1.0 PROJECT MANAGEMENT

1.1 Problem Definition/Background

The Southeastern States Air Resource Managers (SESARM) has been designated by the United States Environmental Protection Agency (EPA) as the entity responsible for coordinating and implementing regional planning for the eight SESARM states (Alabama, Florida, Kentucky, Georgia, Mississippi, North Carolina, South Carolina and Tennessee) plus Virginia, West Virginia, and Tribes. Through a memorandum of understanding, these parties are collaborating in the organization Visibility Improvement State and Tribal Association of the Southeast (VISTAS) on the technical analysis and planning activities that support state implementation plans for regional haze. The participating agencies have concluded that a collaborative regional process is also the most efficient approach for the states to develop the technical analyses supporting attainment demonstrations for the fine particulate matter (PM2.5) and eight-hour ozone standards. Along with the local air regulatory agencies for Jefferson County, AL, Jefferson County, KY, Mecklenberg County, NC, Forsythe County, NC, Knox County, TN, and Shelby County, TN, these agencies have become signatory parties to the collaborative effort called the Association for Southeastern Integrated Planning (ASIP). SESARM will coordinate among participating agencies and oversee the performance of the ASIP inventory and modeling tasks in parallel with the VISTAS regional haze project tasks. Emissions inventory efforts include the development of emissions inventories and forecasts to be utilized in ASIP modeling efforts.
At least one area in seven states (Alabama, Georgia, North Carolina, Kentucky, Tennessee, Virginia, and West Virginia) has been designated as nonattainment for the $PM_{2.5}$. In addition, South Carolina has one three-county area that was designated as unclassifiable. The $PM_{2.5}$ compliance date is April 2010 unless a state demonstrates that more time is necessary in which case up to five additional years may be granted. State implementation plans (SIPs) will be due in April 2008 and the modeling year for the $PM_{2.5}$ attainment demonstration will be 2009.

The States of Alabama, Georgia, Kentucky, North Carolina, South Carolina, Tennessee, Virginia, and West Virginia have one or more nonattainment areas for the eight hour ozone standard. Basic nonattainment areas are required to attain the 8-hour ozone standard by June 15, 2009, while moderate nonattainment areas are required to attain by June 15, 2010. This will require states with basic 8-hour ozone nonattainment areas to demonstrate attainment for the year 2008 and moderate areas will require 2009 as the modeling year

The objective of this project is to compile future year emission inventories to support fine particulate matter and ozone modeling efforts in the ASIP region for all source categories. This project has the following overall design specifications:

- Pollutant Coverage - primary and precursor annual and seasonal emissions necessary to accurately model fine particulate matter and ozone, including primary PM2.5 and

PM10, ammonia (NH3), oxides of sulfur (SOx), volatile organic compounds (VOCs), oxides of nitrogen (NOx) and carbon monoxide (CO)

- Source Coverage – all source categories except biogenic.
- Geographic Areas – the ASIP states (Alabama, Florida, Georgia, Kentucky, Mississippi, North Carolina, South Carolina, Tennessee, Virginia, West Virginia)

The inventories created under this contract will be used in creating future year modeling inventories (modeled under other ASIP work tasks) to support chemical transport modeling of fine particulate matter and ozone in the southeastern U.S. and to evaluate potential control strategies for the National Ambient Air Quality Standards (NAAQS) for fine particulate and ozone. Two future year inventories will be prepared along with evaluations of various controls for those inventories. In addition, updates of the 2002 base year inventory will be performed under this contract as necessary to develop the projection years.

The purpose of this Quality Assurance Project Plan (QAPP) is to outline and guide the process for quality assuring the inventory development to ensure the development of complete, accurate, and consistent emission inventories. The QAPP is consistent with the recommendations in the EPA quality assurance requirements[1] and the Emission Inventory Improvement Program's QA guidance[2]. The QAPP includes tasks associated with obtaining State data, merging and augmenting State submittals with available EPA databases, improving the activity data and emission factors for important source categories, obtaining and developing growth and control factors, obtaining State and stakeholder review of the emission inventory, and providing documentation of the maintenance (revisions, updates, corrections) of the inventory.

1.2 Project/Task Description

EPA[3] has specified that calendar year 2002 be used as the base year for emission inventories to support planning efforts under the 8-hour ozone, PM2.5, and Regional Haze programs. ASIP has planned an iterative process to use and enhance the 2002 base inventory prepared by MATEC for the Visibility Improvement State and Tribal Association of the Southeast (VISTAS) as part of regional haze planning, that incorporates improved information as it becomes available. In addition, work on the PM2.5 and ozone NAAQS calls for continued measures of progress. As a consequence, emissions inventories for 2008 and 2009 will be required to assess such progress.

- A revised 2009 Base G future year inventory based off of the 2009 projections developed previously for VISTAS (Base G due May 2006). This inventory will be developed using the final version of the 2002 VISTAS base year. The revised 2009 inventory is designed to support modeling runs for fine particulate and ozone. It will be created using readily available growth and control information from the Clean Air Interstate Rule (CAIR), the Heavy Duty Diesel Rule (HDD Rule), the DOE's Annual Energy Outlook 2006, and other EPA rules. In addition, control programs under these rules as well as State Implementation Plans (SIP) will be incorporated. The growth and control factors will be those developed for the VISTAS 2009 regional haze and PM2.5 inventory development effort augmented by updated information from other regional inventory development work and modifications based on State comments. Typical year emissions for electric generating units (EGUs), wildfire and prescribed burning sources will be revised as necessary to incorporate new data. Control programs that are "on-the-books" and "on-the-way" will be incorporated into the estimates. Three control strategy inventories will also be developed for 2009.

- A 2008 Inventory Base G (available Spring/Summer 2006). This inventory will be created using information developed for the 2009 inventory with revised growth and control factors to account for a 2008 projection rather than a 2009 projection. The inventory will still include "on-the-books" and "on-the-way" control programs as well as any SIP or other State specific controls.

This QAPP focuses on the tasks associated with developing these inventories.

Projection Inventory Activities. The effort includes the following area source activities:

1. Assemble data needed to update the 2009 VISTAS inventory to account for Base G changes to the base year 2002 inventory and any changes to growth or control factors for 2009 based on State/workgroup review.
2. Prepare the 2009 inventory using data received as part of step 1.
3. Assemble data needed to develop the 2008 ASIP inventory. This includes development of growth and control factors for 2008 which are not currently available.
4. Prepare the 2008 ASIP projection inventory using data developed in step 3.
5. Recommend methods for control strategies for 2009.
6. Prepare 2009 control strategy inventories.
7. Revise the 2002 "typical year" inventory for electric generating units (EGUs) with any updated data.
8. Revise the "typical year" inventory for wild and prescribed fires with any updated data.

Other Activities. In addition to the above tasks related to projecting emissions, a report detailing the methods used to develop the projections will be prepared.

1.3 Project Organization

Figure 1 and Table 1 identify the individuals and organizations participating in the project. Their specific roles and responsibilities include:

- Ms. Pat Brewer, Technical Coordinator, will plan, conduct, and supervise technical and managerial aspects of the project. She will facilitate communications among State/local agencies, MACTEC, and the SESARM Executive Director.
- Mr. Greg Stella, Emission Inventory Technical Advisor, will work with the Technical Coordinator to define the emission inventory development activities needed to support PM2.5 and ozone modeling and planning activities.

