data/
$PM_{2.5}$ Federal Reference Method (**FRM**)	Total $PM_{2.5}$ Mass	1 in 3 days; 24-hour averages	
Speciation Trends Network (**STN**)	Speciated PM	24-hour average	http://www.epa.gov/ttn/amtic/amticpm.html
Southeastern Aerosol Research and Characterization (**SEARCH**)	24-hr PM25 (FRM Mass, OC, BC, SO4, NO3, NH4, Elem.); 24-hr PM coarse (SO4, NO3, NH4, elements); Hourly PM2.5 (Mass, SO4, NO3, NH4, EC, TC); and Hourly gases (O3, NO, NO2, NOy, HNO3, SO2, CO)	Hourly or 24-hour average, depending on parameter.	Electric Power Research Institute (EPRI), Southern Company, and other companies. http://www.atmospheric-research.com
EPA Particulate Matter Supersites	Speciated PM25		http://www.epa.gov/ttn/amtic/supersites.html
Photochemical Assessment Monitoring Stations (**PAMS**)	Varies for each of 4 station types.		http://www.epa.gov/ttn/amtic/pamsmain.html
National Park Service Gaseous Pollutant Monitoring Network	Acid deposition (Dry; SO4, NO3, HNO3, NH4, SO2), O3, meteorological data	Hourly	http://www2.nature.nps.gov/ard/gas/netdata1.htm

4.3.3 Ozone Column Data

Additional data used in the air quality modeling include the Total Ozone Mapping Spectrometer (TOMS). TOMS data is available for 24-hour average and is obtained from http://toms.gsfc.nasa.gov/eptoms/ep.html. The day-specific TOMS data is used in the CMAQ radiation model (JPROC) to calculate photolysis rates. The TOMS data were missing or bad for several periods in 2002: August 2-12; June 10; and November 18-19. Thus, the TOMS data for August 1, 2002 was used for August 2-7 and TOMS data for August 13 was used for August 8-12. Similarly, TOMS data for June 9 was used for June 10 and data for August 17 was used for August 18-19.

4.3.4 Meteorological Data

Meteorological data are being generated using the MM5 prognostic meteorological model by Baron Advanced Meteorological Systems (BAMS). BAMS is operating the MM5 at 5-day increments for 2002 on the 36 km and 12 km grid with a 14 day spin up period for the end of December 2001. Details on the VISTAS Phase II 2002 MM5 modeling can be found at the BAMS VISTAS website: http://www.baronams.com/projects/VISTAS/.

4.3.5 Initial and Boundary Conditions Data

The CMAQ default Initial Concentrations (ICs) will be used along with a ~15 day spin up period to eliminate any significant influence of the ICs.

The CMAQ Boundary Conditions (BCs) for the Inter-RPO 36 km grid and the ASIP simulations will be based on day-specific 3-hourly averages from a 2002 GEOS-CHEM global simulation model output. Boundary conditions for the 12 km grid will be based on CMAQ results from the 36 km rid processed with the CMAQ BCON boundary condition processor.

5.0 MODEL INPUT PREPARATION PROCEDURES

In this section we describe the procedures to be used to develop the CMAQ model inputs for the ASIP 2002 annual 36/12 km model simulations to address 8-hour ozone and $PM_{2.5}$ nonattainment in the Southeastern US States. The development of the CMAQ meteorological and emissions inputs are discussed first followed by the science options to be used by CMAQ. The procedures for developing the initial and boundary conditions and photolysis rates inputs are then discussed along with the model application procedures. With the exception of using a 2009 future-year and performing daily mobile source emissions modeling, the procedures used in the ASIP CMAQ 36/12 km modeling are identical to those used in VISTAS (ENVIRON, 2004; Morris et al., 2004a,b).

5.1 Meteorological Inputs to Emissions and Air Quality Models

The emissions and air quality models require certain meteorological input data including wind fields, estimates of turbulent eddy dispersion, humidity, temperature, clouds, and actinic flux. Spatially gridded and hourly varying meteorological data are needed to estimate biogenic, mobile source emissions, and plume-rise for large, elevated point sources. Meteorological data are needed to drive chemical transport models for solving atmospheric diffusion and chemistry equations for model species. Because observed data are not available for the full gridded model domain, numerical meteorological models are used to provide these inputs.

The National Center for Atmospheric Research (NCAR)/Pennsylvania State University (PSU) Fifth-Generation Mesoscale Model (MM5) (v3.6) is being used by the VISTAS meteorological modeling contactor, Baron Advanced Meteorological Systems (BAMS) (Olerud, 2004a-d) to simulate meteorology at a 36-km resolution for calendar year 2002 over the entire continental United States and including portions of Canada, Mexico, and the Atlantic and Pacific Oceans. MM5 is also being applied over the southeastern U.S. using a 12 km resolution grid. The MM5 is a three-dimensional prognostic meteorological model that is used not only for meteorology studies but also for air quality studies. Some of the physics used in the simulation include one-way nesting; nonhydrostatic dynamics; four-dimensional data assimilation of wind, temperature, and mixing ratio; explicit treatment of moisture; cumulus cloud parameterization; vertical mixing of momentum in the mixed layer; PBL process parameterization; atmospheric radiation; sea ice treatment; and snow cover (see Chapter 2 for more details).

After the MM5 simulation is completed, the MM5 output files are transferred to the emissions and air quality modeling team and analyzed by the Meteorological Gatekeeper. The Meteorological Gatekeeper performs two main roles; (1) to provide an independent evaluation of the 2002 MM5 simulation that also serves to determine whether the MM5 data have been transferred correctly from the VISTAS meteorological modeling contractor and (2) to process the 2002 MM5 output using Version 2.2 of the Models-3 CMAQ Meteorological-Chemical Interface Processor (MCIP) to generate meteorological fields that will be used for emissions processing and air quality simulation.

5.1.1 MCIP Reformatting Methodology

The Models-3 Community Multiscale Air Quality (CMAQ) modeling system is designed to simulate multiscale (urban and regional) and multi-pollutant (oxidants, acid deposition, and particles) air quality problems. But before running the CMAQ Chemical Transport Model (CCTM), the MM5 generated meteorological data must be pre-processed and converted to Models-3 consistent data structures. MCIP Version 3.0 will be used to preprocess the MM5 meteorological output. The "pass through" option in MCIP will be used in the modeling. One of MCIP's functions is to translate meteorological parameters from the output of the Pennsylvania State University/National Center for Atmospheric Research (PSU/NCAR) Mesoscale Modeling System Generation 5 (MM5) to the Models-3 input/output applications program interface (I/O API format) which is required for operation of Models-3 CMAQ processors. Some other necessary parameters not available from the meteorological model are estimated with appropriate diagnostic algorithms in the program. The key functions of MCIP include:

1. Reading in meteorological model output files
2. Extraction of meteorological data for CTM window domain
3. Interpolation of coarse meteorological model output for finer grid
4. Collapsing of meteorological profile data if coarser vertical resolution data is requested
5. Computation or passing through surface and PBL parameters
6. Diagnosing of cloud parameters
7. Computation of species-specific dry deposition velocities
8. Generation of coordinate dependent meteorological data for the generalized coordinate CCTM simulation
9. Output meteorological data in Models-3 I/O API format

The MCIP processor transforms the data into I/O API format while also calculating several new data fields (e.g. low, middle, and high cloud fractions) that are not readily available in the raw MM5 output. It also interpolates temperature and wind speed to observation height (1.5m and 10m, respectively). The MCIP processor culls a minimum of six cells about the domain periphery to minimize edge effects in the MM5 simulation. MCIP can be used to further reduce the rows or columns in the MM5 data so that the domain definition for the MCIP output files precisely matches the domain used in the air quality modeling. MCIP also allows MM5 layers to be "collapsed" (i.e., some layers can be aggregated). When feasible it is desirable to use the same layer structure in the air quality model as in the MM5 to prevent errors associated with aggregating layer data and to maintain consistency between data produced by the meteorological model and those used by the chemistry-transport model. However, due to computational costs associated with using large number of vertical layers, vertical layer collapsing is typically used to reduce the total number of layers used by the CCTM. In the ASIP and VISTAS modeling we will collapse from 34 layers in MM5 output into 19 layers for the CMAQ air quality simulations. The first 8 layers of CMAQ, up to approximately 450 m AGL, will match the MM5 vertical layer structure exactly. The MM5 layers are then "doubled up" in CMAQ, up to a height of approximately 3,500 m AGL. The region top for CMAQ is the same as used by MM5, 100mb (approximately 15 km AGL). The 36 km analysis domain contains 148 columns, 112 rows, and 19 layers. The 12 km analysis domain covers 168 columns, 177 rows, and 19 layers. More details on the CMAQ modeling domain definitions are provided in Chapter 4 with the vertical layer structure of MM5 and MCIP/CMAQ shown at Table 4-3.

5.1.2 Products of the Meteorological Input Development Process

The meteorological input development process produces three two-dimensional and four three-dimensional daily meteorological and geophysical output data in the Models-3 I/O API format. These CCTM-ready meteorological input files are used in both emissions processing and the CCTM simulations. The met fields are 36 km and 12 km horizontal resolution on a Lambert Conformal Projection (LCP) coordinate system with 19 vertical sigma layers extending from the surface to the 100 mb pressure level. The data files include three-dimensional gridded fields of u- and v-wind components, vertical velocity, temperatures, Jacobian, Jacobian weighted air density, total air density, water vapor, cloud water content, rain water content, ice and snow mixing ratio, layer heights, and vertical exchange coefficients. Two-dimensional gridded fields of latitude and longitude, squared map-scaled factor, surface temperatures and pressures, 1.5 and 10 meter temperature, planetary boundary heights, rainfall, total cloud fraction, snow cover, deposition velocities, u* and w*, surface roughness length, as well as dominant land use category are also developed.

Table 5-1 shows the configuration to be used in MCIP Version 3.0 for processing the 2002 MM5 output to produce CCTM-ready meteorology input files.

Table 5-1. MCIP V3.0 Configuration used In the ASIP Modeling.

Module or option	Values or setting	Additional Information
PBL value computation option	1	Use PBL value from input meteorology
Radiation fields	1	Use radiation fields from input meteorology
Dry deposition option	2	Use Models-3 (Pleim) dry deposition routine
Use PURB Kz_min Option	True	Calculate Kz_min as a function of percent urban land use
Sea Salt Deposition	True	Output dry deposition parameters for Na and Cl
Output interval	60	Unit is in minutes
Vertical layer structure	19 layers	See Chapter 4

5.2 Development of Emissions Model Inputs and Resultant Inventories

The base year emissions inventory for ASIP modeling are founded on 2002 Consolidated Emission Reporting Rule (CERR) inventories submitted to VISTAS by participating state or local agencies and compiled by VISTAS emission inventory contractors in NEI Input Format (NIF) 3.0. These emissions were reviewed by VISTAS stakeholders and considered complete in January of 2004, with minor modifications submitted since that time.

Non-VISTAS state emissions are based on inventories obtained by the Study Team and determined to be representative of the 2002 episode year. Base year 2002 emission inventories for non-mobile source categories were obtained from each RPO in the U.S. domain. These data were supplemented with EPA based VMT and MOBILE6 input files necessary to develop onroad mobile source emissions domain-side. Additionally, an inventory of point source resolved agricultural fire emissions were provided by the western state RPO (WRAP) and utilized in the modeling.

Mexican and Canadian emissions are based on the latest available inventories obtainable by the Study Team in formats lending themselves to emissions modeling. At this time, these inventories are the same as in Phase I.

For purposes of air quality model validation, actual 2002 calendar year emissions for EGU and fire activity will be used, while during strategy and future year emission runs, "typical year" emissions for these categories will be processed.

A final revised 2002 VISTAS state emission inventory is expected in February 2006 and will be used in the final model performance demonstration and configuration expected to begin in spring 2006. Non-VISTAS state emissions are expected to be based on RPO updated base year emissions augmented with additional data provided by RPO, State, and international sources. As in the initial revised modeling, actual 2002 calendar year emissions will be modeled for EGU and fires for base case model performance evaluation, while "typical year" emissions for these categories for 2002 and the future years will be processed during the strategy runs.

These emissions will then be converted to Inventory Data Analyzer (IDA) formatted versions and the data will be processed for air quality modeling using Version 2.1 of the Sparse Matrix Operating Kernel Emissions (SMOKE) model. Included in these runs will be the temporal, spatial, and speciation profiles and cross-reference data currently provided with the 2.1 release of the model augmented with any recommended and approved emission profile data provided by the emissions inventory contractor or obtained from EPA prior to initial emissions modeling. The processing will be adjusted for each run to account for the specific air quality model (AQM) input required by CMAQ.

5.2.1 Emissions Modeling Methodology

Emissions inventory development for photochemical modeling must address several source categories including: (a) stationary point sources, (b) area sources, (c) on-road mobile sources, (d) non-road mobile sources, and (e) biogenic sources. For this analysis, these estimates must be developed to support the episode that is being modeled (i.e., the historical base year when the episode actually occurred; 2002).

Development of an emissions inventory customized for the ASIP region requires a merging of: (a) the most recent *pertinent* regional inventory and (b) available high-resolution, locale-specific emissions estimated by local, state, and regional agencies in the VISTAS region. Local air regulatory and transportation planning agencies are generally the best sources of domain specific activity and control factors to use in developing the base year emissions. Often, these local emissions data sets come from a variety of sources, frequently in different formats.

The study team will acquire emissions estimate data from Emissions Inventory Contractor, in the NIF 3.0 format for purposes of generating the emission inventory base year files necessary for the ASIP contract. These data will be augmented with highway mobile source data submitted to the ASIP emission inventory contractors from the VISTAS participating States.

Contacts with ASIP's emission inventory contractors and the U.S. EPA will be established and formal requests made for inventory corrections, updates and ancillary data pertinent to the modeling of emissions in their jurisdictions. Where feasible and consistent with project resources and schedule, these updated data sets will be acquired and will be used to create day-specific modeling inventories specific to the ASIP domain for the base year episodes to be modeled.

5.2.2 Set-up of SMOKE Over the ASIP Domain

SMOKE will be configured to generate point, area, nonroad, highway, and biogenic source emissions. In addition, certain subcategories, such as fires and EGUs will be maintained in separate source category files in order to allow maximum flexibility in producing alternate strategies. Settings for each of the source categories are discussed in relevant sections below. With the exception of biogenic and highway mobile source emissions that are generated using the, BEIS and MOBILE6 modules in SMOKE, respectively, pre-computed annual emissions will be processed using the month, day, and hour specific temporal profiles of the SMOKE model.

To produce an emissions inventory to support annual modeling, representative time periods will be selected and modeled. Area, nonroad, and point sources will be modeled as a block of Thursday, Friday, Saturday, Sunday, Monday one per month (total of 60 days modeled). For 36-km modeling, onroad motor vehicles will be represented by an entire single week for each month. This selection criteria allows for the representation of day-of-the-week variability in the on-road motor vehicles, and models a representation of the meteorological variability in each month. For 12-km runs, onroad motor vehicles will be run for every day of the year. Holidays will be modeled as Sundays. A list of modeled holidays is provided in Table 5-2. The biogenic emissions will be modeled on a day specific basis (365 days).

Table 5-2. SMOKE Modeled Holidays.

Date	Julian Day	Holiday Description
January 1, 2002	2002001	New Year's Day
March 29, 2002	2002089	Good Friday
May 27, 2002	2002147	Memorial Day
July 4, 2002	2002185	July 4th
September 2, 2002	2002245	Labor Day
November 28, 2002	2002332	Thanksgiving Thurs
November 29, 2002	2002333	Thanksgiving Fri
December 24, 2002	2002358	Christmas Eve
December 25, 2002	2002359	Christmas Day

Population will be used as a gridding default for all source categories when the assigned surrogate would cause SMOKE to drop emissions. This can be a case when the county-level emission inventories are prepared using surrogates other than those available for modeling purposes.

The domain for the Phase II episode will be identical to the Phase I domain, which is based on the EPA's 36-km national CMAQ domain, illustrated in Figure 5-1 below (details on the modeling domains are provided in Chapter 4).

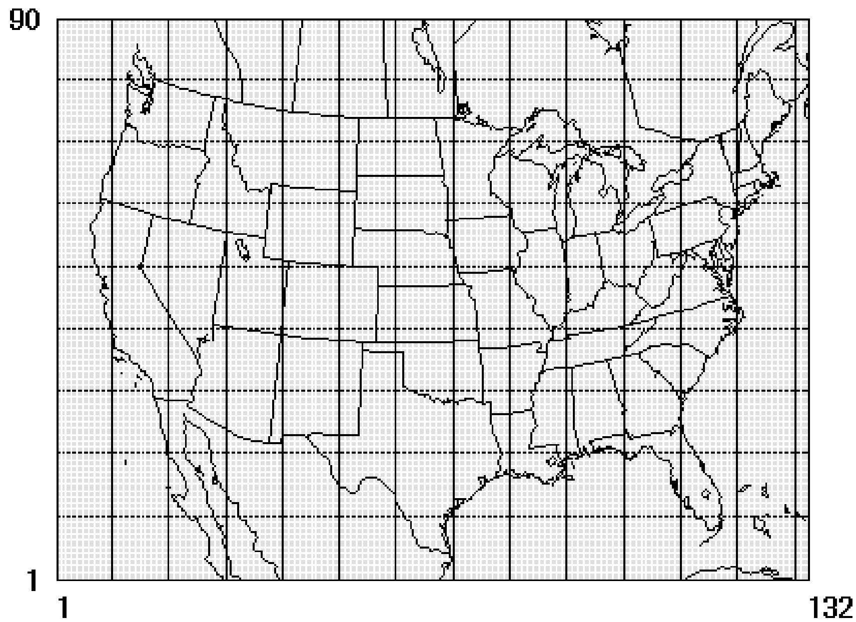

Figure 5-1. EPA 36-km National CMAQ Domain.

The parameters for the SMOKE runs are as follows:

Episodes: 2002 Calendar Base Year. Optional tasks for episodic modeling of up to 60 days that will likely be from 2003.

Future Years: To be determined.

Output Time Zone: Greenwich Mean Time (zone 0)

Projection: Lambert Conformal with Alpha=33, Beta=45, Gamma=-97, and center at (-97,40).

Domain:

- 36 Kilometer Grid: Origin at (-2736, -2088) kilometers with 148 rows by 112 columns and 36-km square grid cells.
- 12 Kilometer Grid: Origin at (108, -1620) kilometers with 168 rows by 177 columns and 12-km square grid cells.

Layer Structure: The CMAQ layer structure will be 19 layers, with specific layer positions defined in the meteorology files (see Chapter 4).

CMAQ Model Species: The CMAQ initial configuration will be for the CB-IV chemical mechanism with PM. The model species in the emission input files will be: CO, NO, NO2, ALD2, ETH, FORM, ISOP, NR, OLE, PAR, TERPB, TOL, XYL, NH3, SO2, SULF, PEC, PMFINE, PNO3, POA, PSO4, and PMC.

Meteorology Data: Daily (25-hour). SMOKE requires the following five types of MCIP outputs: (1) Grid cross 2-d, (2) Grid cross 3-d, (3) Met cross 2-d, (4) Met cross 3-d, and (5), Met dot 3-d. These files need to match the grid projection and overlap with the emissions modeling region but can be larger in the horizontal directions than the modeling region shown in Figure 1. Therefore, the data files for the 36 Kilometer grid domain will be at least 90 columns by 132 rows

Elevated Sources: All sources will be treated by SMOKE as potentially elevated. No plume-in-grid sources will be modeled. Wildfire emissions will be handled as point sources.

Producing 365 day-specific input files for all source categories places a burden on available computing facilities, data management systems, and would adversely affect the ASIP schedule. Selecting representative model days for some or all of the source categories reduces the processing and file handling requirements to a more manageable level and in most cases does not compromise the accuracy of the emissions files.

Other current or recent projects undertaken by EPA, WRAP and MRPO have used a selection approach for all of the source categories (except biogenics) that use a representative weekday/Saturday/Sunday either for each month or each season to model all of the emissions files. In an attempt to better represent the level of temporal and spatial detail available for each source category, we have developed a more detailed strategy.

Biogenic emissions will be modeled for each episode day, using the daily meteorology. Point sources, including CEM-based and fire emissions will be modeled for each episode day to take advantage of the available day-specific emissions and meteorology. Area sources, including nonroad mobile and dust emissions do not utilize meteorological data, and are temporally allocated by monthly, daily and hourly profiles. Reviewing these profiles indicate that maximum temporal definition can be achieved by selecting representative Thursday, Friday, Saturday, Sunday, and Monday profiles for each month.

Motor vehicle emissions are influenced by meteorological variability, but the processing requirements for daily motor vehicle emissions were determined to be prohibitive under the current schedule. Rather than utilizing averaged meteorological data or pre-calculated motor vehicle emissions, for the 36-km domain, a single week per month was selected for modeling. This week was selected from mid-month, to try to best represent the average temperature ranges for the month, and also adjusted to exclude holidays that would require atypical processing. As noted above, in the 12-km domain runs, daily modeling will be conducted. The area source modeling dates were also selected from these ranges to simplify data handling procedures.

5.2.3 Development of Point Source Emissions

Stack parameters are often more important to the reliability of the air quality modeling results than the emissions rates themselves. Stack parameter data are frequently incorrect, especially in some of the current regional modeling inventories and careful QA is required to assure that the point source emissions are properly located both horizontally and vertically on the modeling grid. To screen for simple, but potentially serious inventory errors such as these, the study team has modified procedures originally developed by EPA to quality assure, augment, and where necessary, revise, stack parameters to examine the accuracy of the point source emissions, as well as standardize procedures to identify and correct stack data errors. These procedures will be implemented in the NIF to IDA conversion step of the inventory development. Additionally, SMOKE has a number of built-in QA procedures designed to catch missing or out-of-range stack parameters. These procedures will also be invoked in the processing of the point source data.

For the ASIP initial baseline modeling, we will be separating the point source emissions into EGU and non-EGU categories. The non-EGU category will not be using any day or hour-specific emissions. All non-EGU point source emissions will be temporally allocated to month, day, and hours using annual emissions and source category code (SCC) based allocation factors. These factors will be based on the cross-reference and profile data supplied with the SMOKE 2.1 version and will be supplemented with relevant data provided to the study team by ASIP or its contractors.

For EGU sources with EPA reported CEM data or with hourly emissions provided by stakeholders, actual hourly data will be used to temporally allocate emissions. For those sources where EPA CEM data are utilized, NOx, SO2, and heat input-based hour-specific profiles were developed and applied to NOx, SO2, and all other emissions, respectively. This ensured that the annual emission values provided by the emissions inventory contractor were maintained, but distributed using hourly to annual profiles. For sources providing hour-specific data and where they were approved by the State in which they operated, those data were substituted for EPA CEM-based distributions.

To temporally allocate the remaining EGU point sources, the NOx, SO2, and heat input data were collected from the 2002 Continuous Emissions Monitoring (CEM) datasets, and used to develop unit-level temporal distributions. The hour, day of week, and monthly specific temporal profiles will be used in conjunction with the emissions inventory supplied emissions data to calculate hourly EGU emissions by unit.

All point sources will be spatially allocated in the domain based on the stationary source geographic coordinates. If a point source is missing its latitude/longitude coordinates, the source will be placed in the center of its respective county.

5.2.4 Development of Area and Non-Road Source Emissions

All area and non-road source emissions will be temporally allocated to month, day, and hours using annual emissions and source category code (SCC) based allocation factors. These factors will be based on the cross-reference and profile data supplied with SMOKE Version 2.1 and will be supplemented with relevant data provided to the study team by ASIP or its contractors. Area and non-road sources will be spatially allocated in the domain based on SCC-based spatial allocation factor files. If an area or non-road source SCC does not have an existing cross-reference profile assigned to it, the county-level emissions will be allocated by population density in the respective county.

A crustal PM transport factor will be applied to fugitive dust emission sources that have been identified in U.S. EPA modeling to have only a portion of its mass transportable from the source of the emission generation. The EPA's studies indicate that 60 to 90 percent of PM emissions from fugitive dust sources do not reach an elevated level necessary to be transported or modeled in an episodic simulation. For this reason, we will apply county-specific fugitive dust emissions transport factors to these sources in the modeling files to adjust PM emissions accordingly. These factors can be located at http://www.epa.gov/ttn/chief/emch/invent/statusfugdustemissions_082203.pdf.

5.2.5 Development of On-Road Mobile Source Emissions

The MOBILE6 module of SMOKE will be used to develop the base year on-road mobile source emissions estimates for CO, NOx, PM, and VOC emissions. The MOBILE6 parameters, vehicle fleet descriptions, and VMT estimates will be combined with gridded, episode-specific temperature data to calculate the gridded, temporalized emission estimates. Of note, whereas the on-network emissions estimates are spatially allocated based on link location and subsequently summed to the grid cell level, the off-network emissions estimates are spatially allocated based on a combination of the FHWA Version 2.0 highway networks and population. For the ASIP 36/12 km modeling, no link based data will be used. The MOBILE6 emissions factors are based on episode-specific temperatures predicted by the meteorological model. Further, the MOBILE6 emissions factors model accounts for the following:

- Hourly and daily minimum/maximum temperatures;
- Facility speeds;
- Locale-specific inspection/maintenance (I/M) control programs, if any;
- Adjustments for running losses;
- Splitting of evaporative and exhaust emissions into separate source categories;
- VMT, fleet turnover, and changes in fuel composition and Reid vapor pressure (RVP).

The primary input to MOBILE6 is the MOBILE shell file. The MOBILE shell contains the various options (e.g. type of inspection and maintenance program in effect, type of oxygenated fuel program in effect, alternative vehicle mix profiles, RVP of in-use fuel, operating mode) that direct the calculation of the MOBILE6 emissions factors.

5.2.6 Development of Biogenic Source Emissions

A revised version of a commonly used biogenic emissions model, the Biogenic Emissions Inventory System (BEIS), has recently been developed and tested by EPA over two separate modeling domains/episodes. This version of the model (BEIS-3, v0.9) contains several changes over BEIS-2, including the following:

- Vegetation input data -- are now based on a 1-km Biogenic Emissions Landuse Database (BELD3) vegetation data base,
- Emission factors – many updates including some recent NARSTO modifications,
- Environmental algorithm -- includes a sunlit/shaded leaf solar radiation model.

A series of sensitivity modeling simulations has been completed and concluded that the more recent BEIS-3 methodology will impact base case model ozone predictions in most parts of the U.S. The preliminary tests have also shown that the newer biogenic emissions **do not** appear to have a large effect on: 1) the control signal response, 2) relative reduction factors resulting from a projected emissions change, or 3) overall regional model performance in the eastern U.S.

For this particular application of BEIS-3, Version 0.9 as currently incorporated in the SMOKE processor will be used. This means that: 1) soil NO emissions shall be prepared without the input of specific soil moisture and precipitation data and 2) MEOH emissions will not be modeled explicitly. Otherwise, the modeling should be identical to a BEIS-3 (v1.0) application.

The BELD-3 landuse data on a Lambert conformal grid at 1-km resolution have already been developed, are available, and will be used to estimate biogenic emissions in this study. The BEIS model also requires as input hourly, gridded temperature and solar radiation data to estimate biogenic emissions, and these data will be derived from the MM5 predictions.

5.2.7 Wildfires, Agricultural, and Prescribed Burns, Wind Blown Dust and Sea Salt Source Emissions

Wildfires, Agricultural, and Prescribed Burns

Wildfire, agricultural, and prescribed burn emissions will be handled separately from the standard area source input files. The study team expects to receive monthly estimates of fire emissions from the emissions inventory contractor, which include burn acreage and biomass loading information for the VISTAS states. Depending on the completeness and quality of the data received, attempts will be made to calculate spatial and temporal distributions of the fire emissions, rather than relying on standard distribution profiles. Also, the study team will attempt to calculate vertical distribution of the fire emissions, based on fire size and biomass involvement. The SMOKE 2.1 can model fire plume rise if provided with the following variables:

PTOP – Top of the fire plume profile (meters above ground level)
PBOT – Bottom of the fire plume profile (meters above ground level)
Lay1 – The percent of the emissions entrained in the first modeling layer

The WRAP Fire Emissions Joint Forum Emissions Inventory Report (FEJF, 2002) has documented an approach to calculating these plume descriptors. In this method, the fires are assigned to one of 5 size categories, based on the total burn acreage, and the biomass fuel loading. These categories are then used to calculate representative hourly plume profiles. These profiles are then used by SMOKE 2.1 to distribute the vertical emissions for the fires. To successfully model fires as elevated point sources, the data provided by the emissions inventory contractor will need to include both the day or days on which the fire occurs, and a spatial identifier of the fire location. At a minimum, a latitude and longitude of the fire location can be used, while a polygon coverage would be preferable.

In addition, wildfire and prescribed burn data, including emissions estimates and plume rise distributions, will be obtained from other RPOs and used to supplement the inventory for the non-VISTAS states.

Windblown Dust

PM_{10} and $PM_{2.5}$ emissions from wind erosion of natural geogenic sources (SCCs 2730100000 [total] and 2730100001 [dust devils]) will be excluded from the resulting modeling files using a 100 percent reduction in the control packets.

Sea Salt

CMAQ currently treats sea salt as an inert PM species. That is, the sea salt is not allowed to chemically interact with other species, such as producing particulate sodium nitrate. There are plans to update CMAQ to have chemically active sea salt, but it is unclear whether such an update will occur during the ASIP modeling. Accordingly, the initial modeling will be conducted without any sea salt emissions. If CMAQ is updated to treat chemically active Sea Salt, or if CAMx is run using its full-science options, then Sea Salt emissions will be generated using appropriate procedures (e.g., as was done in VISTAS Phase I).

5.2.8 Speciation and Reformatting of Emissions

SMOKE will be run to speciate the emissions estimates according to the requirements of the Carbon Bond Mechanism version four (CBM-IV, CB-IV or CB4). The SMOKE model will also reformat the emissions estimates for use in CMAQ modeling. For each model-ready emissions inventory, SMOKE will produce at a minimum five (5) separate air quality model-ready files: low-level point source, area source, elevated point source, mobile source, and biogenics. Other source categories, such as EGU and fire emissions may also be handled as separate air quality model-ready files.

5.2.9 Development of Modeling Inventories

The emissions inventories modeled for the VISTAS ASIP can be grouped into four distinct types: (1) 2002 actual annual emission inventories, (2) 2002 typical annual emission inventories; (3) 2009 base case emission inventories; and (4) 2009 control strategy emission inventories. In all cases, the Study Team expects to receive the emissions inventory data for the ASIP states from the emissions inventory contractor, add non-ASIP states and Canadian and Mexican data acquired from alternate EPA and/or RPO sources, and produce the CMAQ ready emissions files.

5.2.9.1 2002 Annual Inventories

2002 36/12 km actual and typical annual inventories will be developed under ASIP for CMAQ modeling. These inventories will be identical to the 2002 36/12 km actual and typical inventories developed under VISTAS, only the 2002 12 km ASIP inventories used everyday on-road mobile source emissions modeling.

5.2.9.2 2009 Annual Future Year Inventories

2009 36/12 km annual emission inventories will be develop for an On-the-Books (OTB) base case emissions scenario and, as needed, control strategy emission scenarios. The 2009 On-the-Books base case will include growth and controls that have been promulgated, such as the following regional rules:

- NOx SIP Call
- Tier 2/Low Sulfur
- Heavy Duty Diesel
- Non-Road Engine
- Clean Air Interstate Rule (CAIR)

Not included in the 2009 OTB base case emissions scenario are Regional Haze controls including Best Available Retrofit Technology (BART) controls and any additional controls needed to attain the 8-hour ozone and $PM_{2.5}$ standards. Control strategies to be modeled will be determined during the course of the study.

5.2.10 Products of the Emissions Inventory Development Process

In addition to the CMAQ-ready input files generated for each hour of the days modeled in the ASIP annual run, a number of quality assurance (QA) files may be prepared and used to check for gross errors in the emissions inputs. Importing the model-ready emissions into PAVE and looking at both the spatial and temporal distribution of the emission provides insight into the quality and accuracy of the emissions inputs.

- Visualizing the model-ready emissions with the scale of the plots set to a very low value, we can determine whether there are areas omitted from the raw inventory or if emissions sources are erroneously located in water cells.
- Spot-check the holiday emissions files to confirm that they are temporally allocated like Sundays.
- Producing pie charts emission summaries that highlight the contribution of each emissions source component (e.g. nonroad mobile).
- Normalizing the emissions by population for each state will illustrate where the inventories may be deficient and provide a reality check of the inventories.
- Spot check vertical allocation of point sources using PAVE.

We will use state inventory summaries prepared prior to the emissions processing to compare against SMOKE output report totals generated after each major step of the emissions generation process.

To check the chemical speciation of the emissions to CB-IV terms and the vertical allocation of the emissions, we will compare reports generated with SMOKE reports to target these specific areas of the processing. For speciation, we will compare the inventory import state totals versus the same state totals with the speciation matrix applied.

For checking the vertical allocation of the emissions, we will create reports by source, hour, and layer for randomly selected states in the domain. We will create these reports for a representative weekday in each of the episodes for each of these selected states.

The quantitative QA analyses often reveal significant deficiencies in the input data or the model setup. It may become necessary to tailor these procedures to track down the source of each major problem. As such, we can only outline the basic quantitative QA steps that we will perform in an attempt to reveal the underlying problems with the inventories or processing. Following are some of the reports that may be generated to review the processed emissions:

- State and county totals from inventory for each source category
- State and county totals after spatial allocation for each source category
- State and county totals by day after temporal allocation for each source category for representative days

- State and county totals by model species after chemical speciation for each source category
- State and county model-ready totals (after spatial allocation, temporal allocation, and chemical speciation) for each source category and for all source categories combined
- Totals by source category code (SCC) from the inventory for area, mobile, and point sources
- Totals by state and SCC from the inventory for area, mobile, and point sources
- Totals by county and SCC from the inventory for area, mobile, and point sources
- Totals by SCC and spatial surrogates code for area and mobile sources
- Totals by speciation profile code for area, mobile, and point sources
- Totals by speciation profile code and SCC for area, mobile, and point sources
- Totals by monthly temporal profile code for area, mobile, and point sources
- Totals by monthly temporal profile code and SCC for area, mobile, and point sources
- Totals by weekly temporal profile code for area, mobile, and point sources
- Totals by weekly temporal profile code and SCC for area, mobile, and point sources
- Totals by diurnal temporal profile code for area, mobile, and point sources
- Totals by diurnal temporal profile code and SCC for area, mobile, and point sources
- PAVE plots of gridded inventory pollutants for all pollutants for area, mobile, and point sources

5.3 Model Configuration and Modeling Approach

5.3.1 CMAQ Science Configuration

This section described the model configuration and science options to be used in the ASIP modeling effort. The recommendations are based on testing and model evaluations of several models or model configurations carried out in the VISTAS study, as well as related studies including WRAP, CENRAP, BRAVO, CAIR and other studies. Table 5-3 summarizes the proposed configuration for CMAQ. The latest version of CMAQ is currently Version 4.5 that was released October 2005. CMAQ Version 4.5 includes several enhancements and corrections over precious versions of the model, including corrections to the mass conservation algorithms and active treatment of Sea Salt. VISTAS has updated CMAQ Version 4.5 with the

SOAmods secondary organic aerosol (SOA) module enhancements (see Section 1). ASIP has adopted CMAQ Version 4.5 with SOAmods as its primary model for demonstrating attainment of the 8-hour ozone and $PM_{2.5}$ standards.

In the CMAQ base configuration we will run both the 36 km and 12 km grids using one-way grid nesting where the boundary conditions for the 12 km grid simulation are extracted from the 36 km run using the CMAQ BCON processor. The base configuration of CMAQ will use 19 vertical layers up to a region top of 100 mb (approximately 15 km AGL).

The PPM advection solver would be used along with the spatially varying (Smagorinsky) horizontal diffusion approach. K-theory will be used for vertical diffusion. The minimum eddy diffusion constant (Kz_min) will be based on the new CMAQ Version 4.5 PURB option that depends on the percent of urban land use in the grid cell with Kz_min ranging from 0.1 m^2/s to 2.0 m^2/s when the grid cell is 100% urban.

The MCIP3.0 will be used to process the MM5 data using the "pass through" option and outputting parameters to treat Sea Salt dry deposition and the PURB Kz_min option.

The AERO4/ISORROPIA aerosol chemistry scheme will be used for inorganic aerosol thermodynamics. During the VISTAS testing of the CMAQ Version 4.3 and Version 4.4 models it was noted that the AERO3/ISORROPIA aerosol modules failed to conserve sulfur and nitrogen mass, an examination of the AERO4/ISORROPIA module revealed that this is also likely true for the new version in CMAW Version 4.5. A mass conservation patch developed by the Georgia Institute of Technology (GIT) was added to the model that renormalized the total sulfur, reactive nitrogen and reduced nitrogen species after the call to the aerosol modules to conserve sulfur and nitrogen mass in the model. Sensitivity simulations with and without the mass conservation patch showed it has a very small effect and does not affect model performance, however mass conservation is a fundamental characteristic of the real-world atmosphere so ASIP and VISTAS have retained the mass conservation patch for the CMAQ aerosol modules in the modeling. Note that the GIT mass conservation patch is different that the corrections to the CMAQ mass conservation in CMAQ Version 4.5, the GIT mass conservation patch corrects for sulfur and nitrogen mass loss or gained within the CMAQ aerosol modules, whereas the CMAQ Version 4.5 mass conservation update corrects mass conservation problems in earlier versions of CMAQ in the advection algorithms. The SORGAM scheme, which includes a reversible thermal equilibrium, will be used for secondary organic aerosols. The CB4 gas-phase mechanism will be used in the ASIP and VISTAS modeling.

Table 5-3. ASIP Model Configuration for the CMAQ Chemical Transport Model.

Model Option	CMAQ
Model Version	Version 4.5 (October 2005)
Horizontal Resolution	36/12 km
No. Vertical Layers	NZ = 19
Horizontal Advection	PPM
Vertical Advection	PPM
Horizontal Diffusion	Spatially Varying
Vertical Diffusion (Kz)	K_V (Eddy Diffusion)
Minimum Kz	PURB 0.1 to 2.0 m^2/s
MM5 Configuration	Pleim-Xiu/ACM

Model Option	CMAQ
MM5 Processing	MCIP3.0 Pass Through
Gas-Phase Chemistry	CB4
Gas-Phase Chemistry Solver	EBI/Hertel
Secondary Organic Aerosol	SORGAM w/ SOAmods
Aqueous-Phase Chemistry	RADM
Aerosol Chemistry	AE4/ISORROPIA
Dry Deposition	Pleim-Xiu
Plume-in-Grid	Off
Initial Concentrations	CMAQ Default w/ ~15 day spin-up
Boundary Conditions	3-Hourly 2002 GEOS-CHEM
Emissions	2002 VISTAS States 2002 RPO Inventories

5.3.2 Spin-Up Initialization

For the 2002 annual CMAQ modeling, the model will be exercised separately for four quarters. The 2002 MM5 modeling started on December 17, 2001 at 12Z. Thus, allowing for 12 hours of spin up of the MM5 model, CMAQ will be initialized at 00Z on December 18, 2001. This results in a 13 day spin up period for CMAQ and the first quarter run segment of 2002. For the other quarter run segments of 2002, CMAQ will be initialized with a 15 day spin up period.

5.3.3 Boundary Conditions

Boundary Condition (BC) concentrations along the lateral edges of the 36 km Inter-RPO modeling domain were based on a 2002 simulation of the GEOS-CHEM global chemistry model (Jacob, Park and Logan, 2005). The 2002 GEOS-CHEM output were processed to the CMAQ 36 km domain boundary cells and vertical layer structure (Byun, 2004). The resultant BCs were 3-hourly day-specific based on the 2002 GEOS-CHEM simulation.

5.3.4 Photolysis Rates

Several chemical reactions in the atmosphere are initiated by the photodissociation of various trace gases. To accurately represent the complex chemical transformations in the atmosphere, accurate estimates of these photodissociation rates must be made. The Models-3 CMAQ system includes the JPROC processor, which calculates a table of clear-sky photolysis rates (or J-values) for a specific date. JPROC uses default values for total aerosol loading and provides the option to use default column O3 data or to use TOMS data for total column O3.

JPROC produces a "look-up" table provides the photolysis rates as a function of latitude, altitude, and time (in terms of the number of hours of deviation from local noon, or hour angle). In the current CMAQ implementation, the J-values are calculated for six latitudinal bands (10º, 20º, 30º, 40º, 50º, and 60º N), seven altitudes (0 km, 1 km, 2 km, 3 km, 4 km, 5 km, and 10 km), and hourly values up to ±8 hours of deviation from local noon. During model calculations, photolysis rates for each model grid cell are estimated by first interpolating the clear-sky photolysis rates from the look-up table using the grid cell latitude, altitude, and hour angle, followed by applying a cloud correction factor.

The photolysis rates input file must be prepared as separate look-up tables for each simulation day. The modeling team has already prepared scripts to automate the production of photolysis rate files for each day of the annual simulation. Photolysis files are ASCII files, and these will be visually checked for selected days to verify that photolysis are within the expected ranges.

During the VISTAS modeling errors were found in the TOMS data for a few short periods that affected the CMAQ photolysis rates input. The days with the bad or missing TOMS ozone column data were identified (June 10, August 2-12; and November 18-19) and the following approach was used to fill the bad data:

- June 9 data were used for June 10;
- August 1 data were used for August 2-7;
- August 13 data were used for August 8-12; and
- November 17 data were used for November 18-19.

6.0 QUALITY ASSURANCE PLAN

In this section we discuss the quality assurance procedures that will be used in the ASIP modeling. More details are provided in the ASIP Quality Assurance Project Plan (QAPP; Morris and Stella, 2005).

6.1 Quality Assurance Objectives

In December 2002, the USEPA publish extensive guidance on developing a Quality Assurance Project Plan (QAPP) for modeling studies (EPA, 2002). The objective of a QAPP is to ensure that a modeling study is scientifically sound, robust, and defensible. The new EPA guidance suggests that a QAPP should include the following elements:

- a systematic planning process including identification of assessments and related performance criteria;
- peer reviewed theory and equations;
- a carefully designed life-cycle development process that minimizes errors;
- clear documentation of assumptions, theory, and parameterization that is detailed enough so others can fully understand the model output;
- input data and parameters that are accurate and appropriate for the problem;
- output data that can be used to help inform decision making;
- documentation of any changes from the original quality assurance plan;

Moreover, the EPA guidance specifies that different levels of QAPP may be required depending on the intended application of the model, with a modeling study designed for regulatory purposes requiring the highest level of quality assurance.

The QAPP also provides a valuable resource for project management. It can be used to document data sources and assumptions used in the modeling study, and it can be used to guide project personnel through the data processing and model application process to ensure that choices are consistent with the project objectives.

The modeling team has already developed QA documents and procedures in the VISTAS effort (Morris, Tonnesen and Tesche, 2003) and ASIP modeling (Morris and Stella, 2005).

6.2 Emissions Model Inputs and Outputs

Emissions Quality Assurance (QA) and Quality Control (QC) are the single most critical step in performing air quality modeling studies. Because emissions processing is tedious, time consuming and involves complex manipulation of many different types of large data sets, errors are frequently made in emissions processing and, if rigorous QA measures are not in place, these errors may remain undetected.

As part of the VISTAS and ASIP QA effort, an "Emissions Gatekeeper" function was implemented to QA the emission inventories. The role of this Gatekeeper is to perform quality assurance activities on the following emission inventory (EI) data:

(1) EI data obtained from the VISTAS and ASIP emissions inventory contractors; and
(2) The emission inventory to be used for modeling outside of the States in the Southeastern US region.

Specifically, the Emissions Gatekeeper will review the content and format of the provided emission inventories ensuring an appropriate appraisal of the emissions data and estimates for the Southeastern US States. Other tasks will include any additional translation from mass emissions files into the emissions modeling input file structure necessary for modeling. The Study Team will supplement these activities with QA checks on the intermediate and model output files using internal and public domain visualization and diagnostic packages.

For ASIP, we propose to continue with multistep emissions the QA/QC approach applied in the VISTAS modeling. This includes the initial emissions QA/QC by the Emissions Gatekeeper described above, as well as QA/QC by the Emissions Modeler during the processing of emissions and then additional QA/QC by the air quality modeler of the processed model ready emission files. This multistep process with three separate groups involved in the QA/QC of the emissions is much more likely to catch any errors prior to the air quality model simulations.

6.2.1 Emissions Modeling QA/QC

EMS and EPA Input Screening Error Checking Algorithms: Although the SMOKE emissions model will be used for emissions processing, some of the more advanced EMS input error checking algorithms will be used to screen the data and identify potential emission input errors. Additionally, EPA has issued a revised stack QA and augmentation procedures memorandum that will be used to identify and augment any outlying stacks.

SMOKE error messages: SMOKE provides various cautionary or warning messages during the emissions processing. We will redirect the SMOKE output to log files and review the log files for serious error messages. An archive of the log files will be maintained so that the error messages can be reviewed at a later date if necessary.

SMOKE emissions summaries: We will use QA functions built into the SMOKE processing system to provide summaries of processed emissions as daily totals according to species, source category and county and state boundaries. These summaries will then be compared with summary data prepared for the pre-processed emissions, e.g., state and county totals for emissions from the augmented emissions data.

6.2.2 QA of the Model-Ready Emissions Impacts

The goal of the post-processed emissions summary QA is to detect possible errors in the final, model-ready binary emissions files by preparing summary plots that characterize spatial and temporal patterns in the emissions data. This step is designed to catch errors that may be missed in the internal SMOKE QA procedures. We will use a QA/QC post-processing program that read the CMAQ-ready I/O API emissions file formats for each of the major source categories (mobile, area, point, biogenic, fire) and produce the following plots.

Spatial Summary: We will sum the emissions for all layers and for all 24 hours that is used to prepare a PAVE plot showing the daily total emissions spatial distribution. For a 20 day simulation this produces approximately 20 days x 20 species x 5 emissions categories = 2,000 plots. In our base case simulations these plots will be presented as tons per day. The objective of this step is to identify errors in spatial distribution of emissions.

Vertical Profile: For point sources the emissions total for each layer will be summed and plotted to show the vertical distribution of emissions. These plots show the emissions on the x-axis for each model layer on the y-axis. The objective of this step is to identify possible errors in vertical distribution of emissions.

Short Term Temporal Summary: The total domain emissions for each hour will be accumulated and time series plots prepared that display the diurnal variation in total hourly emissions. The objective of this step is to identify errors in temporal profiles.

Long Term Temporal Summary: The total domain emissions for each day will be accumulated and displayed as time series plots that show the daily total emissions across the domain as a function of time. The objective of this step is to identify particular days for which emissions appear to be inconsistent with other days for no reason (e.g., not a weekend) and compare against the general trend.

Control Strategy Spatial Displays: Spatial summary plots of the daily total emissions differences between a control strategy and base case emissions scenarios will be generated. These plots can be used to immediately identify a problem in a control strategy. For example, if a VISTAS states SO_2 control strategy is being analyzed and there are changes in emissions for other pollutants or for SO_2 outside of the VISTAS states problems in emissions processing can be identified prior to the air quality model simulation.

6.3 Meteorological Model Outputs

As part of the VISTAS effort, a “Meteorological Gatekeeper” function was implemented. As ASIP is using the exactly same 2002 36/12 km meteorological fields as VISTAS, the VISTAS meteorological QA/QC procedures are also applicable to ASIP. The task of the VISTAS Gatekeeper was to provide an independent review and quality assurance of the meteorological modeling and related data sets developed by the VISTAS meteorological modeling contractor (BAMS) and used subsequently by the emissions and air quality modeling teams. This Gatekeeper QA review serves two specific purposes: (a) to ensure that any potential problems with the data sets (should they exist) are identified and corrected in a timely manner, and (b) to provide the study team with information to support ongoing CMAQ model performance testing and sensitivity analyses. In the case of meteorology, the Gatekeeper's independent QA analysis of the MM5 meteorological data sets serves to provide direct assistance to the emissions and air quality modeling team as it undertakes to ratify the SMOKE model outputs and to diagnose CMAQ model performance and sensitivity analyses.