- State/local Agency Coordinators will compile and submit data to MACTEC, participate in QA/QC reviews, and help revise, update, and correct the inventory.
- William Barnard, MACTEC Program Manager, will direct and monitor technical and financial performance throughout the project and will serve as a senior primary contact with ASIP on contract and project management issues. Mr. Barnard will also direct aspects of the projection inventory development related to area and mobile sources. He will plan and conduct the technical aspects of the development of the area and mobile source inventories, supervise daily activities, identify effective QC procedures and make recommendations on needed QC procedures.
- Edward Sabo, MACTEC Point Source Task Leader, will plan and manage all point source activities. He will plan and conduct the technical aspects of the development of the point source inventory, supervise daily activities, identify effective QC procedures and make recommendations on needed QC procedures.
- Dan Meszler, MACTEC Mobile Source Task Leader, will plan and manage all mobile source activities. He will plan and conduct the technical aspects of the development of input files for the MOBILE and NONROAD models and for nonroad sources not covered by the NONROAD model. He will help identify effective QC procedures and make recommendations on needed QC procedures.
- Douglas Toothman, MACTEC QA Coordinator, will help ensure that adequate QA/QC procedures are incorporated into the inventory development process. He will work independent of the inventory development Task Leaders to assist in the conduct of project QA/QC assessments.

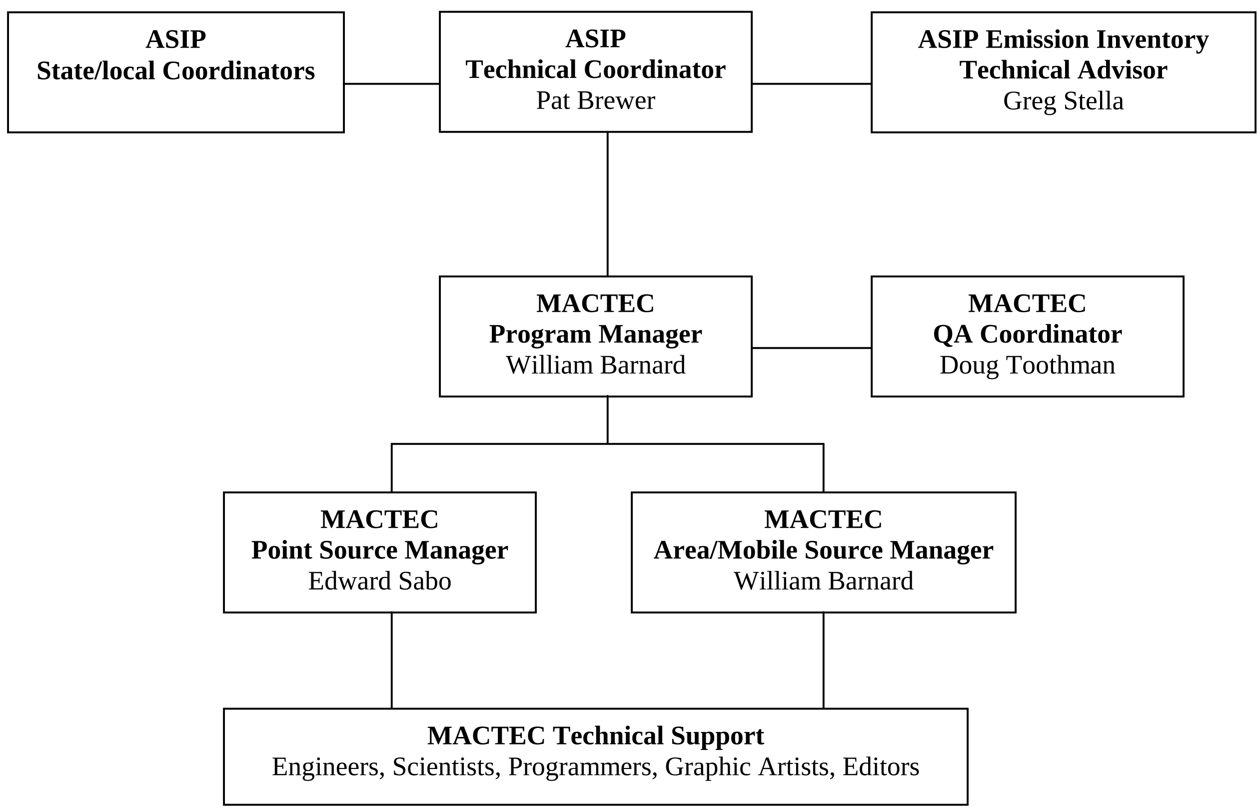

FIGURE 1 – PROJECT ORGANIZATION CHART

1.4 Quality Objectives and Criteria

The goal of the inventory process is to provide the best possible inventory under given resource constraints. Data Quality Objectives (DQO) are statements about the level of acceptable uncertainty or error. Their purpose is to ensure that the final data will be sufficient for the intended use of the inventory. A well-developed and implemented quality assurance program fosters confidence in the inventory and any resulting regulatory program. It also gives the end user important information about the limitations of the emission estimates in order to avoid misuse of data.

Table 1 summarizes the Data Quality Objectives for the ASIP inventories that will be compiled for this contract. The first column of Table 1 defines four data quality objectives: accuracy, completeness, comparability and representativeness. The second column identifies the procedures that will be used to achieve each objective. The third column identifies Data Quality Indicators (DQI), which are qualitative and quantitative descriptors used in interpreting the degree of acceptability or utility of data.

1.5 Special Training/Certification

All staff performing data review and analysis are air quality professionals and have sufficient education/experience to perform emission estimation calculations and work with emission inventory databases. Most staff have received specific emission inventory training through conferences, workshops, self-study programs, and on-the-job work experiences. There are no specifically mandated training requirements for work performed on this project.

1.6 Documents and Records

QAPP Control. Any changes to this QAPP will be initiated either by the Program Manager, the Task Leaders, or the QA coordinator. Each change will be given a revision number and date in the document control block in the upper corner of the affected pages. It will be the responsibility of the initiating person to distribute copies of the changed pages to all the persons on the Distribution List and to the appropriate project team members.

Data Collection Records. Clear documentation of the data collected from the State/local agencies, EPA, and other agencies is integral to the quality analysis review. Records will be maintained containing a description of the data received, the name of the person and agency submitting the data, the date of the submission, and other relevant information about the data submission. The following types of data will be collected during this project:

- EPA's 1999 National Emission Inventory (Version 2 Final)
- State CERR submittals
- State/local agency data submittals in NIF 3.0 format
- Growth factors assembled by EPA

- EPA's Final Summary Emission Reports for 2002 with CEM information for electric utilities regulated by the Acid Rain Program
- EPA's Toxic Release Inventory for 1999/2000 with ammonia emissions data
- Point source surveys for target facilities to obtain missing information
- State/local agency submittals of updated activity data related to fugitive dust sources, primarily paved and unpaved roads, livestock activities and agricultural activity (tilling).
- State agency submittals of information necessary to calculate fire emissions and geographically locate where these fires occurred in 2002.
- State agency submittals of updated activity data for animal operations for use with the Carnegie Mellon University ammonia model.
- State/local agency revisions, updates, corrections in response to various QA/QC checks. These may be provided in a variety of formats depending on the nature of the response.
- Department of Energy fuel efficiency data
- EGAS growth factors
- VMT data