The Meteorological Gatekeeper also has personal responsibility for the quality and chain of custody of the meteorological data sets. In performing the Gatekeeper quality assurance activity, one of the first steps is to conduct an independent operational evaluation on the MM5 model results at 36 km and 12 km grid scale. This evaluation covers surface and aloft wind direction, temperature, mixing ratio, precipitation, and planetary boundary layer (PBL) depths on a continental scale (36 km) and subregional scale (12 km) basis. The specific techniques to be used are described in the MM5 model performance protocol prepared for EPA for annual modeling (McNally and Tesche, 2002). The Gatekeeper will also perform supplemental, ad hoc analysis of pertinent MM5 fields (e.g., PBL depths) where that might be useful to the emissions and air quality modeling teams. Another task of the Gatekeeper will be to exercise the Meteorological Chemistry Interface Processor (MCIP) Version 2.2 is to read the MM5 outputs from BAMS and produce binary input files for the CMAQ Chemical Transport Model (CCTM) to provide the complete set of parameters necessary in the emissions processing and air quality modeling.

In summary, the quality assurance plan for the meteorological data will include the following elements:

- Upon receiving the MM5 and MCIP 2.2 output files from BAMS, we will verify the integrity of the file transfer (e.g., no missing and/or corrupted files);
- Since the CMAQ modeling domain is a subset of the MM5 domain, we will verify that the modeling domain and vertical layer structures in the MCIP files are identical to the CMAQ modeling domain;
- We will select several days of the MM5 output and reprocess the MM5 files with MCIP v2.2 using the predetermined MCIP options. We will then compare the MCIP files with those provided by BAMS to verify that we obtain identical results from the MCIP processing.
- We will create horizontal and vertical plots of temperature, pressure, precipitation, modeled flow patterns, PBL heights, etc. to assess whether the MCIP output fields are reasonable;
- The VISTAS 2002 MM5 simulation will be evaluated using the same surface observations, subdomains and procedures as used to evaluate the WRAP 2002 MM5 simulation as an independent QA and evaluation of the database.

- We will make the plots available on the VISTAS website for viewing and download.

- We will re-process the MM5 output using MCIP3.0 so that ASIP and VISTAS can use the latest (Version 4.5) version of the CMAQ model that includes active treatment of Sea Salt emissions.

6.4 Air Quality Model Inputs and Outputs

Key aspects of QA for the CMAQ input and output data include the following:

- Verification that correct configuration and science options are used in compiling and running each model of the in the CMAQ modeling system, where these include the MCIP, JPROC, ICON, BCON and the CCTM.
- Verification that correct input data sets are used when running each model.
- Evaluation of CCTM results to verify that model output is reasonable and consistent with general expectations.
- Processing of ambient monitoring data for use in the model performance evaluation.
- Evaluation of the CCTM results against concurrent observations.
- Backup and archiving of critical model input data.

The most critical element in the QA plan for CMAQ simulations is the QA/QC of the meteorological and emissions input files. The major QA issue specifically associated with the air quality model simulations is verification that the correct science options were specified in the model itself and that the correct input files were used when running the model. For the CMAQ model we employ a system of naming conventions using environment variables in the compile and run scripts that guarantee that correct inputs and science options are used. We also employ a redundant naming system so that the name of key science options or inputs are included in the name of CMAQ executable program, in the name of the CMAQ output files, and in the name of the directory in which the files are located. This is accomplished by using the environment variables in the scripts to specify the names and locations of key input files. For example, if a model simulation is performed using the CB4 mechanism, all compile and run scripts contain the variable definition "$MECH = CB4", and this variable is hard coded into the script for the executable name, the output file name, and the output directory name. This procedure produces long file/directory names but it effectively prevents mistakes or makes mistakes readily apparent if they do occur.

A second key QA procedure is to never "recycle" run scripts, i.e., we always preserve the original runs scripts and directory structure that were used in performing a model simulation. For example, if we perform simulation with the SAPRC mechanism, instead of editing the original scripts to specify "$MECH = SAPRC" we will create a parallel directory structure with a new set of scripts to perform the SAPRC simulations. This provides a permanent archive of the scripts that were used in performing model simulations. In addition, output from the model simulation will be directed to a log file that provides a record of input file names, warning messages etc that will be archived.

We will also perform a post-processing QA of the CMAQ output files similar to that described for the emissions processing. We will generate animated gif files using PAVE that can be viewed to search for unexpected patterns in the CMAQ output files. In the case of model sensitivity studies, the animated gifs will be prepared as difference plots for the sensitivity case minus the base case. Often, errors in the emissions inputs can be discovered by viewing the animated GIFs. Finally, we will produce 24 hour average plots for each day of the CMAQ simulations. This provides a summary that can be useful for more quickly comparing various model simulations.

7.0 MODEL PERFORMANCE EVALUATION

7.1 OVERVIEW

A critical component of every air quality modeling study is the model performance evaluation where the modeled estimates for the current year base case are compared against observed values to access the model's accuracy and provide an indication of its reliability. As noted previously, the ASIP modeling database, models and modeling approach are intricately linked to the VISTAS modeling. Chapter 11 presents a summary of the current Scope of Work (SOW) for the ASIP Emissions and Air Quality Modeling activities. This ASIP SOW delineates the tasks, approach and schedule for carrying out the various technical activities described in greater detail in this Modeling Protocol. Although the ASIP SOW does not explicitly include the model performance evaluation (MPE) component of the modeling that is being carried out under VISTAS, the MPE is a critically important component of a modeling study so the approaches to be used in the model evaluation of the ASIP/VISTAS databases are described in this section of the ASIP Modeling Protocol.

Consistent with the spirit of a Modeling Protocol for regulatory decision-making, this section lays out the 'roadmap' for achieving an adequately tested modeling system for regulatory usage. But, obviously, this does not mean that every analysis identified in this chapter will be carried out or is indeed even possible given the ASIP and VISTAS schedule and resources, the existing aerometric data bases, and present technology constraints. The roadmap guides the way to the desired destination – in this case, an evaluated, operational PM/regional haze/ozone modeling system – but does not commit the driver to exploring every side street and back country road along the way. Indeed, one expectation of the ASIP and VISTAS is a close working relationship with the modeling team to ensure that the available resources and schedule are applied most efficiently in reaching the aforementioned goal.

This chapter describes a range of model testing methodologies *potentially* available to the Emissions and Air Quality Modeling study team in its efforts to adequately evaluate the performance of the CMAQ air quality modeling system for the 2002 annual period. The final 2002 actual base case modeling will likely be conducted in early 2006. Preliminary 2002 base case simulations and abbreviated model performance evaluation has uncovered several performance issues that have been attempted to be addressed through improvements in model inputs, formulation or both. In this Section we set forth a broad range of methods and techniques that *may* be brought to bear in examining CMAQ model performance. We identify the core operational evaluation procedures, recommended in EPA (2001) $PM_{2.5}$ and regional haze modeling guidance that has been and will continue to be performed as part of the VISTAS modeling efforts. We also describe a broad range of additional performance testing methods that may be worth considering, if deemed needed and resources and time are available.

Clearly, not all of the supplemental evaluative techniques identified in this chapter will ultimately be performed by VISTAS/ASIP. There are three main reasons for this:

- The VISTAS/ASIP SOWs places clear limits on the resources available to perform model evaluation analyses. Accordingly, some evaluation steps, while desirable, simply may not be possible given current funding levels;

- The VISTAS/ASIP SOW places stringent schedule demands on the model evaluation. A number of the model performance evaluation methods introduced in this chapter (e.g. Weight of Evidence analyses, diagnostic testing with individual measurement networks, PM indicator species and ratios analyses could very likely require more time to carry out given their quasi-research nature. Since VISTAS/ASIP is not a model research and development effort, but rather an operational evaluation of existing modeling systems for regulatory decision-making, some interesting, but time consuming analyses simply may not be possible given the present schedule; and

- To conform to the EPA PM guidance documents requirements for PM model testing, it may not be necessary to conduct many of the diagnostic and Weight of Evidence tests identified in this protocol. Indeed, an adequate evaluation of the VISTAS/ASIP modeling system may be possible through straightforward application of the core operational performance evaluation procedures identified in EPA's 2001 draft $PM_{2.5}$ and regional haze and final 2005 8-hour ozone guidance.

At a minimum, the evaluation of the CMAQ modeling system for the annual 2002 simulation will be consistent with EPA's draft guidance on PM model testing and final 8-hour ozone modeling guidance. EPA's guidance essentially calls for an operational evaluation of the model focusing on a specific set of gas phase and aerosol chemical species and a suite of statistical metrics for quantifying model response over the annual cycle. The emphasis is on assessing: (a) How accurately the model predicts observed concentrations? and, (b) How accurately does the model predict responses of predicted air quality to changes in inputs? States are encouraged to utilize the evaluation procedures set forth in the earlier 1991 guidance document (EPA, 1991) for gas phase species and the newer (2001 and 2005) guidance for PM and ozone species. Thus, in carrying out the initial operational evaluation and the subsequent final evaluation, we will implement the suggested EPA performance testing methodologies for the key gas phase and aerosol species. Since these methods are explicitly presented in EPA's guidance documents, there is no need to repeat them here.

We conclude by again emphasizing that most important goal of the CMAQ evaluation is to determine whether the aggregate modeling system (model codes plus input data sets and observational data for testing) offers sufficiently reliable and accurate results that public decision-makers may have reasonable confidence in using the model to help choose between alternative emission control strategies designed to regional haze reduction scenarios. If the CMAQ model evaluation, as outlined in this chapter, provides sufficient evidence that the modeling system is operating reliably and in conformance with measurements and scientific expectations, then specific justifications explaining why the model is acceptable for developing 8-hour ozone, $PM_{2.5}$ and regional haze strategies. Conversely, should the evaluation determine that the modeling system suffers from important flaws or errors that undermine its reliability or use, these findings will also be documented, together with recommendations regarding the use of alternate methods, steps to improve the model and/or data base, or other approaches that can be used in the analysis.

7.2 Context for the Model Performance Evaluation

We begin the discussion of the CMAQ 2002 modeling evaluation methodology by reviewing how the model output is used to project future year 8-hour ozone and $PM_{2.5}$ levels.

When designing a model performance evaluation, it is important to understand how the modeling results will ultimately be used. EPA has published two versions of draft guidance for fine particulate and regional haze modeling (EPA, 2000; 2001), utilizing a Fine Particulate Guidance Workgroup to provide technical input in the development of both documents[1]. More recently, EPA has provided an informal update on the PM/regional haze modeling guidance (Timin, 2002) and conducted a PM model evaluation workshop (see, for example, Timin, 2004; Boylan, 2004) shedding additional light on what the final $PM_{2.5}$ and regional haze guidance document might contain. After issuing several draft guidance documents for 8-hour ozone modeling (EPA, 1999, 2005a, EPA issued the final 8-hour ozone modeling guidance in 2005 (EPA, 2005b). These modeling guidance documents, along with the 1-hour ozone guidance (EPA, 1991) provide a framework for the VISTAS/ASIP model performance evaluation approach.

A key concept in EPA's guidance for addressing 8-hour ozone and $PM_{2.5}$ issues and regional haze is that the modeling results should be used in a relative sense to scale or roll back the observed 8-hour ozone and individual particulate matter (PM) species concentrations. The modeled derived ratios of future-year to current-year scaling factors used to project future-year 8-hour ozone and PM species components are called relative reduction factors (RRFs). As 8-hour ozone concentrations are made up as an average of 1-hour ozone concentrations and there is a wealth of model performance evaluation for 1-hour ozone, then the model performance for 1-hour ozone is important also. Since the model is used to project future year $PM_{2.5}$ species components rather than total $PM_{2.5}$ mass, then the model performance for each of the components that make up $PM_{2.5}$ is actually more important than for total $PM_{2.5}$ mass which the standard was written for. These components are:

- Sulfate (SO4);
- Nitrate (NO3);
- Ammonium (NH4);
- Organic Carbon (OC);
- Elemental Carbon (EC); and
- Other Inorganic fine Particulate (IP or Soil).

The VISTAS/ASIP model testing will concentrate on an operational evaluation of those model predictions that are most necessary for estimating $PM_{2.5}$ (i.e., NH_4, SO_4, NO_3, OC, EC and IP) and 8-hour ozone (i.e., 1-hour and 8-hour ozone) concentrations. Where feasible and supported by sufficient measurement data, we will also evaluate the modeling system for its ability to accurately estimate coarse mass (CM) PM and other gas-phase precursor, product and indicator species. The correct simulation of gas-phase oxidant species is needed for PM since correct, unbiased simulation of gas-phase photochemistry is a necessary element of reliable secondary PM predictions. This evaluation will be carried out across the full Southeastern US domain for the entire year and also on

[1] Members of the VISTAS modeling team participated on this work group over the two-year span of its activities.

subdomains (e.g., ozone and $PM_{2.5}$ nonattainment areas) and month-by-month to daily basis to help build confidence that the modeling system is operating correctly. With this context in mind, we next turn to the philosophy of the model evaluation process.

7.3 Multi-Layered Model Testing Process

EPA's "Draft Guidance for Demonstrating Attainment of Air Quality Goals for $PM_{2.5}$ and Regional Haze" (EPA, 2001) and final guidance for 8-hour ozone modeling (EPA, 2005b) affirms the recommendations of numerous modeling scientists over the past decade (see, for example, Dennis et al., 1990; Tesche et al., 1990, 1994; Seigneur et al., 1998, 2000; Russell and Dennis, 2000; Arnold et al., 2003; Boylan et al., 2003; Tonnesen, 2003) that a comprehensive, multi-layered approach to model performance testing should be performed, consisting of the four components: operational, diagnostic, mechanistic (or scientific) and probabilistic. As applied to $PM_{2.5}$ and 8-hour ozone modeling, this multi-layered framework may be viewed conceptually as follows:

> **Operational Evaluation**: Tests the ability of the model to estimate PM concentrations, the components at PM_{10} and $PM_{2.5}$ (i.e., sulfate, nitrate, ammonium, organic carbon, elemental carbon and other $PM_{2.5}$) and 1-hour and 8-hour ozone concentrations. This evaluation examines whether the measurements are properly represented by the model predictions but does not necessarily ensure that the model is getting "the right answer for the right reason";

> **Diagnostic Evaluation:** For fine PM, this step tests the ability of the model to predict PM chemical composition including PM precursors (e.g., SOx, NOx, and NH_3) and associated oxidants (e.g., ozone and nitric acid); PM size distribution; temporal variation; spatial variation; mass fluxes; and components of light extinction (i.e., scattering and absorption). For 8-hour ozone the diagnostic evaluation tests the models ability to predict the temporal and spatial variations in ozone, ozone precursor species (e.g., VOC, NOx and CO) and key indicator species that provide indication of key photochemical regimes (e.g., NOx/ozone, HNO3/H2O2, NOy, etc.);

> **Mechanistic Evaluation:** Tests the ability of the model to predict the response of PM and ozone to changes in variables such as emissions and meteorology; and

> **Probabilistic Evaluation:** Takes into account the uncertainties associated with the model predictions and observations of PM and ozone.

Within the constraints of the VISTAS/ASIP schedule and resources, the VISTAS/ASIP model evaluation effort will attempt to include elements of each of these components. The operational evaluation will obviously receive the greatest attention since this is the primarily thrust of EPA's 2001 $PM_{2.5}$ and 2005 8-hour ozone guidance. However, we will consider, where feasible and appropriate, diagnostic and mechanistic tests (e.g., use of probing tools, indicator species and ratios, aloft model evaluations, urban vs. rural performance analyses), traditional sensitivity simulations to explore uncertainty, and comparison of the VISTAS/ASIP CMAQ performance with those from other groups (e.g., MANE-VU, MRPO, CENRAP) some of which the use alternative science platforms (e.g., CAMx). The scope of these additional diagnostic and mechanistic tests will be shaped by the resources available and the timing of when such analyses are commissioned relative to the VISTAS/ASIP schedule and resources.

Before discussing the types of testing procedures available for the above evaluation components, we first identify the surface and aloft data sets that are available to support these comparisons.

7.4 Development of Consistent Evaluation Data Sets

7.4.1 Surface Measurements

The ground-level model evaluation database will be developed using several routine and research-grade databases. The first is the routine gas-phase concentration measurements for ozone, NO, NO_2 and CO archived in EPA's Aerometric Information Retrieval System (AIRS/AQS) database. Other sources of information come from the various PM monitoring networks in the U.S. These include the: (a) Interagency Monitoring of Protected Visual Environments (IMPROVE), (b) Clean Air Status and Trends Network (CASTNet), (c) Southeastern Aerosol Research and Characterization (SEARCH), (d) EPA $PM_{2.5}$ and PM_{10} Mass Networks (EPA-FRM), (e) EPA Speciation Trends Network (STN); (f) National Acid Deposition Network (NADP) and (g) EPA Supersites (EPA-SPEC) networks. Typically, these networks provide ozone, other gas phase precursors and product species, PM mass and species, and visibility measurements. Noteworthy for the VISTAS/ASIP evaluation is the 24-hour average and continuous speciated $PM_{2.5}$ and continuous gas-phase concentration measurements available from the SEARCH network for 2002 modeling period. For 2003, additional continuous PM speciated data will be available from the FOCUS network and in the Midwest U.S. ammonia measurements are available. However, since these data were not collected during the 2002 modeling year, their use in the evaluation will be more qualitative and diagnostic.

As an example, the IMPROVE network gives daily (24-hour) average mass concentrations every 3 days for SO_4, NO_3, organic carbon (OC), elemental carbon (EC), soil (IP) and total, $PM_{2.5}$ and PM_{10} mass from which CM can be derived. Some IMPROVE sites also have gas-phase species measurements (e.g., ozone and Great Smokey and Shenandoah National Parks). These data are available at approximately 38 sites in the VISTAS/ASIP 12 km domain. In addition, hourly values of light extinction and deciview are available at several of these sites. The SEARCH network provides 24-hour as well as continuous (hourly) speciated measurements of $PM_{2.5}$ components and other specifics from 8 stations, depending on the time period (Hansen et al., 2003). Of key importance for the ASIP modeling is the ozone and PM performance of the CMAQ model at the, respectively, AIRS/AQS and FRM, and nearby STN, sites that are measuring violations of the 8-hour ozone and $PM_{2.5}$ NAAQS. We will use data from these and the other observational databases listed in Table 7-1, for CMAQ model performance testing.

Ozone measurements are highly accurate and precise, but can be highly influenced by local conditions, such as local NOx sources that can suppress the observed ozone concentrations and make them less representative of the surrounding community. An important consideration in evaluating models for PM is that different PM monitoring networks may use different measurement approaches that "measure" different amounts of the same species that are also different from the modeled species. For example, the IMPROVE network only speciates $PM_{2.5}$ so any sulfate or nitrate in the coarse mode ($PM_{2.5-10}$) is included in the Coarse Mass (CM) species "measurement" (where CM = PM_{10} – $PM_{2.5}$ mass). Because the different monitoring networks may use different measurement technology that results in different "measured" values for the same PM component, the CMAQ model will be evaluated separately for each monitoring network. Ozone is made up of a single species so the mapping of the measured to modeled species is easily accomplished. However, there is sometimes ambiguity in the mapping of modeled PM species to measurements. For example, PM measurements only measure the carbon component of OC, whereas in the model the entire Organic Mass Carbon (OMC) is simulated that includes carbon as well as other elements attached to the carbon (e.g., hydrogen and oxygen). Thus, a factor is assumed to adjust the measured OC to OMC. In the past a 1.4 OMC/OC factor has been used based on urban scale measurements of fresh OC emissions and this is the factor used in the current IMPROVE reconstructed mass equation (Malm, 2000). However, this OMC/OC factor is likely too low, especially for aged OC compounds, and OMC/OC ratios of 1.4 to 2.2 have been observed (Turpin and Lim, 2001) with the current average OMC/OC ratio value of 1.8 being recommended.

The VISTAS Phase I air quality data assessment report (ENVIRON, 2003c) provides more details on the ambient monitoring data available for the VISTAS/ASIP model performance evaluation modeling.

7.4.2 Aloft Measurements

In recent years, the use of instrument aircraft in support of regulatory monitoring and research programs has become much more commonplace. Indeed, in the upper Midwest, the Lake Michigan Air Directors Consortium (LADCo) has been centrally involved in aircraft programs to support model development and applications studies for seventeen (17) years, beginning with pioneering flights in 1987. Supplementing the long-term sampling performed by LADCo in the Midwest, there have been other occasional intensive airborne sampling campaigns throughout the eastern U.S. (e.g., the 1999 SOS field program which provided aloft data for our evaluation of CMAQ for the July '99 episode), that have produced very useful information for air quality model performance testing. Fortunately, during CY-2002, there were at least two mature airborne field programs underway in the eastern U.S. One was centered over the Midwest, the other on the mid-Atlantic coast. A brief characterization of these potentially valuable CMAQ model evaluation data sets is given here. Note that the advanced modeling evaluation using non-routine data sets like aircraft data are not currently planned under the VISTAS/ASIP work efforts. However, their inclusion in the evaluation would provide valuable information on the model accuracy and reliability.

During 2002, the Wisconsin Department of Natural Resources (WDNR) and the Midwest RPO (MRPO) (who funded the Jacko aircraft) collaborated on the support of airborne sampling using two aircraft that, along with ground-based measurements, provided a 3-dimensional representation of air pollution concentrations across the upper Midwest with some flight paths extending south to include the Mammoth Cave, KY and Dolly Sods, WV Class I areas in the VISTAS domain. The goal of the WDNR/MRPO flights was to collect aloft air quality and meteorological data to support model evaluation and data analyses. The aircraft flights were aimed at: (1) characterizing high fine particle and ozone episodes, (2) characterizing air quality over the

Class I areas in the upper Midwest (Isle Royale National Park and Seney National Wildlife Refuge in northern Michigan) on both clean and hazy days, and (3) characterizing urban areas in the Midwest.

As indicated in Table 7-2, airborne sampling was performed over a broad region of the Midwest (including portions of the VISTAS states) from 1 June to 22 November. Lasting 3-5 hours, the WDNR and Jacko aircraft sampled a variety of aerometric parameters (depending upon the flight and aircraft) including wind speed, wind direction temperature, dew point, relative humidity, pressure, O_3, NO, NO_2, NO_x, NO_y, speciated VOCs, carbonyls, HNO_3, NH_3, Hg, SO_4, OC, EC, $PM_{2.5}$, and light scattering (Neph). Still photographs documenting visibility were also collected. Presently, the full WDNR/MRPO aircraft database, from the first flights in 1987 to the recent sampling in 2003 is being aggregated into a master data base archive.

At the University of Maryland, researchers have been using ground-based monitors, radiosondes, profilers, and instrumented aircraft to make observations each year since 1992. Parameters measured included meteorology; selected trace gases; fine particulate chemistry, microphysics and optical properties across broad regions of the middle Atlantic coast. During 2002, the University Research Foundation's Aztec-F aircraft instrument suite included O_3, NO, CO, SO_2 samplers, as well as a NO_2 closed-path tunable diode laser system, and a differential GPS-based meteorology (T, RH) and horizontal wind (*u* and *v* horizontal components) data system. Aztec-F flights were made from 23 May to 3 October, typically lasting 3 hours.

7.5 Model Evaluation Tools

This section introduces the various statistical measures, graphical tools, and related analytical procedures that have proven useful over the years in evaluating grid-based chemical transport models. Many of the methodologies mentioned below have been utilized in the VISTAS Phase I preliminary evaluation and have been refined during the course of the VISTAS and other (e.g., WRAP, MRG, CENRAP) studies. While we plan on calculating a rich variety of statistical performance metrics, only a very limited subset of these measures will actually be relied upon to form judgments concerning model acceptability and in the final reporting.

7.5.1 Statistical Performance Metrics

EPA's 1991 and 2005 ozone and draft 2001 PM and regional haze guidance documents suggests a suite of metrics for use in evaluating model performance. EPA's 1-hour ozone guidance lists three statistical measures with performance goals that a model should achieve before being used to demonstrate ozone attainment in a SIP:

- Mean Normalized Bias (MNB) $\leq \pm 15\%$
- Mean Normalized Gross Error (MNGE) $\leq 35\%$
- Unpaired Peak Accuracy (UPA) $\leq \pm 20\%$

The 1-hour ozone MNB and MNGE performance measures are typically calculated using an observed hourly ozone cutoff threshold of 60 ppb (40 ppb is also used sometimes). These performance measures have also been used for 8-hour ozone model performance evaluation. The newer 8-hour ozone (EPA, 2005b) and draft PM2.5/regional haze (EPA, 2001) modeling guidance focuses more on a holistic model evaluation approach that assesses not only how well the model matches the observation but also whether the model is correctly simulating the processes that produces the elevated ozone and PM concentrations, including a comparison against a conceptual model. In fact some performance measures and goals in earlier versions of the 8-hour ozone guidance (e.g., most daily maximum 8-hour ozone concentrations near the monitor matching to within ±20%; EPA, 1999) were not included in the final version (EPA, 2005b).

Table 7-3 lists a standard set of statistical performance measures that will be used to evaluate fine particulate and ozone models. These performance measures will be calculated using several model performance evaluation software tools for ozone and PM species concentrations, including:

UCR Analysis Tool operates on a Linux platform, performs species and temporal matching of the predictions and observations and generates statistical performance measures, scatter plots and time series plots for user specified subdomains and across all sites and all days, for each site and all days and for each day across all sites.

Alpine Geophysics MAPS Software also operates on a Linux platform generating statistical measures, scatter plots, time series plots and spatial comparisons of predictions and observations. MAPS also spatial averaged performance summaries (e.g., time series of bias and error) that are useful for synthesizing model performance.

PAVE by MCNC is used on a Linux platform to generate spatial maps (tile plots) of model predictions with super imposed observations as colored symbols.

ENVIRON Performance Software calculates performance statistics and exports them along with the predictions and observations to be used with macros operating standard Windows software such as Excel and SURFER to generate graphical displays of model performance that can be customized by the user where the data are also available for further analysis if desired.

The VISTAS/ASIP ozone and PM evaluation of the 2002 36/12 km CMAQ base case simulation will strive to use each of these evaluation packages to some extent to elucidate model performance. Although procedures for assessing ozone model performance are well established since ozone SIPs using photochemical grid modeling in the attainment demonstration have been developed for over a decade (e.g., dating back to the 1994 SIPs; see Morris, 1995). Procedures for evaluating PM models, however, are much less established and research is ongoing. Morris and co-workers (2005) summarize some of the newer PM model evaluation techniques for assessing regional haze models as part of VISTAS, enhancements to these techniques with a focus on urban PM performance will be needed for the ASIP PM2.5 evaluation.

Typically, the statistical metrics are calculated at each monitoring site across the full computational domain for all simulation days. In the VISTAS/ASIP CMAQ evaluation, we will stratify the performance statistics across relevant space and time scales. As part of the operational evaluation, the gas-phase and aerosol statistical measures shown in Table 7-3 will be computed for the full 36 km and 12 km domains, as well as for the individual RPOs (VISTAS, WRAP, CENRAP, MRPO and MANE-VU) and on other subdomains as appropriate (e.g., 8-hour ozone and $PM_{2.5}$ nonattainment areas). Temporally, we will compute the statistical measures for the appropriate averaging times: 1-hour and 8-hour for ozone and hourly for other gas-phase precursors such as NO, NO_2, CO, SO_2; usually 24-hour for sulfate, nitrate, EC, OC, PM and other aerosol species, although some SEARCH sites have continuous PM species and the CASTNet monitoring network measures weekly PM species; and weekly for wet deposition of sulfate, nitrate and ammonium from the NADP network. Where appropriate these results will then be averaged over annual, monthly, and seasonal periods for display, further analysis, and reporting. Should it become necessary as part of model performance diagnosis, we will consider aggregating the statistics in other ways, e.g., (a) day vs. night, (b) weekday vs. weekend, (c) precipitation vs. non-precipitation days, (d) month of the year, and (e) exceedance events, in order to help elucidate model performance problems. The amount of these supplemental time/space analyses would depend on available resources. In subregional performance testing, the focus would likely be on the nonattainment areas, Class I areas and sites where enhanced monitoring (EPA STN and FRM locations, the hourly/daily SEARCH sites) within the VISTAS 12 km domain (Hansen et al., 2003) is available.

As part of the operational evaluation, the metrics defined in Table 7-3 will be calculated for each gas phase species and each fine particulate species in the extinction equation as well as separately for SO_4, NO_3 and ammonium (NH_4) on both the 36 km and 12 km domains. In any diagnostic evaluations that are performed, we will examine the model's ability to estimate the gaseous species listed above from EPA's guidance (EPA, 1991; 2001; 2005). However, in reality ambient gaseous species in 2002 are principally available for ozone, NO_2, SO_2, and CO.

7.5.2 Graphical Representations

The VISTAS/ASIP operational air quality model evaluation will utilize numerous graphical displays to facilitate quantitative and qualitative comparisons between CMAQ predictions and measurements, many of which were used in the VISTAS Phase I Final Report (ENVIRON, 2004) and summarized by Morris and co-workers (2005). Together with the statistical metrics listed in Table 7-3, the graphical procedures are intended to help: (a) identify obviously flawed model simulations, (b) guide the implementation of performance improvements in the 2002 model input files in a logical, defensible manner, and (c) to help elucidate the similarities and differences between the alternative CMAQ simulations. These graphical tools are intended to depict the model's ability to predict the observed fine particulate and gaseous species concentrations.

The VISTAS Phase I modeling helped to refine the suite of graphical tools most effectively in assessing model performance and the differences between the baseline CMAQ runs and sensitivity experiments. The core graphical displays to be considered for use in Phase II include the following:

- Spatial mean concentration time series plots;
- Time series plots at monitoring locations;
- Ground-level gas-phase and particulate concentration maps (i.e., tile plots);
- Concentration scatterplots stratified by station, by time, and by network;
- Bias and error stratified by concentration;

> Bias and error stratified by time;
> Histogram plots of the statistical metrics, stratified by day, by pollutant, by subregion (e.g., 12 km vs. 36 km, by RPO), and by monitoring network; and
> Quantile-Quantile (Q-Q) plots.

These graphical displays will be generated, were appropriate for the full annual cycle as well as for monthly and seasonal periods. The displays will be generated with a consistent suite of products including the UCR analysis tools, Alpine MAPS software and ENVIRON evaluation software.

7.5.3 MAPS/Flying Data Grabber Routines

This section describes the procedures we would implement for the aloft gas phase and PM model evaluation with CMAQ using aircraft data should resources be available to make such a comparison. This aloft performance evaluation would employ aircraft data sets from various sampling programs carried out over the Midwest and eastern U.S. during 2002. Details on how these data are used to evaluate CMAQ performance aloft together with findings from our aloft model evaluations with the 10-21 July 1999 episode are described in the VISTAS Phase I Final Report (ENVIRON, 2004).

The principal challenge in using the aircraft data for meteorological and photochemical model evaluations relates to the 'incommensurability' of Lagrangian aircraft observations with Eulerian (i.e., fixed location) volume-averaged model estimates (see, for example, Hanna, 1994). Aircraft data are essentially continuous, high frequency Lagrangian samples having response times on the order of 30 seconds or less. In contrast, CMAQ model estimates represent hourly-averaged values. Thus, the aircraft data must be averaged in some manner to yield quantities that are at least qualitatively comparable to the air quality fields estimated by CMAQ in the grid volume(s) through which the aircraft passes. The objective is to develop hourly-average time series of measurements and model estimates that are as nearly comparable as possible.

The procedures proposed for processing the aloft meteorological and air quality observations and CMAQ model predictions have been described in several science reports prepared in connection with the Lake Michigan Ozone Study (Tesche and McNally, 1993a-d, 2001) and more recently the Houston-Galveston 1-hr ozone SIP modeling that utilized the TexAQS 2000 data base (Tesche and Jeffries, 2002). These methods, formalized within AG's Flying Data Grabber (FDG*)* model, were employed in Phase I for the 13-21 July 1999 episode. The methods used are substantial extensions of the techniques pioneered a decade ago by Schere and Wayland (1989) for the Regional Oxidant Model (ROM2.0) evaluation against the NEROS database and by Barchet and Dennis (1990) for the RADM/ADOM evaluation (Dennis et al., 1990).

For a typical aircraft (or helicopter flight), the Flying Data Grabber first identifies the specific time interval during which the aircraft was located in a given CMAQ model grid cell along the flight path. The observations are then integrated to produce mean, standard deviation, bias and error estimates for the variable measured within each grid cell of the flight path. This averaging process produces an observed, averaged time series for the above statistical quantities along the flight path. Note, that these time intervals are characteristically much smaller than the one-hour model averaging time. Flight path statistics, together with the mean modeled and observed horizontal winds along the flight paths are also produced by the FDG. The maximum and minimum values during each time segment within a grid cell are also recorded.

The FDG methodology further assumes that the air quality model estimates vary approximately linearly during each hour. It is then straightforward to construct an estimated time series of the modeled values that corresponds to the above-described observed time series derived from the aircraft data. The measurements and model estimates, now on roughly comparable time and space scales, are subsequently processed with the MAPS statistical/graphical software tools described in the Phase I Task 4a report (ENVIRON, 2003d). The statistics of principal interest are the mean values of the observed and modeled concentrations together with estimates of bias and imprecision (i.e., gross error). A variety of graphical representations are also produced to facilitate evaluation an intercomparison.

7.5.4 Use of Multiple Evaluation Packages

In VISTAS Phase I model evaluation (ENVIRON, 2004) relied principally on the UCR evaluation package that was originally developed for WRAP and then enhanced by VISTAS. This package produce scatter plots by site, day or all sites and days, time series plots and statistical measures In the VISTAS/ASIP model evaluation we will attempt to augment the UCR Analysis Tool evaluation software with other software evaluation packages as discussed previously.

7.5.5 Probing Tools and Allied Methods

The VISTAS/ASIP CMAQ model evaluation will employ routine operational evaluation methods and standard statistical metrics (Table 7-4) and graphical displays to support the assessment of whether the model is shown to perform with sufficient accuracy and reliably for its intended purpose. Ideally, this operational evaluation will confirm that the modeling system is performing consistent with its scientific formulation, technical implementation, and at a level that is at least as reliable as other current state-of-science methods. Should unforeseen model performance problems arise in the initial or refined year 2002 model simulations, it may be necessary to draw into the evaluation supplemental diagnostic tools to aid in model testing. These diagnostic techniques are loosely referred to as “probing tools”. The actual need for their use, if any, can only be determined once the initial 2002 CMAQ operational evaluation is completed. Should such diagnostic methods actually be needed, their usage would require additional resources not currently allocated under VISTAS/ASIP. Below, we identify the types of probing tools that could be brought to bear under should their use become necessary.

Current ‘One-Atmosphere” models such as CMAQ and CAMx have been outfitted with a number of “probing tools” that have proven to be very useful in testing and improving model performance and in evaluating emissions control strategies. Among the probing tools available in one or both models are: (a) ozone source apportionment technology (OSAT) algorithms, (b) PM Source Apportionment Technology (PSAT) and Tagged Species Source Apportionment (TSSA) PM source apportionment techniques; (c) process analysis (PA), and (d) the direct decoupled method (DDM) for sensitivity analysis.

Source Apportionment Techniques: CAMx contains a suite of "source attribution" methods for ozone and PM that use reactive tracers that operate in parallel to the host model. The Ozone Source Apportionment Technology (OSAT) tracks ozone formation from user defined source regions and categories based on how the group's ozone precursors contributed to ozone formation. Thus, OSAT decides whether ozone formation is NOx or VOC limited in each grid cell at each time step, and bases ozone attributions on the relative amounts of the limiting precursor from different sources that are present in that grid cell at that time step. These incremental ozone attributions are integrated throughout the model run. The method is generally applicable and has been widely used to aid model diagnosis in the performance testing phase, to guide control strategy development and for ozone culpability assessments (e.g., NOx SIP Call and CAIR). The PM Source Apportionment Technology (PSAT) also uses reactive tracers to rack PM species formation back to user defined source regions and categories based on the primary precursor to the PM species (e.g., sulfate is traced back to SO2 emissions, nitrate is traced back to NOx emissions, etc.). A Tagged Species Source Apportionment (TSSA) approach has also been implemented in CMAQ and tested for sulfate and nitrate (Tonneson, 2004, personal communication). However, TSSA contained unexplained PM source apportionment that has been attributable to mass conservation errors in CMAQ that has been fixed in the latest (Version 4.5, October 2005) of CMAQ (Pleim, 2005).

Decoupled Direct Method (DDM): Various forms of the Decoupled Direct Method (DDM) have been installed in CMAQ and CAMx, based on the original work of Dunker and co-workers (Dunker, 1981; 1984; Dunker et al., 2002) and researchers at Georgia Institute of Technology (GIT). In general, the DDM method: (a) calculates first order sensitivities dC/dP where C is a concentration output and P an input parameter[2], (b) promotes accuracy by using consistent numerical methods and the same time steps for concentrations and sensitivities, (c) optimizes the code for efficiency, but not at expense of accuracy, and (d) calculates sensitivities with respect to parameters representing pollutant sources – emissions, BCs and ICs. Finally, the DDM provides a flexible and powerful user interface for defining various sensitivities including:

- Emissions resolved by geographic area.
- Emissions resolved by source category.
- BCs optionally resolved by boundary edge (N, S, E, W, Top).
- All sensitivities available relative to sources of individual species (NO, PAR, etc.) or species group (VOC, NOx or ALL).
- Simultaneously calculate sensitivities to many initial condition, boundary condition and emissions parameters.

In recent comparisons between CAMx DDM sensitivities and brute-force sensitivities (calculated from +/- 20% perturbations) Dunker et al., (2002a,b) reported that sensitivities of ozone with respect to area source NOx and VOC emissions were calculated and results indicated that the agreement between DDM and brute force sensitivities is excellent. DDM implementation into CMAQ is reported by Kumar (2003).

2 Recent research by Prof. Russell and coworkers at GIT has led to the extension of the CMAQ DDM method to include second order sensitivity coefficients (see, Hakami et al., 2003).

Process Analysis (PA): Photochemical air quality model simulations are usually evaluated primarily in terms of their ability to simulate observed O_3 data. There is an increasing awareness that chemical mechanisms and air quality models must also be evaluated in terms of their ability to simulate the fundamental chemical processes that control O_3 formation and the sensitivity of O_3 to emissions reductions (Arnold et al., 1998). Process analysis is a method for explaining model simulations by adding algorithms to the AQM to store the integrated rates of species changes due to individual chemical reactions and other sink and source processes (Jeffries and Tonnesen, 1994; Tonnesen, 1995). By integrating these rates over time and outputting them at hourly intervals, process analysis provides diagnostic outputs that can be used to explain a model simulation in terms of the budgets of free radicals, production and loss of odd oxygen and O_3, and conversion of NOx to inert forms, as well as the effects of transport and other sink and source terms. Of particular importance to the VISTAS modeling, process analysis can also improve model diagnosis and performance evaluation efforts by identifying processes that are 'out of balance' (Tesche and Jeffries, 2002), by identifying situations for which the model formulation and/or implementation should not be expected to apply and by suggesting how ambient data can be used to evaluate model accuracy for key terms in the chemical processing of VOC and NOx (e.g., Imre et al., 1998). Process Analysis (PA) is implemented in both CMAQ and CAMx and each model supports three complementary aspects of the method: (a) the integrated process rate (IPR), (b) integrated reaction rate (IRR) and (c) chemical process analysis (CPA). Several versions of process analysis (PA) have been implemented in air quality models (AQMs) including both trajectory models (Tonnesen, 1990, 1995) and grid models (Jang et al., 1995, Tonnesen and Dennis, 2000; Arnold et al., 1998; and Wang, 1997). The fundamental approach in all versions of PA is similar: The AQM is modified to calculate the integral over time of the individual sink and source processes and each chemical reaction. These integrated sink/source process rates (IPR) and integrated reaction rates (IRR) can then be stored to a file and analyzed using a post-processor, or some processing can be performed internally in the model and a more limited set of process diagnostic information is output directly by the AQM. Chemical process analysis (CPA) is an improvement on the IRR method whereby some of the processing of IRR information is internalized within the AQM to output chemically meaningful parameters directly (e.g., budget terms for O_3, NOx and odd oxygen).

Process analysis measures for aerosol chemistry have not been analyzed as much as for ozone chemistry. Although the ozone chemistry process analysis is directly related to secondary sulfate and nitrate formation, there is additional process analysis information available in the aerosol modules that are not extracted in either CMAQ or CAMx. In particular, information on sulfate formation and oxidants from the aqueous-phase module and on the sulfate/nitrate equilibrium from the aerosol thermodynamics module would be a useful addition to the current process analysis output.

Because application of all three of these probing tools--source apportionment, DDM, and Process Analysis—are computational intensive and require a fair amount of analysis time to reap the benefits of using the methods, they do not lend themselves directly to annual simulations. However, each method has potential for use in addressing key episodic periods or geographical locations in the VISTAS/ASIP domain where performance in the 2002 simulation may present a problem or where particular attention needs to be focused on emissions controls (a specific nonattainment area for example). In such focused applications, one or more of these probing tools may indeed serve a purpose and will be considered where appropriate.

7.6 Model Evaluation Procedures

EPA draft PM modeling guidance (EPA, 2001, pg. 227) suggests that the performance evaluation focus on two aspects (similar suggestions are contained in the 8-hour ozone modeling guidance, EPA, 2005b):

> How well is the model able to replicate observed concentrations of components of $PM_{2.5}$, total observed mass of $PM_{2.5}$? and
> How accurately does the model characterize the sensitivity of changes in component concentrations to changes in emissions?

Recognizing that the former is much easier to accomplish than the latter, EPA goes on to declare that testing of a model's reliability in estimating the actual effects of emissions changes is the more important. Over the past 20 years, a substantial body of information and analytical techniques has been developed to address the first aspect. Unfortunately, even today there are little rigorous methods available for quantifying the accuracy and precision of a model's predictions of ozone, PM or visibility changes as the result of emissions changes. In this section we explain how the VISTAS/ASIP testing will address the first aspect of the performance evaluation, i.e., how does the model compare against observed data. In section 7.9 we consider the second performance consideration.

7.6.1 Assessment of Ground-Level Gas-Phase and Aerosol Species

Given that $PM_{2.5}$ mass is the sum of the individual components of fine particulate matter and the $PM_{2.5}$ attainment demonstration test involves the separate projection of each PM component, the model should be evaluated separately for each of the key fine particulate matter components that make up $PM_{2.5}$ mass. Current EPA draft PM modeling guidance suggests that the model should also be evaluated for several key gas-phase species that are important for fine particulate modeling. For *particulate species* this includes SO_4 and/or S, NH_4, NO_3, mass associated with SO_4, mass associated with NO_3, elemental carbon (EC), organic carbon (OC), IP, mass of individual constituents of IP, and coarse matter (CM). The *gaseous species* include ozone (O_3), HNO_3, NO_2, PAN, NH_3, NOy, SO_2, CO, and H_2O_2.

For ozone modeling, EPA guidance (EPA, 2001; 2005b) recommends evaluating the model for ozone as well as ozone precursor (e.g., VOC, NOx and CO) as well as key indicator species (e.g., NOy, NOz, HNO3, H2O2, etc.). As noted previously, the 1-hour ozone modeling guidance includes model performance goals, whereas more recent 8-hour ozone (EPA, 2005b) and $PM_{2.5}$ (EPA, 2001) guidance stresses more confirmatory and corroborative techniques and processed based evaluation to assure that the model is getting the right answer for the right reason, in addition to demonstrating that the model exhibits skill in predicting the observed 8-hour ozone and $PM_{2.5}$ concentrations.

At some of the IMPROVE sites there are also direct measurements of hourly extinction using transmissometer or nephelometer instruments that will provide another measure of performance for fine particulate Thus, it would be scientifically interesting to evaluate the model estimated extinction with the hourly measured values at these sites.

As part of the CMAQ operational evaluation, model outputs will be compared statistically and graphically to observational data obtained from the AIRS/AQS, IMPROVE, SEARCH, CASTNet, EPA-FRM, EPA-STN, and other monitoring networks. These monitoring data will be obtained from AIRS, VIEWS, and other appropriate organizations. These comparisons will likely include:

- Daily monthly, seasonal and annual averages for SO_2, SO_4, NO_3, EC, OC, $PM_{2.5}$, and PM_{10}, taking care to exclude periods of sampling interference in the observational data. We will look for systematic biases between the model results and IMPROVE observations, and if biases are found, identify possible sources of error in the model inputs.

- Hourly, high resolution PM species and gaseous species concentrations at sites where available (e.g., SEARCH, AIRS and EPA-Supersites).

- At sites with contrasting aerosol mass loadings, analysis of the temporal behavior of the major scattering and absorbing aerosol constituents along with the visibility trends, to establish correlations.

- For ozone, comparisons against observed hourly and 8-hour ozone concentrations in nonattainment areas.

The types of analysis that could be performed as part of the VISTAS/ASIP CMAQ diagnostic model evaluations that could be considered are:

- Evaluate seasonal trends in observations of organic and inorganic aerosol precursors and their effects on PM composition and visibility, and evaluate the ability of the model to capture these seasonal trends.

- Evaluate how well the model simulates various physicochemical processes by: (a) examining observed and modeled correlations between various species pairs, and (b) comparing model-predicted ratios of various species (individual or families) with observations to evaluate gas/particle partitioning (e.g., nitrate/total nitrate, SO_4/SO_x).

- Investigate the performance of the model at selected observational sites characterized by different chemical regimes that may be encountered either spatially or during different seasons to help identify any inadequacies in the model and to provide a better understanding of conditions under which model inferences may be weak.

- Create scatter plots of modeled vs. observed data and hourly and 24-hour averages by site and subregion to help identify any site-specific biases.

> Create time series plots of predicted and observed concentrations stratified by key variables as appropriate.

> Evaluate for total sulfur ($SO_2 + SO_4$), nitrate ($HNO_3 + NO_3$) and ammonia ($NH_3 + NH_4$).

> Compare observed versus modeled mass fractions of PM constituents at various sites that are characterized by their proximity or remoteness relative to sources, or by specific meteorological conditions (e.g., frontal passage, stagnation, precipitation); these will enable identification of trends in the model of over- or under-prediction of specific PM constituents under these conditions.

> Calculate the measured and predicted relative abundance of key PM components and compare with EPA guideline recommendations and emergent alternative science recommendations (e.g., removing the soil component from the calculations, use of alternative relative importance equations [i.e., Boylan, 2004]).

> Evaluate for ozone precursors and key indicator species and ratios (e.g., HNO3/H2O2) as well as product species.

The suite of statistical metrics and graphical tools identified in the previous section for the core operational evaluation efforts that would likely also be used to diagnose performance problems with the CMAQ simulations should they exist and to highlight differences between model runs. Experience in ozone/PM modeling is the best basis upon which to identify obviously flawed simulation results. Efforts to improve the CMAQ model's base case performance will be made, where necessary, warranted (i.e., to reduce the discrepancies between model estimates and observations), and consistent with the project resources and schedule; however, these model performance improvements efforts must be based on sound scientific principles. "Curve-fitting" exercises will be avoided.

7.6.2 Assessment of Aloft Gas-Phase and Aerosol Species

A substantial number of aircraft flights were conducted during 2002 over the Midwest and Eastern U.S. Should VISTAS elect to fund the optional aloft model performance evaluation, we will endeavor to obtain this information and use it in a scientific performance evaluation of aloft gas-phase and aerosol species (see section 7.3.2).

7.7 Performance Goals and Benchmarks

Establishment of performance goals and benchmarks for regulatory modeling is a necessary but difficult activity. Here, performance goals refer to targets that we believe a good performing model should achieve, where as performance benchmarks are based on historical model performance measures for the best performing simulations. Performance goals are necessary in order to provide consistency in model applications and expectations across the country and to provide standardization in how much weight may be accorded modeling study results in the decision-making process. It is a problematic activity, though, because many areas present unique challenges (e.g., Houston, San

Joaquin Valley, Los Angeles) and no one set of performance goals is likely to fit all needs. Equally concerning is the very real danger that modeling studies will be truncated when the 'statistics look right' before full assessment of the model's reliability is made. This has the potential from breeding built-in compensating errors (Reynolds et al., 1996) as modelers strive to get good statistics as opposed to searching for the explanations for poor performance and then rectifying them. A NARSTO review of more than two-dozen urban-scale ozone SIP applications found this tendency to be all too prevalent in the regulatory modeling of the 1990s. (Roth et al, 1997). In fact more recent

Nearly 15 years ago, research sponsored by the California Air Resources Board (Tesche et al., 1990) led to the agency's adoption of three performance goals for 1-hour ozone modeling in the state:

- > Unpaired (in time and space) peak prediction accuracy (≤ ± 20%);
- > Mean normalized bias in hourly averaged concentrations (≤ ± 15%); and
- > Mean normalized gross error in hourly concentrations (≤ 35%).