TABLE 1

DATA QUALITY OBJECTIVES, PROCEDURES, AND INDICATORS

Data Quality Objective	Procedures	Example Indicators
Accuracy - reduce uncertainty in emission estimates where possible, validate that data elements needed for modeling are within accepted parameters, and verify that emission estimates agree with accepted reference values.	1. Identify weaknesses in existing inventories, identify new methods/data to reduce uncertainty, and obtain new activity/emission factor data where available. 2. Use EPA's NIF QA tool and ad-hoc reports to perform computerized checks of valid codes/data ranges and to identify outliers. 3. Conduct senior technical review of pollutant totals by facility, source category, state, and region. 4. Compare to other published data.	1. Qualitative assessment of the inventory's strengths and weaknesses. 2. 100% of stack data and temporal factors in valid ranges for > 100 tpy sources. 3. 100% of sources have valid geographic coordinates. 4. 100% correction of significant outliers. 5. Agreement of ASIP emissions and EPA CEM data and EPA TRI data. 6. Compare projection emissions to base year emissions to ensure that values are within expected ranges.
Completeness – include all major point sources, include emission estimates for PM2.5 and ammonia, verify that all important areas source categories are included for all counties and all mobile source categories are accounted for.	1. Compare ASIP utility data to EPA CEM data. 2. Compare ASIP point source ammonia data to EPA TRI data. 3. State/local agencies compare facility list to their Title V permit lists. 4. Compare small point source emissions to area source emissions. 5. Compare PM10 and PM2.5 emissions. 6. Plot area source spatial distributions by source category and county.	1. 100% of all utilities accounted for in database. 2. 100% of large ammonia sources in TRI accounted for in database. 3. 100% of Title V sources accounted for in database 4. Small point sources included as either small point sources or as area sources. 5. PM2.5 and ammonia emissions included in inventory 6. Area source emissions for important source categories for all counties in region. 7. All mobile sources accounted for. 8. Explanation of any missing data or sources.
Comparability – verify that emission estimates are similar to other peer-reviewed inventories and that any major deviations are explained.	1. Compare emission totals by source category, pollutant, geographic region, and year with previous emission inventories.	1. Explanation for large discrepancies in emissions
Representativeness – use emission estimation methods that reflect local conditions and the time period of interest.	1. Identify where national defaults used instead of local activity data. 2. Identify where emissions were grown for base year 2002 data were not available. 3. Identify growth factors for projection years.	1. Explanation for use of national defaults. 2. Determination of representative values for "typical years" for some sources for projections (i.e., fires, utility emissions).

Data Handling Records. Another key element of the QA program is maintaining written documentation of calculations, assumptions, and all other activities associated with incorporating the State/local agency submittals and other data with the projection and base year inventories. Nearly all data being developed and/or compiled will use computerized databases or other electronic files. For many of these databases, we will use blank fields in the database tables to keep track of the source of the data. We will also maintain a log of activities to document how the data described above were incorporated to create the ASIP inventories. The log will include complete descriptions of the data sources used, the procedures used to incorporate the data, the approach used to determine the completeness, and any contacts made with data submitters to resolve questions. A file will be maintained to ensure that the data handling records are retained and easily located.

QA/QC Records. We will perform a variety of quality control reviews of the inventory. For example, we will check stack parameters, source classification codes, and geographic coordinates for point sources that emit at least 100 tons of any pollutant per year. Reports containing the results of these checks will be transmitted to the State/local agencies for investigation and correction. Documentation of each finding will include a description of the action or data reviewed that led to the quality concern and will provide recommendations for corrective actions.

Corrective Action Records. Records of corrective and follow-up actions identified during the quality review process will be maintained. Both the corrective action identified and the results of the actions taken in response will be documented for inclusion in the final report. If no corrective action can be made, we will document the implications on the overall quality of the inventory.

Data Reporting Package. The final data reporting package will contain four elements:

- An emission summary report that describes the emissions inventory by pollutant and source category, summarizes the methods and data used to compile the inventory, assesses the limitations and appropriate uses of the inventory data, and contains any other information pertinent to the inventory;
- A quality assurance summary report that describes the quality assurance efforts completed, summarizes the corrective actions taken, and provides suggestions for further inventory improvement based on the results of the quality assurance process;
- Electronic data files containing the ASIP inventories in NIF 3.0 format; and
- Electronic and paper files containing all original data submittals and all backup documentation will be stored on file at MACTEC for a period of no less than three years.

2.0 DATA ACQUISITION

The projection year ASIP inventories will rely primarily on air emission information from existing databases. The data collection, handling, and management process is described below, along with the associated quality control procedures and methods. The QC system is designed to:

- Provide routine and consistent checks and documentation points in the inventory development process to verify data integrity, correctness, and completeness;
- Identify and reduce errors and omissions;
- Maximize consistency within the inventory preparation and documentation process;
- Facilitate internal and external inventory review processes.

The data acquisition process should be viewed as an iterative process. As decisions are made, new questions will surface that require solutions, until the iterations are complete.

2.1 Projection Year Inventory Procedures

For the projection inventories, the following procedures will be used to compile and quality assure the inventory:

1. Use the final version (Base G) of the 2002 VISTAS Base/Typical Year inventory as a starting point.
    a. Back calculate uncontrolled emissions for 2002 Base/Typical Year inventory to use as starting point for sources that will be grown for the projection inventory. (unclear)
2. Prepare/Obtain Growth and Control files
    a. Obtain growth factor files from EGAS for use with categories that will be grown with EGAS growth factors; incorporate Annual Energy Outlook 2006 information into EGAS to replace the AEO 2004 data currently embedded in EGAS.
    b. Obtain control factors for "on-the-book" and "on-the-way" controls as well as any controls for control strategy evaluations. Controls will be obtained from recent EPA rulemakings, proposed rules (e.g., Clean Air Interstate Rule [CAIR]), and State SIPs. For EGUs, control information will be obtained from VISTAS-sponsored IPM runs, supplemented with state-supplied adjustments as to where future controls will be installed.
    c. Determine/obtain growth factors for non-EGAS sources (e.g., agricultural crops, fertilizers, etc.). Growth factors for these sources will be calculated from existing projection inventories prepared by EPA (e.g., EPA Ammonia Inventory). Growth factors will be calculated using linear interpolation of projected emissions if the actual year is not available.
3. Project sources using growth and control factors

   a. For sources to be grown using EGAS growth factors, apply growth and control factors.
   b. For sources not using EGAS growth factors, apply non-EGAS growth factors.
   c. Identify and resolve any errors/discrepancies from the use of EGAS growth factors or other growth factor data
   d. Track comments/concerns received and corrective actions taken

4. Determine emissions for sources requiring "typical" year emission updates.
   a. These sources include EGUs and fires
   b. For fires make any modifications needed including incorporating the long-term effects of prescribed burning programs. Update and revise the typical emissions based on changes submitted by State air and forestry personnel and to include future year projections of prescribed burning.
   c. Update the typical year emission data from EGU sources based on State comments and any revised CEM or IPM data.