These performance goals for 1-hour ozone concentrations were adapted from previous surveys of several dozen urban-scale photochemical grid modeling studies (principally in California) focusing on ozone episodes of 1 to at most 3 days in duration. A surprising number of these studies did not include biogenic VOC emissions in the inventory under the then prevailing belief that biogenics were a negligibly small source category compared to automobile emissions. Most of the studies (Tesche, 1985, 1988; Tesche et al., 1985; 1990) comprising the data base from which the California ozone performance goals were derived entailed hourly ozone concentrations well above background levels 60 ppb. As a result, it was common practice to use a "cutoff values" ranging between 40 ppb to 60ppb to eliminate prediction-observations pairs that would cause these bias and error residual statistics to become extraordinarily large when measured concentrations were low.) Accordingly, normalized statistics such as bias and error proved to be suitable in most applications since the observed concentrations were generally high. These three California ozone model performance goals were adopted by EPA (1991) as part of the nationwide photochemical modeling guidelines and have been heavily used since.

EPA's 1999 draft 8-hour ozone modeling guidance adopted the 1-hour performance goals and added additional performance goals related to 8-hour ozone model performance. For example, the draft 8-hour ozone guidance lists a performance goal to match the observed daily maximum 8-hour ozone concentrations near the monitor to within ±20%.

However, when these evaluation metrics and goals were later applied to evaluate PM species, difficulties arose because performance statistics that divide by low concentration observations become much less useful. Indeed, some observed PM species approach zero (e.g., NO_3) which results in the MNB and MNGE performance metrics approaching infinity. In time, this has led to the introduction of the fractional and normalized mean bias and error metrics (see Table 7-4) in addition to the mean normalized bias and gross error (MNB and MNGE) metrics and related performance expectations based on these alternative measures.

While the 1-hour ozone metrics and goals still have value in interpreting ozone and some gas-phase species performance, it has been necessary to develop new performance metrics and goals for fine particulates. EPA's PM guidance document (EPA, 2001) guidance document identifies particulate matter components of interest to include: SO_4 and/or S, NH_4, NO_3, mass associated with SO_4, mass associated with NO_3, EC, OC, IP, and mass of individual constituents of inorganic primary particulate matter (i.e., IP). Gaseous pollutants of interest include ozone, HNO_3, NO_2, PAN, NH_3, NO_y, SO_2, CO, and H_2O_2. In addition, EPA guidance identifies several potentially useful statistical measures including: (a) accuracy of spatially averaged concentrations near a monitor, (b) fractional bias in means and standard deviations of predictions and observations, (c) normalized bias, (d) normalized gross error, (e) unpaired comparisons between predicted and observed peak concentrations.

As with ozone in the 1980s, actual experience with PM models has led to the development of the current performance expectations for these models. For example, PM_{10} SIP model performance goals for mean normalized gross error of < 30% for southern California (SCAQMD, 1997; 2003) and < 50% for Phoenix (ENVIRON, 1998) have been used. As correctly pointed out by Seigneur and co-workers (2003), the current ability of regional PM models to predicting regional PM and visibility is an area of research with improvements needed for characterizing meteorology and emissions as well as PM models themselves. To this list we would add the need for improvements in model evaluation methodologies as well.

When EPA's draft guidance was developed nearly four (4) years ago, an interim set of fine particulate modeling performance goals were suggested for aggregated mean normalized gross error and mean normalized bias as follows (EPA, 2001):

Pollutant	Gross Error	Normalized Bias
$PM_{2.5}$	~30-50%	~±10%
Sulfate	~30-50%	~±20-30%
Nitrate	~20-70%	~±15-50%
EC	~15-60%	NA
OC	~40-50%	~±38%

Because regional-scale fine particulate and regional haze modeling is an evolving science, and considerable practical application and performance testing has transpired in the intervening years since these goals were postulated, we consider them general guidelines. As part of the VISTAS preliminary model performance evaluation efforts along with the model evaluation studies conducted by WRAP (Tonnesen et al., 2004; CENRAP (Morris et al., 2005), MRPO (Baker, 2005), and other studies has developed model performance goals and criteria for PM species. These goals and a summary of model evaluation display techniques are summarized by Morris and co-workers (2005) and consist of the following:

Fractional Bias	Fractional Error	Comment
≤±15%	≤35%	Ozone model performance goal for which PM model performance would be considered good.
≤±30%	≤50%	A level of model performance that we would hope each PM species could meet
≤±60%	≤75%	At or above this level of performance indicates fundamental problems with the modeling system.

We regard the above goals and criteria not as a pass/fail test, but rather as a basis of intercomparing model performance across studies, sensitivity tests and models.

7-8. Diagnostic and Sensitivity Testing

Rarely does a modeling team find that the first simulation satisfactorily meets all (or even most) model performance expectations. Indeed, our experience has been that initial simulations that 'look very good', usually do so as the result of compensating errors. The norm is to engage in a logical, documented process of model performance improvement wherein a variety of diagnostic probing tools and sensitivity testing methods are used to identify, analyze, and then attempt to remove the causes of inadequate model performance. This is invariably the most technically challenging and time consuming phase of a modeling study. We anticipate that the annual CMAQ model base case simulations will present some performance challenges that may necessitate focused diagnostic and sensitivity testing in order for them to be resolved. Hopefully, these diagnostic and/or sensitivity tests can be adequately carried out within the resources and schedule of Tasks 4a/4b. If not, then it may be necessary to draw upon the Optional Task 14 (Enhanced Model Performance Evaluation) and/or Optional Task 15 (Contingency) resources to conduct the necessary work. Where practical, diagnostic or sensitivity analyses, if needed, could be performed on selected episodes within the annual cycle, thereby avoiding the time-consuming task of running CMAQ for the fully 2002 period. Below we identify the types of diagnostic and sensitivity testing methods that might be employed in diagnosing inadequate model performance and devising appropriate methods for improving the model response.

7.8.1 Traditional Sensitivity Testing

Model sensitivity experiments are useful in three distinct phases or 'levels' of an air quality modeling study and all will be used as appropriate in the VISTAS Phase II modeling with CMAQ. These levels are:

> **Level I**. Model algorithm evaluation and configuration testing;
> **Level II**. Model performance testing, uncertainty analysis and compensatory error diagnosis, and
> **Level III.** Investigation of model output response (e.g., ozone, aerosol, deposition) to changes in precursors as part of emissions control scenario analyses.

Most of the Level I sensitivity tests with CMAQ have already been completed in the Phase I configuration and diagnostic analyses. However, given that open community nature of CMAQ and the frequent science updates to the model and supporting data abases, it is possible that some additional configuration sensitivity testing will be necessary in the early months of Phase II Potential Level I sensitivity runs would be carried out at one or more of the Team's three modeling centers. Potential Level II sensitivity analyses might be helpful in accomplishing the following tasks:

> To reveal internal inconsistencies in the model;
> To provide a basis for compensatory error analysis;

- > To reveal the parameters (or inputs) that dominate (or do not dominate) the model's operation;
- > To reveal propagation of errors through the model; and
- > To provide guidance for model refinement and data collection programs.

At this time, it is not possible to identify one or more Level II sensitivity runs that might be needed to establish a reliable annual 2002 CMAQ base case. The merits of performing Level II sensitivity testing will depend upon whether performance problems are encountered in Tasks 4a/4b. Also, the number of tests possible, should performance difficulties arise, will be limited by the available schedule and Phase II resources under Optional Task 14 (Extended Model Performance Evaluation). Thus, at this juncture, one cannot be overly prescriptive on the number and emphasis of sensitivity runs that may ultimately be desirable in Phase II. However, from past experience with CMAQ and other models, experience it is possible to identify examples of sensitivity runs could be useful in model performance improvement exercises with the annual 2002 CMAQ simulation. These include:

- > Modified biogenic emissions estimates;
- > Modified on-road motor vehicle emissions;
- > Modified air quality model vertical grid structure;
- > Modified boundary conditions;
- > Modified fire emissions;
- > Modified EGU emissions;
- > Modified ammonia emission estimates.
- > Modified aerosol/N_2O_5/HNO_3 chemistry; and
- > Modified NH_3 and HNO_3 deposition velocities.

Note that in a few cases (e.g., vertical grid structure, NH_4 emissions estimates), some sensitivity experimentation has already been carried out in Phase I with the Jan '02, Jul '01 and Jul '99 episodes. To the extent that this Phase I information can help guide the Phase II diagnostics analyses, we will capitalize on this earlier work.

If necessary, Process Analysis extraction outputs can be included in these Level II diagnostic sensitivity simulations in order to provide insight into why the model responds in a particular way to each input modification. Again, the number, complexity, and importance of these types of traditional sensitivity simulations can only be determined once the initial CMAQ annual 2002 simulation(s) are executed.

Level III sensitivity analyses have two main purposes. First, they facilitate the emissions control scenario identification and evaluation processes. Today, four complimentary sensitivity "tools" can be used in regional photochemical models depending upon the platform being used. These methods include: (a) traditional or 'brute force' testing, (b) the direct decoupled method (DDM), (c) Ozone Source Apportionment Technology (OSAT) and PM Source Apportionment Technology (PSAT), and (d) Process Analysis (PA). Each method has its strong points and they will be employed in Phase II where needed. The second purpose of Level III sensitivity analyses is to help quantify the estimated reliability of the air quality model in simulating the atmosphere's response to significant emissions changes. This important model evaluation need is addressed in further detail in section 7.9 below.

Based on experience in other regional studies, examples of Level III monthly or annual sensitivity runs for Phase II might include:

> Ozone, sulfate, nitrate, ammonium and other aerosol sensitivities to SO_2 emissions;
> Ozone, sulfate, nitrate, ammonium and other aerosol sensitivities to elevated point source NO_x emissions;
> Ozone, sulfate, nitrate, ammonium and other aerosol sensitivities to ground level NO_x emissions; and
> Sulfate, nitrate, ammonium and other aerosol sensitivities to ammonia.

Of course, traditional 'brute force' sensitivity experiments are just one way of quantifying these or other Level III sensitivities. Other methods that can be applies include DDM, OSAT, or PSAT simulations.

The need to perform sensitivity experimentation (Levels I, II, or III) will depend on the outcome of the initial operational performance evaluations. If such a need arises, the ability to actually carry out selected sensitivity and/or diagnostic experiments will hinge on the availability of resources and sufficient time to carry out the analyses. Clearly, selection of the specific analysis method will depend upon the nature of the technical question(s) being addressed at the time. Note that as part of VISTAS modeling, Georgia Institute of Technology will be performing emissions sensitivities with CMAQ.

7.8.2 Diagnostic Tests

A rich variety of diagnostic probing tools are available for investigating model performance issues and devising appropriate means for improving the model and/or its inputs. Previously, in section 7.4.4 we introduced the suite of 'probing tools' available for use in the CMAQ and CAMx modeling system for use in Phase II. Where the need exists (i.e., if performance problems are encountered) and assuming VISTAS elects to fund the use of the probing tool applications, these techniques could be employed as appropriate to assist in the model performance improvement efforts associated with the annual 2002 CMAQ basecase development. Here we describe an additional diagnostic method – indicator species and species ratios -- that is potentially useful not only in model performance improvement activities but also in judging the models reliability in estimating the impacts on air quality from future emissions. This method involves the use of so-called 'indicator species' and species ratios. If, during the conduct of Phase II, we determine that application of indicator species and species ratio techniques would be beneficial to the study (and if existing project resources allow), we will discuss with the VISTAS TAWG and ASIP the merits of including this additional probing tool as part of the evaluation effort.

Beginning in the mid 1990s, considerable interest arose in the calculation of indicator species and species ratios as a means of diagnosing photochemical model performance and in assessing model credibility in estimating the effects of emissions changes. Major contributions to the development and refinement of this general diagnostic method over the past decade have been made many scientists including Milford et al., (1994), Sillman (1995, 1999), Sillman et al., (1997), Blanchard (2000), Blanchard and Fairley (2001), and Arnold et al., (2003). Indeed, a recent evaluation of CMAQ using indicator species ratios such as O_3/NO_x, NO_z/NO_y (a measure of chemical aging), and O_3/NO_z (a measure of the ozone production efficiency per NO_x converted), showed not only good agreement with measurements (Arnold et al., 2003) but also convincingly demonstrated the utility of the method for diagnosing model performance in a variety of ways.

Traditionally, indicator species analyses have focused on ozone and its precursor and product species. However the method is equally applicable to PM species and species ratios given sufficient measurement data for comparisons. With some of the high-resolutions monitoring data available from the SEARCH program and the EPA Supersites, it is indeed feasible to compute relevant indicator species and ratios for PM and its component species. For example, Ansara and Pandis (1998) demonstrated how indicator species ratios could be applied to show how the modeled mass of PM might respond to sulfate, nitrate and ammonia emissions-related reductions.

7.9 Corroborative and Weight of Evidence Modeling Analyses

This section identifies additional modeling analyses that might be worth pursuing to add strength to the core model evaluation efforts already planned as part of the VISTAS/ASIP efforts.

7.9.1 Corroborative Models

Noteworthy in EPA's new ozone, PM, and regional haze guidance documents is the encouragement of the use of alternative modeling methods to corroborate the performance findings and control strategy response of the primary air quality simulation model. This endorsement of the use of corroborative methodologies stems from the common understanding that no single photochemical modeling system can be expected to provide exact predictions of the observed ozone and PM species concentrations in a region the size of VISTAS/ASIP, especially over time scales spanning 1-hr to 1 year. Although the photochemical/PM models identified in EPA's PM/regional haze guidance document possess many up-to-date science and computational features, there still can be important differences in modeled gas-phase and aerosol predictions when alternative models are exercised with identical inputs.

As we discovered in the VISTAS/Phase I CMAQ/CAMx inter-comparisons, the general levels of difference revealed between the two model's ozone and PM predictions is typical of what one encounters when inter-comparing alternative state-of-science regional models. These differences provide some insight into the current limits of predictability and reproducibility of today's best photochemical/PM models. In light of these understandable differences in modeling results between state-of-science "One Atmosphere" models, not only is the issue of model selection for VISTAS/ASIP critical[3], but the procedures for the selected model (CMAQ in this instance) and interpreting its output are important as well. Thus, recognizing the uncertainty that attends even the most sophisticated models, the EPA's draft PM/regional haze modeling guidance explicitly addresses the issue of modeling uncertainty by recommending that alternative models (photochemical and observation-based) be considered in the attainment demonstration 'weight of

[3] Model selection is a key issue that all RPOs have addressed and some such as WRAP and VISTAS have chosen CMAQ. Others, such as the MRPO have adopted CAMx instead. Still other RPO's have yet to decide between these two or another model. Clearly, there does not appear to be any one 'right' selection at the present time.

evidence' analyses. Indeed, the Relative Reduction Factor (RRF) approach in the formal attainment demonstration process is designed to address the fact that no model is fully capable of giving precise predictions. In fact the RRF approach was developed in response to the findings of many modelers that alternative, comparable models give somewhat divergent ozone and secondary aerosol predictions.

7.9.2 Weight of Evidence Analyses

EPA's guidance recommends three general types of 'weight of evidence' analyses in support of the attainment demonstration: (a) use of air quality model output, (b) examination of air quality and emissions trends, and (c) the use of corroborative modeling such as alternative models including observation-based (OBM) or observation-driven (OBD) models. We will consider the use of one or more methods in conducting the CMAQ modeling because it could significantly strengthen the credibility and reliability of the modeling available to the states for their subsequent use. The exact details of the 'weight of evidence' analyses must wait until ASIP evolves further. It is premature to prescribe which, if any of the WOE analyses would be performed since the model's level of performance with the 2002 episode is obviously not known at this time and the time and remaining project resources available to support WOE analyses is unknown as well. Also, how much of this WOE analyses will be performed by the modeling team verses states or other has not been determined. Nonetheless, we outline below our thoughts regarding what would likely be considered should the operational CMAQ model evaluation need to be bolstered with WOE analyses.

Use of Air Quality Models. As just discussed, we recommend augmenting the CMAQ annual 2002 and episodic simulations with the use of CAMx to provide additional information on model uncertainty and sensitivity. More specifically the use of CAMx on a somewhat limited basis to corroborate the key model performance evaluation results and emissions control findings of the primary model, CMAQ would be useful. Second, applying the DDM and OSAT/PSAT methods to develop corroborative information on source-receptor relationships and model sensitivities would strengthen the analyses. These supplemental calculations would be performed with one or both models for one or more key periods within the annual 2002 cycle. The results of this additional modeling would be used directly in the 'weight of evidence' analyses to quantify the degree of modeling uncertainty and to corroborate appropriateness of the subsequent PM emissions reductions scenarios.

Use of Emissions and Air Quality Trends. A limited scope emissions and trend analysis could be employed in VISTAS/ASIP to support the 'weight of evidence' determinations. However, traditionally, these types of analyses are performed by the lead agency's own staff. With this expectation, we would coordinate our efforts with the States to develop a trends analysis supporting the future year applications of CMAQ.

Use of Corroborative Observational Modeling. While regulatory modeling studies for ozone attainment demonstrations have traditionally relied upon photochemical models to evaluate ozone control strategies, there has recently been growing emphasis on the use of data-driven models to corroborate the findings of air quality models. As noted, EPA's guidance now encourages the use of such observation-based or observation-driven models (OBMs/ODMs). As part of VISTAS/ASIP, we will consider the merits of using these techniques as supportive weight of evidence. While the OBD/OBM models cannot predict future year air quality levels, they do provide useful corroborative information on the extent to which specific subregions may be VOC-limited or NOx-limited, for example, or where controls on ammonia or SO2 emissions might be most influential in reducing $PM_{2.5}$. Information of this type, together with results of DDM and traditional 'brute-force' sensitivity simulations, can be extremely helpful in postulating emissions control scenarios since it helps focus on which pollutant(s) to control.

7.10 Assessing Model Reliability in Estimating the Effects of Emissions Changes

EPA identifies three methods (EPA, 2001, pg. 228) potentially useful in quantifying a model's reliability in predicting air quality response to changes in model inputs, e.g., emissions. These include:

- Examination of conditions for which substantial changes in (accurately estimated) emissions occur;
- Retrospective modeling, that is, modeling before and after historical significant changes in emissions to assess whether the observed air pollution changes are adequately simulated; and
- Use of predicted and observed ratios of 'chemical indicator species'.

We note that in some urban-scale analyses, the use of weekday/weekend information has been helpful in assessing the model's response to emissions changes.

The first two methods have actually been considered for over 15 years and were the subject of intensive investigations in the early 1990s in Southern California in studies sponsored by the South Coast Air Quality Management District (Tesche, 1991) and the American Petroleum Institute (Reynolds et al., 1996). To date, neither method has proven useful largely because of the great difficulty in developing historical emissions inventories of sufficient quality to make such an analysis credible and the difficulties in removing the influences of different meteorological conditions such that the modeling signal reflects only the model's response to emissions changes. It is difficult enough to construct reliable emissions inventories using today's modeling technology let alone construct retrospective inventories 5-10 years ago prior to the implementation of significant emissions control programs or major land use changes. The use of indicator species, however, offers some promise.

However, recent analytical and numerical modeling studies have demonstrated how the use of ambient data and indicator species ratios can be used to corroborate the future year control strategy estimates of Eulerian air quality models. Blanchard et al., (1999), for example used data from environmental (i.e., smog) chambers and photochemical models to devise a method for evaluating the 1-hr ozone predictions of models due to changes in precursor NOx and VOC emissions. Reynolds et al., (2003) followed up this analysis, augmented with process analysis, to assess the reliability of SAQM photochemical model estimate of 8-hr ozone to precursor emissions cutbacks. With respect to secondary aerosol PM, the recent CMAQ evaluation by Arnold et al. (2003) clearly demonstrated how the use of indicator species analysis could be use to develop insight into the expected reliability and adequacy of a photochemical/PM model for simulating the effects of emissions control scenarios. These researchers used three indicator ratios (or diagnostic ‘probes’) to quantify the model’s response to input changes:

> The ozone response surface probe [O_3/NO_x];
> The chemical aging probe [NO_z/NO_y]; and
> The ozone production efficiency probe [O_3/NO_z].

By closely examining CMAQ’s response to key input changes, properly focused in time and spatial location, Arnold et al., (2003) were able to conclude that the photochemical processing in CMAQ was substantially similar to that in the atmosphere

Thus, the extension of these techniques to address CMAQ predictions for secondary aerosols will doubtless be quite challenging, but the use of indicator species (e.g., ammonia or HNO_3 limitation for nitrate particle formation) and species ratios appears to offer, at this time, the only real opportunity to quantify the expected reliability of the air quality model to correctly simulate the effects of emissions changes. In the CMAQ model evaluation, we will remain alert to opportunities to extend the indicator species ratio analyses to the problem of fine particulate and regional haze. This is one area where technical collaboration between the Emissions and Air Quality Modeling team and the VISTAS and ASIP States and Stakeholders can be especially fruitful in terms of identifying and testing emergent methods for challenging the model’s ability to correctly simulate the effects of future year emissions changes. Finally, we note that this is truly a current research area and as such falls outside the scope of the current modeling effort. However, given its importance, we will remain alert to opportunities to utilize newly available methods should this prove feasible within resources and schedule.

Table 7-1. Ground-Level Ambient Data Monitoring Networks and Stations Available in VISTAS 12 Km Domain for CY-2002.

Monitoring Network	Chemical Species Measured	Sampling Frequency; Duration	Approximate Number of Monitors
IMPROVE	Speciated $PM_{2.5}$ and PM_{10}	1 in 3 days; 24 hr	38
CASTNET	Speciated $PM_{2.5}$, Ozone	Hourly, Weekly; 1 hr, Week	74
SEARCH	24.hr PM25 (FRM Mass, OC, BC, SO4, NO3, NH4, Elem.); 24-hr PM coarse (SO4, NO3, NH4, elements); Hourly PM2.5 (Mass, SO4, NO3, NH4, EC, TC); and Hourly gases (O3, NO, NO2, NOy, HNO3, SO2, CO)	Daily, Hourly;	8
NADP	WSO4, WNO3, WNH4	Weekly	100
EPA-FRM	Only total fine mass ($PM_{2.5}$)	1 in 3 days; 24 hr	313 **(?)**
EPA-SPEC	Speciated $PM_{2.5}$	Varies; Varies	43 **(?)**
AIRS/AQS	CO, NO, NO_2, NO_x, O_3	Hourly; Hourly	6,407

Table 7-2. Aircraft Sampling Programs Performed in the VISTAS 12 Km Domain for CY-2002.

Aircraft Program	Meteorological Parameters & Chemical Species Measured	Sampling Program & Flight Duration	Approximate Number of Flights; Days; Aircraft
University of Maryland (UMD); Univ. Research Foundation (URF)	***Meteorology:*** WS, WD, Temp, RH, ***Air Quality***: O_3, NO, NO_2, CO, SO_2, aerosol absorption, aerosol scattering.	23 May to 3 Oct; Typically 3 hrs	54 flights, 54 days, 1 aircraft
Midwest RPO & Wisconsin DNR	***Meteorology***: WS, WD, Temp, RH, dew point, pressure ***Air Quality***: O_3, NO, NO_2, NO_x, NO_y, speciated VOCs, carbonyls, HNO_3, NH_3, Hg, SO_4, OC, EC, $PM_{2.5}$, light scattering (Neph), visibility pictures.	1 June to 22 Nov; Typically 3-5 hrs	133 flights; 29 days; 2 aircraft (WDNR and Jacko Aircraft)

Table 7-3. Core Statistical Measures to be used in the VISTAS Phase II Air Quality Model Evaluation with Ground-Level Data (see ENVIRON, 2003b,d for details).

Statistical Measure	Shorthand Notation	Mathematical Expression	Notes
Accuracy of paired peak (***A$_p$***)	**Paired_Peak**	$$\frac{P - O_{peak}}{O_{peak}}$$	P_{peak} = paired (in both time and space) peak prediction
Coefficient of determination (***r^2***)	**Coef_Determ**	$$\frac{\left[\sum_{i=1}^{N}(P_i-\overline{P})(O_i-\overline{O})\right]^2}{\sum_{i=1}^{N}(P_i-\overline{P})^2\sum_{i=1}^{N}(O_i-\overline{O})^2}$$	P_i = prediction at time and location *i*; O_i = observation at time and location *i*; $\overline{P}$ = arithmetic average of P_i, i=1,2,…, N; $\overline{O}$ = arithmetic average of O_i, i=1,2,…,N
Normalized Mean Error (***NME***)	**Norm_Mean_Err**	$$\frac{\sum_{i=1}^{N}\lvert P_i-O_i\rvert}{\sum_{i=1}^{N}O_i}$$	Reported as %
Root Mean Square Error (***RMSE***)	**Rt_Mean_Sqr_Err**	$$\left[\frac{1}{N}\sum_{i=1}^{N}(P_i-O_i)^2\right]^{1/2}$$	Reported as %

Statistical Measure	Shorthand Notation	Mathematical Expression	Notes
Fractional Gross Error (F_E)	**Frac_Gross_Err**	$\frac{2}{N}\sum_{i=1}^{N}\left\lvert\frac{P_i - O_i}{P_i + O_i}\right\rvert$	Reported as %
Mean Absolute Gross Error (***MAGE***)	**Mean_Abs_G_Err**	$\frac{1}{N}\sum_{i=1}^{N}\lvert P_i - O_i\rvert$	
Mean Normalized Gross Error (***MNGE***)	**Mean_Norm_G_Err**	$\frac{1}{N}\sum_{i=1}^{N}\frac{\lvert P_i - O_i\rvert}{O_i}$	Reported as %
Mean Bias (***MB***)	**Mean_Bias**	$\frac{1}{N}\sum_{i=1}^{N}(P_i - O_i)$	Reported as concentration (e.g., $\mu g/m^3$)
Mean Normalized Bias (***MNB***)	**Mean_Norm_Bias**	$\frac{1}{N}\sum_{i=1}^{N}\frac{(P_i - O_i)}{O_i}$	Reported as %
Mean Fractionalized Bias (Fractional Bias, ***MFB***)	**Mean_Fract_Bias**	$\frac{2}{N}\sum_{i=1}^{N}\left(\frac{P_i - O_i}{P_i + O_i}\right)$	Reported as %
Normalized Mean Bias (***NMB***)	**Norm_Mean_Bias**	$\frac{\sum_{i=1}^{N}(P_i - O_i)}{\sum_{i=1}^{N}O_i}$	Reported as %
Bias Factor (***BF***)	**Bias Factor**	$\frac{1}{N}\sum_{i=1}^{N}\left(\frac{P_i}{O_i}\right)$	Reported as BF:1 or 1: BF or in fractional notation (BF/1 or 1/BF).

8.0 OZONE AND $PM_{2.5}$ ATTAINMENT DEMONSTRATION

This chapter provides a summary of how the modeling results will be used to demonstrate attainment of the 8-hour ozone and $PM_{2.5}$ standards. The procedures for demonstrating attainment of the 8-hour ozone standard follow those outlined in EPA's final 8-hour ozone modeling guidance (EPA, 2005b). Whereas the procedures for demonstrating attainment of the $PM_{2.5}$ National Ambient Air Quality Standard (NAAQS) follow those given in EPA's draft $PM_{2.5}$ and regional haze modeling standard (EPA, 2001) with updates from the Clean Air Interstate Rule (CAIR; EPA, 2005c) augmented by more recent procedures that use the SANDWICH (Frank, 2005) and Speciated Model Attainment Test (SMAT; Timin, 2005). These procedures are being refined and may be updated during the course of the study including the expected release of EPA's final $PM_{2.5}$ and regional haze modeling guidance in 2006.

8.1 8-Hour Ozone Attainment Demonstration

The procedures for demonstrating attainment of the 8-hour ozone standard are outlined in EPA's final 8-hour ozone modeling guidance document (EPA, 2005b). These procedures include a modeled attainment demonstration test along with performing additional analysis that can be used to support and corroborate the modeled attainment demonstration.

8.1.1 Modeled 8-Hour Ozone Attainment Demonstration Test

The 8-hour ozone modeled attainment demonstration procedures use the modeling results in a relative sense to scale or project the current baseline observed 8-hour ozone Design Values (DVB) to estimate a future-year 8-hour ozone Design Value (DVF) that is compared with the 8-hour ozone NAAQS to determine whether attainment has been demonstrated (DVF < 85 ppb) or not (DVF $\geq$ 85 ppb). The ratio of future-year to current year modeling results is called the Relative Reduction Factor (RRF) and the basic Design Value projection approach for a site i is expressed as follows:

$$DVF_i = RRF_i \times DVB_i$$

Where,

DVB_i = the baseline (current year) 8-hour ozone Design Value (ppb) at monitor i;

DVF_i = the future-year projected 8-hour ozone Design Value (ppb) at monitor i; and

RRF_i = the relative reduction factor, calculated near site i that is the ratio of future to baseline year predicted concentrations near the monitoring site averaged over multiple days.

Although the basic equation for projecting future-year 8-hour ozone Design Values is conceptually simple, there are several assumptions and issues that need to be resolved as follows:

How is the site-specific baseline Design Value [DVB_i] calculated? The baseline 8-hour ozone Design Value is calculated as the three–year average of 8-hour ozone Design Values centered on the 2002 modeling year. As an 8-hour ozone Design Value is the three-year average of the fourth highest daily maximum 8-hour ozone concentration at a site, the DVB "5-year Design Value" will weigh the fourth highest 8-hour ozone concentration from 2000 and 2004 once, 2001 and 2003 twice and 2002 three times.

In calculating the site-specific RRF_i, what is meant by "near the monitor" and which predicted 8-hour ozone concentrations "near" the monitor should be used? Near the monitor is roughly defined as the highest estimated daily maximum 8-hour ozone concentration within 15 km of the monitor. This is obtained by looking for the highest estimated daily maximum 8-hour ozone concentration in an array of NX by NY grid cells centered on the grid cell containing the monitor. EPA guidance presents defaults for the number of cells to use in the array as a function of grid resolution (EPA, 2005b, pg. 16) and for the ASIP 12 km and 36 km resolution grid array sizes centered on the monitor of, respectively, 3 x 3 and 1 x 1 (i.e., just the grid cell containing the monitor) will be used. Thus for each modeling day under consideration, the highest daily maximum 8-hour ozone concentrations near the monitor is extracted for the baseline-year base case simulation out of the 3 x 3 array of cells centered on the monitor for the 12 km simulation. Similarly, the highest daily maximum 8-hour ozone concentrations in the 3 x 3 array of 12 km cells is extracted from the future-year simulation; note that the baseline-year and future-year cell extractions may not be from the same grid cell.

How are future-year projected 8-hour ozone Design Values calculated in unmonitored areas? EPA's 8-hour modeling guidance lists a multistep procedure for projecting future-year 8-hour ozone Design Values away from the monitors:

- Interpolate the observed 8-hour ozone Design Values to generate spatial fields of 8-hour ozone Design Values;
- Adjust the spatial fields using the gridded model output ozone concentrations gradients for the baseline year simulation;
- Apply gridded RRFs to the model adjusted spatial fields of current-year Design Values to obtain gridded fields of future-year projected 8-hour ozone Design Values; and
- Compare spatial fields of projected 8-hour ozone Design Values with the standard to determine whether attainment has been demonstrated across the region.

EPA notes that the Design Value projections in the unmonitored areas is more uncertain and recommends it be done as a separate test to the monitor-based Design Value projections. The procedures for interpolating the observed 8-hour ozone Design Values using modeled ozone gradient predictions is not well defined at this time and EPA is in the process of developing software so that a uniform unmonitored ozone attainment test can be defined. Consequently, initially we will just perform the monitor-based attainment test for the ASIP 8-hour ozone modeling and as a sensitivity we will examine the spatial distribution of the RRFs in each nonattainment area.

Which days should be used in calculating the RRFs? For the ASIP modeling, RRFs will be based on the ratio of the average highest daily maximum 8-hour ozone concentrations near the monitor of the future-year to baseline year for all days in which the baseline year modeled estimated highest daily maximum 8-hour ozone concentration is greater or equal to a threshold-ozone concentration. Initially, a threshold of 85.0 ppb will be used. However, if this results in less than 10 modeling days in the RRF calculation, then the threshold will be successively lowered by 1 ppb until at least 10 modeling days are used in the RRFs or when a minimum threshold of 70.0 ppb is reached. If using a threshold of 70 ppb still results in less than 10 days, then the data will be flagged and discussed with ASIP, especially if less than 5 days are being utilized.

8.1.2 Additional Analysis to Support the Attainment Demonstration

EPA's guidance (EPA, 2005b) lists a series of additional analysis that can be conducted to support and corroborate the modeled ozone attainment demonstration test listed above. EPA notes that cases when the future-year projected 8-hour ozone Design Value is well below (< 82 ppb) the ozone NAAQS less supporting evidence is required then if the projected Design Value is closer to the NAAQS. In fact, EPA recommends that a complete suite of Weight of Evidence (WOE) supporting analysis be performed when the future-year projected 8-hour ozone Design Value is in the 82 to 87 ppb range. EPA notes that with projected Design Values of 88 ppb or above it is very unlikely that supporting analysis could be sufficiently convincing to conclude that the NAAQS will be attained given the results of the modeled attainment test.

EPA lists several additional modeling metrics, supplemental modeling analysis, use of observational models and analyzing emissions and air quality trends data that should be performed as part of the supporting analysis. With the possible exception of calculating additional modeling metrics, most of this additional supporting and WOE analysis will be carried out by the States, although the ENVIRON/Alpine Team may be recruited to assist in this matter at a future date.

8.2 $PM_{2.5}$ Attainment Demonstration

Currently, only the annual average $PM_{2.5}$ NAAQS is violated in the ASIP States so only it will be addressed. However, EPA has proposed to lower the 24-hour $PM_{2.5}$ standard to it may have to be addressed in the future. EPA has issued draft modeling guidance that describes procedures for combining PM monitoring data with modeling results to project future-year $PM_{2.5}$ Design Values for comparison with the NAAQS in an attainment demonstration (EPA, 2001). These procedures are called the Speciated Modeled Attainment Test (SMAT). A preliminary version of the SMAT was applied as part of the proposed Clean Air Interstate Rule (CAIR; EPA, 2004) with the approach refined in the final CAIR (EPA, 2005c,d). Like the ozone projection procedures described above, SMAT uses the modeling results in a relative sense to scale baseline $PM_{2.5}$ Design Values to estimate future-year projected $PM_{2.5}$ Design Values. However, unlike ozone, $PM_{2.5}$ consists of several different components (e.g., sulfate, nitrate, ammonium, etc.). The SMAT develops site-specific separate RRFs for each PM component, projects each PM component to the future-year and then recombines all of the PM components to obtain total $PM_{2.5}$ mass for comparisons with the $PM_{2.5}$ NAAQS.

The SMAT procedures consists of two components: (1) the combination of the $PM_{2.5}$ mass measurements from the Federal Reference Method (FRM) with the speciated $PM_{2.5}$ measurements, such as those from the Speciated Trends Network (STN); and (2) the combination of the modeling results with the speciated FRM $PM_{2.5}$ Design Values to obtain future-year projected $PM_{2.5}$ Design Values.

8.2.1 Speciation of FRM $PM_{2.5}$ Mass Measurements

$PM_{2.5}$ attainment/nonattainment can only be determined from the FRM $PM_{2.5}$ measurements that measure just total $PM_{2.5}$ mass. The FRM $PM_{2.5}$ measurements are used to develop the $PM_{2.5}$ Design Values that determine attainment classification and are used as the starting point for projecting future-year $PM_{2.5}$ Design Values for demonstrating attainment. Thus, representative speciated $PM_{2.5}$ measurements need to be mapped to the FRM measurements. For most FRM sites there is a speciated $PM_{2.5}$ in the same general area that can be used in the mapping. However, in some cases, there is no nearby speciated $PM_{2.5}$ site so speciated $PM_{2.5}$ data must be interpolated from sites surrounding the FRM site.

Speciated $PM_{2.5}$ measurements are routinely collected on the same 1:3 day sampling frequency as used by the FRM network at two monitoring networks in the US: the Speciated Trends Network (STN) and the Interagency Monitoring of Protected Visual Environments (IMPROVE) network. Each of these three monitoring networks use different measurement technologies each of which have their own measurement artifacts. For example, FRM uses a single Teflon filter and includes water in the measurement (after equilibration at ~35% RH) and just measures total $PM_{2.5}$ on the filter. Particulate nitrate may volatilize off of the FRM Teflon filter. The STN measurement technology uses Teflon, Nylon and Quartz filters for measuring the speciated data and does not measure the water component of the $PM_{2.5}$. The STN Quartz filters are also not blank corrected which results in inaccurate OC measurements. IMPROVE also uses multiple filters and does not include ammonium in its measurements.

As the FRM is the de facto regulatory definition of $PM_{2.5}$, EPA has developed procedures for adjusting the STN and IMPROVE speciated $PM_{2.5}$ measurements to account for the measurement artifacts of the different networks and make the speciated PM measurements consistent with the FRM $PM_{2.5}$ mass measurements. These adjustments include the following:

- Adjust nitrates downward to account for volatilization off of the FRM nylon filter;
- Add particle bound water (PBW) that are associated with nitrate and sulfate in the FRM measurements; and
- Estimate total carbonaceous mass accounting for lack of blank correction in the STN measurements.

The resultant fine particle chemical speciation approach has been named the Sulfates, Adjusted Nitrates, Derived Water, Inferred Carbonaceous mass and estimated aerosol acidity (H+), or SANDWICH. Details on the SANDWICH procedures is given in Frank (2005).

8.2.2 Speciated Modeled Attainment Test (SMAT)

The SMAT procedures have been applied for the proposed and final CAIR analysis (EPA, 2004; 2005c) each time with refinements. A SMAT Tool has been developed using the SAS programming language that is populated with 1999-2003 FRM and SANDWICH speciated $PM_{2.5}$ data. Use of 1999-2003 $PM_{2.5}$ data is appropriate for the CAIR modeling since it is centered on the 2001 CAIR modeling year. However, for the ASIP $PM_{2.5}$ projections, FRM and speciated PM data are needed for the 2000-2004 period so that it is centered on the ASIP 2002 modeling year.

Because the CAIR SMAT projections were looking at all FRM monitors, including many without nearby associated speciated $PM_{2.5}$ monitors, the SANDWICH speciated $PM_{2.5}$ data were interpolated to obtained gridded fields of $PM_{2.5}$ speciation that were then used to speciate the FRM data. EPA used a Voroni Nearest-neighbor Approach (VNA) to interpolate the SANDWICH $PM_{2.5}$ speciation components for sulfate, nitrates, OC, EC, crustal/other and a Degree of Neutralization (DON). DON was interpolated instead of ammonium because the IMPROVE network does not measure ammonium and using the DON ammonium can be backed out of the interpolated sulfate values.

Updating the CAIR SMAT Tool with the 2004 data in a consistent fashion and extending it to the 12km grid would be a major undertaking. The interpolation procedures are not well defined. Furthermore, the ENVIRON/Alpine Team has applied the CAIR SMAT Tool and been unable to exactly duplicate EPA's CAIR results, which has been attributable to different versions of SAS used by EPA (PC) and the ENVIRON/Alpine Team (Linux).

ASIP has reviewed the FRM monitors in nonattainment areas in the Southeast US and found that most have an associated STN monitor. However, there is a small subset of FRM sites that the ASIP States did not link to a nearby STN site. In these cases, the State of North Carolina will revise parts of the existing EPA SMAT Tool to get an approximated speciation mix for the FRM site. The State of North Carolina will work with the ASIP States to identify the FRM-STN pairs and process the STN data for 2000-2004 using the SANDWICH procedures so that the FRM PM 2.5 mass measurements can be speciated for the application of the SMAT. Once we have the FRM and associated SANDWICH $PM_{2.5}$ speciation data for the 2000-2004 period, the SMAT procedures involves the following steps:

1. Derive quarterly mean average concentrations for each of the major components of $PM_{2.5}$ and each of the quarters from the 2000-2004 baseline period. This is done by applying the fractional contribution of each major component of $PM_{2.5}$ from the SANDWICH $PM_{2.5}$ speciation data for the same quarter and year. Major components are as follows:

   - Sulfate (SO4);
   - Nitrate (NO3);
   - Ammonium (NH4);
   - Elemental Carbon (EC);
   - Organic Mass Carbon (OMC);
   - Final Crustal/Other; and
   - Particle Bound Water (PBW).

2. Use the model estimated $PM_{2.5}$ components near each monitor and for each of the four quarters of 2002 from the 2009 and 2002 simulations to develop monitor-, quarter- and $PM_{2.5}$ species-specific Relative Reduction Factors (RRFs) using the ratio of the 2009 to 2002 quarterly average modeling results.

3. Apply the monitor-, quarter- and species-specific RRF to each quarterly average observed $PM_{2.5}$ species concentrations from 2000-2004 to obtain 5-years of quarterly average $PM_{2.5}$species concentrations representative of 2009 conditions.

4. Recalculate the Particle Bound Water (PRB) component from the 2009 projected quarterly average sulfate and nitrate concentrations.

5. Average the four quarterly mean 2009 species concentrations to make an annual average $PM_{2.5}$ species concentrations at each monitor and for each of the 5 years (2000-2004). Sum the annual average species components for each of the five years and each monitor to obtain five years of annual average total $PM_{2.5}$ mass concentrations.

6. Calculate the $PM_{2.5}$ Design Values from the five years of 2009 projected annual average $PM_{2.5}$ concentrations and compare against the NAAQS $PM_{2.5}$ in the attainment test.

As in the ozone projections, there are a few issues that need to be resolved and defined to apply the above $PM_{2.5}$ attainment test.

What quarterly average model estimated $PM_{2.5}$ species components are used "near" the monitor? As in the ozone projections, a grid resolution dependent array of cells centered on the monitor is used (i.e., 3 x 3 for 12 km grid and 1 x 1 for 36 km grid). However, for the $PM_{2.5}$ projections the average of the estimated $PM_{2.5}$ species across the array of cells is used, rather than the highest value that is used in the ozone projections.

What $PM_{2.5}$ Design Values should be used in the projections? An average of the 2001, 2002 and 2003 $PM_{2.5}$ Design Values will be used in the $PM_{2.5}$ projections. As a Design Value is a three-year average of annual values, then this three year average of $PM_{2.5}$ Design Values will weigh the annual average $PM_{2.5}$ concentrations from the years 2000 and 2004 once, 2001 and 2003 twice and 2002 three times.

When is $PM_{2.5}$ attainment demonstrated? The SMAT attainment test is passed when the 2009 projected 3-year average Design Value is 14.9 $\mu g/m^3$ or lower. [should this be 15.4 ug/m3???]

8.2.3 Additional Supporting Analysis

Additional supporting analysis to the SMAT modeled $PM_{2.5}$ attainment test will be conducted to corroborate the modeling analysis. The exact definition of the supporting analysis is being analyzed but would like consist of additional modeling metrics as well as emissions and air quality trends and alternative modeling and projection approaches. The supporting analysis to be performed as part of the ASIP $PM_{2.5}$ attainment demonstration will be better defined once EPA has released their final $PM_{2.5}$ modeling guidance. Currently, this additional supporting analysis is planned to be carried out by the ASIP States, although the ENVIRON/Alpine Team may assist at a future date.

9.0 DATA MANAGEMENT

Data management and data security procedures are critical components of the ASIP regional fine particulate and 8-hour ozone modeling. Very large data files are used in each component of the modeling process, including processing of the meteorology data, emissions processing, and $PM_{2.5}$ and ozone modeling with CMAQ. An annual simulation on the ASIP 36-km domain requires approximately 2 Terabytes (Tb) of disk storage, whereas an annual simulation on the ASIP 12-km domain requires over 3 Tb of disk storage. This chapter describes data management practices that will be used in the ASIP 8-hour ozone and $PM_{2.5}$ modeling analyses.

For all critical files we will maintain backup copies either on tapes, storage disks or redundant disk systems. In addition, because ASIP model simulations will be performed separately by the ENVIRON and AG modeling centers, each institution will maintain its own copy and backup of critical input and output files. Because there are differences in system configurations at each of the modeling centers the data backup and archiving are discussed separately for each center, below. Some of the ASIP States will also maintain copies of the modeling data files relevant to their particular nonattainment areas.

CMAQ generates large output files of which most information is rarely used. For example, model output for layers other than the surface layer are typically only used to define boundary conditions for finer grid simulations. Thus, once the boundary condition files have been generated for the ASIP States 12 km and 4 km refined modeling domain, the 3-D CONC files of instantaneous concentrations do not have to be archived. We do not plan redundant archiving for model output files (including output from MCIP and SMOKE) except for key final model outputs (e.g., 2002 and 2009 model-ready emissions) because these files can be regenerated by repeating model simulations, and this is approach more efficient and more cost effective than redundant archiving.

To promote efficient, reliable communication among project participants, the modeling team has created 4 different listservs for VISTAS to aid in dissemination of information and as a primary means for distributing emissions and air quality modeling information. As the ASIP States are a subset of the VISTAS states the same listservs will also be used for ASIP. The listservs are:

- vistas-all@cert.ucr.edu: general project information for all interested persons.
- vistas-modeling@cert.ucr.edu: private list for the VISTAS/ASIP project management team and modeling contractors.
- vistas-emissions@cert.ucr.edu: list for sharing information on emissions processing and QA.
- vistas-met@cert.ucr.edu: list for sharing information on meteorology modeling and processing of MM5 data using MCIP.

These separate listservs are aimed at providing better organization of communications and allowing for detailed discussions of specific topics such as emissions QA.

9.1 Project Website

Depending on the amount of data generated by ASIP, a project website will be established to facilitate the distribution of information. Whether the ASIP website will be part of the VISTAS website or its own has yet to be determined.

9.2 Data Transfer

Data transfer among the modeling centers and between other ASIP participants or contractors will be accomplished using a combination of email, ftp downloads and portable disk drives depending on the size of the data transfer. For data files smaller than a few MB email typically works well and is most efficient. For data files of less than about 500 MB file transfer protocol (ftp) is typically the fastest and most efficient method. ENVIRON and AG each maintain webpages and ftp pages that can be used for exchanging data. In addition, each modeling center has several portable disk drives with both USB2 and firewire interfaces that can be FedEx among project participants to exchange large data sets. Portable disk drives range in size from 80 to 300 GB and are adequate for all large files data transfers. The approach described here has been used throughout the VISTAS project, as well as WRAP, CENRAP and MRPO, and has proven to be economical and efficient.

9.3 Data Backup and Archiving

Data backup and archiving will be performed at each of the modeling centers. Copies of critical project data will be maintained at each modeling center to provide redundant backup of key project data. Each modeling center stores key model inputs on RAID systems that have self re-generation capabilities in case a disk drive fails. In addition, each modeling center will perform backups of key project data to tape or redundant disk storage systems. Data storage and back up resources at each modeling center are described next.

9.3.1 ENVIRON

Over 20,000 Gigabytes (>20 Terabytes, Tb) of disk storage are available to the UNIX/Linux workstations. All of the workstations are networked together and are accessible from each employee's desktop PC. All workstations have CD-ROM drives and can access DLT, 4mm DAT and 8mm Exabyte tape drives for data backup and data transfer. ENVIRON can also create CDs (CD-R and CD-RW) and DVDs (DVD+ and DVD-) for data backup and distribution. For ASIP modeling, all CMAQ simulations will be performed on one of two 13 node Beowulf Linux Clusters that included one master node and 12 processing nodes. Each node consists of two AMD Athlon 2600+ processors. The master nodes have 2 Gb of memory and are connected to a ~3-4 Tb RAID disk system. Each secondary processing node includes 1 Gb of memory. The ENVIRON Novato computing center also includes approximately 10 dual processor Linux workstations with processing speeds of 1700+ to 3000+. Three older Unix workstations are also available, SUN, DEC and SGI. The Linux computer systems are located in their own room with their own dedicated air conditioning (AC) system. The room includes a temperature sensitive power shut off device that will shut off the power to all computers in case the AC breaks down

Appendix D.2

Association for Southeastern Integrated Planning

Modeling Protocol

so that catastrophic failure due to too high temperatures does not occur. Backups are made on IDE disk drives that are removed from the computer and stored on a shelf to protect against power surges destroying the backup data.

9.3.2 Alpine Geophysics

Alpine Geophysics' computing facilities consist of SUN Microsystems SPARCstation computers and a very powerful array of over 20 multiprocessor Linux-based workstations. Disk storage systems include ~20 Tb of aggregate disk space and over 8 Tb of SCSI and IDE Raid-5 protected space. All client data is stored on at least one RAID-5 protected disk array. To further protect client data, two of our main servers backup their disk drives on a weekly basis to a second server that is physically disconnected from the power supply when not doing an active transfer. This way a catastrophic power failure will not compromise the ability for Alpine Geophysics to deliver.

10.0 DOCUMENTATION

This section describes the documentation that be provided during ASIP and the potential for modifications to this Modeling Protocol and Quality Assurance Project Plan (QAPP) that might become necessary as this phase of the study unfolds.

10.1 Planned Documentation

Documentation associated with the ASIP emissions and air quality modeling will include all relevant input data bases and scripts associated with the pre- and post-processing associated with model input development, model application, sensitivity and diagnostic analyses, and performance evaluations. At this time the deliverables consists of disk drives with modeling results and databases for the ASIP States and PowerPoint presentations of the 2009 projections of 8-hour ozone and $PM_{2.5}$ Design Value Projections. Deliverables under the current ASIP modeling contract are as follows:

- ASIP Modeling Protocol (this document)
- ASIP Quality Assurance Project Plan (QAPP)
- CMAQ-ready 2002 36/12 km Typical emissions with every day mobile emissions on the 12 km grid
- CMAQ-ready 2009 36/12 km Typical emissions with every day mobile emissions on the 12 km grid
- PowerPoint presentations of 2009 8-hour ozone and $PM_{2.5}$ Design Value projections
- Disk drive of modeling results and boundary conditions for the NC, ALGA and VA subdomains
- Archive drives of modeling results

Additional deliverables by the modeling team may be added by ASIP at a later date. Chapter 11 contains the current Scope of Work (SOW) for the ENVIRON/Alpine team under the ASIP work effort and the schedule for the deliverables.

10.2 Procedures for Updating Modeling Protocol and QA Plan

One of the underlying realizations stemming from the VISTAS modeling activities was the awareness that the science of 'One-Atmosphere' PM/regional haze modeling is advancing very rapidly. Part of this stems from the parallel activities being carried out by the RPOs; some if it is due to other ongoing 8-hour ozone and PM modeling studies being performed by various states. In addition, EPA is in the process of revising its $PM_{2.5}$ and regional haze guidance documents. Collectively, it is quite likely that there will be new opportunities to strengthen the modeling algorithms, input data sets, and evaluation procedures throughout the duration of the ASIP and VISTAS modeling efforts. Moreover, the ASIP emissions and air quality modeling activities involve the collaboration with the ASIP States as well as other ASIP contractors who will provide the required emissions and meteorological inputs to the SMOKE and CMAQ models. Given the ongoing model refinement activities and the need for strong coordination with other ASIP contractors, it may be necessary to modify certain aspects of this modeling protocol. In this event, modification will be made in consultation with the ASIP project coordinator and the revised protocol will be submitted to the ASIP States for approval.

11.0 ASIP STATEMENT OF WORK AND SCHEDULE

This section describes the current ASIP Statement of Work (SOW) for the ENVIRON/Alpine Modeling Team, the schedule and deliverables under the ASIP work effort. This work currently includes four Tasks that focus on the emissions and air quality modeling for the 2002 calendar year using a 36/12 km grid for two emission scenarios: (1) a 2002 Typical Base Case; and (2) a 2009 Base Case. Unlike VISTAS, ASIP is performing everyday on-road mobile source modeling on the 12 km grid (on the 36 km grid and for VISTAS 36/12 km modeling on-road mobile source emissions modeling are performed for one week from each month). The 2002 and 2009 modeling results will be used to project 2009 8-hour ozone and $PM_{2.5}$ Design Values for the attainment demonstration. The ENVIRON/Alpine Team may be charged with additional Tasks for ASIP in the future at which time this Modeling Protocol will be updated accordingly.

11.1 Task 1: Project Management

The objective of this task is to manage project activities, participate in conference calls, manage the ASIP contract and subcontractors, general oversight and overall quality assurance and the preparation of the Quality Assurance Project Plan (QAPP) and Modeling Protocol (this document).

The management structure for the ASIP Emissions and Air Quality Modeling is similar to what was used in VISTAS with Ralph Morris of ENVIRON serving as Project Manager and Ralph Morris and Gregory Stella of Alpine Geophysics serving as Co-Principal Investigators (Co-PIs) and managing the activities in the ENVIRON and Alpine Geophysics modeling centers, respectively. Section 1.7 provides more details of the ASIP Emissions and Air Quality Modeling management structure. Under this task we are performing all management activities for the ASIP modeling study, including:

- Participation in scheduled conference calls to be held approximately once per month as well as expected ad hoc conference calls to be held as needed.
- Preparation and review of contracts between SESARM and ENVIRON and subcontracts between ENVIRON and Alpine.
- Develop and refine the Scope of Work and conduct contract discussions with the ASIP modeling team and the ASIP technical and project representatives.
- Preparation of monthly reports, invoicing to SESARM and payments to subcontractors.
- Internal project conference calls and discussions among the ENVIRON/Alpine project team.
- Develop and implement the ASIP Quality Assurance Project Plan (QAPP).

- Develop the ASIP Modeling Protocol.

Table 11-1 summarizes the deliverables and expected delivery dates under Task 1 of the ASIP regional ozone and $PM_{2.5}$ SIP support modeling analysis.

Table 11-1. ASIP Task 1 Project Management task deliverables and due dates.

Item	Description	Due Date
1	ASIP Quality Assurance Project Plan (QAPP)	11/30/05
2	ASIP Modeling Protocol	12/15/05
3	Conference Calls with ASIP States	Monthly; 11/05-2006
4	Monthly Reports and Invoices	Monthly; 11/05-2006

11.2 Task 2: 2002/2009 Emissions Modeling

The objective of this task is to perform SMOKE emissions modeling to generate 2002 36/12 km Typical "Base F4" and 2009 36/12 km "Base F4" CMAQ-ready emission inputs using the every day mobile source emissions modeling approach.

Version 2.1 of the SMOKE emissions modeling system will be used to generate 2002 Typical 12 km on-road mobile sources emissions using daily meteorology and the SMOKE MOBILE module. VISTAS has generated 2002 Typical Base F emissions using weekly MOBILE model run for 36 km and 12 km grid as well as generating 2002 Typical Base F 36/12 km emissions for the other source categories (e.g., area, point, non-road, etc.). Under ASIP this task will provide supplemental 2002 daily MOBILE modeling for the 12-km grid. The 2002 12 km Typical daily mobile source emissions will be merged with the other source categories to generate 2002 Typical 12 km emissions inputs based on daily mobile source modeling that will be used in the ASIP ozone and PM modeling.

Also under this task we will process the 2009 Base F annual emissions through the SMOKE emissions processor for all anthropogenic emission source categories to prepare the emissions for use in the CMAQ air quality model. Base F emissions include outputs of the Integrated Planning Model (IPM) for utilities and all inventory revisions from VISTAS and other RPOs that are available by July 2005. Daily 2009 MOBILE run will be used in SMOKE for the 12 km grid and weekly MOBILE run for the 36 km grid.

Table 11-2. ASIP Task 2 2002/2009 Emissions Modeling task deliverables and due dates.

Item	Description	Due Date
1	2002 12 km Typical Base F daily mobile source SMOKE emissions modeling	11/28/05
2	2002 36/12 km Typical Base F CMAQ-ready emissions w/daily mobile source emissions	12/3/05
3	2009 36/12 km Base F CMAQ-ready emissions w/daily mobile sources	12/15/05

11.3 Task 3: 2002/2009 36/12 km Base F CMAQ Modeling

The objective of this task is to run the CMAQ model on the 36 km and 12 km grid for the typical 2002 and 2009 Base F emission scenarios using every day mobile source emissions.

The CMAQ model is applied for the 2002 and 2009 Base F emission scenarios with weekly mobile emissions modeling for the 36 km grid and every day mobile sources emissions on the 12 km grid. QA/QC is performed on the runs including comparisons of the modeling results to the observed PM concentrations. Extractions are made at the ozone and PM monitoring sites, where values at the monitoring site are extracted from the 36 km results and a 3 x 3 grid cell average concentration centered on the monitoring site is extracted for the 12 km modeling results. The 12 km modeling results will be processed to generate boundary condition inputs for the Alabama/Georgia (ALGA) and North Carolina (NC) subdomains and provided to the states of North Carolina and Georgia. Table 11-3 list the deliverables for the ASIP Task 3 CMAQ modeling.

Table 11-3. ASIP Task 3 2002/2009 36/12/ km Base F CMAQ Modeling.

Item	Description	Due Date
1	CMAQ 36/12 km simulations for 2002 Typical Base F w/everyday mobile sources emissions	12/21/05
2	CMAQ 36/12 km simulations for 2009 Base F w/everyday mobile sources emissions	1/15/06
3	Disk with boundary conditions for ALGA and NC subdomains	1/31/06

11.4 Task 4: Data Analysis and Data Management

The objective of this task is to analyze the results of the Task 2 emissions and Task 3 CMAQ air quality modeling, archive and distribute the modeling results.

The SMOKE emissions and CMAQ air quality modeling results will be analyzed. 8-hour ozone projections and annual $PM_{2.5}$ projections will be made at all monitoring sites in and adjacent to the VISTAS states using both the 36 km and the 12 km modeling results. These results will be documented in PowerPoint presentations and presented ASIP states (Table 11-4). The results from the emissions and air quality modeling will also be archived on USB portable disks and delivered to the ASIP states. Summaries of the results will also be available on the Internet.

Table 11-4. ASIP Task 4 2002 CMAQ Modeling task deliverables and due dates.

Item	Description	Due Date
1	PowerPoint Presentation on 2009 8-hour ozone projections	1/31/06
2	PowerPoint Presentation on 2009 $PM_{2.5}$ projections	1/31/06
3	Archive disks of ASIP 2002/2009 modeling results	2/10/06

Appendix E
Emissions Inventory Summary

(This page intentionally left blank)

Tables of Contents

List of Tables of Contents

1. INTRODUCTION

This Appendix contains emission summary tables for the Hickory and Greensboro-Winston Salem-High Point, NC PM2.5 nonattainment areas, all of North Carolina's counties, and the Association for Southeastern Integrated Planning (ASIP) states. The ASIP states include Alabama, Florida, Georgia, Kentucky, Mississippi, North Carolina, South Carolina, Tennessee, Virginia and West Virginia. All the emissions are representative of annual emissions.

The emission summaries are obtained from the emissions modeling reports. In addition to emission summary totals by counties, the stationary point source 2002 emissions are presented by facility for the Hickory county and Greensboro-Winston Salem–High Point counties. The entire county source lists include both EGU and non-EGU. Similarly, the area source and nonroad mobile source 2002 emissions are presented by source category for both Hickory and Greensboro-Winston Salem-High Point areas. These emission summaries are created from an annual source category emissions modeling reports.

2. BASELINE YEAR (2002) INVENTORIES

The emissions in all of the tables of this section are reported in tons/year of pollutant. The emission summary tables below are in the following order:

- 2002 Nonattainment Areas Emissions (Actual and Typical)
- 2002 North Carolina Counties Emissions
- 2002 ASIP States Emissions
- Biogenic Emissions
- 2002 Point Source Emissions by County by Facility
- 2002 Area Source Emissions by Source Category
- 2002 Nonroad Mobile Source Emissions by Source Category

Actual and Typcial emissions for the counties in both nonattainment areas are presented first in Tables 1a, 1b, 2a, and 2b. The "Actual" emissions were used in the air quality model performance evaluation. However, usual wildfire activity and unexpected major point source outages could make the Actual emissions inventory atypical for future year projections. Therefore, a "Typical" emissions inventory was developed to normalize the wildfire activity and include all expected major point sources at usual emissions levels in the nonattainment areas and throughout the entire ASIP region.

Biogenic emissions are temperature dependent and vary from episode to episode. However, since the meteorological inputs are kept constant when modeling the baseline year and future years, the biogenic emissions will remain at the episodic level in both cases. Therefore, the biogenic emissions are only presented at the end of this section.

Note 1: Area source (nonpoint) emissions are as inventoried rather than as modeled. For eight SCC categories, a transport adjustment factor was applied to the particulate emissions (PM 10 and PM 2.5) to reduce the emissions to what will actually travel any significant distance. Also, emissions for SCC 2610000500 (open burning of land clearing debris) and 2801500262 (wheat backfire burning) were accidentally omitted from the modeling by VISTAS. When discovered, there was insufficient money to correct the modeling. See Appendix F.2 for additional information.

Table 1a. Actual 2002 Annual Emissions Summaries For Hickory Nonattainment County

County	Point						Non-road						Area						Mobile					
	VOC	Nox	SO2	PM-10	PM-2.5	NH3	VOC	NOx	SO2	PM-10	PM-2.5	NH3	VOC	NOx	SO2	PM-10	PM-2.5	NH3	VOC	NOx	SO2	PM-10	PM-2.5	NH3

3. FUTURE ATTAINMENT YEAR (2009) EMISSION SUMMARIES

The emissions in all of the tables of this section are reported in tons/year of pollutant. The emission summary tables below are in the following order:

- 2009 Nonattainment Areas Emissions
- 2009 North Carolina Counties Emissions
- 2009 ASIP States Emissions

Table 11. 2009 Annual Emission Summaries For Hickory Nonattainment County

County	Point						Non-road						Area						Mobile					
	VOC	Nox	SO2	PM-10	PM-2.5	NH3	VOC	NOx	SO2	PM-10	PM-2.5	NH3	VOC	NOx	SO2	PM-10	PM-2.5	NH3	VOC	NOx	SO2	PM-10	PM-2.5	NH3
Catawba Co	3501.0	13094.5	10797.5	3755.1	3246.6	8.9	819.0	1178.4	17.2	73.5	70.2	1.5	3964.3	830.0	96.0	4783.8	1333.5	512.6	3984.9	4445.7	31.4	119.2	75.2	251.3

Emissions reported as tons/year.
See Note 1 in section 2

Table 12. 2009 Annual Emission Summaries For Greensboro-Winston Salem-High Point Nonattainment Counties

County	Point						Non-road						Area						Mobile

LIST OF TABLES

1. INTRODUCTION

The attainment modeling for Hickory and Greensboro-Winston Salem-High Point, North Carolina PM2.5 non-attainment areas was performed in conjunction with the regional haze modeling being done by the Southeast Regional Planning Organization, Visibility Improvement State and Tribal Association of the Southeast (VISTAS) and the fine particulate matter (PM2.5) and ozone modeling being done by the Association of Southeastern Integrated Planning (ASIP). VISTAS and ASIP are run by the ten southeast states (Alabama, Florida, Georgia, Kentucky, Mississippi, North Carolina, South Carolina, Tennessee, Virginia and West Virginia). Since the regional haze and PM2.5 modeling uses annual simulations and includes an intermediate year that is the attainment year required for Hickory and Greensboro-Winston Salem-High Point areas, the North Carolina Division of Air Quality (NCDAQ) decided to use the this modeling for its attainment demonstration.

VISTAS/ASIP developed emission estimates for all pollutants of concern for regional haze, fine particulate matter and ozone. The emissions inventory discussions relevant to PM2.5 formation will be discussed in this document.

2. 2002 POINT SOURCE INVENTORY DEVELOPMENT

This section details the development of the 2002 base year inventory for point sources. There were two major components to the development of the point source sector of the inventory. The first component was the incorporation of data submitted by State and Local (S/L) agencies to the United States Environmental Protection Agency (USEPA) as part of the Consolidated Emissions Reporting Rule (CERR) requirements. Work on incorporating the CERR data into the revised base year involved: 1) obtaining the data from the USEPA or the S/L agencies, 2) evaluating the emissions and pollutants reported in the CERR submittals, 3) augmenting CERR data with annual emission estimates for primary coarse particulate matter (PM_{10}-PRI) and $PM_{2.5}$-PRI; 4) evaluating the emissions from electric generating units, 5) completing quality assurance reviews for each component of the point source inventory, and 6) updating the database with corrections or new information from S/L agencies based on their review of the 2002 inventory. The processes used to perform the emission inventory development are described in the first portion of this section.

The second component was the development of a “typical” year inventory for electric generating units (EGUs). The VISTAS/ASIP states determined that a typical year EGU inventory was necessary to smooth out any anomalies in emissions from the EGU sector due to meteorology, economic, and outage factors in 2002. This is consistent with the USEPA's guidance for SIP modeling. The typical year EGU inventory is intended to represent the five-year (2000-2004) period that will be used for the attainment demonstration for the PM2.5 and ozone SIPs, and to determine the regional haze reasonable progress goals. The second part of this section discusses the development of the typical year EGU inventory.

A list of sources located in Hickory and Greensboro-Winston Salem-High Point areas, as well as the annual emissions can be found in Appendix E.

2.1 Development of 2002 Actual Point Source Inventory

VISTAS/ASIP contracted with MACTEC to develop the 2002 emission inventory. NCDAQ submitted the most updated statewide emission inventory to the contractor with the exception of the emissions from the three local programs. For the three local programs, Forsyth, Mecklenburg, and Buncombe Counties, the CERR submittal from the USEPA was used. Once all of the files were obtained, MACTEC ran the files through the USEPA's National Emissions Inventory (NEI) Input Format (NIF) Basic Format and Content checking tool to ensure that the files were submitted in standard NIF format and that there were no referential integrity issues with those files.

The primary task in preparing the 2002 base year inventory was the incorporation of corrections and new information as submitted by the S/L agencies based on their review of the previous draft versions of the inventory. The following subsections document the data sources for the inventory, the checks made on the CERR submittals, the evaluation of EGU emissions, and other quality assurance/quality control (QA/QC) checks. The final subsection summarizes the 2002 NOx and VOC inventory by sector (EGU and non-EGU).

Throughout the development of the point source emissions inventory, the NCDAQ completed detailed reviews of the inventories prepared by the VISTAS/ASIP contractor and provided comments and data corrections when needed.

2.1.1 Consolidated Emissions Reporting Rule

The CERR was published in the Federal Register on Monday, June 10, 2002 (FR Volume 67, Number 111, pp 39602 - 39616). This brief summary is provided as a quick introduction to the CERR and covers the major items in the rule.

The purpose of the CERR is to simplify reporting, offer options for data collection and exchange, and unify reporting dates for various categories of criteria pollutant emission inventories. The rule applies to S/L agencies. Previous reporting requirements have, at times, forced reporting agencies into inefficient collecting and reporting activities. This rule consolidates the emission inventory reporting requirements found in various parts of the Clean Air Act (CAA). Consolidation of reporting requirements will enable S/L agencies to better explain to program managers and the public the necessity for a consistent inventory program, increases the efficiency of the emission inventory program, and provide more consistent and uniform data.

States are required to prepare a comprehensive statewide inventory every three years. The first inventory was for the year 2002 and was due June 1, 2004. This CERR inventory was used for the VISTAS/ASIP 2002 base year.

2.1.2 Initial Data Evaluation

MACTEC conducted an initial review of the 2002 point source CERR data. The following evaluations were completed to identify potential data quality issues associated with the CERR data:

- Compared the number of sites in the CERR submittal to the number of sites in the VISTAS draft 2002 inventory; the number of sites in the CERR submittal was less than in the VISTAS draft 2002 inventory, since the CERR data was limited to major sources, while the VISTAS draft 2002 inventory contained data for both major and minor sources; verified with S/L contacts that minor sources not included in the CERR point source inventory were included in the CERR area source inventory.

- Checked for correct pollutant codes and corrected to make them NIF-compliant.

- Checked for types of particulate matter (PM) codes reported (i.e., PM-FIL, PM-CON, PM-PRI, PM10-PRI, PM10-FIL, PM25-PRI, PM25-FIL); corrected codes with obvious errors (i.e., changed PMPRI to PM-PRI). The PM augmentation process for filling in missing PM pollutants is discussed later in Section 2.1.3.

- Converted all emission values that were not in tons to tons to allow for preparation of emission summaries using consistent units.

- Checked start and end dates in the NIF files to confirm consistency with the 2002 base year.

- Compared annual and daily emissions when daily emissions were reported; in some cases, the daily value was non-zero (but very small) but the annual value was zero. This was generally the result of rounding in an S/L agency's submittal.

- Compared ammonia (NH_3) emissions as reported in the CERR submittals and the 2002 Toxics Release Inventory; worked with S/L agencies to resolve any outstanding discrepancies.

- Compared sulfur dioxide (SO_2) and nitrogen oxides (NOx) emissions for EGUs to the USEPA's Clean Air Markets Division (CAMD) continuous emission monitoring (CEM) database to identify any outstanding discrepancies. A full discussion of the EGU emissions analysis is discussed later in Section 2.1.4.

- Prepared State-level emission summaries by pollutant for both the EGU and non-EGU sectors to allow S/L agencies to compare emissions as reported in the 1999 NEI Version 2, the VISTAS draft 2002 inventory, and the CERR submittals.

- Prepared facility-level emission summaries by pollutant to allow S/L agencies to review facility level emissions for reasonableness and accuracy.

MACTEC communicated the results of these analyses through email/telephone exchanges with the S/L point source contacts as well as through Excel summary spreadsheets. The VISTAS S/L agencies submitted corrections and updates as necessary to resolve any QA/QC issues from these checks.

2.1.3 PM Augmentation

Particulate matter emissions can be reported in many different forms, as follows:

PM Category	**Description**
PM-PRI	Primary PM (includes filterable and condensable)
PM-CON	Primary PM, condensable portion only (all less than 1 micron)
PM-FIL	Primary PM, filterable portion only
PM_{10}-PRI	Primary PM_{10} (includes filterable and condensable)

PM_{10}-FIL	Primary PM_{10}, filterable portion only
$PM_{2.5}$-PRI	Primary $PM_{2.5}$ (includes filterable and condensable)
$PM_{2.5}$-FIL	Primary $PM_{2.5}$, filterable portion only

North Carolina reports PM-PRI, PM_{10}-PRI, and $PM_{2.5}$–PRI in the CERR. From any one of these pollutants, the USEPA has developed augmentation procedures to estimate PM10-PRI, PM_{10}-FIL, $PM_{2.5}$-PRI, $PM_{2.5}$-FIL, and PM-CON. If not included in a S/L inventory, PM_{10}-PRI and $PM_{2.5}$-PRI were calculated by adding PM_{10}-FIL and PM-CON or $PM_{2.5}$ -FIL and PM-CON, respectively.

The procedures for augmenting point source PM emissions are documented in detail in the USEPA's document *Documentation for the Final 1999 National Emissions Inventory {Version 3} for Criteria Air Pollutants and Ammonia – Point Sources*, January 31, 2004. (http://www.epa.gov/ttn/chief/net/1999inventory.html). Briefly, the PM data augmentation procedure includes the following five steps:

- Step 1: Prepare S/L/Tribal PM and PM_{10} Emissions for Input to the PM Calculator
- Step 2: Develop and Apply Source-Specific Conversion Factors
- Step 3: Prepare Factors from PM Calculator
- Step 4: Develop and Apply Algorithms to Estimate Emissions from S/L/Tribal Inventory Data
- Step 5: Review Results and Update the NEI with Emission Estimates and Control Information.

Please refer to the USEPA documentation for a complete description of the PM augmentation procedures.

Table 2.1.3-1 compares the original PM emission estimates from the North Carolina CERR submittals and the revised 2002 VISTAS emissions estimates calculated using the above methodology. This table is intended to show that MACTEC took whatever State/Local provided in the way of PM and filled in gaps to add in PM-CON where emissions were missing in order to calculate PM_{10}-PRI and $PM_{2.5}$ -PRI for all processes to get a complete set of particulate data.

MACTEC did not compare any other pollutants besides PM, since for other pollutants CERR emissions equal VISTAS emissions

Table 2.1.3-1. Comparison of North Carolina PM Emissions: CERR versus the 2002 VISTAS Point Source Inventory

Database	PM-PRI	PM-FIL	PM-CON	PM10-PRI	PM10-FIL	PM2.5-PRI	PM2.5-FIL
CERR	48,110	0	0	36,222	0	24,159	0
VISTAS	48,114	41,407	6,708	36,992	30,284	27,512	21,113

Note 1: CERR refers to data as submitted by S/L agencies; VISTAS refers to data calculated by MACTEC using the PM augmentation methodologies described in this document.

Note 2: The emission values in the VISTAS emission rows above differ slightly from the final values in the inventory. This is due to several corrections and updates to the 2002 inventory submitted by S/L agencies after the PM augmentation was performed as discussed in Section 2.1.3.

After the PM augmentation process was performed, MACTEC executed a series of checks to identify potential inconsistencies in the PM inventory. These checks included:

- PM-PRI less than PM_{10}-PRI, $PM_{2.5}$ -PRI, PM_{10}-FIL, $PM_{2.5}$ -FIL, or PM-CON;
- PM-FIL less than PM_{10}-FIL or $PM_{2.5}$ -FIL;
- PM_{10}-PRI less than $PM_{2.5}$ -PRI, PM_{10}-FIL, $PM_{2.5}$ -FIL or PM-CON;
- PM_{10}-FIL less than $PM_{2.5}$ -FIL;
- PM25-PRI less than $PM_{2.5}$ -FIL or PM-CON;
- The sum of PM_{10}-FIL and PM-CON not equal to PM_{10}-PRI; and
- The sum of $PM_{2.5}$ -FIL and PM-CON not equal to $PM_{2.5}$ -PRI.

MACTEC asked S/L agencies to review this information and provide corrections where the inconsistencies were significant.

Note that for the inventory, only the PM_{10}-PRI and $PM_{2.5}$-PRI emission estimates were retained since they are the only two PM species that are included in the air quality modeling. Other PM species were removed from the inventory to facilitate emissions modeling.

2.1.4 EGU Analysis

MACTEC made a comparison of the annual sulfur dioxide (SO2) and NO_x emissions for EGUs as reported in the S/L agencies CERR submittals and the data from the USEPA's Clean Air Markets Division (CAMD) continuous emission monitoring (CEM) database to identify any outstanding discrepancies. Facilities report hourly CEM data to the USEPA for units that are subject to CEM reporting requirements of the NOx SIP Call rule and Title IV of the CAA. The USEPA sums the hourly CEM emissions to the annual level, and MACTEC compared these annual CEM emissions to those in the S/L inventories. The 2002 CEM inventory containing NOx and SO2 emissions and heat input data were downloaded from the USEPA CAMD web site (www.epa.gov/airmarkets). The data were provided by quarter and emission unit.

The first step in the EGU analysis involved preparing a crosswalk file to match facilities and units in the CAMD inventory to facilities and units in the S/L inventories. In the CAMD inventory, the Office of Regulatory Information Systems (ORIS) identification (ID) code identifies unique facilities and the unit ID identifies unique boilers and internal combustion engines (i.e., turbines and reciprocating engines). In the North Carolina point source emissions inventories, the State and county code (FIPS code) and State facility ID together identify unique facilities and the emission unit ID identifies unique boilers or internal combustion engines. In most cases, there is a one-to-one correspondence between the CAMD identifiers and the S/L identifiers. However, in some of the S/L inventories, the emissions for multiple emission units are summed and reported under one emission unit ID. MACTEC created an Excel spreadsheet that contained an initial crosswalk with the ORIS ID and unit ID in the CEM inventory matched to the State and county FIPS, State facility ID, and emission unit ID in the emissions inventories. The initial crosswalk contained both the annual emissions summed from the CAMD database, as well as, the S/L emission estimate. The matching at the facility level was nearly complete. In some cases, however, S/L agencies or stakeholders' assistance was needed to match some of the CEM units to emission units in the S/L inventories.

The second step in the EGU analysis was to prepare an Excel spreadsheet that compared the annual emissions from the hourly CAMD inventory to the annual emissions reported in the S/L inventory. The facility-level comparison of CEM to emission inventory NOx and SO2 emissions found that for most facilities, the annual emissions from the S/L inventory equaled the CAMD CEM emissions. Minor differences could be explained because the facility in the S/L inventory contained additional small or emergency units that were not included in the CAMD database.

The final step in the EGU analysis was to compare the SO2 and NOx emissions for select Southern Company units in the VISTAS/ASIP region. Southern Company is a super-regional company that owns EGUs in four VISTAS/ASIP States – Alabama, Florida, Georgia, and Mississippi – and participates in VISTAS as an industry stakeholder. Southern Company independently provided emission estimates for 2002 as part of the development of the preliminary VISTAS 2002 inventory. Emission estimates were reviewed by the States and incorporated into the States CERR submittal. There were no major inconsistencies between the Southern Company data, the CAMD data, and the S/L CERR data.

The minor inconsistencies found included small differences in emission estimates (<2 percent difference), exclusion/inclusion of small gas-fired units in the different databases, and grouping of emission units in S/L CERR submittals where CAMD listed each unit individually. MACTEC compared SO_2 and NO_x emissions on a unit-by-unit basis and did not find any major inconsistencies.

2.1.5 Emission Inventory QA Review

Throughout the inventory development process, QA steps were performed to ensure that no double counting of emissions occurred, and to ensure that a full and complete inventory was developed for VISTAS. QA was an important component to the inventory development process and MACTEC performed the following QA steps on the point source component of the VISTAS revised 2002 base year inventory:

1. Facility level emission summaries were prepared and evaluated to ensure that emissions were consistent and that there were no missing sources.

2. State-level EGU and non-EGU comparisons (by pollutant) were developed between the 2002 base year inventory, the draft VISTAS 2002 inventory, and the 1999 NEI Version 2 inventory.

3. Data product summaries and raw NIF 3.0 data files were provided to the VISTAS Emission Inventory Technical Advisor and to the Point Source, EGU, and non-EGU Special Interest Work Group representatives for review and comment. Changes based on these comments were reviewed and approved by the S/L point source contact prior to implementing the changes in the files.

Version numbering was used for all inventory files developed. The version numbering process used a decimal system to track major and minor changes.

2.1.6 Summary of the 2002 Actual Inventory

Tables 2.1.6-1 summarize the final 2002 actual base year inventory for North Carolina. All values are in tons per year. The EGU emissions include the emissions from all processes with a Source Classification Code (SCC) of either 1-01-xxx-xx (External Combustion Boilers – Electric Generation) or 2-01-xxx-xx (Internal Combustion Engines – Electric Generation). Emissions for all other SCCs are included in the non-EGU column.

Table 2.1.6-1 2002 Actual Point Source Inventory for North Carolina

State	All Point Sources	EGUs	Non-EGUs
SO2	522,113	477,990	44,123
NOx	196,782	151,854	44,928
VOC	62,170	988	61,182
CO	64,461	13,885	50,576
PM_{10}-PRI	36,592	22,754	13,838
$PM_{2.5}$-PRI	26,998	16,498	10,500
NH_3	1,234	54	1,180

2.2 Development of Typical Year EGU Inventory

VISTAS/ASIP developed a typical year 2002 emission inventory for EGUs to avoid anomalies in emissions due to variability in meteorology, economic, and outage factors in 2002. The typical year inventory represents the five year (2000-2004) period, which are the years used to calculate the average design value.

Data from the USEPA's CAMD were used to develop normalization factors for producing a 2002 typical year inventory for EGUs. The VISTAS/ASIP contractor used the ratio of the 2000-2004 average heat input and the 2002 actual heat input to normalize the 2002 actual emissions. MACTEC obtained data from the USEPA CAMD for utilities regulated by the Acid Rain program. Annual data for the period 2000 to 2004 were obtained from the CAMD web site. The parameters available were the SO2 and NOx emission rates, heat input, and operating hours.

MACTEC used the actual 2002 heat input and the average heat input for the 5-year period from 2000-2004 as the normalization factor, as follows:

$$\text{Normalization Factor:} \quad \frac{\text{2000-2004 average heat input}}{\text{2002 actual heat input}}$$

If the unit did not operate for all five years, then the 2000-2004 average heat input was calculated for the one or two years in which the unit did operate. The annual actual emissions were multiplied by the normalization factor to determine the typical emissions for 2002, as follows:

Typical Emissions = 2002 actual emissions x Normalization Factor

After applying the normalization factor, some adjustments were needed for special circumstances. For example, a unit may not have operated in 2002 and thus have zero emissions. If the unit had been permanently retired prior to 2002, then MACTEC used zero emissions for the typical year. If the unit had not been permanently retired and would normally operate in a typical year, then MACTEC used the 2001 (or 2000) heat input and emission rate to calculate the typical year emissions.

The final step was to replace the 2002 actual emissions with the 2002 typical year data described above. MACTEC provided the raw data and results of the typical year calculations in a spreadsheet for S/L agency to review and comment. Any comments made were incorporated into the typical 2002 inventory.

Table 2.2-1 summarizes emissions by State and pollutant for the actual 2002 EGU inventory and the typical year EGU inventory. For the entire VISTAS region, actual 2002 NOx emissions were about 0.1 percent lower than the typical year emissions. North Carolina's actual 2002 NOx emissions were 2.0 percent higher than the typical year emissions.

Table 2.2-1 2002 NO_x Emissions Comparison for EGUs

	NO_x Emissions (tons/year)		
State	**Actual 2002**	**Typical 2002**	**Percentage Difference**
AL	161,038	154,704	3.9
FL	257,677	282,507	-9.6
GA	147,517	148,126	-0.4

KY	198,817	201,928	-1.6

VA	86,886	85,081	2.1
WV	230,977	222,437	3.7

3. 2009 POINT SOURCE EMISSIONS INVENTORY DEVELOPMENT

Different approaches were used for different sectors of the point source inventory. For the EGUs, VISTAS/ASIP relied primarily on the Integrated Planning Model® (IPM) to project future generation, as well as, to calculate the impact of future emission control programs. The IPM results were adjusted based on S/L agency knowledge of planned emission controls at specific EGUs. For non-EGUs, VISTAS/ASIP used recently updated growth and control data consistent with the data used in the USEPA's Clean Air Interstate Rule (CAIR) analyses, and supplemented these data with available S/L agency input and updated fuel use forecast data for the United States Department of Energy.

For both sectors, VISTAS/ASIP generated 2009 inventory with control scenarios that account for post-2002 emission reductions from promulgated and proposed federal, State, local, and site-specific control programs as of July 1, 2004. Section 3.1 discusses the EGU projection inventory development, while Section 3.2 discusses the non-EGU projection inventory development.

3.1 EGU Emission Projections

The following subsections discuss the aspects of the development of the EGU projections.

- A chronology of the EGU development process used by MACTEC and discuss key decisions in selecting the final methods for performing the emissions projections.
- The development of the final set of IPM runs that are included in the VISTAS/ASIP 2009 inventory.
- The process of transforming the IPM parsed files into NIF format.

- The process for ensuring that units accounted for in IPM were not double-counted in the non-EGU inventory.

- The QA/QC checks that were made to ensure that the IPM results were properly incorporated into the VISTAS/ASIP inventory.

- The changes to the IPM results that S/L agencies requested be included in the VISTAS/ASIP inventory based on new information that was not accounted for in the IPM runs.

- Summary of 2002 and 2009 EGU emissions by state for NOx and VOC

3.1.1 Chronology of the Development of EGU Projections

Initially, VISTAS/ASIP considered three options for developing the 2009 projection inventory for EGUs:

- Option 1 – Use the results of IPM modeling conducted in support of the proposed CAIR base and control case analyses as the starting point and refine the projections with readily available inputs from stakeholders; these IPM runs were conducted for 2010, which VISTAS would use to represent projected emissions in 2009.

- Option 2 – Use the VISTAS/ASIP 2002 typical year as the starting point, apply growth factors from the Energy Information Administration, and refine future emission rates with stakeholder input regarding utilization rates, capacity, retirements, and new unit information.

- Option 3 – Use the results of a new round of IPM modeling sponsored by VISTAS and the Midwest Regional Planning Organization (MRPO). These runs incorporated VISTAS specific unit and regulation modified parameters, and generate results for 2009 explicitly.

An additional consideration for each of the three options was the inclusion of emission projections developed by the Southern Company specifically for their units. Southern Company is a super-regional company that owns EGUs in Alabama, Florida, Georgia, and Mississippi and participates in VISTAS as an industry stakeholder. Southern Company used their energy budget forecast to project net generation and heat input for every existing and future Southern Company EGU for the year 2009. Further documentation of how Southern Company generated the 2009 inventory for their units can be found in *Developing Southern Company Emissions and Flue Gas*

Characteristics for VISTAS Regional Haze Modeling (April 2005, presented at 14th International Emission Inventory Conference).

Each of these three options and the Southern Company projections were discussed in a series of conference calls with the VISTAS EGU Special Interest Work Group (SIWG) during the fall of 2004. During a conference call on December 6, 2004, the VISTAS EGU SIWG approved the use of the latest VISTAS/MRPO sponsored IPM runs (Option 3) to represent 2009 EGU forecasts of emissions the future year cases.

The Option 3 IPM modeling resulted from a joint agreement by VISTAS and MRPO to work together to develop future year utility emissions based on IPM modeling. The decision to use IPM modeling was based in part on a study of utility forecast methods by E.H. Pechan and Associates, Inc. (Pechan) for MRPO, which recommended IPM as a viable methodology (see *Electricity Generating Unit {EGU} Growth Modeling Method Task 2 Evaluation*, February 11, 2004). Although the USEPA used IPM recently to support their rulemaking for the CAIR, VISTAS stakeholders felt that certain model inputs needed to be improved. Thus, VISTAS and MRPO decided to hire contractors to conduct new IPM modeling and to post-process the IPM results. Southern Company projections in 2009 were roughly comparable with IPM.

In August 2004, VISTAS/ASIP contracted with ICF to run IPM to provide utility forecasts for 2009 under two future scenarios – Base Case and CAIR Case. The Base Case represents the current operation of the power system under currently known laws and regulations, including those that come into force in the study horizon. The CAIR Case is the Base Case with the proposed CAIR rule superimposed. The run results were parsed at the unit level for 2009. The IPM output files were delivered by ICF in November, and the post-processed data files were delivered by Pechan in December 2004. Only the CAIR case was used in the final 2009 modeling.

On March 10, 2005, the USEPA issued the final CAIR. VISTAS and MRPO, in conjunction with other RPOs, conducted another round of IPM modeling, which reflected changes to control assumptions based on the final CAIR as well as additional changes to model inputs based on S/L agency and stakeholder comments. Several conference calls were conducted in the spring/summer of 2005 to discuss and provide comments on IPM assumptions related to six main topics: power system operation, generating resources, emission control technologies, set-up parameters and rule, financial assumptions, and fuel assumptions.

For the summer 2006 set of IPM runs, ICF generated two different parsed files. One file includes all fuel burning units (fossil, biomass, landfill gas), as well as, non-fuel burning units (hydro, wind, etc.). The second file contains just the fossil-fuel burning units (e.g., emissions from biomass and landfill gas are omitted). The RPOs decided to use the fossil-only file for modeling to be consistent with the USEPA, since the USEPA used the fossil only results for CAIR analyses. For the 10 VISTAS states, non-fossil fuels accounted for only 0.13 percent of the NOx emissions and 0.04 percent of the SO2 emissions in the 2009 IPM runs

VISTAS/ASIP asked S/L agencies to review the results of the summer 2006 set of IPM runs, which were incorporated into the VISTAS inventory. The NCDAQ primarily reviewed and commented on the IPM results with respect to IPM decisions on NOx post-combustion controls and SO2 scrubbers.

3.1.2 VISTAS/MRPO IPM runs for EGU sources

The following summary of the VISTAS/MRPO IPM® modeling is based on ICF's documentation *Future Year Electricity Generating Sector Emission Inventory Development Using the IPM® in Support of Fine Particulate Mass and Visibility Modeling in the VISTAS and Midwest RPO Regions,* April 2005. The ICF documentation is to be used as an extension to EPA's proposed CAIR modeling runs documented in *Documentation Supplement for EPA Modeling Applications (V.2.1.6) Using the IPM,* EPA 430/R-03-007, July 2003.

IPM provides "forecasts of least-cost capacity expansion, electricity dispatch, and emission control strategies for meeting energy demand and environmental, transmission, dispatch, and reliability constraints." The underlying database in this modeling is USEPA's National Electric Energy Data System (NEEDS) released with the CAIR Notice of Data Availability (NODA). The NEEDS database contains the existing and planned/committed unit data in the USEPA modeling applications of IPM. NEEDS includes basic geographic, operating, air emissions, and other data on these generating units. VISTAS States and stakeholders provided changes for:

- NO_x post-combustion control on existing units
- SO_2 scrubbers on existing units
- SO_2 emission limitations
- PM controls on existing units
- Summer net dependable capacity
- Heat rate for existing units
- SO_2 and NO_x control plans based on State rules or enforcement settlements

The years 2009 and 2018 were explicitly modeled in this set of runs.

3.1.3 Post-Processing of IPM Parsed Files

The following summary of the VISTAS/MRPO IPM modeling is based on Pechan's documentation *LADCO IPM Model Parsed File Post-Processing Methodology and File Preparation*, February 8, 2005. The essence of the IPM model post-processing methodology is to take an initial IPM model output file and transform it into air quality model input files. ICF via VISTAS/MRPO provided an initial spreadsheet file containing unit-level records of both (1) "existing" units and (2) committed or new generic aggregates.

All records have unit and fuel type data; existing, retrofit (for SO2 and NOx), and separate NOx control information; annual SO2 and NOx emissions and heat input; summer season (May-September) NOx and heat input; July day NOx and heat input; coal heat input by coal type; nameplate capacity (MW), and State FIPS code. Existing units also have county FIPS code, a unique plant identifier (ORISPL) and unit ID (also called boiler ID) (BLRID); generic units do not have these data. The processing includes estimating various types of emissions and adding in control efficiencies, stack parameters, latitude-longitude coordinates, and State identifiers (plant ID, point ID, stack ID, process ID). Additionally, the generic units are sited in a county and given appropriate IDs. This processing is described in more detail below.

The data are prepared by transforming the generic aggregates into units similar to the existing units in terms of the available data. The generic aggregates are split into smaller generic units based on their unit types and capacity, are provided a dummy ORIS unique plant and boiler ID, and are given a county FIPS code based on an algorithm that sites each generic by assigning a sister plant that is in a county based on its attainment/nonattainment status. Within a State, plants (in county then ORIS plant code order) in attainment counties are used first as sister sites to generic units, followed by plants in PM2.5 nonattainment counties, followed by plants in 8-hour ozone nonattainment counties. Note that no LADCO or VISTAS States provided blackout counties that would not be considered when siting generics, so this process is identical to the one used for the USEPA IPM post-processing.

SCCs were assigned for all units; unit/fuel/firing/bottom type data were used for existing units' assignments, while only unit and fuel type were used for generic units' assignments. Latitude-longitude coordinates were assigned, first using the USEPA-provided data files, secondly using the September 17, 2004 Pechan in-house latitude-longitude file, and lastly using county centroids. These data were only used when the data were not provided in the 2002 NIF files. Stack parameters were attached, first using the USEPA-provided data files, secondly using a

March 9, 2004 Pechan in-house stack parameter file based on previous EIA-767 data, and lastly using an USEPA June 2003 SCC-based default stack parameter file. These data were only used when the data were not provided in the 2002 NIF files.

Additional data were required for estimating VOC, CO, filterable primary PM_{10} and PM2.5, PM condensable, and NH_3 emissions for all units. Thus, ash and sulfur contents were assigned by first using 2002 EIA-767 values for existing units or SCC-based defaults; filterable PM10 and PM2.5 efficiencies were obtained from the 2002 EGU NEI that were based on 2002 EIA-767 control data and the PM Calculator program (a default of 99.2 percent is used for coal units if necessary); fuel use was back calculated from the given heat input and a default SCC-based heat content; and emission factors were obtained from an USEPA-approved October 7, 2004 Pechan emission factor file based on AP-42 emission factors. Note that this updated file is not the one used for estimating emissions for previous USEPA post-processed IPM files. Emissions for 28 temporal-pollutant combinations were estimated since there are seven pollutants (VOC, CO, primary PM_{10} and $PM_{2.5}$, NH_3, SO_2 and NO_x) and four temporal periods (annual, summer season, winter season, July day).

The next step was to match the IPM unit IDs with the identifiers in VISTAS/ASIP 2002 inventory. A crosswalk file was used to obtain FIPS State and county, plant ID (within State and county), and point ID. If the FIPS State and county, plant ID and point ID are in the 2002 VISTAS NIF tables, then the process ID and stack ID are obtained from the NIF; otherwise, defaults, described above, were used.

Pechan provided the post-processed files in NIF 3.0 format. Two sets of tables were developed: "NIF files" for IPM units that have a crosswalk match and are in the 2002 VISTAS inventory, and "NoNIF files" for IPM units that are not in the 2002 VISTAS inventory (which includes existing units with or without a crosswalk match as well as generic units).

For the 2009 projections, VISTAS/ASIP states reviewed the PM and NH_3 emissions from EGUs as provided by Pechan and identified significantly higher emissions in 2009 than in 2002. It was determined that Pechan used a set of PM and NH_3 emission factors that are "the most recent USEPA approved uncontrolled emission factors" for estimating 2009 emissions. These factors are most likely not the same emission factors used by States for estimating these emissions in 2002 for EGUs in the VISTAS/ASIP region. Thus, the emission increase from 2002 to 2009 was simply an artifact of the change in emission factor, not anything to do with changes in activity or control technology application. Also, VISTAS/ASIP states identified an inconsistent use of SCCs for determining emission factors between the base and future years. The resolution of the PM and NH_3 problem is fully documented in *EGU Emission Factors and Emission Factor*

Assignment, memorandum from Greg Stella to VISTAS State Point Source Contacts and VISTAS EGU Special Interest Workgroup, June 13, 2005 (attached in Appendix P). The first step was the adjustment of the 2002 base year emissions inventory. Using the latest "USEPA-approved" uncontrolled emission factors by SCC, Alpine Geophysics utilized CERR or VISTAS/ASIP reported annual heat input, fuel throughput, heat, ash and sulfur content to estimate annual uncontrolled emissions for units identified as output by IPM. This step was conducted for non-CEM pollutants (CO, VOC, PM, and NH_3) only. For PM emissions, the condensable component of emissions was calculated and added to the resulting PM primary estimations. The resulting emissions were then adjusted by any control efficiency factors reported in the CERR or VISTAS data collection effort. The second adjustment was to the future year inventories. Alpine Geophysics updated the SCCs in the future year inventory to assign the same base year SCC. Using the same methods as described for the 2002 revisions, those non-IPM generated pollutants were estimated using IPM predicted fuel characteristics and base year 2002 SCC assignments.

3.1.4 Eliminating Double Counting of EGU Units

The following procedures were used to avoid double counting of EGU emissions in the 2009 point source inventory. The 2002 VISTAS point source emission inventory contains both EGUs and non-EGUs. Since this file contains both EGUs and non-EGU point sources, and EGU emissions are projected using the IPM, it was necessary to split the 2002 point source file into two components. The first component contains those emission units accounted for in the IPM forecasts. The second component contains all other point sources not accounted for in IPM.

As described in the previous section, Pechan developed 2009 NIF files for EGUs from the IPM parsed files. All IPM matched units were initially removed from the 2009 Point source inventory to create the non-EGU inventory (which was projected to 2009 using the non-EGU growth and control factors described in Section 3.2.1). This was done on a unit-by-unit basis based on a cross-reference table that matches IPM emission unit identifiers (ORISPL plant code and BLRID emission unit code) to VISTAS NIF emission unit identifiers (FIPSST state code, FIPSCNTY county code, State Plant ID, State Point ID). When there was a match between the IPM ORISPL/BLRID and the VISTAS emission unit ID, the unit was assigned to the EGU inventory; all other emission units were assigned to the non-EGU inventory.

If an emission unit was contained in the NIF files created by Pechan from the IPM output, the corresponding unit was removed from the initial 2009 Point source inventory. The NIF 2009 EGU files from the IPM parsed files were then merged with the non-EGU 2009 files to create the 2009 Point source files.

Next, MACTEC prepared several ad-hoc QA/QC queries to verify that there was no double-counting of emissions in the EGU and non-EGU inventories:

- MACTEC reviewed the IPM parsed files to identify EGUs accounted for in IPM. MACTEC compared this list of emission units to the non-EGU inventory derived from the VISTAS cross-reference table to verify that units accounted for in IPM were not double-counted in the non-EGU inventory. As a result of this comparison, MACTEC made a few adjustments in the cross-reference table to add emission units for four plants to ensure these units accounted for in IPM were moved to the EGU inventory.

- MACTEC reviewed the non-EGU inventory to identify remaining emission units with a Standard Industrial Classification (SIC) code of "4911 Electrical Services" or SCC of "1-01-xxx-xx External Combustion Boiler, Electric Generation".

- MACTEC compared the list of sources meeting these selection criteria to the IPM parsed file to ensure that these units were not double-counted.