5. Develop mobile source emission inventories
   a. Prepare projected VMT for review by States/stakeholders for onroad mobile sources.
   b. Prepare SMOKE ready MOBILE input files for review by States/stakeholders. MOBILE input files will contain required control programs either "on-the-books" or "on-the-way". (my understanding is this subtask is not MACTEC's responsibility)
   c. Prepare NONROAD model input files for review by States/stakeholders. NONROAD input files will contain required control programs either "on-the-books" or "on-the-way".
   d. Run the NONROAD 2005 model, develop emission summaries and provide to States/Stakeholders for review/comment.
   e. Develop growth factors and projected emissions for nonroad sources not in the NONROAD model. Growth factors will be based on existing estimates from EPA rulemaking projections (e.g., Heavy Duty Diesel and other rules). Provide growth factors for review by States/Stakeholders.
   f. Prepare non-NONROAD model emission estimates. Provide for States/Stakeholder review/comment.

6. Conduct QA/QC to identify errors and inconsistencies
   a. Prepare ad-hoc reports to identify gaps and logical inconsistencies.
   b. Ask States/local agencies to provide feedback on large scale inconsistencies and on missing sources.
   c. Update database with State/local supplied revisions.
   d. Track comments/concerns received and corrective actions taken

7. Provide inventory for review by stakeholders

a. Prepare an emission summary report that describes the emissions inventory by pollutant and source category, summarizes the methods and data used to compile the inventory, assesses the limitations and appropriate uses of the inventory data, and contains any other information pertinent to the inventory
b. Prepare a quality assurance summary report that describes the quality assurance efforts completed, summarizes the corrective actions taken, and provides suggestions for further inventory improvement based on the results of the quality assurance process
c. Provide electronic data files containing the ASIP inventories in NIF 3.0 format
d. Track comments/concerns received and corrective actions taken

8. Incorporate feedback from stakeholders and prepare final reports and electronic files

3.0 ASSESSMENT AND OVERSIGHT

The subsections in this group address the activities for assessing the effectiveness of project implementation and associated QA and QC activities. The purpose of the assessment is to ensure that the QA Project Plan is implemented as prescribed. The assessment consists of external activities that include a planned system of review and audit procedures by personnel not actively involved in the inventory development process. The key concept of this component is independent objective review by a third party to access the effectiveness of the internal Quality Control program and the quality of the inventory, and to reduce or eliminate any inherent bias in the inventory process.

3.1 Assessments and Response Actions

The MACTEC Quality Assurance Coordinator will conduct technical systems audits throughout the project. Audits are managerial tools used to evaluate how effectively the emission inventory team complies with predetermined specifications for developing an accurate and complete inventory. The MACTEC QAC will conduct audits at the initiation of each project to review the Work Plan and QAPP, at the 50% complete and 75% complete levels to review the technical aspects of each project and at the 95% completion level to review the data submittal package. This provides assessment of the project during the planning stage, the data collection stage, the emissions calculations stage, and the report preparation stage. An example audit checklist for point sources is presented in Figure 2.

3.2 Reports to Management

Audit reports will be distributed within two weeks of the conduct of each audit to the persons interviewed and the MACTEC Task Leaders. A summary of the types of quality concerns found will be periodically forwarded to the MACTEC Program Manager to keep him informed of the quality issues found and actions being taken to resolve them. Audit reports will be retained in a file and used to conduct subsequent audits and plan follow-up activities. When an audit team finds items that require immediate action, they will inform the MACTEC Program Manager of the necessary corrective actions.

AUDIT CHECKLIST

Auditor: ______________________________________

Date: ____

Data/Procedure Reviewed: ____
____

Project Personnel Involved in Work: ____
____

Instructions: Select a facility or source category with high emissions and evaluate the quality of the data and adequacy of the data handling procedures. Record the findings and recommendations for corrective actions, if any, on this checklist and comment sheet. If recommendations for corrective actions are made, discuss them with the Project Manager immediately following the audit. Conduct follow-up activities to determine if the actions taken in response to the recommendations appropriately resolved the quality issues identified.

I. DATA

A. Identify the source category evaluated: ____

B. Describe the data included in the master file for the facility or source category.

____
____

C. Are the data documented in a manner that will not have the potential to be misinterpreted? Y/N

Were the instructions for documenting the data followed? .... Y/N

D. Are there missing data fields? .... Y/N

What procedures are taken by the Task Leaders to ascertain missing?

____
____

At what point in the inventory process are requests for missing data made?

____
____

How is the receipt of the missing data handled?

____
____

Is the procedure followed to ascertain missing data efficient and adequate? .... Y/N

E. How do emissions compare to other inventories?

1999 NEI Version 2 Final ____

2000 TRI ____

2002 ETS/CEM ____

Are differences in emissions understandable and explainable? .... Y/N

If any of the values are incorrect, explain how the emissions data were corrected.

____

Figure 2 Audit Check Form

II. EMISSIONS DATABASE

A. Who provided the data for incorporation into the database? ____________________________
____

B. Was there evidence that the data were reviewed for accuracy and completeness prior to incorporation in the database? .... Y/N

C. Were data logs maintained to describe how the data was incorporated? .... Y/N

D. Ask the data incorporation personnel to explain the QC procedures followed to ensure data quality. Do they agree with the procedures described in the QAPP? .... Y/N

E. Does the computer system appear to be adequate for its intended use? (Ask the data processing personnel about the problems they have experienced with the system.) .... Y/N

F. Is the data entry progressing as expected and are the procedures followed adequate to ensure data quality? .... Y/N

III. RECOMMENDATIONS FOR CORRECTIVE ACTIONS

Figure 2 Audit Check Form (Concluded)

4.0 DATA VALIDATION AND USABILITY

Section 4 addresses the QA activities that occur after the data collection phase of the project is completed. Implementation of these subsections determines whether or not the data conform to the specified criteria, thus satisfying the project objectives.

4.1 Accuracy Assessment

A qualitative discussion of accuracy will include an assessment of the extent to which the initially identified weaknesses in the inventory have been remedied through the use of improved activity data, emission factors, or other sources of information. Remaining weaknesses will be assessed.

The accuracy assessment will include a summary of whether any data identified as outside of its valid range remained outside of the valid range in the final inventory. If any data remained outside of its valid range, an explanation will be given. The qualitative discussion will also include a summary of errors or discrepancies identified in the QA/QC process.

A final semi-quantitative discussion of accuracy will consist of pollutant summaries for individual facilities, industry types, source categories, and statewide totals. The ASIP inventory will be compared to other peer-reviewed inventories, and where major discrepancies exist, we will provide an assessment of the reasons for the differences in emission estimates.

4.2 Completeness Assessment

A statement will be prepared assessing whether all required facilities, source categories, pollutants, and data elements were included in the inventory. If any facilities or source categories were not included, an explanation of the omission will be provided. If any individual data elements were not provided, we will discuss the elements, frequency of omissions, and overall impact on the quality of the inventory.

4.3 Comparability Assessment

Several summations of emissions data will be made to address comparability. Overall percentage differences for individual facilities (current year to prior year), industry types, processes, and statewide inventory will be calculated. Explanations of any large differences will be made.

4.4 Representativeness Assessment

A statement will be prepared describing where national defaults have been used instead of local activity data.

Appendix H

Emissions Modeling and Related Documentation

Appendix H.1
Emissions Modeling Documentation

Background

The Sparse Matrix Operator Kernel Emissions (SMOKE) modeling system is an emissions modeling system that generates hourly gridded speciated emission inputs of mobile, nonroad mobile, area, point, fire and biogenic emission sources for photochemical grid models. SMOKE is the fastest emissions processing tool currently available to the air quality modeling community. The sparse matrix approach utilized throughout SMOKE permits both rapid and flexible processing of emissions data. The processing is rapid because SMOKE utilizes a series of matrix calculations instead of less efficient algorithms used in previous systems. The processing is flexible because the processing steps of temporal projection, controls, chemical speciation, temporal allocation, and spatial allocation have been separated into independent operations wherever possible. The results from these steps are merged together at a final stage of processing. Each of these emissions processing steps are detailed below.

Temporal Allocation

VISTAS 2002, 2009 and 2018 annual emissions modeling was configured to generate point, area, nonroad mobile, on-road mobile, and biogenic source emissions. In addition, certain subcategories, such as fires and EGUs were maintained in separate source category files in order to allow maximum flexibility in producing alternate strategies. With the exception of biogenic and on-road mobile source emissions that are generated using the BEIS and MOBILE6 modules in SMOKE, pre-computed annual emissions were processed using the month, day, and hour specific temporal profiles of the SMOKE model. Point and biogenic sources were modeled for each day of the annual period while area and nonroad sources were modeled as a block of Thursday, Friday, Saturday, Sunday, Monday, one per month (total of 60 days modeled).

VISTAS based its temporal profiles and source category cross-reference files on the USEPA CAIR/CAMR/CAVR modeling platform with files located on USEPA's CAIR file transfer website (ftp://www.airmodelingftp.com/). Modifications were made to reflect State specific profiles or updated state of knowledge application of these profiles. Some of these changes included the reallocation of North Carolina NONROAD generated emission categories to a regional set of temporal profiles more consistent with the operation of these source types in the State. Additionally, EGU CEM-based temporal profiles and onroad emissions modeling were prepared in manners deviating from USEPA's original CAIR platform.

New temporal profiles used by VISTAS during modeling of the 2002, 2009 and 2018 EGU emissions took the place of USEPA provided default temporal profiles that are generally accepted as not accurately depicting temporal distribution of emissions from EGUs in the U.S. (see Attachment 1 by Stella et. al.). VISTAS EGU temporal profiles were developed using hourly CEM data as reported to USEPA's Clean Air Market's Division (CAMD) for the Acid Rain Program.

The work conducted in this process had the main objective of developing temporal profiles for VISTAS EGUs necessary to apply in the generation of SMOKE PTHOUR formatted emissions. Additionally, State-level monthly, day-of-week, and diurnal profiles were developed for application to non-CEM matched units in the VISTAS emissions inventory. These temporal distributions represent a significant improvement over the USEPA defaults.

On-road mobile modeling in SMOKE was done for selected weeks (seven days) of each month - using these days as a "representative week" of the entire month. This selection allows for the representation of day-of-the-week variability in the on-road motor vehicles, and models a representation of the meteorological variability in each month. The modeled weeks were selected from mid-month, avoiding inclusion of major holidays. Holidays were modeled as the Sunday of the representative week, while the day after a holiday was modeled as a Monday. VISTAS executed sensitivity tests to examine this "representative week" methodology versus an everyday on-road mobile modeling method. VISTAS determined that the use of representative week on-road mobile emissions produced ozone and particulate matter concentrations (and thus regional haze) that were nearly indistinguishable from the "everyday" mobile method. VISTAS determined that the difference in the modeled air quality - resulting from the on-road mobile modeling methods - was insignificant. For more information on this study see Attachment 2 by Abraczinskas et. al.

<u>On-road mobile emissions are represented by the following weeks per month:</u>

January 15-21
February 12-18
March 12-18
April16-22
May 14-20
June 11-17
July 16-22
August 13-19
September 17-23
October 15-21
November 12-18
December 17-23

Speciation

Speciation is the process of disaggregating inventory pollutants into individual chemical species components or groups of species. The need for speciation is determined by the inventory purpose. Inventory applications that require detailed speciation include photochemical modeling, air toxics inventories, chemical mass balance modeling, and visibility modeling.

Depending on the purpose of a particular emissions inventory, the inventory may include TOG, NOx, sulfur oxides (SOx), CO, total suspended particulate matter (TSP), particulate matter less than 10 micrometers in aerodynamic diameter (PM10), or ammonia (NH3). However, modeling inventories may require these emissions to be expressed in terms of other pollutants. Additionally, for some models, NOx emissions may need to be specified as NO and NO2. Also, PM may need to be separated into various fractions, such as PM10 and PM less than 2.5 micrometers in aerodynamic diameter (PM2.5).

SMOKE was configured to speciate the emissions estimates according to the requirements of the Carbon Bond Mechanism version four (CBM-IV, CB-IV or CB4). The SMOKE model reformats the emissions estimates for use in CMAQ modeling based on source category code (SCC) and speciation profile cross-reference files. The speciation profiles and source category cross-references use in VISTAS modeling are based on USEPA's CAIR/CAVR/CAMR modeling platform with files located on USEPA's CAIR file transfer website (ftp://www.airmodelingftp.com/). Minor modifications were made to reflect State specific profiles or updated state of knowledge application of these profiles. One major change made in the VISTAS modeling was the modification of coal combustion cross-reference from speciation profile "NCOAL" to profile "22001."

Spatial Allocation

Because air quality modeling strives to replicate the actual physical and chemical processes that occur in an inventory domain, it is important that the physical location of emissions be determined as accurately as possible. In an ideal situation, the physical location of all emissions would be known exactly. In reality, however, the spatial allocation of emissions in a modeling inventory only approximates the actual location of emissions.

Gridding surrogates are used to spatially allocate emission sources from a coarse geographic area to finer grid cells used for modeling. There can be hundreds of unique source categories in an emissions inventory, which is typically developed for counties, states, or other areas. The exact location of most major emission sources is known and their geographic coordinates are usually contained in the inventory. These usually are referred to as major point sources and include electric utilities and major industrial facilities. However, other emission sources are estimated for the entire county or other area as an aggregate since the exact locations of each source are not included in the modeling inventory. Surrogates are human activities or land use information that are used to represent a more precise location of emission source category groups. A gridded surrogate ratio is the ratio of the amount of a surrogate in a modeling grid cell to the total amount of that surrogate in a county. Grid cell emissions are calculated by multiplying the cell's gridded surrogate ratio by the county emissions.

These surrogates and their associated SCC cross-references were originally developed by USEPA (http://www.epa.gov/ttn/chief/emch/spatial/newsurrogate.html) and converted to the gridded domain definitions of the VISTAS model requirements.

Development of Gridded Surrogate Files

The general process for creating the SMOKE-ready gridded surrogate files from the ArcGIS shape files is as follows:

1. Overlay the grid on the surrogates. Generate the grid polygons (36/12km) with the specifications of the VISTAS domain and spatially overlay (intersect) the grid onto the surrogate area polygons or points. The resulting geodatabase contains, for each surrogate, the county FIPS code, the grid column and row number, and the amount (area, miles or count) of the county's portion of the surrogate in that cell.

2. Extract and convert each geodatabase table to a useful dataset. Each table contains the gridded area, miles or count in each county for a specific surrogate. The variables include FIPS code, column number, row number and area, miles or count.