MACTEC asked S/L agencies to review the 2009 Point source inventory to verify whether there was any double counting of EGU emissions.

3.1.5 Quality Assurance steps

Quality assurance was an important component to the inventory development process and MACTEC performed the following QA steps on the EGU component of the VISTAS revised 2009 EGU inventory:

1. Provided parsed files (i.e., Excel spreadsheets that provide unit-level results derived from the model plant projections obtained by the IPM) to the VISTAS EGU SIWG for review and comment.

2. Provided facility level emission summaries for 2009 for both the base case and CAIR case to the VISTAS EGU SIWG to ensure that emissions were consistent and that there were no missing sources.

3. Compared State-level emissions from the IPM parsed files with the post-processed NIF files to verify that the post-processed NIF files were consistent with the IPM parsed file results.

VISTAS requested S/L review of these files – the changes specified by North Carolina as a result of this review are documented in the following subsection.

3.1.6 S/L Adjustments to IPM Modeling Results

After the S/L agency review of the final set of IPM runs, S/L agencies specified a number of changes to the IPM results to better reflect current information on when and where future controls would occur. These changes to the IPM results primarily involved S/L agency addition or subtraction of future emission controls based on the best available data from state rules, enforcement agreements, compliance plans, permits, and discussions/commitments from individual companies.

For example,Duke Energy and Progress Energy have updated their plans for complying with North Carolina's Clean Smokestack Act. The emissions outlined in the North Carolina's Clean Smokestacks Act compliance plans varied substantially from the IPM results. As a result, NCDAQ requested that the IPM emission projections for 2009 be adjusted to correspond with the compliance plans submitted in 2006 from the Duke Energy and Progress Energy.

Some S/L agencies specified changes to the controls assigned by IPM to reflect their best estimates of emission controls. The VISTAS/ASIP contractors used a scrubber control efficiency of 90 percent when adding or removing SO2 scrubber controls, used a control efficiency of 90 percent when adding or removing NOx SCR controls at coal-fired plants, 80 percent when adding or removing NOx SCR controls at gas-fired plants, and 35 percent when adding or removing NOx SNCR controls. The specific changes from NCDAQ to the IPM results are also summarized in Table 3.1.6-1.

S/L agencies provided information and/or comment on changes in stack parameters from the 2002 inventory for the 2009 inventory. Changes to stack parameters were also made in cases where new controls are scheduled to be installed. In cases where an emission unit projected to have a SO_2 scrubber in 2009, some states were able to provide revised stack parameters for some units based on design features for the new control system. Other units projected to install scrubbers by 2009 are not far enough along in the design process to have specific design details. For those units, the VISTAS EGU SIWG made the following assumptions: 1) the scrubber is a wet scrubber; 2) keep the current stack height the same; 3) keep the current flow rate the same, and 4) change the stack exit temperature to 169 degrees F (this is the virtual temperature derived from a wet temperature of 130 degrees F). VISTAS determined that exit temperature (wet) of 130 degrees F +/- 5 degrees F is representative of different size units and wet scrubber technology.

Table 3.1.6-1 NCDAQ Adjustments to IPM Results for the 2009 EGU Inventory.

Plant Name and ID	Unit	Nature of Update/Correction
G G Allen (2718) Belews Creek (8042)1 Buck (2720) Cliffside (2721) Dan River (2723) Marshall (2727) Riverbend (2732)	All	Replaced all IPM 2009 results with emission projections from Duke Power's NC Clean Smokestacks Act Compliance Plan for 2006.
Asheville (2706) Cape Fear (2708) Lee (2709) Mayo (6250) Roxboro (2712) Sutton (2713) Weatherspoon (2716)	All	Replaced all IPM 2009 results with emission projections from Progress Energy's NC Clean Smokestacks Act Compliance Plan for 2006.
Dwayne Collier Battle Cogeneration Facility ORISID=10384	GEN1 GEN2	Dwayne Collier Battle is a duplicate entry. This is Cogentrix of Rocky Mount (37-065-3706500146, stacks G-26 and G-27). Duplicate entries were removed from the 2009 inventory.
Kannapolis Energy Partners ORISID=10626	GEN2 GEN3	Kannapolis Energy emissions are being used as credits for another facility. IPM emissions from this facility (37-025-ORIS10626) were removed from the EGU inventory for 2009. Emissions from Kannapolis Energy (37-025-3702500113) were carried forward in the 2009 inventory.

3.1.7 Summary of 2009 EGU Point Source Inventory

Tables 3.1.7-1 and 3.1.7-6 summarize the 2002 base year inventory and 2009 projection inventory for the EGU source sector. The 2009 inventory include the adjustments to the IPM results specified by the S/L agencies in the previous section.

Table 3.1.7-1 EGU Point Source SO_2 Emission Comparison for 2002 and 2009

State	2002 VISTAS	2009 IPM Based with S/L Adjustments

3.2 Non-EGU Emission Projections

The general approach for assembling future year data was to use recently updated growth and control data consistent with the data used in the USEPA's CAIR analyses, supplement these data with available stakeholder input, and provide the results for stakeholder review to ensure credibility. The VISTAS/ASIP contractor used the 2002 VISTAS/ASIP base year inventory, based on the 2002 CERR submittals as the starting point for the non-EGU projection inventory. The 2002 VISTAS/ASIP point source emission inventory contains both EGUs and non-EGUs. Since this file contains both EGUs and nonEGU point sources, and EGU emissions are projected using the IPM, it was necessary to split the 2002 point source file into two components. The first component contains those emission units accounted for in the IPM forecasts. The second component contains all other point sources not accounted for in IPM and constitutes the non-EGU emissions inventory.

MACTEC performed the following activities to apply growth and control factors to the 2002 non-EGU emissions inventory to generate the 2009 projection inventory:

- Obtained, reviewed, and applied the most current growth factors developed by EPA, based on forecasts from an updated Regional Economic Models, Inc. (REMI) model (version 5.5) and the latest *Annual Energy Outlook* published by the Department of Energy (DOE);

- Obtained, reviewed, and applied any State-specific or sector-specific growth factors submitted by stakeholders;

- Obtained and incorporated information regarding sources that have shut down after 2002 and set the emissions to zero in the projection inventories;

- Obtained, reviewed, and applied control assumptions;

- Provided data files in NIF3.0 format and emission summaries in EXCEL format for review and comment; and

- Updated the database with corrections or new information from S/L agencies based on their review of the 2009 inventory.

The following sections discuss each of these steps.

3.2.1 Growth assumptions for non-EGU sources

The growth factor data used in developing the emission inventory were consistent with the USEPA's analyses for the CAIR rulemaking. These growth factors are fully documented in the reports entitled *Development of Growth Factors for Future Year Modeling Inventories* (dated April 30, 2004) and *CAIR Emission Inventory Overview* (dated July 23, 2004). Three sources of data were used in developing the growth factors for the 2009 emissions inventory:

- State-specific growth rates from the Regional Economic Model, Inc. (REMI) Policy Insight® model, version 5.5 (being used in the development of the EGAS Version 5.0). The REMI socioeconomic data (output by industry sector, population, farm sector value added, and gasoline and oil expenditures) are available by 4-digit SIC code at the State level.

- Energy consumption data from the DOE's Energy Information Administration's (EIA) *Annual Energy Outlook 2004, with Projections through 2025* for use in generating growth factors for non-EGU fuel combustion sources. These data include regional or national fuel-use forecast data that were mapped to specific SCCs for the non-EGU fuel use sectors (e.g., commercial coal, industrial natural gas). Growth factors for the residential natural gas combustion category, for example, are based on residential natural gas consumption forecasts that are reported at the Census division level. These Census divisions represent a group of States (e.g., the South Atlantic division includes eight southeastern States and the District of Columbia). Although one would expect different growth rates in each of these States due to unique demographic and socioeconomic trends, all States within each division received the same growth rate.

- Specific changes for sectors (e.g., plastics, synthetic rubber, carbon black, cement manufacturing, primary metals, fabricated metals, motor vehicles and equipment) where the REMI-based rates were unrealistic or highly uncertain. Growth projections for these sectors were based on industry group forecasts, Bureau of Labor Statistics (BLS) projections and Bureau of Economic Analysis (BEA) historical growth from 1987-2002.

In addition to the growth data described above, VISTAS received two sets of growth projections from stakeholders. The American Forest and Paper Association (AF&PA) supplied growth projections for the pulp and paper sector, which were applied to SIC 26xx Paper and Allied Products, for growth from 2002 to 2009. The AF&PA projection factor (1.067) is for the United States industry and apply to all States equally. The number come from the 15-year forecast for world pulp and recovered paper prepared by Resource Information Systems Inc. (RISI). The

VISTAS/ASIP contractor used the above AF&PA growth factors by SIC instead of the factors obtained from the USEPA's CAIR analysis for the 2009 emission inventory.

NCDAQ considered recent projections for three key sectors in North Carolina where declining production was anticipated – SIC 22xx Textile Mill Products, 23xx Apparel and Other Fabrics, and 25xx Furniture and Fixtures. For the 2009 inventory, NCDAQ decided to use a growth factor of 1.0 for these SIC codes. Although NCDAQ has data that shows a steady decline in these industries in North Carolina, NCDAQ wanted to maintain the emission levels at 2002 levels so the future emission reduction credits were available in the event that they are needed for nonattainment areas.

For the 2009 inventory, the VISTAS/ASIP contractor made one additional change to the growth factors. The AEO2004 data was replaced with the more recent AEO2006 forecasts (released in February 2006) to reflect changes in the energy market and to improve the emissions growth factors produced. The VISTAS/ASIP contractor obtained the corresponding AEO2006 projection tables from DOE's web site. VISTAS developed tables comparing the growth factors based on AEO2004 and AEO2006 and these comparison tables were reviewed by the S/L agencies. Based on this review, the VISTAS/ASIP states decided to use the AEO2006 growth factors for fuel burning SCCs.

VISTAS used the USEPA's EGAS model and updated the corresponding AEO2006 projection tables to create growth factors by SCC. VISTAS applied the updated growth factors to 2002 actual emissions and replaced the 2009 emissions in NIF EM tables for the affected SCCs.

3.2.2 Control Programs applied to non-EGU sources

VISTAS developed two control scenarios: on-the-books (OTB) controls and on-the-way (OTW) controls. The OTB control scenario accounts for post-2002 emission reductions from recently promulgated federal, State, local, and site-specific control programs. The OTW control scenario accounts for proposed (but not final) control programs that are reasonably anticipated to result in post-2002 emission reductions. The methodologies used to account for the emission reductions associated with these emission control programs are discussed in the following sections.

Table 3.2.2-1 Non-EGU Point Source Control Programs Included in 2009 Inventory.

On-the-Books (Cut-off of July 1, 2004 for Base 1 adoption)
• Atlanta / Northern Kentucky / Birmingham 1-hr SIPs

- Industrial Boiler/Process Heater/RICE MACT
- NO_x RACT in 1-hr NAA SIPs
- NO_x SIP Call (Phase I- except where States have adopted II already e.g. NC)
- RFP 3 percent Plans where in place for one hour plans
- VOC 2-, 4-, 7-, and 10-year MACT Standards
- Combustion Turbine MACT

On-the-Way

- NO_x SIP Call (Phase II – remaining States & IC engines)

3.2.2.1 OTB - NOx SIP Call (Phase I)

Phase I of the NOx SIP call applies to certain large non-EGUs, including large industrial boilers and turbines, and cement kilns. States in the VISTAS region affected by the NOx SIP call have developed rules for the control of NOx emissions that have been approved by the USEPA. VISTAS reviewed the available State rules and guidance documents to determine the affected sources and ozone season allowances. VISTAS also obtained and reviewed information in the EPA's CAMD NOx Allowance Tracking System – Allowances Held Report. Since these controls are to be in effect by the year 2007, VISTAS capped the emissions for NOx SIP call affected sources at 2007 levels and carried forward the capped levels for the 2009 future year inventory.

3.2.2.2 OTB - Industrial Boiler/Process Heater MACT

The USEPA anticipates reductions in PM and SO2 as a result of the Industrial Boiler/Process Heater MACT standard. The methods used to account for these reductions are the same as those used for the CAIR analysis. Reductions were included for existing units firing solid fuel (coal, wood, waste, biomass), which had a design capacity greater than 10 mmBtu/hr. The USEPA prepared a list of SCCs for solid fuel industrial, commercial/ institutional boilers and process heaters. The VISTAS/ASIP contractor identified boilers greater than 10 mmBtu/hr using either the boiler capacity from the VISTAS 2002 inventory, or if the boiler capacity was missing, a default capacity based on a methodology developed by the USEPA for assigning default capacities based on SCC code. The applied MACT control efficiencies were 4 percent for SO2 and 40 for percent for PM10 and PM2.5.

3.2.2.3 OTB - 2, 4, 7, and 10-year MACT Standards

Maximum achievable control technology (MACT) requirements were also applied, as documented in the report entitled *Control Packet Development and Data Sources,* dated July 14, 2004. The point source MACTs and associated emission reductions were designed from Federal Register (FR) notices and discussions with the USEPA's Emission Standards Division (ESD) staff. VISTAS did not apply reductions for MACT standards with an initial compliance date of 2001 or earlier, assuming that the effects of these controls are already accounted for in the 2002 inventories supplied by the States. Emission reductions were applied only for MACT standards with an initial compliance date of 2002 or greater.

3.2.2.4 OTB Combustion Turbine MACT

The projection inventory does not include the NOx co-benefit effects of the MACT regulations for Gas Turbines or stationary Reciprocating Internal Combustion Engines, which the USEPA estimates to be small compared to the overall inventory.

3.2.2.5 OTW - NOx SIP Call (Phase II)

The final Phase II NOx SIP call rule was finalized on April 21, 2004. States had until April 21, 2005, to submit SIPs meeting the Phase II NOx budget requirements. The Phase II rule applies to large IC engines, which are primarily used in pipeline transmission service at compressor stations. VISTAS identified affected units using the same methodology as was used by the USEPA in the proposed Phase II rule (i.e., a large IC engine is one that emitted, on average, more than 1 ton per day during 2002). The final rule reflects a control level of 82 percent for natural gas-fired IC engines and 90 percent for diesel or dual fuel categories. North Carolina provided more specific information on the anticipated controls at the compressor stations. This information was used in the 2009 inventory instead of the default approach used by the USEPA in the proposed Phase II rule.

3.2.2.6 Clean Air Interstate Rule

CAIR does not require or assume additional emission reductions from non-EGU boilers and turbines.

3.2.3 Quality Assurance steps

Final QA checks were run on the revised projection inventory data set to ensure that all corrections provided by the S/L agencies and stakeholders were correctly incorporated into the

S/L inventories and that there were no remaining QA issues that could be addressed during the duration of the project. After exporting the inventory to ASCII text files in NIF 3.0, the USEPA QA program was run on the ASCII files and the QA output was reviewed to verify that all QA issues that could be addressed were resolved.

Throughout the inventory development process, quality assurance steps were performed to ensure that no double counting of emissions occurred, and to ensure that a full and complete inventory was developed for North Carolina. Quality assurance was an important component to the inventory development process and MACTEC performed the following QA steps on the point source component of the VISTAS inventory:

1. Facility level emission summaries were prepared and evaluated to ensure that emissions were consistent and reasonable. The summaries included base year 2002 emissions, 2009 projected emissions accounting only for growth, 2009 projected emissions accounting for both growth and emission reductions from CAA controls.

2. State-level non-EGU comparisons (by pollutant) were developed for the base year 2002 emissions, 2009 projected emissions accounting only for growth, 2009 projected emissions accounting for both growth and emission reductions from CAA controls.

3. Data product summaries and raw NIF 3.0 data files were provided to the VISTAS Emission Inventory Technical Advisor and to the Point Source, EGU, and non-EGU Special Interest Work Group representatives for review and comment. Changes based on these comments were reviewed and approved by North Carolina point source contact prior to implementing the changes in the files.

4. Version numbering was used for all inventory files developed. The version numbering process used a decimal system to track major and minor changes.

3.2.4 Summary of 2009 non-EGU Point Source Inventory

Tables 3.2.4-1 and 3.2.4-6 summarize the 2009 non-EGU point source inventory for NOx and VOC emissions.

1. INTRODUCTION AND SCOPE

The attainment modeling for the Davidson-Guilford-Catawba Counties, North Carolina Annual PM2.5 nonattainment area (referred to as the PM2.5 nonattainment area) was performed by the Association of Southeastern Integrated Planning (ASIP) and done in conjunction with the regional haze modeling being done by the Southeast Regional Planning Organization, Visibility Improvement State and Tribal Association of the Southeast (VISTAS) and the ozone modeling being done by the ASIP. VISTAS and ASIP are run by the ten Southeast states (Alabama, Florida, Georgia, Kentucky, Mississippi, North Carolina, South Carolina, Tennessee, Virginia and West Virginia). Since the regional haze modeling uses annual simulations and includes an intermediate year that is the attainment year required for the PM2.5 nonattainment area, the North Carolina Division of Air Quality (NCDAQ) decided to use this modeling for its attainment demonstration.

A portion of the emissions inventory was developed by the NCDAQ and the VISTAS/ASIP contractors developed a portion. In all cases, a statewide emissions inventory was developed for modeling purposes and the emission estimates were calculated in tons per year. Sections 3 documents the portion of the 2002 base year area source annual emissions inventory that was developed by the NCDAQ. Section 4 documents the area source developed by VISTAS/ASIP and Section 5 addresses the development of the 2009 area source emissions inventory. Section 6 and 7 document the nonroad mobile source emissions inventory for 2002 and 2009, respectively.

A summary of the area source and nonroad mobile source annual PM2.5 emissions, by source category, can be found in Appendix E.

2. OVERALL METHODOLOGY

2.1 SOURCE CATEGORY IDENTIFICATION

The area source categories were identified from U. S. Environmental Protection Agency's (USEPA's) guidance document EPA-450/4-91-016, *Procedures for the Preparation of Emission Inventories of Carbon Monoxide and Precursors of Ozone, Vol. 1*, from this point on this document will be referred to as the Procedures document; USEPA guidance document EPA-454/R-05-001, *Emissions Inventory Guidance for Implementation of Ozone and Particulate Matter National Ambient Air Quality Standards (NAAQS) and Regional Haze Regulation*; the *Emissions Inventory Improvement Program (EIIP) Technical Reports, Volume 3, Area Sources* as of December 2002 (the most current version at the time of the inventory development), from this point on this document will be referred to as EIIP Tech Report; and a report entitled, *Documentation of the Base G 2002 Base Year, 2009 and 2018, Emission Inventories for VISTAS* and written by the VISTAS contractor company, MACTEC, Inc.

Nonroad mobile sources were identified from the USEPA's guidance document EPA-450/4-91-016, *Procedures for the Preparation of Emissions Inventories for Carbon Monoxide and Precursors of Ozone* (Procedures document); and USEPA guidance document EPA-454/R-05-001, *Emissions Inventory Guidance for Implementation of Ozone and Particulate Matter National Ambient Air Quality Standards (NAAQS) and Regional Haze Regulation*. Nonroad mobile source emissions are estimated by the methodologies suggested in the USEPA document, EPA-454/R-05-001, *Emissions Inventory Guidance for Implementation of Ozone and Particulate Matter National Ambient Air Quality Standards (NAAQS) and Regional Haze Regulations*; EPA-450/4-81-026d (Revised) *Procedures for Emission Inventory Preparation, Volume IV; Mobile Sources* (Mobile Source Procedures); and from the USEPA's nonroad mobile model NONROAD2005c released March 21, 2006.

2.2 AREA SOURCE EMISSION ESTIMATION APPROACH

Area source emissions are estimated by multiplying an emission factor by some known indicator of collective activity for each source category within the inventory area. An indicator is any parameter associated with the activity level of a source that can be correlated with the air pollutant emissions from that source, such as production, number of employees, or population.

In general, one of the following emissions estimation approaches is used to calculate the area source emissions: per capita emission factors, employment-related emission factors, commodity consumption-related emission factors, and level of activity based emission factors. The emission factors used were obtained from the EIIP Tech Reports, the Procedures document or the USEPA's *AP-42 Compilation of Air Pollutant Emission Factors, Fifth Edition*, referred to as AP-42.

There are several methods for estimating the activity level for a specific area source category. These are: treating area sources as point sources, surveying local activity levels, apportioning national or statewide activity totals to local inventory areas, using population or employment data. All of these methods were used to estimate area source emissions

Certain emission categories were adjusted for such things as season or rule effectiveness and rule penetration. These are discussed in the particular source categories descriptions.

For certain categories, there can be overlap between the point source emissions and the area source emissions calculated with emission factors. The 2002 point source emissions in these categories were identified so that they could be subtracted where appropriate.

There are a number of categories where emissions were calculated with emission factors based on employment. These emission factors were developed by the USEPA when employment reports were organized by Standard Industrial Classification (SIC) code. Since 1997 employment statistics are organized by the North American Industry Classification System (NAICS). For the solvent cleaning industries, the SIC codes do not directly correspond to single NAICS code. Sometimes several partial NAICS employment values will relate to a SIC code. A crosswalk was used to determine what percentage of a NAICS employment value would correspond to the SIC codes. The tables from the US Census showing the NAICS-SIC crosswalk are reproduced in Section 8 – Additional Data. It should be noted that the crosswalk is based on national totals and is not specific to any particular state. In Section 8.2, the employment fraction of the NAICS codes used to create the SIC code employment data is tabulated.

The employment numbers were obtained from the on-line 2002 County Business Patterns for the various NAICS codes at the county level for North Carolina. In addition to having employment values (or employment ranges due to confidentiality rules) by NAICS, the County Business Patterns breaks down the number of facilities by employment categories. The employment categories are 1 – 4, 5 – 9, 10 – 19, 20 – 49, 50 – 99, 100 – 249, 250 – 499, 500 – 999, >1000 employees. To account for point sources, it was assumed that facilities with 100 employees or greater were point sources and were not considered in the calculations.

When a NAICS category gave a number of employees and there were no establishments with 100 employees or greater, then the value was used. However, in most cases the County Business Patterns gave a range of total employees in the county instead of the actual number. When this occurred, facility sizes were considered and the mid-range of employees was assumed, in accordance with the EIIP Tech. Report. For example, if a NAICS category for a county had a range of employment of 100-249 with two establishments with 1 – 4 employees, one with 20-49 employees, and one with 100-249 employees. Assuming 3 to be the mid-range of 1 –4 and 35 to be the mid-range of 20-49, the employment used for the area source calculation was estimated as:

(2 x 3) + (1 x 35) = 41 employees

The larger establishment was assumed to be a point source and not taken into consideration for the area source calculation.

If a total number of employees was provided and there were establishments with 100 employees or greater, then the mid-range of the smaller facilities were used as described above. The estimated employment was compared to the value given to ensure that remainder would account for the large establishment. In cases where the remainder would not be enough employment to account for the larger establishment, the area source employment was adjusted down. For example, if a NAICS category had 250 employees with one establishment with 20 – 49 employees (mid-range 35), two establishments with 50 – 99 employees (mid-range 75), and one establishment with 100 – 249 employees. The employment estimated for the area source and the remainder employment was estimated as:

(1 x 35) + (2 x 75) = 185 employees
250 – 185 = 65 employees

The remainder of 65 employees is not enough to account for an establishment of 100 – 249 employees. Therefore, the area source employment was adjusted down by 35 so that there were 100 employees remaining to account for the large establishment.

2.3 NONROAD MOBILE SOURCE EMISSION ESTIMATION APPROACH

Non-highway mobile sources, sometimes referred to as off-road mobile, are those sources that can move but do not use the highway system. Off-road mobile sources are further divided into non-road mobile, railroad locomotives, aircraft engines, and commercial marine vessels (CMV).

The estimation of emissions from mobile sources, like area sources, involves multiplying an activity level by an emission factor.

The majority of the off-road mobile emissions were estimated by using the USEPA's off-road mobile model NONROAD2005c. Direct emissions are generated with this model. For aircraft engine emissions, the Federal Aviation Administration (FAA) Emissions and Dispersion Modeling System (EDMS) model was used. Aircraft operations were inputted into the model and the model predicts the engine emissions based on average landing and take-off practices for the aircraft type. For railroad locomotive emissions, emission factors were obtained from the Mobile Source Procedures document and the activity level was obtained from the various railroad companies.

3. NORTH CAROLINA-DEVELOPED 2002 AREA SOURCE INVENTORY

Area sources represent a collection of many small, unidentified points of air pollution emissions within a specified geographical area, emitting less than the minimum level prescribed for point sources. Because these sources are too small and/or too numerous to be surveyed and characterized individually, all area source activities are collectively estimated. The county is the geographic area for which emissions from area sources are compiled, primarily because counties are the smallest areas for which data used for estimating emissions is readily available. Emissions are calculated on an annual basis in tons per year.

3.1 GASOLINE DISTRIBUTION

The area source emissions attributed to this category are associated with various operations related to gasoline and aircraft fuel handling and distribution. Since tank farms and bulk plants are specifically addressed in the point source inventory, the area source category is limited to fuel handling, storage, and distribution operations associated with the service stations and in the refueling of aircrafts.

3.1.1 Gasoline Dispensing Facilities

Since service stations are so numerous, they are collectively considered as an area source. The area source emissions that are derived for this subsection involve determining the estimated emissions that occur at each of the following operations: 1) losses during storage tank filling, 2) storage tank breathing and working losses, 3) spillage and 4) truck transit losses. The emissions from vehicle refueling are captured in the mobile source inventory in the emission factors produced by the USEPA's MOBILE6.2 model and therefore are not estimated as part of the area source inventory.

As part of the air toxics program, Stage I controls for gasoline dispensing facilities were adopted by the State, effective May 1990 with final compliance by January 1, 1994. Stage I is the vapor recovery technology on the underground storage tanks and reduces the emissions during the tank filling operations at service stations.

The North Carolina Department of Agriculture, Standards Division is responsible for going to all gasoline dispensing facilities and testing the fuels to ensure that they meet the quality standards of the State. The NCDAQ has worked out an agreement with the Standards Division to also check for Stage I controls. A notice is sent to the NCDAQ for every facility checked by the Standards Division verifying if a facility has properly maintained control equipment. If a facility is not found to be properly maintaining the control equipment, then the NCDAQ sends a notice of violation informing the facility that the controls are required and gives the facility time to correct the violation before fines are assessed. From this information the rule effectiveness and rule penetration can be estimated. The rule effectiveness is the percentage of facilities with proper equipment maintenance and use and represents the actual degree of source compliance. Rule penetration is the percentage of facilities covered by the rule and thus require Stage I equipment. Control efficiency is the expected percent reduction from proper application of this control technology.

The volatile organic compound (VOC) emission factor for underground storage tank filling was calculated by using an equation from AP-42, in Section 5.2, Transportation And Marketing Of Petroleum Liquids on page 5.2-4 (equation).

$$EF = 12.46 \left[\frac{SPM}{T}\right] \times [1-(RE \times CE \times RP)]$$

where EF = emission factor in pounds of VOC per 1000 gallons
S = Saturation factor
P = True vapor pressure (in pounds per square inch area)
M = Molecular weight of vapors (lb/lb-mole)
T = Temperature of bulk liquid (^{o} Rankin)
RE = Rule Effectiveness
CE = Control Efficiency
RP = Rule Penetration

The saturation factor was obtained from AP-42, Table 5.2-1 and the true vapor pressure and molecular weight of vapors were obtained from AP-42, Table 7.1-2. For the temperature an average of the June, July and August average monthly temperature for 2002 was used. A worst case temperature estimate was used year round in calculating annual emissions. These temperatures were obtained from the North Carolina Climatological Data, a publication of the National Oceanic and Atmospheric Administration. All of the factors used to calculate the emission factor for Stage I, i.e. balanced submerged filling, are listed in Table 3.1.1-1.

Table 3.1.1-1 Factors Used For Calculating Emission Factor

S	P	M	T
1	6.49	67	537.6^{o}R (77.6^{o}F)

$$EF = 12.46 \left[\frac{1 \times 6.49 \times 67}{537.6}\right] \times [1 - (.97 \times .95 \times .99)]$$

$$= 0.884 \text{ lb VOC/1000 gal. Gasoline}$$

The emission factors for tank truck transit, breathing losses and spillage were obtained from the EIIP Tech Report, Chapter 11 Gasoline Marketing, Table 11.3-1 and are listed below in Table 3.1.1-2. The tank truck transit emission factor includes the emission rate for an empty tank plus a full tank and was adjusted by a factor of 1.25 as recommended by the EIIP Tech Report, pg. 11.5-3.

Table 3.1.1-2 Emission Factors For Gasoline Dispensing

Underground Storage Tank Filling	Tank Truck Transit	Breathing Losses	Spillage
0.884 lb/1000gal	0.000075 lb/gal	0.001 lb/gal	0.00068 lb/gal

The activity data needed to calculate the emissions is number of gallons of fuel sold in each county per year. This was obtained from a report from the North Carolina Petroleum Marketers Association. A weighting factor was devised by producing the sum of county population (1000's), county registered vehicles (1000's), and county motor fuel outlets. The factors were summed for the 100 counties and a fractional part of the whole found for each county. This fraction was multiplied by the state total gallons of gasoline and diesel sold in 2002 to get an estimate of gallons of fuel per county.

According to the EIIP Tech Report, the activity days per week for truck transit and underground storage tank filling are 6 and 7 days per week and for spillage and breathing losses, respectively.

Note that diesel fuel used is combined with gasoline for the sake of simplification. This will result in some overestimation of VOC emissions because the volatility of gasoline is higher than diesel fuel.

Annual VOC emissions for underground storage tank filling, tank truck transit, breathing losses and spillage were calculated and SMOKE modeling was later used to allocate annual emissions to a daily level. Underground storage tank annual VOC emissions for each county were calculated using the following equation.

$$EM = FC \times (1/1000) \times EF \times (1 \text{ ton}/2000 \text{ lbs.})$$

where EM = annual county VOC emissions in tons per year
FC = county fuel consumption of gasoline and diesel in gallons
EF = emission factor in pounds of VOC per 1000 gallons

Tank truck transit, breathing losses, and spillage annual VOC emissions for each county were calculated individually, using the following equation.

$$EM = FC \times EF \times (1 \text{ ton}/2000 \text{ lbs.})$$

where EM = annual county VOC emissions in tons per year for tank truck transit, breathing losses, or spillage
FC = county fuel consumption of gasoline and diesel in gallons
EF = emission factor in pounds of VOC per gallon for tank truck transit, breathing losses, or spillage

3.1.2 Aircraft Refueling

Like vehicle refueling, aircraft refueling results in VOC emissions from displacement of the vapor-laden air in the aircraft's fuel tank. This source category is generally estimated only for large commercial airports. There are a few small commuter and general aviation airports in the State; however, the amount of emissions from these is typically negligible.

The emissions from aircraft refueling were determined by using the number of gallons of fuel supplied to the airports and multiplying it by the appropriate emission factor. The businesses that supply the fuel to the airports were contacted to determine the amount and type of fuel supplied to each airport during 2002. The information obtained was for the two fuel types supplied, Jet A Kerosene and Aviation Gasoline.

The emission factors used are 11.38 lb VOC/1000 gallons of aviation gasoline and 0.065 lb VOC/1000 gallons of Jet A kerosene. Airport refueling occurs on a daily basis, therefore the activity days per week are 7.

The annual emissions for the base year were calculated using equation 3.1.2-1.

$$EM_i = \frac{\text{Thousand Gallons/year} \times EF_i}{(2000 \text{ lbs/ton})} \qquad 3.1.2\text{-}1$$

where EM_i = emissions for source category (i)
EF_i = emission factor for source category (i)

3.2 STATIONARY SOURCE SOLVENT EVAPORATION

There are eleven subcategories that involve stationary source solvent evaporative emissions. They include: dry cleaning, graphic arts, solvent cleaning, automotive refinishing, architectural coatings, traffic markings, industrial surface coating, asphalt paving, roofing operations, pesticide application, and consumer/commercial solvent use. The methodology used to calculate the emissions from these sources are described in detail in each subsection.

3.2.1 Dry Cleaning

The VOC emissions from dry cleaning vary with the type of process and the solvent used. For the most part, dry cleaners (coin-operated and conventional commercial) are small business entities. As a result of their size, dry cleaning emissions are typically not captured as point sources. However, dry cleaning operations can be a significant emission source for VOC emissions, when taken collectively.

The emissions from dry cleaners are estimated by multiplying the number of employees at dry cleaners by a national per-employee emission factor, 1800 lbs. of VOC/employee/year, found in the EIIP Tech. Report. The guidance also stated that the number of employees can be found in the County Business Patterns for SIC code 7215 (coin-operated) and 7216 (commercial). In 1997, the SIC code system was replaced with the NAICS. Thus, the number of employees was obtained for NAICS codes 812310 (coin-operated) and 812320 (commercial). The NAICS employment numbers were previously processed to exclude any facilities with 100 or more employees, which were deemed to be point sources. According to the SIC to NAICS crosswalk, 80% of employment for NAICS 812320 represents the number of employees for commercial dry cleaners (SIC 7216).

As reported in the EIIP Tech. Report, the activity days per week is 6 days. The emissions for 2002 were calculated using equation 3.2.1-1.

$$EM = \frac{\text{Employees x EF}}{(2000\ \text{lb/tons})} \qquad 3.2.1\text{-}1$$

where EM = emissions for source category in tons/year
EF = emission factor for source category, 1800 lbs. VOC/employee/yr

3.2.2 Graphic Arts/Printing

Graphic arts include operations that are involved in printing of newspapers, magazines, books, and other printed materials, which can be divided into several subsets based upon printing technology. Over the last decade ink-jet and offset lithography have emerged as the dominant technologies. The use of oils as ink solvents and the reduction of alcohols in the fountain solution and in the cleanup solutions have resulted in notable reductions in emissions for offset lithography. Ink-jet printing results in essentially no VOC emissions.

A number of establishments that generate emissions in this source category are in-house graphic arts operations at plants that are in non-printing industries. Therefore, an employee per SIC code emission factor is not very reliable. The per-capita emission factor of 1.3 lbs VOC/person/year provided by the EIIP Tech. Report was used to calculate the VOC emissions. This emission factor estimates the emissions from facilities less than 100 tons VOC/year. It assumes that facilities greater than 100 tons VOC/year will be in the point source inventory. The population used to calculate the base year emissions was obtained from the North Carolina Office of State Budget and Management (OSBM).

According to the Procedures document, Table 5.8-1, the activity days per week is 5. The annual emissions for the base year were calculated using equation 3.2.2-1.

$$EM = ((EF)*(Population_{2002})*(1 \text{ ton}/2000 \text{ lb})) \qquad 3.2.2\text{-}1$$

where EM = emissions for source category for county (a) in tons/yr
EF = emission factor for source category, 1.3 lbs VOC/person/yr

3.2.3 Solvent Cleaning and Degreasing

Solvent cleaning operations are integral to many businesses and industries, and are conducted for the purpose of removing grease, oils, waxes, carbon deposits, etc. from metals, plastic, or glass surfaces. Solvent cleaning is usually performed prior to painting, plating, inspection, repair, assembly, etc. The solvents used in the cleaning operations can be either in a liquid or vapor phase. Generally, these solvents have high vapor pressures and therefore emit VOC emissions.

There are two basic types of solvent cleaning techniques, cold cleaning and vapor cleaning. Cold cleaning machines use solvents in the liquid phase to clean and remove foreign material such as oils and grease from the surface of materials. These machines are batch loaded, and cleaning operations include spraying/flushing solvent or parts agitation, wipe cleaning, brushing, and immersion.

The vapor cleaning technique can be further divided into open top degreasing and in-line cleaning. The open top degreasing machines are tanks designed to generate and contain solvent vapor. The tank is equipped with a heating system that boils the liquid solvent. As the solvent boils, dense solvent vapors rise and displace the air in the tank. Coolant is circulated in condensing coils on the top of the tank to create a controlled vapor zone within the tank. Condensing solvent vapors dissolve the contaminants on the surface of the workload and flush both the dissolved and undissolved contaminants from the workload.

In-line cleaning machines employ automated loading on a continuous basis. These machines are often custom made for large-scale operations. A continuous or multiple-batch loading system greatly reduces or even eliminates the manual parts handling associated with batch cleaning. In-line cleaning machines are enclosed to prevent solvent losses; however, entry and exit openings cannot be sealed.

The VOC emissions for this category are estimated by using the per employee factors (from the EIIP Tech. Report, Chapter 6, Table 6.5-2) listed in Table 3.2.3-1 below:

Table 3.2.3-1 Emission Factors Cleaning & Degreasing

Source Category	Lbs. VOC/employee/yr
Electronic and Other Elec: Open Top Degreasing	29
Miscellaneous Manufacturing: Open Top Degreasing	9.8
Miscellaneous Manufacturing: Cold Cleaning	24
Auto Repair Services: Cold Cleaning	270

Employment data was derived from the 2002 County Business Patterns provided by the U. S. Census Bureau. For each of these categories, employment in a number of SIC groups is needed. These employment numbers were generated from the NAICS employment numbers for each county and summed as needed. See SIC Codes from NAICS Codes for Employment Based Categories in Section 8.1 for the full listing of NAICS and SIC for each source category. Fractional employee numbers are a result of the NAICS to SIC conversion process.

The annual emissions for the base year were calculated using equation 3.2.3-1.

$$EM = \frac{(Employment_{2002}) \times EF}{(2000\ lb/tons)} \qquad 3.2.3\text{-}1$$

where EM = emissions for source category, tons per year
EF = emission factor for source category

3.2.4 Auto Body Refinishing

Auto body refinishing operations consist of: vehicle preparation, primer application, topcoat application, and spray equipment cleaning. These operations result in significant VOC emissions. The solvent is typically 100% volatile and can constitute up to 6.5 pounds of VOC per gallon of cleaner or paint.

The EIIP methodology for estimating emissions from this source category recommends apportioning a national VOC emission estimate to the county level by the number of employees reported for NAISC code 811121. The national estimate of 79,429.59 tons of VOC per year was based on 1997 data. In order to estimate the emissions for 2002, the 1997 national VOC estimate provided by the EIIP Tech. Report was divided by the 1997 national employment data to create a per employee emission factor.

This emission factor was used with the 2002 employment data to estimate emissions from auto body refinishing. The employment data was obtained from the 2002 County Business Patterns.

According to the EIIP Tech. Report the activity days per week is 5 days. The emissions for 2002 were calculated using equation 3.2.4-1.

$$EM = Employees \times EF \qquad 3.2.4\text{-}1$$

where EM = emissions for source category
EF = emission factor for source category, 0.387 tons VOC/employee/yr

3.2.5 Architectural Coatings

This category includes the application of paint, primer, varnish or lacquer to architectural surfaces, and the use of solvents as thinners and for cleanup.

The VOC emissions for this source category were estimated by multiplying county population data by a usage factor for either water or solvent based coatings, and an emissions factor for either water or solvent based coatings. This method entails gathering national architectural paint usage from the County Business industrial report MA325F and generating per capita usage factors. It is important to be able to differentiate between the water based usage from the solvent based usage since the emission factor for solvent based paints is over 5 times higher than the factor for water based paints.

Emissions Factor: Water based = 0.74 lb VOC/gallon;
Solvent Based= 3.87 lb VOC/gallon

$VOC_a = (POP_a * UF_b * EF_b)/(2000 lbs/ton)$ -- tons/year

Where:

	VOC_a	=	VOC emissions for county (a)
	POP_a	=	Population for county (a)
	EF_b	=	Emission factor for paint type (b)
	UF_b	=	Usage factor for paint type (b)

The usage factor is found by dividing the national total architectural surface coating quantities for either solvent or water-based coatings by the U.S. population for that year. For 2002, the usage factor for each paint type is estimated below:

UF solvent: (127,703,000 gallons of solvent based) / (287,973,924) = 0.443 gal./person
UF water : (589,527,000 gallons of water based) / (287,973,924) = 2.047 gal./person

3.2.6 Traffic Markings

The paint used in traffic markings operations (the painting of center lines, shoulders, etc.) emits VOC emissions during the drying process. The extent of emissions is largely a function of the paint being solvent or water based. The North Carolina Department of Transportation (NCDOT) utilizes three general types of paint, which can be classified as water based paint, epoxy paint containing organic solvents, and thermoplastic paint. The use of thermoplastic paint results in negligible VOC emissions and therefore is not included in the emissions inventory.

Although the NCDOT utilizes both water and solvent based paints, there is uncertainty with respect to what percentage of the paint used is organic solvent based. To avoid under estimating the emissions from this source category, it is assumed that all paint, excluding thermoplastic, is organic solvent-based.

The NCDOT reported that 854,215 gallons of paint were used statewide in 2002. The gallons of paint by county were apportioned by number of lane miles in the county divided by the state total (equation 3.2.6-1) and the estimated gallons used. The emission factor was obtained from the EIIP Tech. Report, Table-14.4-1, which gave the emission factor as a function of gallons of paint (3.64 lb VOC/gal.). The solvent-based emission factor was chosen because all paint was assumed to be organic solvent-based as described above.

$$\text{Gallons Paint}_{County} = (\text{Gallons Paint}_{State}) \times \frac{(\text{\# Paved Lane Miles})_{County}}{(\text{\# Paved Lane Miles})_{State}} \qquad 3.2.6\text{-}1$$

The emissions for 2002 were calculated using equation 3.2.6-2.

$$EM = \frac{\text{Gallons Paint} \times EF}{(2000 \text{ lb/ton})} \qquad 3.2.6\text{-}2$$

where EM = emissions for source category
EF = emission factor for source category

3.2.7 Industrial Surface Coating

Surface coating operations involve applying a thin layer of coating (e.g. paint, lacquer, enamel, varnish, etc.) to the surface of an object for decorative or protective purposes. The coating products, which are solvent based, emit VOC emissions as the result of solvent evaporation during the drying or curing process.

Ideally, the VOC emissions from industrial surface coating activities should be captured as point sources. From a practical standpoint, this is not always accomplished. For example, three of the industrial surface coating subcategories, namely other product coatings, high-performance maintenance, and other special purpose coatings, only utilized per capita emission factors and have no NAICS associated with them. The emission factors, obtained from the EIIP Tech. Report, Table 8.5-2, for these surface coating subcategories are listed in the Table 3.2.7-1 below.

Table 3.2.7-1 Per Capita Emission Factors For Industrial Surface Coating

Subcategory	Per Capita Factor (lb/yr/person)
Other product coatings	0.6
High-performance maintenance.	0.8
Other special purpose coatings	0.8

The emissions for the remaining industrial surface coating subcategories were estimated using per employee emission factors. These emission factors were obtained from the EIIP Tech. Report, Table 8.5-1 and are listed below in Table 3.2.7-2.

Table 3.2.7-2 Per Employee Emission Factors for Industrial Surface Coating

Subcategory	Per Employee Factor (lb VOC/employee/yr)
Furniture & Fixtures	944
Metal Containers	6,029
Automobile (new)	794
Machinery & Equipment	77
Appliances	463
Other Transportation Equipment	35
Sheet, strip & Coil	2,877
Factory Finished Wood	131
Electrical Insulation	290
Marine Coatings	308

The EIIP Tech. Report also listed SIC codes for these industrial surface coating subcategories. As stated earlier, the SIC codes were replaced in 1997 with NAICS. The employment data was estimated using the method previously outlined in Subsection 3.2.1.

According to the EIIP Tech. Report the activity days per week is 5 days. The annual emissions for population and employment based emission factors were calculated using equations 3.2.7-1 and 3.2.7-2, respectively.

$$EM = \frac{\text{Population} \times EF}{(2000\ \text{lb/ton})} \qquad 3.2.7\text{-}1$$

$$EM = \frac{\text{Employees x EF}}{\text{(2000 lb/ton)}} \qquad 3.2.7\text{-}2$$

where EM = emissions for source category
EF = emission factor for source category

3.2.8 Asphalt Paving

Two types of asphalt paving are used for road paving and repair; emulsified asphalt and cutback asphalt. Emulsified asphalt is a type of liquefied road surfacing material made from a blend of water with an emulsifier. Cutback asphalt is a type of liquefied road surface that is prepared by blending or "cutting back" asphalt cement with various kinds of petroleum distillates. VOC emissions occur as the asphalt cures.

Cutback asphalt emissions are included in the asphalt paving category. Since the assembly of the final VISTAS 2002 inventory, it was found that the NCDOT specification for asphalt in 2002 was hot mix and emulsified asphalt with hot mix but not cutback asphalt. Surrounding states have precluded the use of cut back by statutory provisions; which has driven asphalt manufactures to discontinue cutback production throughout the region. The absence of the use of cutback has resulted in substantial reductions in emissions from asphalt paving operations in North Carolina. Cutback asphalt emissions are included in the 2002 inventory, and 5.23 tons of VOC per year were emitted in 2002 in the PM2.5 nonattainment area. The 5.23 tons of VOC per year represents a relatively small amount and does not significantly affect the accuracy of the inventory.

Hot-mix is composed of high molecular weight organics with minimal vapor pressures; consequently, VOC emissions are negligible. The use of emulsified asphalt does result in VOC emissions; but the emissions are significantly less than cutback. New formulations of emulsified asphalt, such as cationic, continue to result in reduced emissions. The use of emulsified asphalt is primarily for tack coating, which is a surface preparation for the hot-mix layer. The tonnage of hot-mix asphalt is accounted for by the NCDOT districts and not on a county basis. District tonnage was allocated on a county basis by apportioning county paved mileage as reported in the NCDOT 2000 Highway Summary Report. However, the amount of emulsified asphalt used is not tracked by the NCDOT in any useable way. As a consequence, the NCDOT provided the following methodology to predict emulsified usage:

Square Yd. of hot-mix = <u>(Tons of Hot-mix) x (2000 lbs./Ton)</u> 3.2.8-1

(220 lbs/ Square Yd. of Hot-mix)

Gallons of Emulsified asphalt = (Sq. Yd. of hot-mix) x (0.08 gal./Sq. Yd. of hot-mix) 3.2.8-2

The VOC emissions were calculated using the emissions factor for emulsified asphalt (9.2 lb VOC/barrel) and the number of gallons of emulsified asphalt per barrel (42 gal./barrel) from Table 17.5-2 of the EIIP Tech. Report.

The emissions for the base year were calculated using equation 3.2.8-3.

$$EM = \frac{(\text{gallons Emulsified Asphalt}) \times EF}{(42\ \text{gal/barrel}) \times (2000\ \text{lb/tons})} \quad 3.2.8\text{-}3$$

where EM = emissions for source category
EF = emission factor for source category

3.2.9 Roofing Operations

This category covers the installation and repair of asphalt roofs on commercial and industrial buildings. This category includes only hot-applied asphalt roofing, for which the only significant emissions source is the kettle used to heat the asphalt. The amount of asphalt roofing activity is estimated by summing the number of felt, cap, and flashing squares used in North Carolina during the year 2002. This information was ascertained from the Asphalt Roofing Manufacturing Association. The amount of asphalt used is given by the equation 3.2.9-1, which uses the default value of 20 lbs. of asphalt / square found in the EIIP Tech. Report. The emissions by county, shown in equation 3.2.9-2, were apportioned by roofing establishments in the county divided by the state total, using the number of establishments from NAISC code 23561 from the 2000 County Business Patterns. The 2000 County Business Patterns was the latest available data at the time of the inventory development.

$$\text{Asphalt (Ton/yr)} = \frac{(\#\ \text{squares}) \times (20\ \text{lbs. of asphalt/square})}{(2000\ \text{lbs./ton})} \quad 3.2.9\text{-}1$$

$$\text{Asphalt}_{County} = \frac{(\text{Tons Asphalt}_{State}) \times (\#\ \text{Roofing Establishments})_{County}}{(\#\ \text{Roofing Establishments})_{State}} \quad 3.2.9\text{-}2$$

Asphalt roofing activities are assumed to have uniform operations throughout the year with a 5-day work week per the EIIP Tech. Report. Additionally, the EIIP Tech. Report reported the emissions factor as 6.2 lbs. VOC/ton asphalt for roofing operations.

The emissions for the base year inventory were calculated using equation 3.2.9-3.

$$EM = \frac{(\text{tons Asphalt}) \times EF}{(2000 \text{ lb/tons})} \qquad 3.2.9\text{-}3$$

where EM = emissions for source category
EF = emission factor for source category

3.2.10 Pesticide Application

Pesticides broadly include any substance used to kill or retard the growth of insects, rodents, fungi, weeds, or microorganisms. Formulations of organic pesticides are commonly made by combining synthetic materials with various petroleum products. The petroleum products, or inert ingredients, act as a carrier of the active component and usually evaporate into the atmosphere.

Agricultural Pesticides

Agricultural pesticides are applied in various manners, which directly affect the possible emissions associated with the application, regardless of the amount of solvent contained in the pesticide. There are basically three types of pesticide/herbicide application methods. One is the "incorporated" type, in which the product is applied and immediately incorporated into the soil. It is expected that little if any evaporation of solvent occur in this type of application. The next type, "pre-emergence", is where the product is put on the ground immediately after the crop is planted. This provides a protective layer. Some evaporation of solvent would be expected with this type of application. The largest emissions would occur from "over the top" application of pesticides. These pesticides are sprayed directly on the foliage to kill weeds or insects. This application would provide an opportunity for a great deal of solvent to evaporate.

The overall pesticide usage associated with agricultural crop production continues to slowly decrease in North Carolina driven by conservative pest management practices and the cost of pesticides as reported by the North Carolina Cooperative Extension office. The large majority of pesticide usage is confined to the production of tobacco and cotton crops. Because of the small crop size and high cash value, significant tobacco acreage is found in North Carolina.

The planted crop acreage from the North Carolina Agricultural Statistic Division and crop profile reports prepared by the North Carolina Cooperative Extension office, and other university extension services, for the US Department of Agriculture Pest Management Center were used to estimate agricultural pesticide usage. Crop acreage from the North Carolina Agricultural Statistic Division was obtained from http://www.ncagr.com/stats/. Crop profile reports conducted by NCSU are based on surveys; where participation is reported to be as high as 90 percent for the more important cash crops. Crop profile reports for grains and soybeans do not exist for North Carolina, therefore data for these crops were obtained from other state profiles and from discussions with representatives of the North Carolina Cooperative Extension office.

The individual crop profiles outline the current agricultural pesticide practices, i.e. the pesticide agents (insecticides, herbicides, fungicides), the percentage of acres treated, and the pounds of active ingredient pesticide applied per acre. The crop profiles often report the application of the active ingredient (pounds of active ingredient per acre) as a range of values. For the worst case scenario, the highest reported value was used. The number of applications of a single pesticide was usually one per year for all pesticides. The few exceptions to one application are more than accounted for by the conservative practice of using the highest value of application rate.

The pounds of active ingredients for each crop were calculated by using equation 3.2.10-1 and an example calculation for soybeans follows. Table 3.2.10-1 presents the pesticides associated with a particular crop, the % of treated acres, and the lbs. of active pesticide ingredient per year.

$$(\text{lbs. AI/acre})_{CROP} = \sum (\%\ \text{acres treated}) \times (\text{lb AI/acre})_{PESTICIDE} \qquad 3.2.10\text{-}1$$

where AI = active ingredient.

For soybeans, the pounds of active ingredients for the crop is:

Pesticide	% Acres Treated	Lb AI/acre
Paraquat	20	0.47
Glyphosate	10	4
Sulfusate	5	4
Carbaryl	10	1.5

$$(\text{lbs. AI/acre})_{SOYBEAN} = (0.20 \times 0.47) + (0.10 \times 4) + (0.05 \times 4) + (0.10 \times 1.5)$$
$$= 0.844 \text{ lbs. AI/acre for soybeans}$$

The emission factors for each crop were calculated utilizing information from the EIIP Tech. Report, p 9.5-4, which relates active ingredients to VOC emissions. According to the EIIP Tech. Report, for every pound of active ingredient there are 2.45 pounds of VOC, of this 90% is evaporated. The emission factors for each crop were calculated using Equation 3.2.10-2, with an example calculation for soybean following.

$$EF_{CROP} = (\text{lb } AI_{CROP}/\text{acre}) \times (2.45 \text{ lb. VOC/lb. of AI}) \times (0.90) \qquad 3.2.10\text{-}2$$

Where EF_{CROP} = Emission factor in lbs. VOC/active ingredient for each crop
AI_{CROP} = Active ingredient for each crop

For soybeans the emission factor is:
Lbs. AI/acre for soybean = 0.844 lbs. AI/acre

$$EF_{SOYBEAN} = (0.844 \text{ lb active ingredient/acre}) \times (2.45 \text{ lb VOC/active ingredient}) \times (0.90)$$
$$= 1.861 \text{ lbs. VOC/acre}$$

An exception to the above calculation was for the usage of the pesticides: chloropicrin and 1,3 dichloropropene. These fumigants are widely used for treating tobacco beds for nematodes and constitute a major portion of the pesticide inventory. They have a moderate vapor pressure of 18.3 and 34 millimeters of mercury (at 77° F), respectively, and their formulation is approximately 96% to 98% of the active ingredient. In light of these properties, the VOC emissions are assumed to be equal to the application per acre, which are 79 pounds/acre for chloropicrin and 89.5 pounds/acre for 1,3 dichloropropene. Table 3.2.10-2 list the pounds of active ingredients per acre and the calculated emission factor for each crop.

Table 3.2.10-2 Emission Factors by Crop Type

Crop	Lbs. Active Ingredients/acre	Lbs. VOC/Acre
Soybeans	0.844	1.861
Cotton	2.267	4.999
Barley	0.004	0.009
Corn – Silage	1.79	3.947
Corn – Grain	1.79	3.947
Wheat	0.025	0.055
Oats	0.025	0.055

Tobacco		
- *Non-fumigant*	2.317	5.109
- *Fumigant*	64.043	64.043
Total Tobacco		69.152
Peanuts		
- *Non-fumigant*	2.9175	6.433
- *Fumigant*	0.128	0.282
Total Peanuts		6.715
Irish Potatoes	1.9350	4.267
Sorghum	0.0375	0.083

The emissions for 2002 were calculated using equation 3.2.10-3.

$$EM_a = \frac{\sum (CROP)_a \times EF_{CROP}}{(2000 \text{ lb/tons})} \qquad 3.2.10\text{-}3$$

where EM_a = emissions for source category in county (a)
CROP = acres of specific crop in county (a)
EF_{CROP} = emission factor for specific crop

Nonagricultural Pesticide

Nonagricultural pesticide applications are considered as part of the commercial/consumer solvent use emission factor and no longer a separate subcategory. Please refer to the next section.

3.2.11 Commercial/Consumer Solvent Use

This category includes only non-industrial solvents that are used in commercial or consumer applications. The solvent containing products consist of a diverse grouping, e.g. personal care products, household products, automotive aftermarket products, adhesives and sealants, pesticides, some coatings, and other commercial and consumer products that may emit VOC emissions.

There are seven categories. They are named and their emission factors listed in Table 3.2.11-1 below.

Table 3.2.11-1 Misc. Non-Industrial Consumer-Commercial Emission Factors

Subcategory	lb VOC/yr/person.	lb NH_3/yr/person.
All Coatings and Related Products	0.95	-
All FIFRA Related Products	1.78	-
Miscellaneous Products (Not Otherwise Covered)	0.07	-
Personal Care Products	2.32	-
Household Products	0.079	0.031
Automotive Aftermarket Products	1.36	-
Adhesives and Sealants	0.57	-

VOC emissions for this category is estimated by using nationally based per capita emissions factors. The county population values are used to estimate the emissions from this source category.

According to the EIIP Tech. Report, emissions from this source category occur 365 days per year. The emissions for the base year inventory were calculated using equation 3.2.11-1.

$$EM = \frac{(Population_{2002}) \times EF}{(2000 \text{ lb/tons})} \qquad 3.2.11\text{-}1$$

where EM = emissions for source category, tons per year
EF = emission factor for source category

3.3 BIOPROCESS EMISSION SOURCES

Bioprocess emission sources include those sources whose emissions result from biological processes (e.g., fermentations). Source categories include bakeries, breweries, wineries and distilleries.

3.3.1 Bakeries

Ethanol, a VOC, is a by-product of fermentation of bread dough. The ethanol emissions from large commercial bakeries are accounted for as point sources; however, ethanol emissions occur from grocery store bakery departments and small business bakeries not accounted for under the point source inventory.

The EIIP Tech. Report prescribes accounting for these emissions by the use of a per capita consumption factor of 70 pounds of bread per person per year and an emission factor of 0.5 pounds of VOC per 1000 pounds of baked bread. The county populations obtained from the North Carolina Office of State Budget and Management were used to estimate the emissions from this source category.

According to the EIIP Tech. Report, emissions from this source category occur 365 days per year. The emissions for the base year inventory were calculated using equation 3.3.1-1.

$$EM = \frac{(Population)_b \times CF \times EF}{(2000\ lb/tons)} \qquad 3.3.1\text{-}1$$

where EM = emissions for source category
$Population_b$ = Population in base year
CF = Consumption factor, 70 lb bread/person/year
EF = emission factor for source category, 0.5 lb VOC/1000 lb bread baked

3.4 OTHER MAN MADE AREA SOURCES

Other man made area sources include forest fires, slash burning and prescribed burning, agricultural burning, structure fires, and orchard heaters. The methodology used to calculate the emissions from these sources are described in detail in each subsection.

3.4.1 Structure Fires

Burning fires can produce short term emissions of organic compounds and nitrogen oxides (NOx). The U.S. Fire Administration (USFA) of the Department of Homeland Security maintains statistics on the number of fires per county. The number of fires per county for 2002 was derived from 2001 and 2002 population statistics and 2001 USFA fire statistics. The USFA fire statistics were obtained from the USFA website at http://www.usfa.fema.gov/safety/. As 2002 fire statistics were not available, a fires per person factor for 2001 was calculated and found to be equal to 0.00184 fires/person. The 2001 county population values were obtained from the North Carolina State Demographics website at http://demog.state.nc.us/. The 2001 population values were the latest data available. The 0.00184 fires per person was applied to the 2002 population for each county to determine the number of fires in each county for 2002.

The emission factors and fuel loading factors were obtained from the EIIP Tech. Report, Table 18.4-1 and Table 18.4-2, respectively. The emission factors are 11 pounds of VOC per ton burned, 1.4 pounds of NOx per ton burned, 10.8 pounds of PM_{10} per ton burned, and 10.8 pou/pnds $PM_{2.5}$ per tons burned. The loading factor is 1.15 tons of material burned per structural fire.

According to the EIIP Tech. Report, emissions from this source category occur 365 days per year.

The emissions for the base year 2002 inventory were calculated using Equation 3.4.1-1.

$$EM_P = \frac{(2002\ \text{County population})\ \times\ (FPP) \times\ (CF)\ \times\ (EF_P)}{(2000\ \text{lb/tons})} \qquad 3.4.1\text{-}1$$

where EM_P = emissions for structure fires for pollutant (P)
FPP = fires per person in 2001, 0.00184 fires/person
CF = Conversion factor, 1.15 tons burned/structure fire
EF_P = emission factor for pollutant (P)

3.4.2 Charbroiling

The commercial charbroiling of ground beef emits VOC emissions. According to the methodology in the EIIP Tech. Report, county Health Departments should be able to provide the number of restaurants in a county as well as the percentage of those restaurants that charbroil meat. The NCDAQ was able to ascertain the number of restaurants in each county in 2002 from the North Carolina Division of Environmental Services, Inspection, Statistics, and Fee Branch.

To determine the percentage of charbroiling restaurants, the county Health Departments of several counties were surveyed.

According to the EIIP Tech. Report, the average throughput of meat per restaurant with a charbroiler is 1160 pounds per week and the emissions factor is 3.94 pounds of VOC per 1000 pounds of meat. Emissions from this source category occur 365 days per year.

The emissions for the base year inventory were calculated using Equations 3.4.2-1.

$$EM_a = \frac{(\#\ Restaurants)\ x\ (\%\ Charbroiling)\ x\ (CF)\ x\ (EF)}{(2000\ lb/tons)\ x\ (1\ yr/52\ wks)} \qquad 3.4.2\text{-}1$$

where EM_a = emissions for source category in county (a), tons/yr
CF = conversion factor, 1160 lb meat charbroiled/week
EF = emission factor, lbs. pollutant/1000 lb meat charbroiled

3.4.3 Open Burning – Municipal Solid Waste and Yard Trimmings

This subsection describes the combined emission inventory methodology for source classification code (SCC) 2610030000 Residential Open Burning – Household and SCC 2610000100 Open Burning – Yard Trimmings. Open burning is treated as a means of waste disposal in rural areas. Materials burned generally include agricultural refuse, landscaping refuse, or scrap wood. Local authorities could not provide assistance with estimating the tons of refuse burned or the amount burned. According to local authorities, burning permits are issued year round without requiring a notation for the amount burned.

It was assumed that all municipal solid waste (MSW) and yard trimmings, were burned in the open for solid waste generated outside the municipal corporate limits. According to the EIIP Tech. Report, Table 16.5-1, it is estimated that 3.77 pounds of MSW is generated per person per day and 0.64 pounds of yard trimmings are generated per person per day. Since it is illegal to burn within the corporate limits, the rural population was estimated by using the same percentage of rural population in each county as what was reported in the 2000 census. The 2000 total and rural populations for each county were obtained from the North Carolina Office of State Budget and Management, State Data Center. The 2000 total and rural populations was the latest data available.

VOC, NOx, CO, SO_2, and NH_3 emission factors for open burning of MSW were obtained from EIIP Tech. Report, Table 16.4-1, Open Burning of Municipal Refuse. The emission factors are

6.676 pounds VOC per ton MSW burned, 6 pounds NOx per ton MSW burned, 1 pounds SO_2 per ton MSW burned, and 6.0 E-07 pounds NH_3 per ton MSW burned.

The VOC emission factor for open burning of yard trimmings was obtained from EIIP Chapter 16, Table 16.4-7. The factor is 28 pounds VOC per ton yard trimmings. The rural percent of the populations for the statewide counties were obtained from the 2000 census data. Since burning permits are issued year round, the activity days per year was 365. These values were used to calculate the tons per year emissions for the base year. The emissions from the burning of MSW for the base year 2002 inventory were calculated using equation 3.4.3-1. The emissions from the burning of yard trimmings for the base year 2002 inventory were calculated using equation 3.4.3-2.

$$EM_{P,MSW} = \frac{(\text{Rural Population in 2002}) \times (CF_{MSW}) \times (EF_P) \times (365\ \text{days/yr})}{(2000\ \text{lb/tons})} \qquad 3.4.3\text{-}1$$

$$EM_{P,YT} = \frac{(\text{Rural Population in 2002}) \times (CF_{YT}) \times (EF_P) \times (365\ \text{days/yr})}{(2000\ \text{lb/tons})} \qquad 3.4.3\text{-}2$$

where $EM_{P,MSW}$ = emissions from burning MSW for pollutant (P)
$EM_{P,YT}$ = emissions from burning yard trimmings for pollutant (P)
CF_{MSW} = conversion factor, 3.77 lb MSW/person/day
= 0.001885 ton MSW/person/day
CF_{YT} = conversion factor, 0.64 lb yard trimmings/person/day
= 0.00032 ton yard trimmings/person/day
EF_P = emission factor for pollutant (P)

3.4.4 Small Stationary Source Fossil Fuel Use

In general, fossil fuels are burned for space and hot water heating. This source category covers VOC, NO_x, SO_2, PM_{10}, $PM_{2.5}$, and NH_3 emissions from natural gas (NG) and liquid petroleum gas (LPG), oil, coal, and wood combustion in the residential, commercial/institutional (called commercial), and industrial sectors.

The "demand for energy" for these fuel types is known as fuel usage. Fuel usage data for North Carolina was taken from NC Energy Outlook 2003 by Global Insight, Inc for the base year 2002. The following table shows the data used.

Table 3.4.4-1 Fuel Use in North Carolina 2002

Fuel	Units	Residential	Commercial	Industrial
NG	10^6 ft^3	64,014	40,580	95,718
LPG	gallons	282,775,596	47,960,199	198,606,965
Oil	gallons	215,804,019	113,088,933	343,414,390
Coal	tons	46,872	85,735	0
Wood	tons	1,625,111	164,327	8,583,778

Emission factors used are shown in Table 3.4.4-2 below.

Table 3.4.4-2 Combustion Emission Factors

Sector	Fuel	Units	VOC	NOx	SO_2	PM_{10}	$PM_{2.5}$	NH3
Residential	NG	lb/10^6 ft^3	5.5	94	0.6	7.6	7.6	20

Industrial	Wood	Lb/ton	0.255326	3.304224	0.37548	6.48	5.47	0.086

3.4.4.1 Fuel Oil Combustion

Fuel oil consumption covers the use of kerosene, distillate oil and residual oil. Distillate oil includes fuel oil grades 1, 2, and 4; residual oil includes fuel grades 5 and 6. In most areas, residual oil is not used by residential sources. Kerosene and distillate oils are primarily used for space heating in domestic and small commercial buildings, while residual oils are used primarily for industrial and large commercial applications. It was assumed that residential fuel oils are normally used only for heating and therefore, no residential fuel oil emissions were calculated for summer months.

The base year statewide annual fuel oil demand for energy, obtained from the NC Energy Outlook 2003, was converted British Thermal Units (BTUs) to gallons of fuel used for each heating classification (i.e., residential, commercial, and industrial). The conversion factors used were obtained from the NC Energy Outlook 2003 and are 135,000 BTU per gallon of kerosene, 138,690 BTU per gallon of distillate oil, and 149,690 BTU per gallon of residual oil.

Once converted to gallons of fuel, the statewide fuel use was then apportioned to the county level. This was accomplished by multiplying the number of gallons of fuel used in the state by the fraction of housing units heated by fuel oils in the county compared to that of the whole state (see the equation below).

$$\text{\# gal. fuel for County X} = (\text{\# gal. fuel oil for State}) \times \frac{(\text{\# housing units heated by fuel oil in County X})}{(\text{\# housing units heated by fuel oil in State})}$$

The fraction of housing units was used to distribute the fuel on a county level for the residential heating classifications. The number of housing units heated by fuel oils was obtained from the 2000 Census.

Commercial and industrial fuel usage was apportioned according to the number of business establishments in the State and counties. The numbers were taken from 1997 (last year of SIC based statistics) County Business Patterns. Establishments with SICs from 50*xx* through 99*xx* were summed. Industrial sources were calculated in a manner similar to commercial sources burning oil or coal.

Emission factors were obtained from AP-42, Table 1.3-1 and from AP-42, Table 1.3-3. Fuel oil combustion emission factors are listed in Table 3.4.4-2, as shown above.

According to the Procedures document, Table 5.8-1, the activity days per week is 7 for residential heating and 6 for commercial and industrial heating. These values were used to calculate the emissions in tons per year for the base year.

Point source emissions with SCC 1-03-004-xx and 1-03-005-xx identified commercial residual oil and distillate oil emissions, respectively; while source emissions with SCC 1-02-004-xx and 1-02-005-xx identified industrial residual and distillate oil emissions, respectively. The point source emissions in tons per year were subtracted from the area source emissions.

3.4.4.2 Coal Combustion

There are three types of coal used for space heating: anthracite, bituminous and lignite. According to AP-42, anthracite, or hard coal, is mined almost exclusively in Pennsylvania and is consumed in Pennsylvania and in states that are within easy shipping distance. In addition, lignite coal is mined in North Dakota and Texas and is consumed near where it mined. Since the incidence of anthracite and lignite coal burning is low in North Carolina, the emissions from coal combustion were calculated utilizing only the emission factors for bituminous coal.

It was assumed that residential coal is normally used only for heating and therefore, no residential coal emissions were calculated for summer months.

The base year statewide annual coal demand for energy, obtained from the NC Energy Outlook 2003, were converted from BTU to tons of coal used for each heating classification (i.e., residential, commercial, and industrial). The conversion factor used was 21,100,000 BTU per ton of coal.

Once converted to tons of coal, the statewide coal use was then apportioned to the county level. This was calculated by multiplying the number of tons of coal used in the state by the fraction of housing units heated by coal in the county, compared to that of the whole state (see the equation below).

$$\text{\# ton of coal for County X} = (\text{\# ton of coal for State}) \times \frac{(\text{\# housing units heated by coal in County X})}{(\text{\# housing units heated by coal in State})}$$

The fraction of housing units was used to distribute the coal on a county level for both heating classifications. The number of housing units heated by coal was obtained from the Federal Bureau of the Census and the 2003 NC State Energy Plan (http://www.doa.state.nc.us/doa/energy).

There were several emission factors for bituminous coal combustion listed in AP-42, Table 1.1-3. For the purpose of estimating the emissions from coal combustion, the equipment listed in AP-42, Table 1.1-3 were grouped into industrial, commercial/institutional and residential type equipment. The emission factors were averaged for each type and the averaged emission factors were used to calculate the emissions. Table 3.4.4-2 shown above lists the averaged emission factors used in the calculations. It should be noted that fluidized bed combustors (FBC) were not included in the averaged emission factors because FBC does not constitute a significant percentage of the total boiler population, according to AP-42, Section 1.1. The Procedures document, Table 5.8-1, lists the activity days per week as 7 for residential heating and 6 for commercial and industrial heating. Point source emissions with SCC 1-03-002-xxidentified commercial coal combustion emissions. The point source annual emissions in tons per year were subtracted from the area source emissions.

Residential Coal Combustion Emissions:

$$\text{Pollutant emitted by coal combustion} = \frac{(\text{\# tons/year Coal}) \times EF}{(2000 \text{ pounds/ton})}$$

Commercial Coal Combustion Emissions:

$$\text{Pollutant emitted by coal combustion} = \frac{(\text{\# tons/year Coal}) \times EF}{(2000 \text{ pounds/ton})}$$

Industrial Coal Combustion Emissions:

There is no industrial coal combustion in the area source inventory because it is included in the point source emissions inventory.

3.4.4.3 Natural Gas Combustion

Currently in the United States, natural gas is one of the major types of fuels used for heating. It is mainly used for industrial process stream and heat production, commercial and residential space heating and for electric power generation. Although natural gas is a relatively clean burning fuel, some emissions can result from its combustion.

The base year statewide annual demand for natural gas energy, obtained from the NC Energy Outlook 2003, was converted from BTU to 10^6 cubic feet of natural gas used for each heating classification (i.e., residential, commercial, and industrial). The conversion factor used was 1,000 BTU per cubic foot of natural gas.

Once converted to cubic feet of natural gas, the statewide natural gas use was then apportioned to the county level. This was calculated by multiplying the number of cubic feet of natural gas used in the state by the fraction of housing units heated by natural gas in the county, in comparison to the state (see the equation below).

$$\#\ ft^3 \text{ nat gas for County X} = (\#\ ft^3 \text{ nat gas for State}) \times \frac{(\#\text{ housing units heated by nat gas in County X})}{(\#\text{ housing units heated by nat gas in State})}$$

The fraction of housing units was used to distribute the natural gas usage on a county level for each heating classification. The number of housing units heated by natural gas was obtained from the 2000 Census.

The North Carolina Utilities Commission provided data from the U.S. Department of Energy, Energy Information Administration giving monthly usage of natural gas by residential and commercial customers in North Carolina for 2002.

There were several emission factors listed for industrial and commercial natural gas boilers in AP-42, Table 1.4-1. For the purpose of estimating the emissions from natural gas combustion, an average of the emission factors were used. Table 3.4.4-2 shown above lists averaged emission factors used in the calculations. According to the Procedures document, Table 5.8-1, the activity days per week is 7 for residential heating and 6 for commercial and industrial heating. These values were used to calculate the annual emissions in tons per year for the base year.

Point source emissions with SCC 1-03-006-xxx and 1-02-006-xxx, identified commercial and industrial natural gas combustion emissions, respectively. Where point source emissions were indicated, these were deducted from the 2002 annual emission estimates.

Residential Natural Gas Combustion Emissions:

$$\begin{array}{l}\text{Pollutant emitted by} \\ \text{Nat. gas combustion}\end{array} = \frac{(\#\ ft^3/\text{year natural gas}) \times EF}{(2000 \text{ pounds/ton})}$$

Commercial Natural Gas Combustion Emissions:

$$\begin{array}{l}\text{Pollutant emitted by} \\ \text{Nat. gas combustion}\end{array} = \frac{(\#\ ft^3/\text{year natural gas}) \times EF}{(2000 \text{ pounds/ton})}$$

Industrial Natural Gas Combustion Emissions:

$$\text{Pollutant emitted by Nat. gas combustion} = \frac{(\#\ ft^3/\text{year natural gas}) \times EF}{(2000\ \text{pounds/ton})}$$

3.4.4.4 Liquefied Petroleum Gas Combustion

Liquefied petroleum gas (LPG) consists of propane, propylene, butane, and butylenes. The largest market for LPG is the domestic/commercial market, followed by the chemical industry and agricultural markets. LPG is also used as a stand-by fuel for facilities that have natural gas service contracts that can be interrupted. The form of LPG used primarily for domestic heating is propane. Liquefied petroleum gas is considered a clean fuel because it does not produce visible emissions. However, gaseous pollutants such as VOC, NO_x, SO_2, PM_{10}, and $PM_{2.5}$ do occur.

The base year statewide annual LPG demand for energy, obtained from the NC Energy Outlook 2003, was converted from BTU to 10^3 gallons of LPG used for each heating classification (i.e., residential, commercial, and industrial). The conversion factor was 95,475 BTU per gallon of LPG.

Once converted to gallons of LPG, the statewide LPG use was then apportioned to the county level. This was accomplished by multiplying the number of gallons of LPG used in the state by the fraction of housing units heated by LPG in the county compared to that of the whole state (see the equation below).

$$\#\ \text{gal LPG for County X} = (\#\ \text{gal LPG for State}) \times \frac{(\#\ \text{housing units heated by LPG in County X})}{(\#\ \text{housing units heated by LPG in State})}$$

The fraction of housing units was used to distribute the LPG usage on a county level for each heating classification. The number of housing units heated by LPG was obtained from the 2000 Census.

The North Carolina Utilities Commission provided data from the U.S. Department of Energy, Energy Information Administration giving monthly usage of LPG by residential and commercial customers in North Carolina for 2002.

The emission factors listed in AP-42, Table 1.5-1 were averaged for industrial and commercial sources. There is no residential LPG emission factor listed in AP-42. Since the form of LPG used primarily for domestic heating is propane, the commercial propane emission factor was used for residential LPG combustion. The emission factors listed in AP-42, as well as the average emission factors used for estimating the emissions from LPG combustion are listed in Table 3.4.4.4-1. According to the Procedures document, Table 5.8-1, the activity days per week is 7 for residential heating and 6 for commercial and industrial heating. Point source emissions with SCC 1-03-010-xxx and 1-02-010-xxx, identified commercial and industrial LPG combustion emissions, respectively. Where point source emissions were indicated, these were deducted from the 2002 annual emission estimate.

Residential LPG Emissions:

$$\text{Pollutant emitted by LPG combustion} = \frac{(\#\ \text{gal/year LPG}) \times EF}{(2000\ \text{pounds/ton})}$$

Commercial LPG Combustion Emissions:

$$\text{Pollutant emitted by LPG combustion} = \frac{(\#\ \text{gal/year LPG}) \times EF}{(2000\ \text{pounds/ton})}$$

Industrial LPG Combustion Emissions:

$$\text{Pollutant emitted by LPG combustion} = \frac{(\#\ \text{gal/year LPG}) \times EF}{(2000\ \text{pounds/ton})}$$

Table 3.4.4.4-1 Emission Factors for Liquefied Petroleum Gas

Application/Fuel Type	Emission Factors (lb /gallon)		
	Industrial	*Commercial*	*Residential*
Butane	0.0036	0.0021	-
Propane	0.0032	0.0019	0.0019

Averaged $PM_{2.5}$ Emission Factor	0.001125	0.00906	0.00906

3.4.4.5 Wood Combustion

The use of wood as a source of heat occurs in the residential and industrial sectors. It was assumed that residential wood is normally used only for heating and therefore, no residential wood emissions were calculated for summer months. The burning of wood waste in boilers is mostly confined to those industries where the wood is available as a byproduct. Most often this is in the lumber, furniture and plywood industries. These types of industries are included in the point source inventory, therefore, no area source emissions will be calculated for industrial wood combustion. Wood stoves, commonly used in residences as space heaters, are used both as the primary source of heat and as a supplement to conventional heating systems.

The base year statewide annual wood demand for energy, obtained from the NC Energy Outlook 2003, was converted from BTU to tons of wood used for residential heating. The conversion factor was 4,500 BTU per pound of wood, which is the mid-point of the range (4,000 to 5,000 BTU per pound of wood) given in AP-42, Section 1.6.

Once converted to tons of wood, the statewide wood use was then apportioned to the county level. This was accomplished by multiplying the number of tons of wood use in the state by the fraction of housing units heated by wood in the county compared to that of the whole state (see the equation below).

$$\text{\# tons Wood for County X} = (\text{\# ton Wood for State}) \times \frac{(\text{\# housing units heated by Wood in County X})}{(\text{\# housing units heated by Wood in State})}$$

The fraction of housing units was used to distribute the wood usage on a county level. The number of housing units heated by wood was obtained from the 2000 Census.

Table 3.4.4-2 shown above lists emission factors used in the calculations. The residential wood combustion emission factors were obtained from the Table 2.4-1 of the EIIP Tech. Report, Volume III, Chapter II. According to the Procedures document, Table 5.8-1, the activity days per week is 7 for residential heating.

Wood Combustion Emissions:

$$\text{Pollutant emitted by Wood combustion} = \frac{(\text{\# ton/year Wood}) \times EF}{(2000 \text{ pounds/ton})}$$

3.4.4.6 Small Electric Utility Boilers

This source subcategory has been treated as a point source since the information was available for each facility. Refer to the point source category discussion in Appendix F.1 for further details.

3.4.5 Vehicle Fires

Vehicle fire emissions within the State demonstration area are estimated by considering the estimated number vehicles burned in the State, the amount of material burned (the fuel loading) in a vehicle fire, and the emission factors for the open burning of automobile components. The assumptions for amount of material burned and the emission factors were based on the USEPA's AP-42, Section 2.5 Open Burning.

The estimated number of vehicle fires was determined by apportioning a national fire statistic to a county level. The USFA of the Department of Homeland Security maintains national-level fire statistics. The number of fires nationwide in 2002 was 1,734,500 and was available from the USFA website at http://www.usfa.fema.gov/statistics/national/. The percentage of vehicle fires was applied to the national-level total number of fires. The number of national-level vehicle fires was then apportioned to a state-level. The ratio of North Carolina vehicle miles traveled (VMT) to U.S. VMT (92,894,000,000 VMT / 2,855,756,000,000 VMT) was applied to the number of national-level vehicle fires to obtain the number of North Carolina vehicle fires. The VMT statistics were obtained from the U.S. Department of Transportation, Federal Highway Administration website at http://www.fhwa.dot.gov/policy/ohim/hs02/vm2.htm. The number of state-level vehicle fires was then apportioned to a county level based on paved mile per county in 2002. Paved mile per county data was obtained from the NCDOT. Using the above method, 2002 vehicle fire emissions were calculated.

The amount of vehicle material burned (the fuel loading) in a vehicle fire was estimated by assuming that an average vehicle has 500 pounds of components (0.25 tons) that can burn in a fire, based on a 3,700 pounds average vehicle weight (CARB, 1995).

The emission factors were obtained from Table 2.5-1, Emission Factors for Open Burning of Municipal Refuse, of the USEPA's AP-42, Section 2.5 Open Burning. The emission factors are 32 pounds of VOC per ton burned and 4 pounds of NOx per ton burned.

The emissions for the base inventory were calculated using equation 3.4.5-1.

$$EM_P = \frac{(\text{\# of Vehicle Fires per year}) \times (CF) \times (EF_P)}{(2000 \text{ lb/tons})} \qquad 3.4.5\text{-}1$$

where EM_P = annual emissions for structure fires for pollutant (P)
CF = Conversion factor, 0.25 tons burned/vehicle fire
EF_P = emission factor for pollutant (P)

3.4.6 Agricultural Burning

This source subcategory covers burning practices used to clear and/or prepare land for planting. These operations include stubble burning, burning of agricultural crop residues, and the burning of stand field crops as part of harvesting (e.g., sugar cane). According to the North Carolina Department of Agriculture, when soybeans are double cropped with wheat, the wheat stubble is usually burned back after harvest about one fourth of the time. According to Dr. J. Dunphy, a soybean specialist at North Carolina State University, the acres of soybean double cropped with wheat in North Carolina is approximately equal to the acres of wheat planted. Therefore, one fourth of the acreage of wheat planted in 2002 was used to calculate the emissions from agricultural burning practices in North Carolina.

The fuel loading factor and the yield of VOC for burning wheat stubble was obtained from AP-42, Table 2.5.5. The fuel loading factor is 1.9 tons of fuel consumed per acre burned. The yield of pollutant was dependent upon whether the field was head-fire burned or back-fire burned. The percentage of each burning type used was not available, therefore, the assumption was made that each type was used 50 percent of the time. The yield of VOC used, 11 pounds of VOC per ton of fuel consumed, is an average of the two types of burning. To calculate the emission factor for VOC emissions, the fuel loading factor is multiplied by the yield of pollutant.

$$EF_{VOC} = (1.9 \text{ tons/acre})\ (11 \text{ lb VOC/ton burned})$$
$$= 20.9 \text{ lb VOC/acre burned}$$

The annual emissions were calculated using the number of acres burned and the per acre emission factor. According to the North Carolina Department of Agriculture, field burning occurs only during June and July.

The number of acres of wheat planted was obtained from the North Carolina Department of Agriculture, Agriculture Statistics Division. The emissions for the 2002 base year inventory were calculated using equation 3.4.6-1.

$$EM = \frac{(\frac{1}{4} \times (\text{wheat acreage})) \times EF}{(2000 \text{ lb/ton})} \qquad 3.4.6\text{-}1$$

where EM = emissions for source category for VOC
EF = emission factor for VOC

3.4.7 On Site Incineration

On-site incineration is the confined burning of waste leaves, landscape refuse and other refuse or rubbish. In North Carolina, commercial/institutional and industrial incinerators are required to have an Air Quality Permit in order to operate. Therefore, all industrial incinerators are identified in the point source inventory. There may be small commercial/institutional incinerators that have not been identified in the point source inventory and as a result emissions were calculated for commercial on-site incinerators.

No data was available to determine the amount of waste burned in on-site incinerators. Therefore, the amount of solid waste burned was estimated with the fuel loading factor (L) given in Table 4.6-1 of the Procedures document. The commercial fuel loading factor is 23 tons of refuse/1,000 population/year. The yield for commercial incineration was obtained from several sources. The yield of NOx, SO_2, PM_{10}, $PM_{2.5}$ (P) was obtained from AP-42, Table 2.1-12 and are listed in Table 2.1.4.7-1. The yield value used of NOx, SO_2, PM_{10}, and $PM_{2.5}$ was the average of the yield values listed in AP-42. The yield of VOC is 8.556 lb/ton of refuse and was obtained from EIIP Technical Report, Open Burning, Table 16.4-1. The yield of NH_3 is 1.19 lb/ton of refuse and was obtained from EIIP Area Source Methods Document, "Estimating Emissions from Anthropogenic Nonagricultural Sources".

Table 3.4.7-1 Yield of Pollutant Values for Uncontrolled Refuse Combustors

Pollutant	Multiple Chamber Combustor Yield Value (lb Pollutant/ton refuse burned)	Single Chamber Combustor Yield Value (lb Pollutant/ton refuse burned)	Average Yield Value (lb Pollutant/ton refuse burned) (lb Pollutant/ton refuse burned)
NOx	3	2	2.5
CO	10	20	15
SO_2	2.5	2.5	2.5
PM_{10}	7	15	11
$PM_{2.5}$	7	15	11

To calculate the per capita pollutant emission factor (EF) for on-site commercial incinerators, the fuel loading factor was multiplied by the yield of the pollutant, as shown in the following equation.

$$EF_P = L_{COMMERCIAL} \times P_{INCINERATION}$$

$$= (23 \text{ tons of refuse/1000 population/year}) \times (2.5 \text{ lb NOx/ton of refuse burned})$$

$$= 57.5 \text{ lb NOx/1000 population/year}$$

The emissions from commercial on-site incineration for the base year 2002 inventory were calculated using equation 3.4.7-1.

$$EM_P = \frac{(\text{Rural Population in 2002}) \times (EF_P)}{(2000 \text{ lb/tons})} \qquad 3.4.7\text{-}1$$

where EM_P = emissions from on-site incineration for pollutant (P) in tons/year

EF_P = emission factor for pollutant (P)

The population was obtained from the 2000 census data. The 2000 census data was the latest data available. According to the Procedures document, on-site incineration occurs uniformly year round and operates 7 days per week. Point source emissions with SCC 5-xx-xxx-xx identified waste incineration emissions. The point source emissions in tons per year were subtracted from the area source emissions.

4. VISTAS DEVELOPED 2002 AREA SOURCE INVENTORY

Section 4.0 details the portion of the 2002 base year area source inventory, which was developed for VISTAS/ASIP by the VISTAS contractor, MACTEC, Inc. This information was obtained from the report entitled *Documentation of the Base G 2002 Base Year, 2009, and 2018, Emission Inventories for VISTAS* prepared for VISTAS by MACTEC, Inc. This report is included in Appendix P.

Several major components of the area source sector of the inventory, which were developed by VISTAS, are discussed in Sections 4.1 through 4.5. Ammonia emissions from livestock and fertilizer sources are discussed in Section 4.1. $PM_{2.5}$ and PM_{10} emissions from paved and unpaved roads are discussed in Section 4.2. Stage II emissions are discussed in Section 4.3 and were removed from the area source inventory and included in the mobile sector of the inventory. Also, emissions from portable fuel containers were added and are discussed in Section 4.4. Section 4.5 describes the development of the fires emissions inventory and distinguishes the difference between an actual versus typical inventory with regards to fires.

The following Sections are based on excerpts, with some editing, taken from a document entitled, *Documentation of the Base G 2002 Base Year, 2009 and 2018 Emission Inventories for VISTAS* and prepared by MACTEC, Inc.

4.1 Ammonia from Agricultural Sources

VISTAS used version 3.6 of the Carnegie Mellon University (CMU) NH_3 model (http://www.cmu.edu/ammonia/) to calculate NH_3 emission estimates for livestock and fertilizers. Results from this model were used for all VISTAS States. The CMU model version 3.6 was used in large part because it had been just recently been updated to include the latest (2002) Census of Agriculture animal population statistics.

For the ammonia inventory, VISTAS removed all wildlife and human perspiration emissions due to uncertainty of inaccurate emission factors. Thus all emissions from these two categories were deleted in the 2002 inventory.

4.2 Paved and Unpaved Road Emissions

VISTAS used the most recent PM emission estimates developed by EPA as part of the NEI development effort (Roy Huntley, U.S. EPA, email communication, 8/30/2004). EPA had developed and used an improved methodology for estimating paved road emissions for 2002. MACTEC obtained those emissions in March 2004 in NIF format from the EPA FTP site.

$PM_{2.5}$ emissions from several fugitive dust sources were also updated for the 2002 inventory. The Western Regional Air Partnership (WRAP) and U.S. EPA had been investigating overestimation of the $PM_{2.5}$ / PM_{10} ratio in several fugitive dust. Based on data received from U.S. EPA, VISTAS decided to revise the $PM_{2.5}$ emissions from construction, paved roads and unpaved road sources. $PM_{2.5}$ emissions in the emission inventory, which was developed by EPA were multiplied by 0.67, 0.6, and 0.67 for construction, paved roads and unpaved roads respectively to produce the values found in 2002 inventory. No changes were made to PM_{10}, only to $PM_{2.5}$.

4.3 Vehicle Refueling (Stage II) emissions

For the 2002 inventory, the VISTAS/ASIP States all agreed to remove the Stage II refueling emissions from the area source inventory and include them in the non-road and on-road sectors.

4.4 Portable Fuel Containers

Portable fuel containers (PFCs), SCC 2501060300, covers emissions from residential and commercial sector portable gasoline containers. Permeation, diurnal, transport, spillage, and vapor displacement emissions are typically accounted for in this category. Spillage from refueling operations and vapor displacement emissions were not included in the inventory to avoid double counting refueling in the non-road sector.

MACTEC found that the USEPA had prepared a national inventory of emissions by State for portable fuel containers. Data on emissions from this source prepared by the USEPA were presented in the report, *Estimating Emissions Associated with Portable Fuel Containers (PFCs), Draft Report*, Office of Transportation and Air Quality, USEPA, Report # EPA420-D-06-003, February 2006.

The 2002 county-level emission estimates were obtained through an allocation method based on fuel usage. Initially, 2005 emission estimates, except those from vapor displacement and spillage from refueling operations, were obtained from the USEPA’s report and assumed to be equal to 2002 values. Permeation, diurnal, and transport emission estimates were summed and allocated to the county-level, based on the fuel usage information obtained from the NONROAD2005 model. The SCCs that use containers for refueling were acquired from the spillage file of the NONROAD model. Then the fuel usages by county from the NONROAD 2005 runs prepared for VISTAS/ASIP were summed for those SCCs by county. The county level fuel use was then divided by the State total fuel use for the same SCCs to determine the fraction of total State fuel usage and that fraction was used to allocate the State-level emissions to the county.

4.5 Fires Including Forest Fires

The fires source category includes wildfire, prescribed burning, and land clearing fires. These fires can be intermittent in nature, but many of these can produce large quantities of air pollutant emissions. Wildfires in certain rural areas can produce large, short-term organic emissions. Prescribed burning is used a as a forest management practice to establish favorable seedbeds, remove competing underbrush, accelerate nutrient cycling, control tree pests and contribute other ecological benefits. Agricultural burning covers agricultural burning practices used to clear and/or prepare land for planting. In land clearing fires, waste from logging operations is often burned under controlled conditions to reduce the potential fire hazards in forests and to remove brush that can serve as a host for destructive insects.

The total wildfire acreage burned was obtained from the NCDFR for each county in the State. These numbers however are replaced with the 2002 "typical" year for the purpose of modeling. Fire emissions are not easily grown or projected. Thus, the replacement was done so that the fires represented in the area source inventory are considered typical and do not reflect an abnormally low or high year as far as fires. The typical year forest fire inventories were developed by MACTEC, Inc. with input from state and federal forest resource staff. The typical year covered wildfire, prescribed burning, agricultural fires and land clearing fires. The development of the typical year inventory is described below.

State level ratios of acres over a longer-term record (three or more years) developed for each fire type relative to 2002. The 2002 acreage was then scaled up or down based on these ratios to develop a typical year inventory. VISTAS Fire Special Interest Work Group based the ratio on county-level data for States that supplied long-term fire-by-fire acreage data rather than State-level ratios. Where States did not supply long-term fire-by-fire acreage data, MACTEC reverted to using State-level ratios. With one broad exception (wildfires) this method was implemented for all fires. MACTEC solicited long term fire-by-fire acreage data by fire type from each VISTAS State. A minimum of three or more years of data were used to develop the ratios. Those data were then used to develop a ratio for each county based on the number of acres burned in each county for each fire type relative to 2002.

If VISTAS had long term county prescribed fire data from a State, a county acreage ratio, described below, was developed.

$$Ratio = \frac{\text{Long term average county level Rx acres}}{\text{2002 actual county level Rx acreage}}$$

This ratio was then multiplied times the actual 2002 acreage to get a typical value (basically the long term average county level acres). Wherever possible this calculation was performed on a fire-by-fire basis. The acreage calculated using the ratio was then used with the fuel loading and emission factor values to calculate emissions.

There were three exceptions to this method.

Exception 1: Use of State Ratios for Wildfires

Wildfires estimates were developed using State ratios rather than county ratios because some counties were showing unrealistic ratios, which were created by very short term data records or missing data. In addition, exceptionally large and small fires were removed from the database. VISTAS also removed all fires less than 0.1 acres from the dataset.

Exception 2: Correction for Blackened Acres on Forest Service Lands

Acres, submitted by the U.S. Forest Service (USFS) for wildfires and prescribed fires on USFS lands, represented perimeter acres rather than "blackened" acres. Therefore, for prescribed fires greater than 100 acres in size, the acreage was adjusted to be 80 percent of the initial reported value. For prescribed fires of 100 acres or less, the acreage values were maintained as reported. All reported acreage values for wildfires were adjusted to be 66 percent of their values, as initially reported.

Exception 3: Missing/Non-reported data

When VISTAS did not receive data from a VISTAS State for a particular fire type, a composite average for the entire VISTAS region was used to determine the typical value for that type fire. This technique was applied to all fire types when data was missing.

For wildfires and prescribed burning, ratios were also developed for "northern" and "southern" tier States within the VISTAS region and those ratios were applied to each State with missing data depending upon whether they were considered a "northern" or "southern" tier State.

Development of “southern” and “northern” tier data was an attempt to account for a change from a predominantly pine/evergreen ecosystem (southern) to a pine/deciduous ecosystem (northern).

Table 4.5-1 below presents a comparison in tons per year of the 2002 actual fire emissions and the 2002 typical fire emissions for NO_x, VOC, SO_2, PM_{10}, $PM_{2.5}$ and NH_3 for wildfires, and prescribed burning in North Carolina.

The typical wildfire and prescribed burning emissions for Catawba, Davidson, and Guilford counties for 2002 are found in Appendix E, Table 9. Note that there were no prescribed burning emissions in Catawba and Guilford counties.

The emissions shown in Table 4.5-2 below were inadvertently omitted from modeling by the VISTAS contractors. This was also true for the same source categories in other counties. There were not sufficient funds to perform new modeling. However, these emissions, compared to total emissions, are believed to be too small to make any noticeable difference in the results.

Table 4.5-1 2002 North Carolina Actual and Typical Fire Emissions

Actual Fire Emissions (TPY)						
Fire Type	**NOx**	**VOC**	**SO_2**	**PM_{10}**	**$PM_{2.5}$**	**NH_3**
Wildfires	458.18	1005.04	124.89	2126.61	1825.84	95.14
Prescribed Burning	282.28	619.19	67.00	1210.00	1035.00	48.00
Typical Fire Emissions (TPY)						
Wildfires	763.72	1692.57	206.78	3504.44	3002.50	157.69
Prescribed Burning	763.89	1678.59	207.66	3472.12	2977.75	157.87

Table 4.5-2 2002 Fire Emissions Data (Typical) Omitted From Modeling in Tons Per Year (TPY)

County	SCC	SCC Description	VOC	NOX	SO2	PM_{10}	$PM_{2.5}$	NH_3
Catawba	2610000500	Open Burning of Land Clearing Debris	159.87	68.91		234.29	234.29

Triad		**Total TPY**	**544.24**	**225.57**	**0.00**	**800.21**	**800.21**	**0.00**

4.6 Application of Transportable Fraction Adjustment Factors for Modeling

For modeling purposes only, VISTAS applied a transportable fraction adjustment factor to paved and unpaved road emissions; residential, industrial/commercial/institutional, and road construction emissions; mining and quarrying emissions; crop tilling emissions; and beef cattle finishing emissions. The applicable SCC's are 2294000000, 2296000000, 2311010000, 2311020000, 2311030000, 2325000000, 2801000003, and 2805001000 respectively For additional information about transportable fraction factors, see the paper titled *Methodology to Estimate the Transportable Fraction (TF) of Fugitive Dust Emissions for Regional and Urban Scale Air Quality Analysis* in Appendix P.

5. 2009 AREA SOURCE EMISSION INVENTORY DEVELOPMENT

This Section describes the methodology used to develop the 2009 area source inventory. Separate methods for projecting emissions were used for non-agricultural (stationary area), agricultural area sources and forest fire area sources. The agricultural area sources method is for ammonia emissions, as ammonia contributes to the formation of regional haze and fine particulate matter.

The following Sections are based on excerpts, with some editing, taken from a document entitled, *Documentation of the Base G 2002 Base Year, 2009 and 2018 Emission Inventories for VISTAS* and prepared by MACTEC, Inc.

5.1 Projection of Stationary Area Sources

VISTAS 2002 base year inventory emissions were used as a starting point for calculating 2009 emissions. MACTEC, Inc. first back calculated uncontrolled emissions from the 2002 base year inventory. Growth and control factors were then applied based on controls initially identified for the Clean Air Interstate Rule (CAIR) and growth factors identified for the CAIR projections. In some cases, Economic Growth Analysis System version 5.0 (EGAS 5.0) growth factors were used if no growth factor was available from the CAIR growth factor files.

The 2009 growth factors were obtained from the USEPA growth factors and indirectly from 2010 and 2015 CAIR growth factors. Using a 2001 base year, interpolation of 2010 and 2015 CAIR growth factors yielded 2009 growth factors. MACTEC used the TREND function of Microsoft Excel for interpolation. Interpolated growth factors were calculated at the State and SCC level.