3. Calculate surrogate ratios. Surrogate ratios are calculated for each surrogate using a series of program files. The programs sum the surrogates for each county and calculate each the ratio by dividing the county cell surrogate value by the total county surrogate value. Combination surrogates where both are of the same type (i.e., Heavy and High Tech Industrial are both area) were summed prior to calculating the ratio. Combination surrogates with unlike data (i.e., 3/4 Roadway Miles plus 1/4 Population are line and area data) were summed after calculating the ratios and then normalized. The surrogate cross-reference code was also assigned here.

4. Gap-fill surrogates for counties missing data. There will be many instances where inventory emissions exist for a particular county but there is no data, for that county, for the surrogate assigned. For example, a county with class 1 locomotive emissions may not have data for the class 1 railroad surrogate. In this case we have selected to incorporate, within the assigned surrogate, a different source of data (a different surrogate) for that particular county. We incorporate secondary surrogates even if there is no emission source that requires it for that particular county. We denote this process as "gap-filling." All surrogates resulting from the gap-filling process have ratios for all counties.

For each surrogate, we assign a secondary or tertiary surrogate where needed for gap filling. For the class 1 railroad surrogate example mentioned above, we chose total railroads as the secondary surrogate. The secondary or tertiary surrogate chosen would be the same across all counties and apply to all SCCs that use the particular primary surrogate. We pull in and substitute the secondary surrogate for counties where the primary surrogate is missing. Tertiary surrogates will then be assigned to those counties that are still without surrogates.

For identified counties having no values for each surrogate, we assign the data based on the appropriate secondary or tertiary surrogate to these counties. A check to see that surrogate ratios for each county sum to approximately 1.00 is also performed in our surrogate development. Ratios will not always sum exactly to 1.00 due to rounding. However, SMOKE will normalize surrogates greater than 1.00.

5. Create SMOKE-formatted spatial surrogate files. The resulting data from the previous steps is then reconfigured into SMOKE-ready format and used in the spatial allocation process.

Treatment of Large Fire Plume Rise

Wildfire, agricultural, and prescribed burn emissions were handled separately from the standard area source input files. We used day specific or monthly estimates of fire emissions from VISTAS, which include burn acreage and biomass loading information for the VISTAS states. Depending on the completeness and quality of the data received, VISTAS-specific calculations were made to calculate spatial and temporal distributions of the fire emissions, rather than relying on standard distribution profiles. We calculated vertical distribution of the fire emissions, based on fire size and biomass involvement. SMOKE v2.1 can model fire plume rise when provided with the following variables:

PTOP – Top of the fire plume profile (meters above ground level)
PBOT – Bottom of the fire plume profile (meters above ground level)
Lay1 – The percent of the emissions entrained in the first modeling layer

For those fires as having the necessary data elements to site these files with distinct time and space coordinates, these variables were prepared and included in the modeling files used to process this emission source type.

The WRAP Fire Emissions Joint Forum Emissions Inventory Report (see http://www.wrapair.org/forums/fejf/documents/WRAP_2002_PhII_EI_Report_20050722.pdf) has documented an approach for calculating these plume descriptors. In this method, the fires are assigned to one of 5 size categories, based on the total burn acreage, and the biomass fuel loading. These categories are then used to calculate representative hourly plume profiles. These profiles are then used by SMOKE 2.1 to distribute the vertical emissions for the fires. To successfully model fires as elevated point sources, the data included both the day or days on which the fire occurs, and a spatial identifier of the fire location.

Quality Assurance

The Quality Assurance (QA) is one of the most important steps in performing an air quality modeling study. Because emissions inventory development is tedious, time consuming and involves complex manipulation of many different types of large data sets, errors are frequently made and, if rigorous QA measures are not in place, these errors may remain undetected.

A number of QA files were prepared and used to check for gross errors in the emissions inputs. Importing the model-ready emissions into PAVE and looking at both the spatial and temporal distribution of the emission provides insight into the quality and accuracy of the emissions inputs. Some of the additional steps for checking the emissions are summarized in the bulleted list below.

- Visualizing the model-ready emissions with the scale of the plots set to a very low value, we can determine whether there are areas omitted from the raw inventory or if emissions sources are erroneously located in water cells.
- Spot-check the holiday emissions files to confirm that they are temporally allocated like Sundays.
- Producing pie charts emission summaries that highlight the contribution of each emissions source component (e.g. nonroad mobile).
- Normalizing the emissions by population for each state will illustrate where the inventories may be deficient and provide a reality check of the inventories.
- Spot check vertical allocation of point sources using PAVE.

State inventory summaries prepared prior to the emissions processing were compared against SMOKE output report totals generated after each major step of the emissions generation process.

For speciation, a comparison of the inventory state totals versus the same state totals with the speciation matrix applied was completed.

For checking the vertical allocation of the emissions, reports by source, hour, and layer for randomly selected states in the domain were created. These reports were created for a representative weekday in each of the episodes for each of these selected states.

The quantitative QA analyses often reveal significant deficiencies in the input data or the model setup. It may become necessary to tailor these procedures to track down the source of each major problem. As such, we will only outline the basic quantitative QA steps that were performed in an attempt to reveal the underlying problems with the inventories or processing.

Following are some of the reports that were generated to review the processed emissions:

- State and county totals from inventory for each source category
    - (example provided in Table 1 below for Area sources)
- State and county totals after spatial allocation for each source category
- State and county totals by day after temporal allocation for each source category for representative days
- State and county totals by model species after chemical speciation for each source category
- State and county model-ready totals (after spatial allocation, temporal allocation, and chemical speciation) for each source category and for all source categories combined
- If elevated source selection is chosen by user, the report indicating which sources have been selected as elevated and plume-in-grid will be included.

- Totals by source category code (SCC) from the inventory for area, mobile, and point sources
- Totals by state and SCC from the inventory for area, mobile, and point sources
- Totals by county and SCC from the inventory for area, mobile, and point sources
- Totals by SCC and spatial surrogates code for area and mobile sources
- Totals by speciation profile code for area, mobile, and point sources
- Totals by speciation profile code and SCC for area, mobile, and point sources
- Totals by monthly temporal profile code for area, mobile, and point sources
- Totals by monthly temporal profile code and SCC for area, mobile, and point sources
- Totals by weekly temporal profile code for area, mobile, and point sources
- Totals by weekly temporal profile code and SCC for area, mobile, and point sources
- Totals by diurnal temporal profile code for area, mobile, and point sources
- Totals by diurnal temporal profile code and SCC for area, mobile, and point sources
- PAVE plots of gridded inventory pollutants for all pollutants for area, mobile, and point sources

Additional State QA Procedures

Once the on-road mobile SMOKE outputs were acquired by NCDAQ, a number of metrics were generated to further QA and summarize the emissions. Those included:

- County emissions totals, bar charts to visually examine whether the counties with the highest emissions are consistent with what was expected from county VMT distribution. (example provided in Figure 1)
- County emissions by SCC code (vehicle and facility) were examined with pie charts to ensure distribution of emissions by vehicle type fits the conceptual model.
- PAVE plots were generated to check to ensure emissions where showing up in all counties in NC. Scale was lowered to make sure no emissions were omitted.
- PAVE plots were animated over a 24-hr period to ensure diurnal changes in emissions were as they should be.
- PAVE plots were visually inspected to make sure emissions were highest/lowest in logical places.