In a few cases, additional growth factors had to be added for sources that had not initially been included in a draft 2002 inventory. These growth factors were obtained from EGAS 5.0. Finally updates to growth factors from EGAS 5.0 were made for fuel fired emission sources. The updated growth factors reflected the most recent data from the Department of Energy's Annual Energy Outlook (AEO). These data were used to reflect changes in energy efficiency resulting from new or updated fuel firing technologies.

North Carolina provided 2009 updated emission files used to update the emissions for each year for several source categories. However not all sources in the inventory were included in these North Carolina updates. As a consequence, the final 2009 inventory for North Carolina included emissions updated using the North Carolina supplied files and emissions developed using growth and control factors as outlined above.

5.2 Projection of Agricultural Area Sources

MACTEC used the version 3.1 2002 base year inventory data (which was based on the CMU ammonia model version 3.6). MACTEC obtained State specific growth, if available. Otherwise, growth factors were used, which were developed from the USEPA Interstate Air Quality Transport Rule (IAQTR)/Ammonia inventory. Growth factors for several agricultural livestock categories were developed by the USEPA, as part of the NEI.

In addition, ammonia growth factors for a few categories (mainly feedlots) were assigned to be the same as growth factors for PM emissions from the NEI projections. This assignment was made because the CMU model showed emissions from these categories but the NEI projections did not show ammonia emissions but did show PM emissions. No growth factors were found for horse and pony emissions. These emissions were held constant at 2002 levels.

No controls were identified by North Carolina; thus, all projected emissions for agricultural area sources represent simple growth with no controls.

Wild animal and human perspiration emissions were removed from the 2009 inventory because of considerable uncertainty in the accuracy of emission factors. All swine emissions for North Carolina were maintained at 2002 levels for the 2009 inventory to capture a moratorium on swine production in that State.

5.3 Projection of Forest Fires Area Sources

Several Federal agencies indicated that they had plans for increased prescribed fire burning in future years and that the “typical” fire inventory would likely not adequately capture those increases. Thus, MACTEC acquired the data necessary to provide 2009 specific projections for the prescribed fire component of the fire inventory.

The U.S. Fish and Wildlife Service (USFWS) submitted annual acreage data by National Wildlife Refuge (NWR) and by county with estimates of acres burned per day for each NWR. USFS provided fire-by-fire acreage estimates based on mapping projected burning acreage to current 2002 modeling days. However, USFWS did not submit data for VISTAS original base year preparation process, thus there was no known USFWS data in the 2002 actual or typical inventories. MACTEC therefore developed a method that could use the county-level data submitted by USFWS.

Several VISTAS/ASIP States run a prescribed fire-permitting program. To avoid double counting, only State data and not USFWS or USFS data was used in those States for the 2002 actual inventory.

The method used by MACTEC to include the USFS data applied a county level data approach for USFS data where a State had a prescribed fire permitting program and a fire-by-fire replacement for USFS data in States without permit programs. MACTEC used a county level approach for all of the USFWS data. The approach used for each data set is discussed below.

For USFWS data, 2002 annual county acres burned was subtracted from the USFWS projected acreage. A 0.8 factor was applied to the difference to account for blackened acres instead of the total perimeter acres that were reported. The revised total additional USFWS acreage was then added to the total county "typical" acreage to determine future acreage burned for 2009.

MACTEC then allocated the increased acreage to current modeling days. The average daily acres burned data provided by USFWS per NWR/county was used to allocate the acreage to the correct number of days required to burn all of the acres. Guidance supplied by USFWS indicated that up to three times the average daily acres burned could potentially be allocated to any one day.

For the USFS fire-by-fire acreage estimates, MACTEC summed the USFS data at a county-level for States that had permit programs, then added the sum to the typical acreage and allocated the acres to current modeling days. For States that do not have a State prescribed fire permit program, MACTEC simply replaced the current fire-by-fire records in the database with fire-by-fire records from the USFS and recalculated emissions based on fuel model and fuel loading. VISTAS also applied the same 0.8 correction for blackened acres applied to all USFS supplied acreage as the supplied values represented perimeter acres.

An additional problem with developing year-specific prescribed fire projections was how to adequately capture the temporal profile for those fires. In the 2002 actual fire inventory, fires occur on same days as state/FLM records. In the 2002 "typical" year inventory, fire acreage increased or decreased from acreage on the same fire days as were in the 2002 actual inventory, since the acres were simply increased for each day based on a multiplier used to convert from actual to typical.

When prescribed fires acreage was added to a future year, MACTEC added acreage to individual fire days proportional to the annual increase (if acreage on a day is 10 percent of annual, add 10 percent of projected increase to that same day).

6. VISTAS DEVELOPED 2002 NONROAD MOBILE SOURCE INVENTORY

Development of emission estimates for nonroad mobile sources is documented in the MACTEC, Inc. document titled *Documentation of the Base G 2002 Base Year, 2009 and 2018, Emission Inventories for VISTAS*.

Nonroad mobile sources are those sources that can move but do not use the highway system. Examples include lawn mowers, agricultural equipment, construction equipment, aircraft engines, railroad locomotives, powerboats, and commercial marine (ships). All but the aircraft engine, railroad locomotive emissions and commercial marine activity were estimated using the USEPA's off-road mobile model NONROAD2005c, which was released March 21, 2006. Direct emissions are generated with this model. This version incorporates all the USEPA final nonroad mobile engine emission standards, including the recreational and large spark-ignition engines rules that were published in the Federal Register in November 2002. Although this model is considered to be a final model, an updated version is planned that may incorporate revised inputs for the small spark-ignition (SI) (<19 kW) and recreational marine SI categories in conjunction with additional promulgated nonroad mobile engine standards.

Nonroad mobile sources calculated through the NONROAD model are discussed in Section 6.1. Aircraft, railroad and commercial marine emissions are discussed in Sections 6.2 through 6.4.

6.1 NONROAD Model Sources

The nonroad mobile source category includes a diverse collection of equipment such as lawn mowers, chain saws, tractors, all terrain vehicles, fork lifts and construction equipment. The USEPA NONROAD2005c model generates emissions directly and includes more than 80 different types of equipment. To facilitate analysis and reporting, the USEPA grouped the equipment types into ten equipment categories. These include:

Agricultural equipment
Airport ground support equipment
Commercial equipment
Construction equipment
Industrial equipment
Lawn and garden equipment
Logging equipment
Railroad maintenance equipment
Recreational marine equipment
Recreational equipment

Additionally, the emissions are broken out by five different engine types. These include: 2-stroke and 4-stroke spark engines, diesel engines, liquid petroleum gas (LPG) and compressed natural gas (CNG) fueled engines.

One of the default input files was edited to reflect North Carolina specific information. In the "SEASON.DAT" file, the region representative of North Carolina was changed from Mid-Atlantic to Southeast. This was done after an evaluation of the meteorological data in the two files and comparing it to that of Charlotte. Default data was used for the remaining input files used in the NONROAD model.

6.2 Aircraft Engines

Aircraft engines, like other engines, emit pollutants whenever the engines are in operation. However, the only emissions that are of concern for this inventory are the portion of the operation that occurs below the mixing layer. This is because the emissions tend to disperse whenever the aircraft is above the mixing layer and therefore has little or no effect on ground level ozone.

The aircraft operations of interest are termed the landing and takeoff (LTO) cycle. The cycle begins when the aircraft approaches the airport, descending below the mixing layer, lands and taxis to the gate. It continues as the aircraft idles at the gate and then taxis back out to the runway for the subsequent takeoff and climbout as it heads back to cruising altitudes, above the mixing layer.

Aircraft can be categorized by use into four classifications: commercial, air taxis, general aviation and military. Commercial aircraft include those used for scheduled service transporting passengers and/or freight. Air taxis, or commuter aircraft, also fly scheduled service carrying passengers and/or freight but usually are smaller aircraft and operate on a more limited basis than commercial carriers. General aviation include all other non-military aircraft used for recreational flying, personal transportation, and various other activities. Military aircraft cover a wide range of sizes, uses and operating missions. The military aircraft are treated as a separate classification since the LTO operations reported at the airports group all military aircraft together.

Emission factors are available for the many aircraft and engine combinations that exist. Factors for each aircraft exist for four operating modes in the LTO cycle. Emissions are calculated by obtaining data for the number of LTO cycles of the various aircraft at each airport in question, multiplying by the appropriate factors, and summing the results for the year under consideration.

Development of the 2002 aircraft emissions are described in the MACTEC document titled *Documentation of the Base G 2002 Base Year, 2009 and 2018 Emission Inventories for VISTAS* . This document refers back to a document titled *"Development of the VISTAS Draft 2002 Mobile Source Emission Inventory (February 2004 Version)"* prepared by E.H. Pechan & Associates, Inc. Both of these documents are included in Appendix P.

The starting point for development of aircraft emissions estimates is the 1999 National Emission Inventory (1999 NEI) prepared by the USEPA. These emissions were grown to appropriate values for 2002 and 2009 using growth factors developed by the USEPA for the CAIR. Along the way there was input by the various States including North Carolina to arrive at more accurate emission estimates.

6.3 Railroad Locomotives

Railroads are categorized by size (Class I, Class 2) and passenger service (Amtrak and North Carolina Department of Transportation (NCDOT) Rail Division). Class I railroads are long haul operations, consisting of Norfolk Southern Corporation and CSX Corporation in North Carolina. Class II and Class III railroads are short lines, serving localized markets. Passenger service is provided by Amtrak and the NCDOT Rail Division in North Carolina. These entities lease trackage from Class I railroads.

Development of railroad emissions is described in the MACTEC document titled *Documentation of the Base G 2002 Base Year, 2009 and 2018 Emission Inventories for VISTAS*. The VISTAS/ASIP railroad emission estimates started with 1999 emission estimates developed for the USEPA's 1999 NEI Version 2 as base year estimates for the VISTAS region. Additional information is provided in *"Development of the VISTAS Draft 2002 Mobile Source Emission Inventory (February 2004 Version)"* prepared by E.H. Pechan & Associates, Inc.

Projected emissions for 2002 were developed in two steps as described below. For 1999 to 2001, State-level rail fuel consumption was obtained from the Department of Energy, Energy Information Administration's (EIA's) *Fuel Oil and Kerosene Sales.* For 2001 to 2002, VISTAS applied national growth factors developed from fuel consumption projections in EIA's *Annual Energy Outlook.* A growth factor of 1.4 was used for locomotives and applied to 1999 emissions to first develop 2001 emissions. Table 6.3-1 lists the growth factors used to generate 2002 emissions.

Table 6.3-1 2002 National Rail Transportation Energy Use by Fuel Type (Trillion BTU)

	2001	2002	Growth Factor (GF)
Intercity Rail (Electric)	10.17	10.40	1.0226
Intercity Rail (Diesel)	16.60	16.88	1.0169
Transit Rail (Electric)	46.36	47.40	1.0224
Intercity/Transit Rail Average (SCC 2285002008)			**1.0206**
Commuter Rail (Electric)	16.13	16.49	1.0223
Commuter Rail (Diesel)	26.31	26.76	1.0171
Commuter Rail Average (SCC 2285002009)			**1.0197**
Freight Rail (Distillate) (SCCs 2285002000, 2285002005, 2285002006, 2285002007, 2285002010)	512.81	492.32	0.9600

Source: Department of Energy, Energy Information Administration, Annual Energy Outlook 2003: Table 34. Transportation Sector Energy Use by Fuel Type Within a Mode

6.4 Commercial Marine Vessel (CMV)

The following description of development of commercial marine emission estimates is based on excerpts, with some editing, taken from the MACTEC document titled *Documentation of the Base G 2002 Base Year, 2009 and 2018 Emission Inventories for VISTAS* and a document titled *"Development of the VISTAS Draft 2002 Mobile Source Emission Inventory (February 2004 Version)"* prepared by E.H. Pechan & Associates, Inc

An initial 2002 base year emissions inventory for commercial marine vessels (CMV) was prepared for VISTAS in early 2004. The methods and data used to develop the inventory are presented in a February 9, 2004 report "*Development of the VISTAS Draft 2002 Mobile Source Emission Inventory (February 2004 Version)*" prepared by E.H. Pechan & Associates, Inc. Revisions to the initial 2002 emissions inventory (prepared by Pechan) were implemented to ensure that the latest State and local data were incorporated. For CMV, North Carolina provided no revised data.

For 2002 commercial marine vessels (CMVs), Pechan used 1999 emission estimates developed for the USEPA's 1999 NEI Version 2 as base year estimates for the VISTAS region. Pechan then improved the spatial distribution of CMV emission estimates for the VISTAS region.

Ideally, CMV emission estimates would be developed using local activity data that account for vessel type, engine type and mode of operation (cruise, maneuvering, and hotelling). Creating this type of "bottom-up" emission inventory requires a large amount of effort. Therefore, Pechan utilized port-specific emission estimates developed for the 1999 NEI, distributed using a revised allocation methodology, which incorporates information on the number of port facilities in each county.

The 2002 VISTAS commercial marine inventory is based on the USEPA's 1999 NEI Version 2.0, projected to 2002 using appropriate growth factors. The 1999 NEI estimated emissions for these categories according to the following SCCs:

SCC	Descriptor 1	Descriptor 3	Descriptor 6	Descriptor 8
2280002100	Mobile Sources	Marine Vessels, Commercial	Diesel	Port emissions
2280002200	Mobile Sources	Marine Vessels, Commercial	Diesel	Underway emissions
2280003100	Mobile Sources	Marine Vessels, Commercial	Residual	Port emissions
2280003200	Mobile Sources	Marine Vessels, Commercial	Residual	Underway emissions

For the 1999 NEI, commercial marine diesel emissions were developed by obtaining 2000 emission estimates for all pollutants except SO_2 from the USEPA's Office of Transportation and Air Quality (OTAQ) marine diesel regulatory background documentation (*Draft Regulatory Impact Analysis - Control of Emissions from Compression-Ignition Marine Engines*). To estimate emissions for 1999, 2000 estimates were backcast using growth factors obtained from the draft Regulatory Impact Analysis (RIA) cited above. Steam-powered residual CMV emission estimates were developed by obtaining fuel usage data from OTAQ and applying fuel-based emission factors. A similar method was used for diesel SO_2 emissions. National diesel usage was estimated assuming a sulfur content of 0.25 percent and USEPA emission factors.

In apportioning, distillate and residual fuels are considered separately. National diesel emissions were disaggregated into port and underway emissions estimates based on the assumption that 75 percent of distillate fuel is consumed within the port, while the remaining fuel is consumed while underway, consistent with USEPA guidance. National residual emissions were disaggregated into port and underway emissions estimates based on the assumption that 25 percent of residual fuel is consumed within the port, while the remaining fuel is consumed while underway.

To allocate to counties, port emissions were assigned to the 150 largest U.S. ports based on activity obtained from the U.S. Army Corps of Engineers (USACE). The percentage of total traffic for each port was calculated by dividing the port-level traffic by the total traffic. Emissions for each port were then assigned to a single county.

Underway emissions are assigned to counties based on a county's shipping lane traffic. The Bureau of Transportation Statistics' (BTS) *National Transportation Atlas Databases-1999* contains data on the thousand tons per mile traveled for each shipping lane link in the United States (BTS-CD26). Where navigable rivers form a county or State boundary, the shipping lane traffic is proportioned to individual counties based on the length of shoreline that is shared. For example, if two counties share a navigable river, and both counties have the same length of shoreline, the shipping traffic is split evenly between the two counties. Shipping lanes that are not within counties, for example in the ocean, are associated to States based on BTS assignments. These waterway weights are then evenly distributed among the counties within these States that have navigable waterways. All shipping activity is summed at the county-level and compared with national shipping activity to determine what portion of activity can be attributed to individual counties. These proportions were used in disaggregating the national CMV emission estimates to the county level.

States that share borders with non-VISTAS States along the Mississippi and Ohio Rivers have expressed concern about the representativeness of port emission estimates at a county-level. Revising the county-level emissions estimates would allow more accurate modeling of emissions in the VISTAS states.

For underway emissions, Pechan believes that the allocation procedure results in a reasonable distribution of county-level emissions. However, the methodology to allocate port emissions results in all the emissions being assigned to a single county.

Port areas encompass multiple States and counties and in some cases, multiple waterways. Therefore, the emissions allocation process must incorporate all counties in the vicinity of the port where activity is occurring. This is especially true for inland rivers where activity takes place on both riverbanks and for ten river miles or more outside the port city. The revised methodology allocates port emissions based on a surrogate for port-related activity in each county, rather than using a single county to define the port.

The report, Waterborne Commerce of the United States, Calendar Year 1999, hereafter referred to as Waterborne Commerce, presents the cargo tonnage and number of vessel trips in major waterways of the United States. The report defines port areas, which USACE uses to develop the Top 150 Ports in the United States by amount of cargo tonnage. As discussed previously, the 1999 NEI allocates all the port emissions to these 150 ports based on the cargo tonnage handled by the port. Pechan uses this allocation of emissions to each port area as the starting point of its revised allocation process. Morehead City Harbor and the Port of Wilmington are the two main ports in North Carolina.

The next step was to develop a list of counties that make up the port area. Port area definitions were obtained from *Waterborne Commerce*. The port area definition for Morehead City Harbor port was "Morehead City Harbor, NC". The port area definition for Wilmington City port was "Both banks of the Cape Fear River extending from a point about 18 miles below the foot of Castle St. in Wilmington to a point about 2 miles above the Railroad Bridge at Navassa, and both banks of Northeast (Cape Fear) River from its mouth to a point about 1.67 miles above the Hilton Railroad Bridge". Using the port definitions by river mile, Pechan established which counties are included in each port area. The Port of Wilmington is included in the counties of Hanover and New Brunswick. The Morehead City Harbor is included in Carteret county.

The next step in allocating emissions is to develop a surrogate for the amount of CMV activity in each county of the port area. Pechan assumed that the activity of vessels in each county is related to the number of port facilities operating in a given county. Port facilities include terminals, piers, wharves, and docks that are involved in all types of commercial activity and support services. Pechan obtained the number of port facilities in each county from USACE reports, The Port Series Reports. The USACE periodically surveys the commercial marine industry to obtain information on port facilities and publishes it in The Port Series Reports. The reports give the name, location, operations, and describe the physical and inter-modal characteristics of the facilities. The data includes the location of the facility by river mile, State, and county.

For each port area, Pechan calculated the ratio between the number of port facilities in each county to the total number of facilities in all counties that make up the port area. This ratio was used to allocate emissions for each port area to the county-level. The ratio for Morehead City Harbor was 1.0 in Carteret county and the ratios for the Port of Wilmington were 0.8974 in New Hanover county and 0.1026 in Brunswick county. Pechan was directed to perform the reallocation for all VISTAS ports.

There are no commercial marine emissions in the Hickory or Triad areas.

7. 2009 NONROAD MOBILE SOURCE EMISSION INVENTORY DEVELOPMENT

The subsections that follow describe the projection process used to develop 2009 nonroad mobile source projection estimates for sources found in the NONROAD model and those sources estimated outside of the model (locomotives, airplanes, and commercial marine vessels).

7.1 Projection of NONROAD Mobile Sources

NONROAD model input files were prepared based on the 2002 base year inventory input files with appropriate updates for the projection years. Other specific updates for the projection years for NONROAD model sources consist of:

1. Revise the emission inventory year in the model (as well as various output file naming commands) to be reflective of the projection year.

2. Revise the fuel sulfur content for gasoline and diesel powered equipment.

3. Implement a limited number of local control program changes (national control program changes are handled internally within the NONROAD model, so explicit input file changes are not required).

All equipment population growth and fleet turnover impacts are handled internally within the NONROAD model, so that explicit input file changes are not required.

The final NONROAD2005c that was used for inventory development is capable of handling separate diesel fuel sulfur inputs for land-based and marine-based nonroad mobile source equipment in a single model execution. The following diesel fuel sulfur values were used:

Diesel S (ppm)	**2002**	**2009**
Land-Based	2500	348
Marine-Based	2638	408

7.2 Projection of Non-NONROAD Model Sources

Using the 2002 base year emissions inventory for aircraft, locomotives, and CMV prepared as described earlier in this document, corresponding emission projections for 2009 were developed. The following description is largely taken from the MACTEC document titled *Documentation of* *the Base G 2002 Base Year, 2009 and 2018 Emission Inventories for VISTAS*. Briefly, the methodology relies on growth and control factors developed from inventories used in support of recent USEPA rulemakings, and consists of the following steps:

(a) Begin with the 2002 base year emission estimates for aircraft, locomotive, and CMV.

(b) Detailed inventory data (both before and after controls) for these same emission sources for 1996, 2010, 2015, and 2020 were obtained from the USEPA's CAIR Technical Support Document. Using these data, combined growth and control factors for the period 2002-2009 were estimated using straight line interpolation between 1996 and 2010 (for 2009). This is done at the State-county-SCC-pollutant level of detail.

(c) The USEPA growth and control data are matched against the 2002 VISTAS base year data using State-county-SCC-pollutant as the match key. Ideally, there would be a one-to-one match and the process would end at this point. Unfortunately, actual match results were not always ideal, so additional matching criteria were required. For subsequent reference, this initial (highest resolution) matching criterion is denoted as the "CAIR-Primary" criterion.

(d) A second matching criterion is applied that utilizes a similar, but higher-level SCC (lower resolution) matching approach. For example, SCC 2275020000 (commercial aircraft) in the 2002 base year inventory data would be matched with SCC 2275000000 (all aircraft) in the CAIR data. This criterion is applied to records in the 2002 base year emissions file that are not matched using the "CAIR-Primary" criterion, and is also performed at the State-county-SCC-pollutant level of detail. For subsequent reference, this is denoted as the "CAIR-Secondary" criterion. At the end of this process, a number of unmatched records continued to remain, so a third level matching criterion was required.

(e) In the third matching step, the most frequently used SCC in the USEPA CAIR files for each of the aircraft, locomotive, and commercial marine sectors is averaged at the State level to produce a "default" State and pollutant-specific growth and control factor for the sector. The resulting factor is used as a "default" growth factor for all unmatched county-SCC-pollutant level data in each State. In effect, State-specific growth data are applied to county level data for which an explicit match between the VISTAS 2002 base year data and the USEPA CAIR data could not be developed. The default growth and control SCCs are 2275020000 (commercial aircraft) for the aircraft sector, 2280002000 (commercial marine diesel total) for the CMV sector, and 2285002000 (railroad equipment diesel total) for the locomotive sector. Matches made using this criterion are denoted as "CAIR-Tertiary" matches.

(f) According to USEPA documentation, the CAIR baseline emissions include the impacts of the (then proposed) Tier 4 (T4) nonroad mobile diesel rulemaking, which implements a low sulfur fuel requirement that affects both future CMV and locomotive emissions. However, the impacts of this rule were originally intended to be excluded from the initial VISTAS 2018 forecast, which was to include only "on-the-books" controls. (The T4 rule was finalized subsequent to the development of the preliminary 2018 inventory in March of 2004.) Given its final status, T4 impacts have now been moved into the "on the books" inventory for nonroad mobile source equipment. In addition, since there are no other proposed rules affecting the nonroad mobile source sector between 2002 and 2018, there is no difference between the 2018 "on the books" and 2018 "on the way" inventories for the sector; so that only a single forecast inventory (for each evaluation year) was developed. Nevertheless, since the algorithms developed to produce the VISTAS forecasts were developed when there was a distinction between the "on the books" and "on the way" inventories, the distinct algorithms used to produce the two inventories have been maintained even though the conceptual distinctions have been lost. This approach was taken for two reasons. First, it allowed the previously developed algorithms to be utilized without change. Second, it allowed for separate treatment of the T4 emissions impact which was important as those impacts have changed between the proposed and final T4 rules. Thus, previous USEPA inventories that include the proposed T4 impacts would not be accurate. Therefore, the procedural discussion continues to reflect the distinctions between non-T4 and T4 emissions, as these distinctions continue to be intrinsically important to the forecasting process. Therefore, a second set of USEPA CAIR files that excluded the Tier 4 diesel impacts was obtained and the same matching exercise described above in steps (b) through (e) was performed using these "No T4" files. It is important to note that the matching exercise described in steps (b) through (e) cannot simply be replaced because the "No T4" files obtained from the USEPA include only those SCCs specifically affected by the T4 rule (i.e., diesel CMV and locomotives). So in effect, the matching exercise was augmented (rather than replaced) with an additional three criteria analogous to those described in steps (c) through (e), and these are denoted as the "No T4-Primary," "No T4-Secondary," and "No T4-Tertiary" criteria. Because they exclude the impacts of the proposed T4 rule, matches using the "No T4" criteria supersede matches made using the basic CAIR criteria (as described in steps (c) through (e) above).

(g) The CAIR matching criteria were overridden for any record for which States provided local growth data. Only North Carolina provided these forecasts, as North Carolina has provided specific growth factors for airport emissions in four counties. Because the provided data were based on forecasted changes in landings and takeoffs at major North Carolina airports, the factors were applied only to commercial (SCC 2275020000) and air taxi (SCC 2275060000) emissions. Emissions forecasts for military and general aviation aircraft operations, as well as all aircraft operations in counties other than the four identified in the North Carolina growth factor submission, continued to utilize the growth factors developed according to steps (b) through (f) above. The locally generated growth factor (2002 to 2009) applied in Guilford County was 0.97.

(h) Using this approach, each State-county-SCC-pollutant was assigned a combined growth and control factor using the USEPA CAIR forecast or locally provided data. The 22,838 data records for aircraft, locomotives, and CMV in the 2002 base year emissions file were assigned growth factors in accordance with the following breakdown:

48 records matched State-provided growth factors,
4,179 records matched using the CAIR-Primary criterion,
240 records matched using the CAIR-Secondary criterion,
7,463 records matched using the CAIR-Tertiary criterion,
720 records matched using the No T4-Primary criterion,
3,858 records matched using the No T4-Secondary criterion, and
6,330 records matched using the No T4-Tertiary criterion.

(i) Finally, the impacts of the T4 rule as adopted were applied to the grown "non T4" emission estimates. The actual T4 emission standards do not affect aircraft, locomotive, or CMV directly, but associated diesel fuel sulfur requirements do affect locomotives and CMV. Lower fuel sulfur content affects both SO_2 and PM emissions. Expected fuel sulfur content was obtained for 2009 from the USEPA technical support document for the final T4 rule (*Final Regulatory Analysis: Control of Emissions from Nonroad Diesel Engines*, EPA420-R-04-007, May 2004). According to that document, the average diesel fuel sulfur content for locomotives and CMV is expected to be 408 parts per million by weight (ppmW) in 2009. This compares to expected non-T4 fuel sulfur levels of 2599 ppmW in 2009. Table 7.2-1 uses calculated emissions estimates for base and T4 control scenarios to estimate emission reduction impacts.

Table 7.2-1 Estimated Emission Reduction Impacts based on T-4 Rule

				2009
CMV SO_2	=	Non-T4 SO_2	×	0.1569
Locomotive SO_2	=	Non-T4 SO_2	×	0.1569
CMV PM	=	Non-T4 PM	×	0.8962
Locomotive PM	=	Non-T4 PM	×	0.8117

However, since the diesel fuel sulfur content assumed for the 2002 VISTAS base year inventory, upon which the 2009 inventory was based, is 2500 ppmW, a small adjustment to the emission reduction multiplier calculated from the T4 rule is appropriate since they are measured relative to modestly different sulfur contents (2599 ppmW for 2009). Correcting for these modest differences produces the emission reduction impact estimates relative to forecasts based on the VISTAS 2002 inventory shown in Table 7.2-2.

Table 7.2-2 Estimated Emission Reduction Impacts Relative to VISTAS 2002 Base Year Values

				2009
CMV SO_2	=	Non-T4 SO_2	×	0.1632
Locomotive SO_2	=	Non-T4 SO_2	×	0.1632
CMV PM	=	Non-T4 PM	×	0.9004
Locomotive PM	=	Non-T4 PM	×	0.8187

These factors were applied directly to the non-T4 emission forecasts to produce the final VISTAS 2009 emissions inventories for aircraft, locomotive, and CMV.

During the development of the preliminary 2018 VISTAS inventory in March 2004, this process yielded reasonable results and exhibited no particular systematic concerns. However, when the 2009 Base F inventory was developed, significant concerns related to SO_2 and PM were encountered. Essentially, what was revealed by the Base F 2009 forecast was a series of apparent inconsistencies in the CAIR 2010 and 2015 emission inventories (as compared to the 1996 and 2020 CAIR inventories) that were masked during the construction of the "longer-term" 2018 inventory.

For the most part, the issue seems to be centered on SO_2 and PM records, which are those records primarily affected by the T4 rule. But, as noted above, there does not seem to be any pattern of consistency that would indicate that either inclusion or exclusion of T4 rule impacts is the underlying cause. Moreover, where they occur, the observed growth extremes generally affect both SO_2 and PM equally, while one would expect PM effects to be buffered if the T4 rule was the underlying cause, since changes in diesel fuel sulfur content will only affect a fraction of PM (i.e., sulfate), while directly reducing SO_2.

While forecast inventories for aircraft, locomotives, and CMV were developed for 2009 and 2018 using both growth methods, it was ultimately decided to utilize the 1996-2020 growth basis since it provided more reasonable growth rates for 2009.

8. QUALITY ASSURANCE OF EMISSIONS INVENTORY

8.1 2002 Area and Nonroad Mobile

Many emission estimation methods are based on AP-42 factors located on the USEPA website at http://www.epa.gov/ttn/chief/ap42/, factors given in the Procedures document, and factors given in the documents of the Emission Inventory Improvement Program website located at http://www.epa.gov/ttn/chief/eiip/. Sources of error would primarily be associated with multiplier values, data entry errors, and the accuracy of formulas.

For the portion of the 2002 inventory developed by North Carolina, specific quality assurance (QA) procedures were followed. Under the direction of the Quality Assurance Coordinator, emission sources whose contribution were either at the high or low end of the range of estimates were scrutinized more closely to ensure that the emission estimates were estimated correctly. In addition, the raw data used in the calculations were verified to make sure transference to the spreadsheets was accomplished accurately. Furthermore, the formulas used to calculate the emissions were reviewed and checked for correctness. Random independent checks of the calculations were also performed to ensure the accuracy of the inventory.

For the portion of the 2002 inventory developed by VISTAS and MACTEC, specific QA procedures were followed. These procedures are outlined in the document titled *Documentation of the Base G 2002 Base Year, 2009, and 2018, Emission Inventories for VISTAS* prepared for VISTAS by MACTEC, Inc. Throughout the inventory development process, quality assurance steps were performed to ensure that no double counting of emissions occurred, and to ensure that a full and complete inventory was developed for VISTAS. Quality assurance was an important component to the inventory development process and MACTEC performed the following QA steps on the area source component of the 2002 inventory:

1. All CERR and NIF format State supplied data submittals were run through the USEPA's Format and Content checking software.

2. SCC level emission summaries were prepared and evaluated to ensure that emissions were consistent and that there were no missing sources.

3. Fields were either added or used within each NIF data table to track the sources of data for each emission record.

4. Data product summaries were provided to both the VISTAS Emission Inventory Technical Advisor and to Area Source and Fires SIWG representatives for review and comment. Changes based on these comments were implemented in the files.

5. Version numbering was used for all inventory files developed. The version numbering process used a decimal system to track major and minor changes. For example, a major change would result in a version going from 1.0 to 2.0. A minor change would cause a version number to go from 1.0 to 1.1. Minor changes resulting from largely editorial changes would result in a change from 1.00 to 1.01.

6. All final NIF files were checked using the USEPA Format and Content checking software and summary information by State and pollutant were prepared comparing the previous versions of the inventory to the latest.

For the fires inventory, data related to fuel loading and fuel consumption was reviewed and approved by the VISTAS Fire SIWG to ensure that values used for each type of fire and each individual fire were appropriate. Members of the VISTAS Fire SIWG included representatives from most State Divisions of Forestry (or equivalent) as well as U.S. Forest Service and National Park Service personnel.

In addition, for the nonroad portion of the inventory prepared by VISTAS, tier comparisons (by pollutant) were developed between the revised 2002 base year inventory and the initial base year inventory.

8.2 2009 Area and Nonroad Mobile

For the portion of the 2009 inventory developed by North Carolina, specific QA procedures were followed. Under the direction of the Quality Assurance Coordinator, emission sources whose contribution were either at the high or low end of the range of estimates were scrutinized more closely to ensure that the emission estimates were estimated correctly. In addition, the raw data used in the calculations were verified to make sure transference to the spreadsheets was accomplished accurately. Furthermore, the formulas used to calculate the daily emissions were reviewed and checked for correctness. Random independent checks of the calculations were also performed to ensure the accuracy of the inventory.

For the portion of the 2009 inventory developed by VISTAS and MACTEC, Inc., specific QA procedures were followed. These procedures are outlined in the document titled *Documentation of the Base G 2002 Base Year, 2009, and 2018, Emission Inventories for VISTAS* prepared for VISTAS by MACTEC, Inc. Throughout the inventory development process, quality assurance steps were performed to ensure that no double counting of emissions occurred, to ensure that a full and complete inventory was developed for VISTAS, and to make sure that projection calculations were working correctly. Quality assurance was an important component to the inventory development process and MACTEC performed the following QA steps on the area source and the nonroad mobile source components of the 2009 inventory:

1. All final files were run through EPA's Format and Content checking software.

2. SCC level emission summaries were prepared and evaluated to ensure that emissions were consistent and that there were no missing sources.

3. Tier comparisons (by pollutant) were developed between the 2002 base year inventory and the 2009 projection inventory. In addition, total VISTAS pollutant summaries were prepared to compare total emissions by pollutant between earlier and later versions of the inventory.

4. Data product summaries were provided to both the VISTAS Emission Inventory Technical Advisor and to the SIWG representatives for review and comment. Changes based on these comments were implemented in the files.

5. Version numbering was used for all inventory files developed. The version numbering process used a decimal system to track major and minor changes. For example, a major change would result in a version going from 1.0 to 2.0. A minor change would cause a version number to go from 1.0 to 1.1. Minor changes resulting from largely editorial changes would result in a change from 1.00 to 1.01.

SIC 33: Primary metal industries - 4-digit SIC to 6-digit NAICS

Includes only establishments with payroll. Introductory text includes scope and methodology. Figures to the left of NAICS codes indicate the percent of NAICS receipts represented by this part; and link to Table 1 where other parts of the NAICS are shown. 97/92 links to 1997 and 1992 Comparative Statistics for whole SICs.

N=Comparable data not available D=Withheld to avoid disclosure

Σ=sum of NAICS parts listed below the symbol 97/92 links to Comparative Statistics for 1992 and 1997

(Bridge complete.)	Comparable	SIC derivable from NAICS data.
(Drawbridge slightly open.)	Almost comparable	Sales or receipts from NAICS are within 3% of SIC sales or receipts.
(Drawbridge open.)	Not comparable	SIC sales or receipts cannot be estimated within 3% from NAICS data.

N=Comparable data not available D=Withheld to avoid disclosure

Σ=sum of NAICS parts listed below the symbol 97/92 links to Comparative Statistics for 1992 and 1997

(Bridge complete.) Comparable SIC derivable from NAICS data.

(Drawbridge slightly open.) Almost comparable Sales or receipts from NAICS are within 3% of SIC sales or receipts.

(Drawbridge open.) Not comparable SIC sales or receipts cannot be estimated within 3% from NAICS data.

N=Comparable data not available D=Withheld to avoid disclosure

Σ=sum of NAICS parts listed below the symbol 97/92 links to Comparative Statistics for 1992 and 1997

(Bridge complete.) Comparable SIC derivable from NAICS data.

(Drawbridge slightly open.) Almost comparable Sales or receipts from NAICS are within 3% of SIC sales or receipts.

(Drawbridge open.) Not comparable SIC sales or receipts cannot be estimated within 3% from NAICS data.

SIC 36: Electronic and other electric equipment - Finder by 3-digit SIC

Includes only establishments with payroll. Introductory text includes scope and methodology.

1. INTRODUCTION

The attainment modeling for the Hickory (Catawba County) and the Triad (Davidson and Guilford Counties) fine particulate matter ($PM_{2.5}$) nonattainment areas were performed in conjunction with the regional haze modeling being done by the Southeast Regional Planning Organization, Visibility Improvement State and Tribal Association of the Southeast (VISTAS) and the fine particulate matter and particulate modeling being done by the Association of Southeastern Integrated Planning (ASIP). VISTAS and ASIP are run by the ten southeast states (Alabama, Florida, Georgia, Kentucky, Mississippi, North Carolina, South Carolina, Tennessee, Virginia and West Virginia). The North Carolina Division of Air Quality (NCDAQ) decided to use this modeling for its attainment demonstration since the modeling uses annual simulations and includes the intermediate year 2009, which is the attainment year for $PM_{2.5}$.

On-road mobile sources are those vehicles that travel on the highways and the roadways. On-road mobile sources emissions comprise a small percentage of the total particulate for all of North Carolina. Particulate emissions from motor vehicles only occur while the vehicle is moving or idling. These emissions are direct tailpipe (both gas and diesel), sulfate, tire wear, and brake wear. Only direct particulate emissions processes will be estimated in order to properly reflect the total particulate emissions from this source category. In its simplest terms, emissions from on-road mobile sources are calculated by multiplying an activity level, in this case daily vehicle miles traveled (VMT) as provided by the North Carolina Department of Transportation (NCDOT) and Metropolitan Planning Organization (MPOs), by an emission factor.

The US Environmental Protection Agency (USEPA) developed the MOBILE model to estimate emission factors based on information on the way vehicles are driven in a particular area. The newest version of the MOBILE model, MOBILE6.2, was used. In 2004, MOBILE6.2 was incorporated into SMOKEv2.1, which was used in the VISTAS/ASIP modeling. Key inputs for MOBILE6.2 include information on the age of vehicles on the roads, the average speed of those vehicles, what types of roads those vehicles are traveling on, any control technologies in place in an area that reduce emissions for motor vehicles (e.g., emissions inspection programs), and ambient temperature and humidity.

MOBILE6.2 particulate outputs contain both primary particulates (soot from tailpipes, tire, and brake wear) and secondary (particulate precursors). Secondary particulate matter is formed by chemical reactions of gas-phase precursors in the atmosphere (FR Vol.70, No. 210, p65992). The specific primary outputs are GASPM, i.e. particles directly emitted from all gasoline vehicles, OCARBON (organic carbon) and ECARBON (elemental carbon) from diesel engines, (sulfate) SO_4 from both fuels, and tire and brake dust from all vehicles.

A very important component of the on-road mobile emissions estimation process is interagency consultation. The transportation partners involved in this State Implementation Plan (SIP) and development of the motor vehicle emissions budgets (MVEBs) included: USEPA, NCDOT, Federal Highway Administration (FHWA), Greater Hickory (MPO), Unifour Rural Planning Organization (RPO), Piedmont Triad RPO, Greensboro MPO, High Point MPO, and the Burlington-Graham MPO. Specifically, the NCDOT and the MPOs were consulted on input data such as speeds and VMT derived from the travel demand model (TDM).

The documentation for the on-road mobile sources is broken out into two components:

1) how the inventory was developed for the particulate matter emissions modeling used for the attainment demonstration and,

2) how the motor vehicle emissions budgets were developed for the three North Carolina counties that comprise the $PM_{2.5}$ nonattainment areas.

2. MOBILE6.2 INPUT ASSUMPTIONS FOR EMISSIONS MODELING

The MOBILE6.2 module of SMOKE was used to develop the 2009 on-road mobile source emissions estimates for fine particulate matter. The MOBILE6.2 parameters, vehicle fleet descriptions, and VMT estimates were combined with gridded, episode-specific temperature data to calculate the gridded, temporalized emission estimates. Of note, whereas the on-network emissions estimates are spatially allocated based on link location and subsequently summed to the grid cell level, the off-network emissions estimates are spatially allocated based on a combination of the FHWA Version 2.0 highway networks and population. For the VISTAS/ASIP 36/12 km modeling, no link based data was used. The MOBILE6.2 emission factors are based on episode-specific temperatures predicted by the meteorological model. Furthermore, the MOBILE6.2 emission factor model accounts for the following:

- Daily minimum/maximum or 24 hourly temperatures;
- Facility speeds;
- Locale-specific inspection/maintenance (I/M) control programs, if any;
- VMT, fleet turnover, and changes in fuel composition and Reid Vapor Pressure (RVP).

2.1 Speed Assumptions

Emissions from motor vehicles vary with the manner in which the vehicle is operated. Vehicles traveling at 65 miles per hour (mph) emit a very different mix and concentrations of pollutants than the car that is idling at a stoplight. In order to estimate emissions from vehicles for a typical day, NCDOT and the MPOs provided speeds for their respective counties.

The speeds for several urban counties covered by the MPOs were generated from their latest travel demand models (TDMs) at the time emissions modeling began. NCDOT recommended using Wake County off-peak speeds for all remaining counties in North Carolina not covered by TDMs.

Interstates are modeled as "non-ramp" instead of "freeways" because both speed and VMT for ramps are included in the functional classification for the major facility it is connected to in the TDM. This is consistent with the USEPA guidance.

2.2 Vehicle Age Distribution

The vehicle age distribution is based on annual registration data for North Carolina and is provided by NCDOT. For this analysis the age distribution was generated based on 2005 data, representing the latest quality assured information available. The NCDOT provided vehicle count data for each vehicle classification from years 1974 and prior through 2005. Vehicles greater than 25 years old were combined and included as the 25^{th} model year. The vehicle count information is provided for nine vehicle types; light duty gas vehicles (LDGV), light duty diesel vehicles (LDDV), light duty gas trucks 1 (LDGT1), light duty gas trucks 2 (LDGT2), light duty diesel trucks 1 (LDDT1), light duty diesel trucks 2 (LDDT2), heavy duty gas vehicles (HDGV), heavy duty diesel vehicles (HDDV) and motorcycles (MC). LDDT1 and LDDT2 are combined and labeled as light duty diesel trucks (LDDT). This vehicle distribution convention corresponds to the old MOBILE5 format and does not correlate to the USEPA MOBILE6.2 model vehicle types. In order to convert the data provided by the NCDOT into the MOBILE6.2 model format, the NCDAQ used a utility developed by the USEPA that disaggregates the 8 MOBILE5 model vehicle types into the 16 MOBILE6.2 vehicle types. The count data provided by the NCDOT is converted into fractions by dividing each count per vehicle type per year by the total number of vehicles in that classification for all years. For example, the number of 2005 light duty vehicles divided by the total number of light duty vehicles for all years. The fractions are arranged into MOBILE5 format for conversion to the 16 vehicle types required by the MOBILE6.2 model using the USEPA conversion utility.

2.3 Vehicle Mix Assumptions

2.3.1 North Carolina Statewide Vehicle Mix Development

The vehicle mix refers to the percentage of different vehicle types on each of the 12 FHWA road types. These road types are listed below in Table 2.3.1-1. It is critical when estimating mobile emissions in an area to use data that accurately reflects the vehicle types traveling on each of these different road types.

Table 2. 3. 1 – 1. 1999-2001 Percent Vehicles by FHWA Vehicle Class by Functional Classification

The NCDAQ created a statewide mix based on the methodology outlined in the August 2004 USEPA guidance document EPA420-R-04-013, *Technical Guidance on the Use of MOBILE6.2 for Emission Inventory Preparation*. Below is the methodology used to convert the 13 Highway Performance Monitoring System (HPMS) vehicle types count data reported to FHWA to generate a state specific vehicle mix.

The North Carolina HPMS data that was used to generate the statewide vehicle mix was based on 1999 through 2001 data counts. This was the latest available statewide count information at the time of the emissions modeling. Table 2.3.1-1 shows the percent of vehicles per vehicle type for each of the 12 road classes.

Disaggregating State Specific Information

The *Technical Guidance on the Use of MOBILE6.2 for Emission Inventory Preparation*, Section 4.1.5, illustrates how to map the HPMS statewide vehicle data to general vehicle categories. This mapping is outlined below:

HPMS Category	**General Category**
Motorcycle	Motorcycle (MC)
Passenger Car	Passenger Car (LDV)
Other 2-Axel, 4-Tire Vehicles	Light Truck (LDT)
Buses	Bus (HDB)
All Other Trucks: Single unit, 2-axel, 6-tire Single unit, 3-axel Single unit, 4 or more axel Single trailer, 4 or fewer axel Single trailer, 5-axel Single trailer, 6 or more axel Multi-trailer, 5 or fewer axel Multi-trailer, 6-axel Multi-trailer, 7 or more axel	Heavy Duty Truck (HDV)

The HPMS data in Table 2.3.1-1 was grouped into these five general categories for each road type. In order to expand the five general categories to the 16 vehicle types used in MOBILE6.2, the national average VMT fractions by each vehicle class were used. The 2000 fractions were used since the state specific data is from 1999 through 2001. The national average data was obtained from Table 4.1.2 in _Technical Guidance on the Use of MOBILE6.2 for Emission Inventory Preparation_. An example for rural interstates is illustrated below:

From Table 2.3.1-1 above:

Passenger Cars	=	56.93%	5 axel Trailer	=	19.23%
Pickup Trucks	=	10.80%	6 axel Trailer	=	0.48%
Buses	=	1.06%	5 axel Multi Trailer	=	0.73%
2 axel Trucks	=	2.50%	6 axel Multi Trailer	=	0.24%
3 axel Trucks	=	1.56%	7 axel Multi Trailer	=	0.11%
4 axel Trucks	=	1.09%	Motorcycles	=	0.49%
4 axel Trailer	=	4.79%			

Therefore, the five general categories are:

Motorcycles	=	0.49%
Light Duty Vehicles	=	56.93%
Light Duty Trucks	=	10.80%
Heavy Duty Buses	=	1.06%
Heavy Duty Vehicles	=	30.73%

From Table 4.1.2 in _Technical Guidance on the Use of MOBILE6.2 for Emission Inventory Preparation_, the 2000 national average vehicle mix for light duty trucks, buses and heavy duty trucks are:

Light Duty Trucks

LDT1	=	0.0655
LDT2	=	0.2179
LDT3	=	0.0672
LDT4	=	0.0309
Total	**=**	**0.3815**

Buses

HDBS	=	0.0019
HDBT	=	0.0009
Total	**=**	**0.0028**

Heavy Duty Trucks

HDV2B	=	0.0380
HDV3	=	0.0038
HDV4	=	0.0029
HDV5	=	0.0022
HDV6	=	0.0082
HDV7	=	0.0098
HDV8A	=	0.0108
HDV8B	=	0.0386
Total	**=**	**0.1143**

Using the methodology described in *Technical Guidance on the Use of MOBILE6.2 for Emission Inventory Preparation*, Section 4.1.5, the 2000 North Carolina statewide mix was developed. The basic formula for developing the mix is shown below,

$$\text{Vehicle Type} = (\text{2000 M6.2 fraction for vehicle}) \times \frac{(\text{99-01 State total for group})}{(\text{2000 M6.2 total for subcategory})}$$

Table 2.3.1-2 displays the calculation for each vehicle type for the 2000 rural interstate vehicle mix.

Table 2.3.1-2. Calculation of New 2000 Statewide Rural Interstate Vehicle Mix

Vehicle Type		Calculation		New 2000 Mix
LDV	=	LDV	=	0.5693
MC	=	MC	=	0.0049
Light Duty Trucks				
LDT1	=	0.0655 x (0.1080/0.3815)	=	0.0185
LDT2	=	0.2179 x (0.1080/0.3815)	=	0.0617
LDT3	=	0.0672 x (0.1080/0.3815)	=	0.0190
LDT4	=	0.0309 x (0.1080/0.3815)	=	0.0087
Total Light Duty Vehicles				0.6822
Heavy Duty Vehicles				
HDV2B	=	0.0380 x (0.3073/0.1143)	=	0.1022
HDV3	=	0.0038 x (0.3073/0.1143)	=	0.0102
HDV4	=	0.0029 x (0.3073/0.1143)	=	0.0078

Buses				
HDBS	=	0.0019 x (0.0106/0.0028)	=	0.0072
HDBT	=	0.0009 x (0.0106/0.0028)	=	0.0034
Total Heavy Duty Vehicles				0.3178

2009 Statewide Vehicle Mix

Once the 2000 vehicle mix was generated, the other years were created using the methodology described in *Technical Guidance on the Use of MOBILE6.2 for Emission Inventory Preparation*, Section 4.1.4. This method grouped light duty vehicles(light duty trucks and motorcycles) together and heavy duty vehicles (heavy duty buses and heavy duty trucks) together. The combined percentages for these groupings are listed below.

Light Duty Vehicles	=	68.22%
Heavy Duty Vehicles	=	31.78%

The MOBILE6.2 vehicle mix fractions for the year being developed were obtained from Table 4.1.2 in *Technical Guidance on the Use of MOBILE6.2 for Emission Inventory Preparation*. The MOBILE6.2 vehicle fractions for 2009 are listed below.

Light Duty Vehicles

LDV	=	0.3669
LDT1	=	0.0869
LDT2	=	0.2894
LDT3	=	0.0892
LDT4	=	0.0410
MC	=	0.0054
Total	**=**	**0.8788**

Heavy Duty Vehicles

HDV2B	=	0.0389
HDV3	=	0.0038
HDV4	=	0.0032
HDV5	=	0.0024
HDV6	=	0.0087
HDV7	=	0.0103
HDV8A	=	0.0112
HDV8B	=	0.0398
HDBS	=	0.0020
HDBT	=	0.0010
Total	**=**	**0.1213**

The North Carolina 2009 vehicle mix was normalized to the MOBILE6.2 fractions using the following formula:

$$\text{Vehicle Type} = (\text{2009 M6 fraction for vehicle}) \times \frac{(\text{2000 State total for group})}{(\text{2009 M6 total for group})}$$

Table 2.3.1-3 below displays the calculations used to generate the 2009 North Carolina vehicle mix for rural interstate.

Table 2.3.1-3. Calculation of 2009 NC Statewide Rural Interstate Vehicle Mix

Vehicle Type		Calculation		2009 State Mix
Light Duty Vehicles				
LDV	=	0.3669 x (0.6822/0.8788)	=	0.2848
LDT1	=	0.0869 x (0.6822/0.8788)	=	0.0675
LDT2	=	0.2894 x (0.6822/0.8788)	=	0.2247
LDT3	=	0.0892 x (0.6822/0.8788)	=	0.0692
LDT4	=	0.0410 x (0.6822/0.8788)	=	0.0318
MC	=	0.0054 x (0.6822/0.8788)		0.0042
Heavy Duty Vehicles				
HDV2B	=	0.0389 x (0.3178/0.1213)	=	0.1019
HDV3	=	0.0038 x (0.3178/0.1213)	=	0.0100
HDV4	=	0.0032 x (0.3178/0.1213)	=	0.0084
HDV5	=	0.0024 x (0.3178/0.1213)	=	0.0063
HDV6	=	0.0087 x (0.3178/0.1213)	=	0.0228
HDV7	=	0.0103 x (0.3178/0.1213)	=	0.0270
HDV8A	=	0.0112 x (0.3178/0.1213)	=	0.0293
HDV8B	=	0.0398 x (0.3178/0.1213)	=	0.1043
HDBS	=	0.0020 x (0.3178/0.1213)	=	0.0052
HDBT	=	0.0010 x (0.3178/0.1213)	=	0.0026

2.4 Temperature, Relative Humidity and Barometric Pressure Assumptions

Although, MOBILE6.2 $PM_{2.5}$ emission factors used by SMOKE are not significantly influenced by temperature and humidity, the other pollutants that are needed for one atmosphere modeling, such as nitrogen oxides and volatile organic compounds, are influenced by temperature and humidity. Therefore, the most desirable approach is to model on-road mobile emissions using gridded, temporalized data from the meteorological model. The VISTAS on-road mobile inventories were developed using this approach.

2.5 Vehicle Inspection and Maintenance Program Assumptions

In the early 1990's, North Carolina adopted emissions inspection requirements for vehicles in 9 urban counties. This program tested emissions at idle for 1975 and newer gasoline powered light duty vehicles. This "idle test" was assumed to have a compliance rate of 95 percent and covered

Gaston, Mecklenburg, Union, Cabarrus, Forsyth, Guilford, Orange, Durham and Wake Counties. In addition, the inspection stations are required to administer an anti-tampering check to ensure that emissions control equipment installed originally are on the vehicle and that the equipment has not been altered.

In 2002, North Carolina implemented a new vehicle emissions inspection program referred to as onboard diagnostics (OBD-II). This program covers all light duty gasoline powered vehicles that are model year 1996 and newer. The program was initially implemented in the 9 counties that originally had the "idle test" and was expanded to include a total of 48 counties between July 2002 and January 2006. Because the OBD-II program did not begin until midway through 2002, the 2002 annual on-road mobile inventory to support VISTAS/ASIP modeling was developed with the "idle test" only in the 9 counties listed above in addition to the anti-tampering in all counties. By 2009 the OBD-II program will be fully implemented resulting in all three nonattainment counties, Catawba, Davidson, and Guilford, to be subject to the OBD-II I/M program. In addition, the inspection stations are required to administer an anti-tampering check to ensure that emissions control equipment on any vehicle 35 model years old and newer has not been altered.

2.6 Reid Vapor Pressure Assumptions

The RVP is a measure of gasoline's volatility. An RVP of 7.8 pounds per square inch (psi) is required during May through September in the former 1-hour ozone nonattainment areas, which includes Guilford and Davidson Counties. The remainder of North Carolina is required to have an RVP of 9.0 psi, used in Catawba County, during May through September. For the months of October, November, February, March and April, the RVP is 13.5 psi. The RVP in January and December is 15.0 psi.

2.7 Vehicle Miles Traveled Assumptions

In order to calculate emissions from on-road mobile sources, emission factors are developed as discussed throughout this document. The emission factors are then multiplied by an activity level, which for on-road mobile sources is VMT.

For most counties in North Carolina, the 2002 VMT was derived from the 2002 Highway Performance Maintenance System (HPMS) data provided by NCDOT and the 2009 was grown based on a linear interpolation of the most recent 10 years (1995-2004) of HPMS data. Similar to the speed data explained above, VMT from several urban counties TDMs were used instead of

HPMS VMT. Where travel demand model data was available, it was the recommendation of the North Carolina transportation partners to use it instead of the HPMS data.

In situations where certain North Carolina counties are partially covered by a travel demand model, and the North Carolina transportation partners anticipate future versions of the travel models to cover the entire county, an adjusted HPMS VMT number was used. This upward adjustment (30%) of the countywide HPMS VMT data is based on an analysis by NCDAQ that shows that travel demand model VMT can be as much as 30% higher than the HPMS VMT.

2.8 Diesel Fuel Sulfur Content Assumptions

The diesel fuel sulfur content is required in MOBILE6.2 to generate $PM_{2.5}$ emission factors because the amount of sulfur in diesel fuel directly correlates to sulfate particulate emissions. For the emissions modeling, the diesel sulfur content is 500 parts per million (ppm) in 2002 and 43 ppm in 2009. The same diesel sulfur content is used for all of the nonattainment counties. These values come from Section 5.5 in Technical Guidance on the Use of MOBILE6.2 for Emission Inventory Preparation. Office of Transportation and Air Quality (OTAQ) was contacted prior to this submission to verify that there was no update to this guidance.

3. QUALITY ASSURANCE MEASURES

The Quality Assurance (QA) of the data is one of the most important steps in performing an air quality modeling study. Because emissions inventory development is tedious, time consuming and involves complex manipulation of many different types of large data sets, errors are frequently made and, if rigorous QA measures are not in place, these errors may remain undetected. For the on-road mobile source category, QA can be broken into two components: 1) input files/data, and 2) SMOKE outputs/summaries. On-road mobile input data QA is summarized below. SMOKE output QA is summarized in Appendix H.1 of this document for all source categories.

On-road mobile input data was collected from the NCDOT and specific MPOs throughout North Carolina. The NCDAQ checked the speed information for reasonableness against previous sets of speeds for that specific area. Additionally, the following data elements are checked for accuracy in the input files prior to use in the modeling: pollutants, fuel RVP, I/M program settings, anti-tampering program settings, calendar year, evaluation month. All input files are printed and checked by hand against a “key” with the original source of the information. This QA step is always performed by a person other than the one who generated the files. If any discrepancies are found, they are marked on the hard copy supplied by to the person who generated the input files for correction. Vehicle age distribution is another input referenced in the actual MOBILE6.2 input file. This file is checked against the original spreadsheet from which it is generated. Again, if any discrepancies are found, they are noted and returned to the person responsible for generating those files. VMT and vehicle mix (also referred to as VMT mix) are additional data elements that are checked after they are formatted for SMOKE. This file is checked against the original source of the VMT and VMT mix data.

4. MOBILE6.2 INPUTS FOR MOTOR VEHICLE EMISSIONS BUDGETS

The purpose of transportation conformity is to ensure that Federal transportation actions occurring in a nonattainment areas does not hinder the area from maintaining the annual $PM_{2.5}$ standard. This means that the level of emissions estimated by the NCDOT or the MPOs for the Transportation Implementation Plan and Long Range Transportation Plan must not exceed the motor vehicle emissions budgets (MVEBs) as defined in this attainment demonstration SIP.

The sections below describe the MOBILE6.2 input assumptions used to calculate the MVEBs. The MOBILE6.2 input files and output files used in the development of the on-road mobile source emissions for the attainment demonstration are compiled in Section 6.

MOBILE6.2 is insensitive to temperatures, RVP, and inspection and maintenance commands when calculating $PM_{2.5}$ emission factors. The NCDAQ has decided to model a typical summer day for the MVEBs and multiply the resulting emissions by 365 to get annual $PM_{2.5}$ emissions.

In our coordinated planning phase for the PM 2.5 SIP, all of the partners came forward with their individual planning data/assumptions to be used in the development of the SIP. These data were the most current data at that time and included road types, speeds, VMT, I&M data, meteorological data, etc. These data were to be used in Mobile6.2 by NCDAQ to obtain emission factors and to set budgets if required.

Since the SIP submittal deadline in April 2008, the vehicle age distribution has a 2007 update that is now available. 2007 accident data has become available to update the I/M fraction for 2009. Additionally, 2007 counts used for the vehicle-mix have become available. The NCDAQ consulted with partners as to the use of the new data, which does not significantly change from that used in the SIP modeling.

The NCDAQ used quarterly NOx emission estimates based on the relative data pertinent to each quarter. Mobile6.2 is limited to two months, January and July 2002. The first quarter was designated 1 for January. The second and third quarters will be designated 7 for July. The forth

quarter was designated as 1 for January of the following year as recommended by the USEPA guidance document Technical Guidance on the Use of MOBILE6.2 for Emission Inventory Preparation (USEPA, August 2004).
Meteorological data is from the Triad Regional Airport for Davidson and Guilford counties. Data for Catawba County is from the Hickory airport. Averages are determined for RVP for each quarter per county. I&M fraction is calculated from annual accident data used as a surrogate for the percentage of cars on the road in each county during the year with and without I&M. Our most current accident data was from 2007.

4.1 Speed Assumptions

The MOBILE6.2 command "AVEAGE SPEED" was used to enter the daily speeds. This command requires the average speed on a given roadway scenario.

In order to estimate emissions from vehicles for a typical day, NCDOT and the MPOs provided speeds for their respective counties. The speeds were generated from their latest travel demand model. The speeds provided are based on a daily average.

Updated speed data was available at the time the MVEBs were developed. Although this updated data may be different from what was modeled in the attainment demonstration, the differences were not significant and will not result in different attainment test results.

Table 4.1-1 below provides a summary of the updated speeds used for the development of the MVEBs. The column headings in Table 4.1-1 represent the 12 FHWA road types used in the modeling and are listed below. The 12 FHWA road types are:

RI	Rural Interstate	UI	Urban Interstate
RPA	Rural Other Principle Arterial	UF	Urban Freeway & Expressway
RMA	Rural Minor Arterial	UPA	Urban Other Principal Arterial
RMjC	Rural Major Collector	UMiA	Urban Minor Arterial
RMiC	Rural Minor Collector	UC	Urban Collector
RL	Rural Local	UL	Urban Local

Table 4.1-1. 2009 Daily Speeds Used to Calculate the MVEBs

County	RI	RPA	RMA	RMjC	RMiC	RL	UI	UF	UPA	UMiA	UC	UL
Catawba TDM	0	0	0	0	0	0	60	57	27	29	33	29
Catawba Non-TDM	66	47	44	43	42	42	63	56	29	32	31	31

Davidson TDM	68	60	44	44	48	46	66	52	40	40	37	43
Davidson Non-TDM	65	44	43	43	42	42	62	56	28	32	31	32
Guilford TDM	59	57	45	47	46	44	60	54	40	38	38	37

4.2 Vehicle Age Distribution

The vehicle age distribution used in developing the MVEBs is not the same as what was used in the VISTAS/ASIP modeling. The NCDOT supplied updated vehicle age distribution based on 2005 vehicle count data on May 1, 2007, after the emissions modeling was completed. The vehicle age distribution used in the emissions modeling was based on 2004 vehicle count data. A MOBILE6.2 run was performed to determine if there is any difference between the two data sets. There was minimal difference in the emission factors, therefore, the NCDAQ utilized the 2005 vehicle age distribution to establish the MVEBs for PM2.5 because it was the most up-to-date data available at the time of PM2.5 emission modeling.

For NOx budgets developed in fall 2008, NCDAQ calculated a vehicle age distribution based on the most current 2007 count data supplied by NCDOT in June 2008. This newer age distribution was not seen to vary much from the 2005 distribution.

4.3 Development of Vehicle Mix

The vehicle mix used to project the MVEBs for PM2.5 is developed from 2006 vehicle counts data provided by the NCDOT Division of Motor Vehicles on May 1, 2007. The MVEBs are calculated using the updated vehicle mix since it is the most up-to-date data available and sensitivity runs performed using MOBILE6.2 show very little difference between the vehicle mix used in the emissions modeling, which is based on 1999-2001 vehicle count data, and the updated data provided for 2006.

The same methodology used to derive the vehicle mix as described in Section 2.3 was employed to derive the vehicle mix based on the 2006 vehicle count data. The updated vehicle counts data can be found in Table 4.3-1.

For NOx budgets developed in fall 2008, NCDAQ calculated a vehicle mix based on 2007 count data supplied by NCDOT in June 2008. This newer age distribution was not seen to vary much from the 2006 count data.

4.4 Temperature Assumptions

Since the $PM_{2.5}$ emission factors are not sensitive to temperature, the MOBILE6.2 command "MIN MAX TEMPERATURES" was used to enter temperatures to estimate mobile source emissions for particulate matter. For the nonattainment area, the NCDAQ used the 2002 annual minimum/maximum temperature profile from the Triad Airport Meteorological Station for Guilford and Davidson Counties. The Hickory Airport 2002 data was used for Catawba County.

Table 4.4-1. 2002 Catawba County Temperatures

Annual average MIN/MAX Temperatures	
49 ^{o}F	70 ^{o}F

Table 4.4-2. 2002 Davidson and Guilford Counties Temperatures

Annual average MIN/MAX Temperatures	
50 ^{o}F	70 ^{o}F

NOx emission factors are sensitive to temperature and relative humidity. Hourly average for temperature and relative humidity were calculated for each of the four quarters. Meteorological data is from the Hickory Airport for Catawba County. Data for Davidson and Guilford counties is from the Triad Regional airport.

4.5 Vehicle Inspection and Maintenance Program Assumptions

The ODB-II program is administered in all of the counties in the $PM_{2.5}$ nonattainment area. All counties in North Carolina have a vehicle safety inspection program. Inspection stations are required to administer an anti-tampering check to ensure that emissions control equipment on any vehicle, less than 35 model years old, has not been altered. $PM_{2.5}$ sensitivity runs demonstrate that the inspection and maintenance program does not have an effect on direct $PM_{2.5}$ emission factors. Therefore, for purposes of the PM2.5 MVEBs, the I/M program was assumed to be 100% penetration.

NOx emission factors were determined for 2009 for both I/M and non I/M fractions using 2007 accident data supplied be NCDOT in August 2008. The table below shows the calculated I/M fractions used to set the NOx MVEBs.

Table 4.5. 2009 County-level I/M Fractions

County	2009 I/M Fraction
Catawba	91%
Davidson	94%
Guilford	94%

4.6 Reid Vapor Pressure Assumptions

Per North Carolina's Rules in Section 15A NCAC 2D.1300 the RVP is required to be 7.8 psi June through September in areas that were nonattainment for the 1-hour ozone standard, which includes Davidson and Guilford Counties. Catawba County follows the rest of State RVP of 9.0 psi for the summer. RVP was determined to have no effect on $PM_{2.5}$ emission factors. For the development of the PM2.5 MVEBs, a typical summer day is modeled using an RVP of 7.8 psi for Guilford and Davidson Counties and 9.0 psi for Catawba County.

For NOx MVEBs quarterly average RVPs per county were calculated. Table 4.6 lists the RVP for each county used for the Mobile6 runs to calculate NOx emission factors.

Table 4.6. Quarterly RVP Used to Calculate NOx MVEBs

County	Q1 - Jan, Feb, Mar	Q2 – Apr, May, June	Q3- July, Aug, Sept	Q4 – Oct, Nov, Dec
Catawba	14.0	10.5	9.0	14.0
Davidson	14.0	10.1	7.8	14.0
Guilford	14.0	10.1	7.8	14.0

4.7 Vehicle Miles Traveled Assumptions

In order to calculate emissions from on-road mobile sources, emission factors are developed as discussed throughout this document. The emission factors are then multiplied by an activity level, which for on-road mobile sources is daily VMT.

The daily VMT for the nonattainment area was provided by NCDOT. Table 4.7-1 lists the VMT used in the MVEBs calculations.

Table 4.7-1. 2009 Daily VMT Used to Calculate the MVEBs

4.8 Diesel Fuel Sulfur Content Assumptions

The diesel fuel sulfur content is required in MOBILE6.2 to generate $PM_{2.5}$ emission factors because the amount of sulfur in diesel fuel directly correlates to sulfate particulate emissions. For the MVEBs calculation, the diesel fuel sulfur content is 43 parts per million (ppm) for all of the nonattainment counties. This is the same value used in the 2009 emissions modeling.

5. MOTOR VEHICLE EMISSIONS BUDGETS FOR CONFORMITY

5.1 Transportation Conformity

The purpose of transportation conformity is to ensure that Federal transportation actions occurring in a nonattainment areas does not hinder the area from attaining and/or maintaining the annual $PM_{2.5}$ standard. This means that the level of emissions estimated by the NCDOT or the MPOs for the Transportation Implementation Plan and Long Range Transportation Plan must not exceed the MVEBs as defined in this attainment demonstration SIP.

The NCDAQ consults with the transportation partners as one of the requirements in developing the attainment demonstration SIP and setting MVEBs. The NCDAQ sent out a request for comments on setting the geographic extent of the MVEBs to all of the transportation partners. A copy of the letter and responses from the transportation partners can be found in Appendix B. In the letter, NCDAQ expressed its preference for setting county level budgets and some of the reasons why NCDAQ believed county level budgets were appropriate. Additionally, the NCDAQ consulted the partners for the data used in the development of the MVEBs, as well as the data used in the VISTAS/ASIP modeling. The consultation plan can also be found Appendix B along with the responses from the transportation partners.

With respect to the $PM_{2.5}$ nonattainment areas, the NCDAQ received comments from the Greensboro MPO regarding the geographic extent of the MVEBs. The Greensboro MPO agreed with the NCDAQ that MVEBs should be set at the county level. Copies of the letters received can be found in Appendix B. Therefore, if MVEBs are established, they will be set at the county level.

5.2 Pollutants to be Considered

40 CFR 93.119(f)(7) through (10) identifies the pollutants for $PM_{2.5}$ for which regional emissions analysis needs to be performed for transportation conformity purposes. These parts of the rule are listed below:

§119(f)(7) – $PM_{2.5}$ in $PM_{2.5}$ areas;

§119(f)(8) – Reentrained road dust in $PM_{2.5}$ areas only if the EPA [Environmental Protection Agency] Regional Administrator or the director of the State air agency has made a finding that emissions from reentrained road dust within the area are a significant contributor to the $PM_{2.5}$ nonattainment problem and has so notified the MPO and DOT [Department of Transportation];

§119(f)(9) – NOX [nitrogen oxides] in $PM_{2.5}$ areas, unless the EPA Regional Administrator and the director of the State air agency have made a finding that emissions of NOX from within the area are not a significant contributor to the $PM_{2.5}$ nonattainment problem and has so notified the MPO and DOT; and

§119(f)(10) – VOC [volatile organic compounds], SO2 [sulfur dioxide] and/or ammonia in $PM_{2.5}$ areas if the EPA Regional Administrator or the director of the State air agency has made a finding that any of such precursor emissions from within the area are a significant contributor to the $PM_{2.5}$ nonattainment problem and has so notified the MPO and DOT.

Only primary, or direct, $PM_{2.5}$ tailpipe emissions must be considered for transportation conformity regional emissions analysis. The other precursor pollutants and reentrained road dust only need to be considered if the State air agency and/or the USEPA has deemed the pollutant as a significant contributor to the $PM_{2.5}$ nonattainment problem. The following sections discuss the significance of the precursor pollutants and reentrained road dust to the $PM_{2.5}$ nonattainment problem.

5.2.1 Precursor Pollutants NOx, VOC and Ammonia

The $PM_{2.5}$ precursor NO_x is presumed to be a significant contributor to the $PM_{2.5}$ nonattainment problem by the USEPA. The NCDAQ has determined that NOx is a relatively minor contributor to the $PM_{2.5}$ concentrations in North Carolina. However, the NCDAQ is not asserting that NOx is an insignificant precursor for the 1997 or 2006 revisions of the $PM_{2.5}$ standard. Therefore, the NCDAQ will establishe county level MVEBs for NOx for all three $PM_{2.5}$ nonattainment counties.

For the purpose of this attainment demonstration, VOC and ammonia are presumed to be insignificant contributors to the $PM_{2.5}$ nonattainment problem by the USEPA. The NCDAQ agrees with the USEPA that both VOC and ammonia are insignificant contributors to the $PM_{2.5}$ nonattainment problem in North Carolina. The discussion of the insignificance of these precursors is presented in Apendix O. Since these precursors have been deemed insignificant, no MVEBs are being established for VOC or ammonia.

5.2.2 Reentrained Road Dust

The majority of the roads in North Carolina are paved so there is minimum road dust due to the paved roads. The factor to calculate reentrained road dust on paved roads is very small. What dust is generated, has been shown in the literature, *Methodology to Estimate the Transportable Fraction (TF) of Fugitive Dust Emissions for Regional and Urban Scale Air Quality Analyses, US EPA, August 3, 2005*, to be inconsequential.

This fact is affirmed by the small crustal component in the $PM_{2.5}$ speciated data which measures only 3% at Hickory monitoring site (Catawba County) in 2002 and only 2% at Lexington monitoring site (Davidson County) in 2004 (see Figure 5.2.2-1 below).

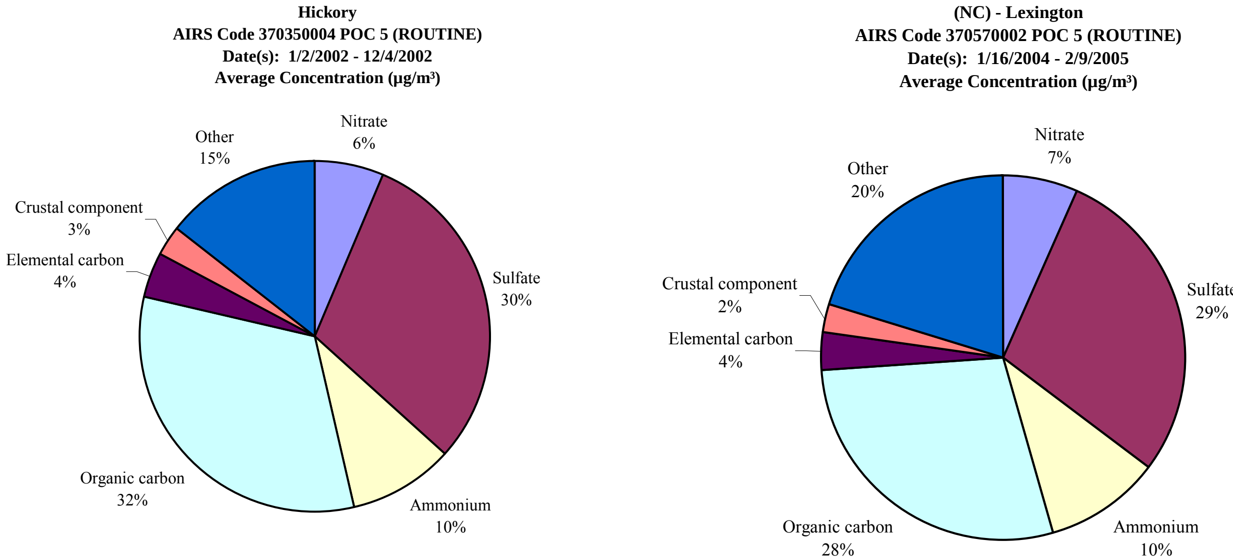

Figure 5.2.2-1. Speciated Data for the Hickory area (left) and the Triad area (right)

Since the reentrained road dust is not a significant contributor to the $PM_{2.5}$ nonattainment problem, the NCDAQ will not be establishing MVEBs for this source category. An affirmative insignificance finding from the USEPA only relieves the transportation partners from a regional emissions analysis for reentrained road dust emissions for these areas and does not relieve them of the other transportation conformity requirements. The transportation partners will need to note the reentrained road dust insignificance finding (if found adequate and approved by the USEPA) in future conformity determinations.

5.2.3 Precursor Pollutant SO_2

The $PM_{2.5}$ precursor SO_2 could not be deemed insignificant to the $PM_{2.5}$ nonattainment problem. However, the NCDAQ has determined that SO_2 emitted by the mobile source sector is insignificant. The USEPA in its Federal Register notice for $PM_{2.5}$ does not address the mobile sector in its listing of significant emissions. North Carolina agrees with the following statements addressing SO_2 from on-road mobile emissions as published in the May 6, 2005 Federal Register, 70 FR 24283:

"While speciated air quality data show that sulfate is a relatively significant component (e.g., ranging from nine to 40 percent) of $PM_{2.5}$ mass in all regions of the country, emissions inventory data and projections show that on-road emissions of SOx constitute a ''de minimis'' (i.e., extremely small) portion of total SOx emissions. Emissions inventory data for 1999 for the 372 potential $PM_{2.5}$ nonattainment counties for $PM_{2.5}$ (based on 1999–2001 air quality data) show that on-road sources were responsible for only two percent of total SOx emissions.

Furthermore, EPA has already adopted two regulations that will greatly reduce emissions of SOx from on-road sources by the time such regulations are both in full effect in 2009. First, in 2004 the low sulfur gasoline program began to be phased in and will be fully effective in 2007 (February 10, 2000, 65 FR 6697). This regulation will reduce the sulfur content of gasoline by approximately 90 percent when fully effective. Second, in 2006 the low sulfur diesel program will begin to be phased in and will be fully effective by 2009 (January 18, 2001, 66 FR 5001). This regulation will reduce the sulfur content of diesel fuel by approximately 97 percent nationally when fully effective.

Projections of on-road emissions of SO_2 in 2020 indicate that on-road sources will be responsible for less than one percent of the total SO_2 emissions in 2020 in the 372 potential $PM_{2.5}$ nonattainment counties (based on 1999– 2001 air quality data). These projections confirm that the implementation of the fuel regulations discussed above will ensure that as a general matter of SO_2 emissions from on-road sources remain at insignificant levels in all areas."

Although sulfate is a significant component to the $PM_{2.5}$ nonattainment problem in North Carolina, the majority of the SO2 emissions in 2009 come from the stationary point source sector (see Figure 5.2.3-1). The mobile source sector only contributes one half of one percent (0.05 %) of the 2009 statewide SO_2 emissions. This is consistent with what the USEPA stated above.

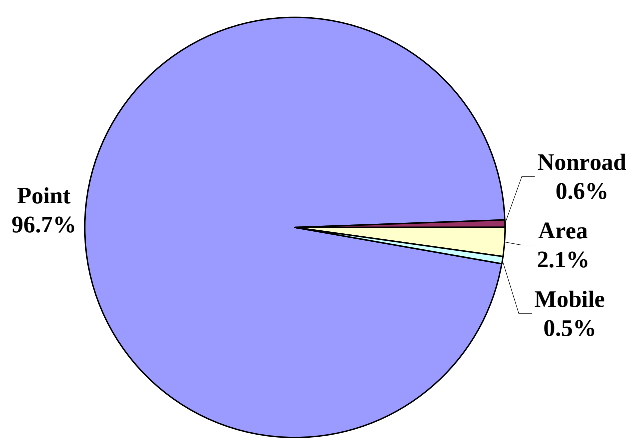

Figure 5.2.3-1. North Carolina's 2009 Statewide SO_2 Emissions

Since the mobile source SO_2 contribution is insignificant, the NCDAQ is not establishing MVEBs for this precursor. An affirmative insignificance finding from the USEPA only relieves the transportation partners from a regional emissions analysis for SO_2 emissions for these areas and does not relieve them of the other transportation conformity requirements. The transportation partners will need to note the SO_2 insignificance finding (if found adequate and approved by the USEPA) in future conformity determinations.

5.3 Highway Mobile Source Direct $PM_{2.5}$ Emssions

The mobile source pollutants to be addressed for transportation conformity purposes are direct $PM_{2.5}$ emissions for the Triad and NOx for both Hickory and the Triad. 40 CFR 93.109(k) in the Transportation Conformity Rule Amendments for the new 8-hour ozone and fine particulate matter National Ambient Air Quality Standards (NAAQSs) addresses areas with insignificant motor vehicle emissions as follows,

> *"Notwithstanding the other paragraphs in this section, an area is not required to satisfy a regional emissions analysis for §93.118 and/or §93.119 for a given pollutant/precursor and NAAQS, if EPA finds through the adequacy or approval process that a SIP demonstrates that regional motor vehicle emissions are an insignificant contributor to the air quality problem for that pollutant/precursor and NAAQS. The SIP would have to demonstrate that it would be unreasonable to expect that such an area would experience enough motor vehicle emissions growth in that pollutant/precursor for a NAAQS violation to occur."*

The rule suggests that such a finding would be based on a number of factors, including the percentage of motor vehicle emissions in the context of the total SIP inventory, the current state of air quality as determined by monitoring data for that NAAQS, the absence of SIP motor vehicle control measures, and historical trends and future projections of the growth of motor vehicle emissions. Although there is an inspection and maintenance program in the nonattainment areas, this control measure does not control primary $PM_{2.5}$, but rather is in place to reduce the ozone precursors.

The NCDAQ believes strongly that the primary $PM_{2.5}$ emissions from mobile sources do not contribute significantly to the $PM_{2.5}$ nonattainment problem. However, USEPA has indicated they will not approve a SIP that does not set MVEBs for primary $PM_{2.5}$ for the Triad. Therefore, the NCDAQ will establishe county level MVEBs for primary $PM_{2.5}$ for the Triad. The sections that follow discuss the insignificance of PM2.5 emissions.

5.3.1 Insignificance of Primary $PM_{2.5}$ Emissions

The NCDAQ has examined the sources of $PM_{2.5}$ emissions and their contribution to $PM_{2.5}$ formation in the nonattainment counties. This was accomplished using the 2009 emissions inventories developed for the VISTAS/ASIP modeling. Figure 5.3.1-1 and 5.3.1-2 provides the percent contributions from point, area, nonroad mobile and on-road mobile source sectors for the Hickory and Triad nonattainment areas, respectively.

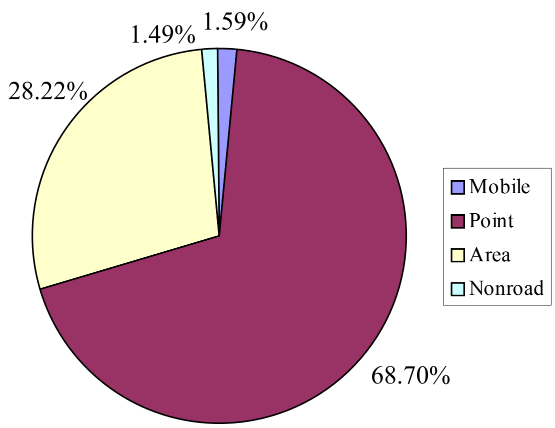

Figure 5.3.1-1. Hickory Area 2009 Primary $PM_{2.5}$ Emissions

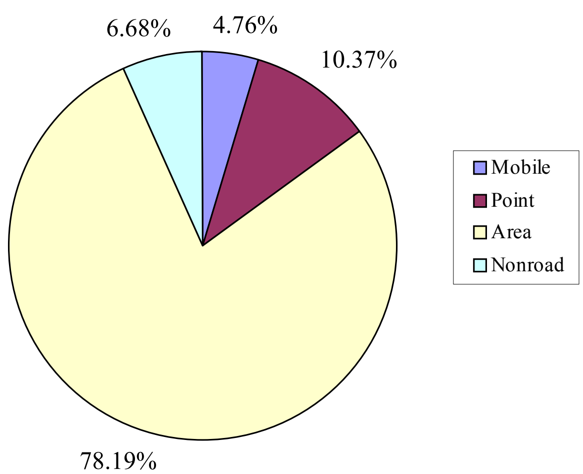

Figure 5.3.1-2. Triad Area 2009 Primary $PM_{2.5}$ Emissions

The 2009 on-road mobile $PM_{2.5}$ emissions contributed only 1.6% of the total $PM_{2.5}$ emissions for the Hickory area. In the Triad area, the 2009 mobile $PM_{2.5}$ emissions were 4.8% of the total $PM_{2.5}$ emissions. Therefore, in both areas it is demonstrated, in the opinion of NCDAQ, that the $PM_{2.5}$ emissions compared to the total $PM_{2.5}$ emissions are insignificant. However, USEPA has indicated that they only agree with the insignificance finding for on-road direct PM2.5 for Hickory. It should be noted that the mobile source $PM_{2.5}$ emissions slightly decrease from 2002 to 2009 despite an increase in VMT. The Hickory $PM_{2.5}$ emissions go from 100 tons/year in 2002 to 75 tons/year in 2009 and the Triad area goes from 319 tons/year to 245 tons/year. Meanwhile, we see an increase in VMT in the Hickory area from 4,444,280 miles/day in 2002 to 5,081,590 miles/day in 2009. For the Triad, the VMT grows from 15,000,150 miles/day in 2002 to 16,399,220 miles/day in 2009. Further justification for the case insignificance of direct PM2.5 emission follows.

The NCDAQ performed sensitivity modeling using 2008 emissions modeling in order to address the challenge of Section 93.109(k) in the Transportation Conformity Rule Amendments, *"The SIP would have to demonstrate that it would be unreasonable to expect enough motor vehicle emissions growth in that pollutant/precursor for a NAAQS violation to occur"*. The modeling system used was the same as the VISTAS/ASIP modeling and consisted of three components: 1) the Penn State University/National Center for Atmospheric Research Mesoscale Model (MM5 version 3.6.1+), 2) the Sparse Matrix Operator Kernel Emissions Modeling System (SMOKE version 2.1), and 3) the Community Multiscale Air Quality (CMAQ version 4.4) model. Model configurations, input data, and modeling methods are consistent with those suggested by the USEPA in *Guidance on the Use of Models and Other Analyses in Attainment Demonstrations for the 8-hour Ozone NAAQS*.

The primary $PM_{2.5}$ emissions from on-road mobile sources were doubled in Catawba, Davidson and Guilford Counties, therefore, simulating a doubling of the VMT during a 7-day summer time simulation. The results of the emissions sensitivities showed such similar results that looking at just the difference between two air quality model simulations, one with base case emissions and another with reduced emissions inputs, showed no change. To show what the differences were between the two runs, line graphs of the hourly emissions for the time period modeled for all three counties are displayed in Figures 5.3.1-3 through 5.3.1-5 below**.** The sensitivity modeling design value (DV) increased by 0.04 $\mu g/m^3$ in Catawba County. In the Triad nonattainment area, the sensitivity modeling DV increased by 0.05 $\mu g/m^3$ and 0.07 $\mu g/m^3$ in Davidson and Guilford Counties, respectively. In both nonattainment areas, the modeling DV increased by less than one-tenth $\mu g/m^3$. These differences are barely visible as seen in the figures below.

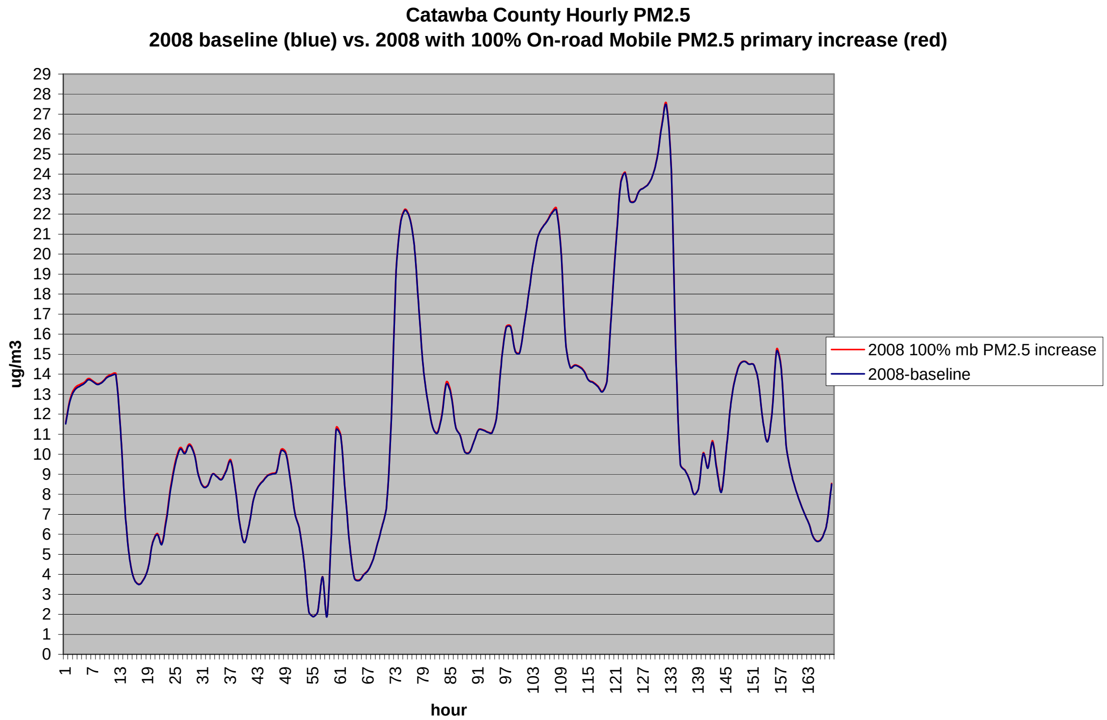

Figure 5.3.1-3. Catawba County Hourly PM25 Emissions

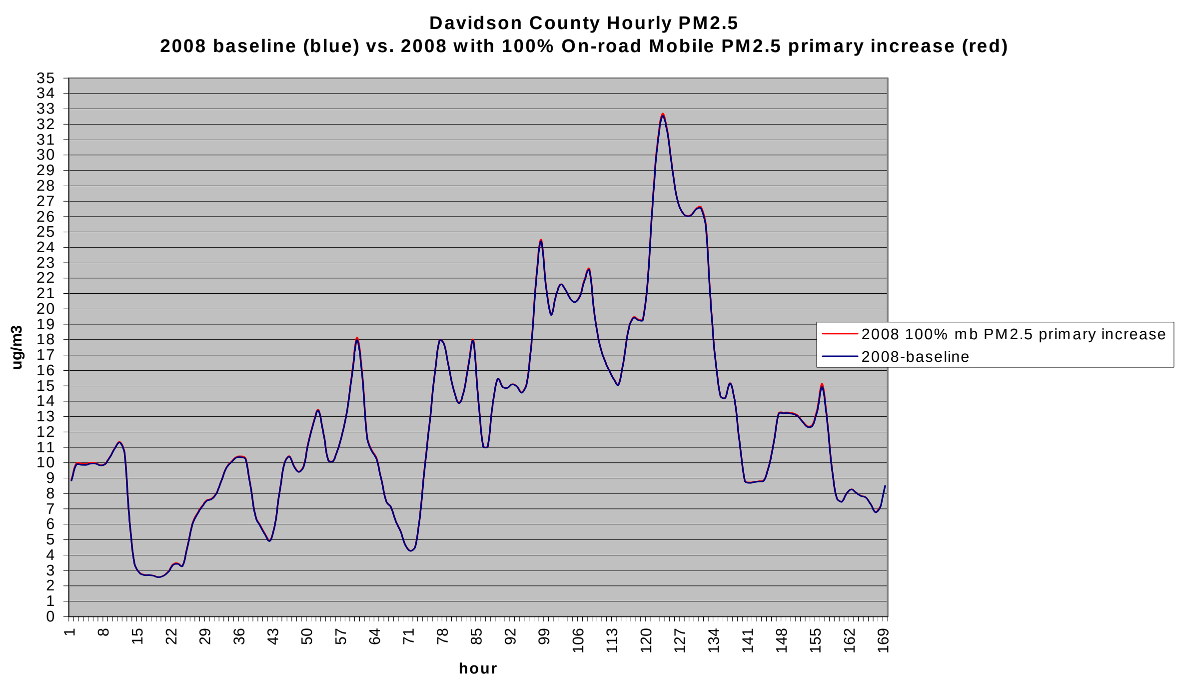

Figure 5.3.1-4. Davidson County Hourly PM25 Emissions

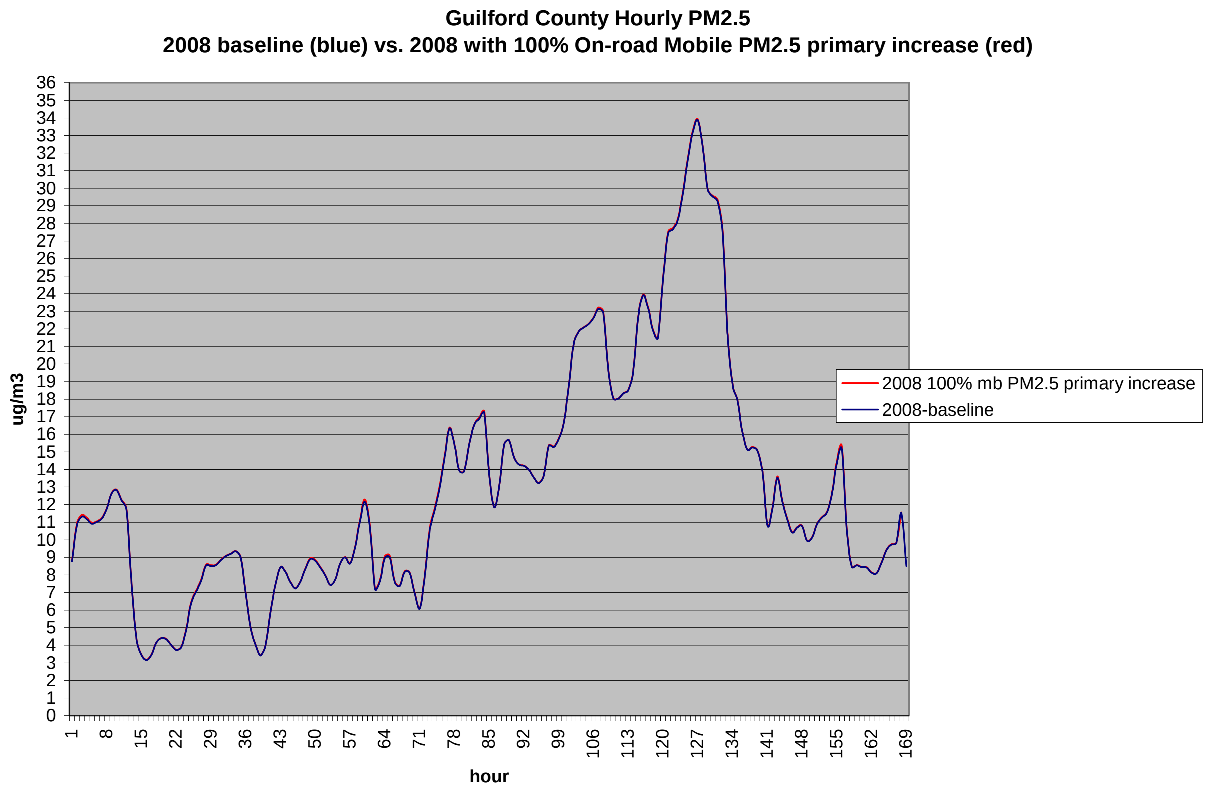

Figure 5.3.1-5. Guilford County Hourly PM_{25} Emissions

Based on the information discussed above, the NCDAQ steadfastly believes that the on-road mobile $PM_{2.5}$ emissions are insignificant contributors to the $PM_{2.5}$ nonattainment problem. Emission estimates indicate that the on-road mobile $PM_{2.5}$ emissions are a small percentage of the total $PM_{2.5}$ emissions in the nonattainment areas. On-road mobile $PM_{2.5}$ emissions are projected to decrease into the future notwithstanding VMT increases. Air quality modeling sensitivities show that doubling the mobile source $PM_{2.5}$ emissions has very little effect on the future design values. Furthermore, both nonattainment areas are modeled to be well below the annual $PM_{2.5}$ NAAQS by 2009 as discussed in the attainment demonstration SIP narrative and the NCDAQ considers it unreasonable to expect that the $PM_{2.5}$ nonattainment areas will experience enough motor vehicle $PM_{2.5}$ emissions growth for a future $PM_{2.5}$ violation to occur due to mobile sources.

Due to above analysis and agreement from EPA, budgets for direct PM2.5 will not be set for the Hickory nonattainment area. An affirmative insignificance finding from the USEPA only relieves the transportation partners from a regional emissions analysis for $PM_{2.5}$ emissions for this area and does not relieve them of the other transportation conformity requirements. The transportation partners will need to note the $PM_{2.5}$ insignificance finding (if found adequate and approved by the USEPA) in future conformity determinations.

5.3.2 PM_{25} and NOx Motor Vehicle Emissions Budgets

As part of the consultation process on setting MVEBs, the NCDAQ sent out a request for comment on setting the geographic extent of the MVEBs to all of the transportation partners. A copy of the letter can be found in Appendix B. In the letter, the NCDAQ expressed its preference for setting county level budgets and some of the reasons why the NCDAQ believed county level budgets were appropriate. With respect to the $PM_{2.5}$ nonattainment areas, the NCDAQ received comments from the Greensboro MPO regarding the geographic extent of the MVEBs. The Greensboro MPO agreed with the NCDAQ that MVEBs should be set at the county level. Copies of the letters received that relate to the $PM_{2.5}$ nonattainment areas can be found in Appendix B. Therefore MVEBs will be set at the county level.

MVEBs will be set for the attainment year 2009. By the time the MVEBs are found adequate or approved by the USEPA, the next transportation conformity regional emissions analysis should be for years 2009 and beyond. Therefore, MVEBs will not be set for the baseline year 2002.

Although the emissions are usually expressed in terms of tons, the MVEBs will be set in terms of kilograms (kg). The reason for this assertion is because the MOBILE model generates the emissions factors in grams per mile. In past conformity exercises, there have been some issues with conversion to tons, as well as concerns with how the MVEBs were rounded. Setting MVEBs in kilograms will avoid these issues in future conformity determinations.

Tables 5.3.2-1 and 5.3.2-2 below display the Triad highway mobile $PM_{2.5}$ and the Triad and Hickory highway mobile NO_X emissions expressed in tons per year and the corresponding kilograms per year values for 2009. These two tables are for reference purposes only and are not the tables presenting the 2009 MVEBs, which is discussed next.

Table 5.3.2-1. County Level $PM_{2.5}$ Highway Mobile Emissions for 2009

County	MVEB (Tons/year)	MVEB (Kilograms/year)
Davidson	78.4	71,152
Guilford	181.1	164,286

Table 5.3.2-2. County Level NO_X Highway Mobile Emissions for 2009

County	MVEB (Tons/year)	MVEB (Kilograms/year)
Catawba	3183.4	2,887,955
Davidson	4780.2	4,336,567
Guilford	11,034.9	10,010,856

The NCDAQ will set MVEBs, for transportation conformity purposes, as county budgets for 2009. Tables 5.3.2-3 and 5.3.2-4 below present the Triad $PM_{2.5}$ and the Triad and Hickory NOx MVEBs in kilograms per year, by county. Upon the USEPA's affirmative adequacy finding for these county level sub-area MVEBs, these MVEBs will become the applicable MVEBs for each county.

Table 5.3.2-3. County Level PM_{25} MVEBs for 2009

County	MVEB (Kg/year)
Davidson	71,152
Guilford	164,286

Table 5.3.2-4. County Level NOx MVEBs for 2009

County	MVEB (Kg/year)
Catawba	2,887,955
Davidson	4,336,567
Guilford	10,010,856