The following QA checks were performed both together and separate for EGU and non-EGU point sources:

- Data product summaries and raw NIF 3.0 data files were examined.
- County emissions totals were examined to assure the counties with the highest emissions were consistent with what was expected.
- PAVE plots were generated to check to ensure emissions where showing up in all counties in NC. Scale was lowered to make sure no emissions were omitted.
- PAVE plots were animated over a 24-hr period to ensure diurnal changes in emissions were as they should be.
- PAVE plots were visually inspected to make sure emissions were highest/lowest in logical places.
- Errors detected in earlier model runs were rechecked with each successive model run to assure their correction was carried forward in subsequent runs.
- NIF files were examined to identify problems with latitude and longitude, as well as, stack parameters.
- Parsed files were examined (i.e., Excel spreadsheets that provide unit-level results derived from the model plant projections obtained by the IPM) for accuracy.
- Facility level emission summaries for 2018 were examined for both the base case and CAIR case to ensure that emissions were consistent and that there were no missing sources.
- Emissions and controls for Duke Energy and Progress Energy were compared to their latest updated plans for complying with North Carolina's Clean Smokestack Act. (These plans varied substantially from the IPM results both in terms of current and future controls and timing of these controls. As a result, NCDAQ replaced the IPM emission projections for 2009 with projections from the Duke Energy and Progress Energy compliance plans. NCDAQ elected to use the IPM

results for 2018, with the exception of Duke Lee 3, for which IPM imposed a scrubber that will not exist. This scrubber was removed from the final run.)

- Ensured that stack parameters were modified appropriately and where necessary at facilities where new controls are scheduled to be installed.
- Input files were examined to assure there were no double counted facilities (example would be if a facility was known by two different names and counted under each).

Typical fire emissions SMOKE output in the VISTAS states were acquired by NCDAQ from Alpine Geophysics. The plots and summary reports for these area source fire emissions were spot-checked for QA and included:

- County emissions totals and County emissions by SCC code, were visually examine whether the counties with the highest emissions are consistent with what was expected.
- PAVE plots were generated to check to ensure emissions where showing up in all counties in NC. Scale was lowered to make sure no emissions were omitted.
- PAVE plots were animated over a 24-hr period to ensure diurnal changes in emissions were as they should be.
- PAVE plots were visually inspected to make sure emissions were highest/lowest in logical places.

TABLE OF CONTENTS

1.0 Introduction

The objective of this analysis was to develop temporal profiles for EGUs in the VISTAS states (AL, GA, FL, KY, MS, NC, SC, TN, VA, and WV). These temporal profiles will be used by the VISTAS Emissions and Air Quality Modeling Team during modeling of the VISTAS 2002 and 2018 EGU emissions, in place of SMOKE default temporal profiles that are accepted to not accurately depict temporal distribution of emissions from EGUs in the U.S. VISTAS EGU temporal profiles were developed using hourly CEM data as reported to EPA's Clean Air Market's Division (CAMD) for the Acid Rain Program.

This technical memorandum describes the work conducted by Alpine Geophysics (Alpine) in order to assist VISTAS in this task with the main objective of developing temporal profiles for VISTAS EGUs necessary to apply in the generation of SMOKE PTHOUR formatted emissions. Additionally, State-level monthly, day-of-week, and diurnal profiles were developed for application to non-CEM matched units in the VISTAS emissions inventory. These temporal distributions represent a significant improvement over the SMOKE defaults, and will be used for both actual 2002 and "typical" 2002 and 2018 modeling.

Two sets of monthly profiles were developed by Alpine:

1. Profiles based solely on actual 2002 CEM-based data at the state level. The 2002-only profiles are intended to be used by VISTAS in developing model performance evaluation metrics necessary for configuring air quality models in attainment demonstration analyses.

2. Profiles based on historical averages of 2000 through 2004 CEM-based data. These historical 2000-2004 average profiles were developed and are recommended to be used to represent consistent "typical" operating conditions at EGUs in the VISTAS domain for the base year and future year emission estimates.

Analyses conducted by Alpine Geophysics indicate an added benefit to the modeling results with the application of CEM-based day-of-week and diurnal profiles, in addition to the monthly profiles for each state. As part of this analysis, specific day-of-week (Monday, Tuesday, Wednesday, etc.) and diurnal profiles were developed for each month and State to better represent operating conditions at units within each State. The day of week and diurnal profiles were developed from averages of CEM-based emissions and heat input activity occurring on that day-of-week or during that hour-of-day. These profiles are intended to be applied to units were CEM matches cannot be made to VISTAS emission inventories.

2.0 Data Obtained

2.1. Source of Information

Five years (2000 through 2004) of hourly CEM information from EPA's CAMD website were obtained for each unit in the VISTAS states[1]. The "Prepackaged Data" option allows the download of files containing emissions data for a specific state, quarter or month, and year. Each prepackaged data file is in .csv (comma delimited) format and contains the following fields: State, Facility Name, Facility ID (ORISPL), Unit ID, Date, Hour, SO_2 Emissions (lbs), CO_2 Emissions (tons), NO_x Emissions Rate (lb/mmBtu), NO_x Emissions (lbs), Heat Input (mmBtu), Operating Time (hours), Gross Load (MW), and Steam Load (1000 lb/hr). For this analysis, we obtained the prepackaged monthly unit-level hourly emissions data by state and year. Using these data, we reformatted the files and quality assured for applicability to this analysis.

[1] http://cfpub.epa.gov/gdm/index.cfm?fuseaction=prepackaged.select

2.2. File Contents

The reformatted files were prepared as identified in Table 1.

Table 1. CEM data file format.

Column	Description
State	State in which the facility is located.
Facility Name	The name given by the owners and operators to a facility.
Facility ID (ORISPL)	The unique six-digit facility identification number, also called an ORISPL, assigned by the Energy Information Administration, a component of the Department of Energy.
Unit ID	Each unit at a facility has a unique identification number. It is alphanumeric and may be from one to six characters in length. For utility units and other units that generate energy for sale, the unit ID used for Part 75 reporting is the same unit ID that appears in the National Allowance Database (NADB) (for Acid Rain Program units) or in the State's allowance allocation list.
Day	Day on which a unit was operating.
Hour	Hour on which a unit was operating.
Operating Hours	Percent of hour in which a unit was operating.
Gross Load (MW)	Gross load is the output of the unit as measured in megawatts.
Steam Load (1000 lb/hr)	Steam load is the output of the unit as measured in 1000 lb/hr of steam.
SO_2 Mass (lbs)	SO_2 released for the hour in pounds.
SO_2 Mass Measurement Flag	Indicates whether the value for SO_2 mass was measured or derived due to missing data.
SO_2 Rate (lbs/mmBtu)	SO_2 emissions rate in pounds per million British thermal units (lbs/mmBtu).
SO_2 Rate Measurement Flag	Indicates whether the value for SO_2 rate was measured or derived due to missing data.
NO_x Rate (lb/mmBtu)	NOx emissions rate in pounds per million British thermal units (lbs/mmBtu).
NO_x Rate Measurement Flag	Indicates whether the value for NO_x rate was measured or derived due to missing data.
NO_x Mass (lbs)	NO_x released for the hour in pounds.
NO_x Mass Measurement Flag	Indicates whether the value for NO_x mass was measured or derived due to missing data.
CO_2 Mass (lbs)	CO_2 released for the hour in pounds.
CO_2 Mass Measurement Flag	Indicates whether the value for CO_2 mass was measured or derived due to missing data.
CO_2 Rate (lbs/mmBtu)	CO_2 emissions rate in pounds per million British thermal units (lbs/mmBtu).
CO_2 Rate Measurement Flag	Indicates whether the value for CO_2 rate was measured or derived due to missing data.
Heat Input (mmBtu)	Heat per hour as calculated by multiplying the quantity of fuel by the fuel's heat content.

2.3. Quality Control / Quality Assurance

Each file was reviewed to determine if NOx, SO2 and heat input values were represented for each hour of every day for each unit in the obtained data. Zero values were considered to be valid if operating time identifiers indicated no operation during that hour (e.g., data value of zero but operating hours greater than zero).

Using the measurement flags and field values in the reformatted files, numerous spot checks were made of anomalous or missing variable data to ensure that data corruption was not impacting the statistical analyses. Additionally, each year's hourly total of NOx, SO2, and heat input (per state) were summed and compared to EPA annual summaries of the same data elements.

When there were facilities or units with no emissions data or unit characteristics, we verified that these sources are not required to report emissions data or had not yet reported emissions data to EPA. In some cases, certain months or quarters of the year were blank for individual units or facilities and using EPA data caveat reports, we verified these units were not in operation during those times.

3.0 Inventory Matching

Prior to the development of the unit-specific SO2, NOx, and heat input ratios for each hour, the step of matching CEM units to the VISTAS 2002 modeling inventory started. Because naming convention and facility or unit numbering can be unique at the Federal, State, local, or facility level, the step of matching existing units from an emissions inventory to the CEM data base proved to be more complicated than anticipated.

The VISTAS EGU emission inventory accounted for approximately 3.7 million tons of SO2 and 1.5 million tons of NOx in calendar year 2002. There were 861 units reporting to the CEM database in 2002 for the ten VISTAS States. The primary objective of the inventory matching steps was to account for as many units and tons as possible allowing for the unit-specific application of hourly temporal distribution profiles.

Under the direction of VISTAS, staff at MACTEC Engineering and Consulting, Inc. prepared comparisons of the VISTAS 2002 emission inventory of EGU sources to that of CEM-based emissions, heat input, and operating characteristics. For each unit identified as an EGU source in the VISTAS inventory, an attempt was made to match it to a CEM unit and associated data.

Automated facility (ORIS) and unit identification was made for a majority of units who maintained the same numbering and nomenclature between the two data sets. This first computerized step captured the majority of emissions by matching some of the largest units in the VISTAS domain. The remaining steps were followed in order to match the outstanding facilities and emissions as reported by VISTAS States in the 2002 emission inventory.

MACTEC developed county-level reports of the remaining unmatched facilities and units from the VISTAS inventory and made comparisons of annual emissions of SO2 and NOx to the CEM-based SO2 and NOx for sources also identified within the same county. This step of the matching process allowed an incremental amount of emissions and units to be accounted for and assigned unit-specific profiles for model performance evaluation.

Finally, remaining VISTAS inventory and CEM sources were manually compared to each other in an effort to determine if reporting errors in State or county codes or facility or unit identification codes accounted for this reminder of unmatched sources. These manual matches were confirmed or revised with VISTAS State and stakeholder participation and input. With this step, a few sources were identified to have facility identification changes or misreported county codes preventing automated matching from occurring and corrected for the final application of factors.

Once all methods of comparison were exhausted, the remaining unmatched VISTAS emission inventory of EGU sources was excluded from the unit-specific profile assignment steps and was allocated more generalized facility or State temporal profiles as described in the following section.

This inventory comparison process allowed for the match of over 650 of the 861 CEM identified units (76%) to the VISTAS EGU emission inventory for 2002. More importantly, however, was the match of 99.95 percent of the SO2 emissions and over 99.4 percent of the NOx emissions from these sources in the VISTAS domain.

4.0 Assumptions and Calculations

4.1. Profile Calculations

Two sets of profile types have been developed for modeling EGU emissions within the VISTAS domain. The first set are to be applied to individual units able to be matched to CEM data, the second are to be applied to EGU sources within the VISTAS domain where CEM-based matches could not be identified.

The first set of temporal profiles have been developed for specific hour-of-date periods based on historical actual 2002 or average NOx, SO2, and heat input data for sources reporting under EPA's CEM program between 2000 and 2004. These profiles are based on the actual or statistical average of the CEM data variables (NOx, SO2, and heat input) for each hour-of-date (e.g., Hour 12 of March 3) during the year. In the typical profile calculation, variables are calculated for each hour when the operating time of the CEM is greater than 0 (e.g., the unit is in operation during that hour). In the case of 2002-only calculations, all reported NOx, SO2, and heat input data were used in the averaging, including those identified as non-operating hours. This allowed for the best representation of actual 2002 conditions for the expected use of these profiles for model validation studies.

In the second set of profiles, NOx, SO2, and heat input values were averaged over each unit to allow for the calculation of State level monthly, day-of-week, and diurnal profiles for VISTAS States.

For the 2000-2004 averaging period, representation of typical operating conditions was desired, so in the averaging calculation only valid operating hour NOx, SO2, and heat input values were used. This prevented the introduction of equipment shutdown because of power outages, control installation, or planned maintenance into the temporal profile calculation.

4.1.1. Actual 2002 Profiles

Through the EPA's Clean Air Market's Data and Maps website, quarterly unit-level hourly emissions data by State and calendar year 2002 were obtained for purposes of developing temporal allocation factors applicable to EGU sources within the VISTAS domain. Key elements in these data sets include the State where the unit is located, facility name, facility identification (ORISPL) code (assigned by the Department of Energy at the Energy Information Administration), unit identification code, date of record, hour of record, SO2, CO2, and NOx mass (in lbs per hour), heat input (million British thermal units [MMBtu]), and NOx emission rate (lbs/MMBtu).

SO2 and NOx mass and heat input values were summed for each unit to an annual level to allow for the calculation of an hour of date-to-annual ratio estimation. Equation 1 provides this calculation for heat input. Table 1 provides an example result of the ratio calculation.

Equation (1) $$hi_{ratio,hr,date} = hi_{hr,date} / \sum_{Dec31}^{Jan1} hi$$

where hi = heat input (MMBtu)

Since it was assumed that all sources in the VISTAS EGU inventory would not be matched to individual CEM-based units, the same calculations were performed for each State so that a hierarchical application of ratios (unit first, State second) could be assigned as necessary. Table 2 shows example ratios calculated for each month by State. Table 3 reflects an example of the State-month-day of week ratio calculation and Table 4 shows a State-month-diurnal ratio calculation example. Each of these ratios were calculated for each State in the VISTAS domain and used in instances where CEM unit matches could not be made to the VISTAS base year emissions inventory.

Three parameter values (SO2 mass, NOx mass, heat input) were calculated at each aggregation as NOx and SO2 emissions vary due to fuel blend, sulfur content, or seasonal control and are not necessarily representative of the other variables' seasonal, daily, or even hourly variation. As seen in Figure 1, when viewed on a VISTAS-domain total, the monthly variation in relative distribution of SO2, NOx, and heat input differs enough to justify calculating each parameter value set of temporal profiles with CEM data.

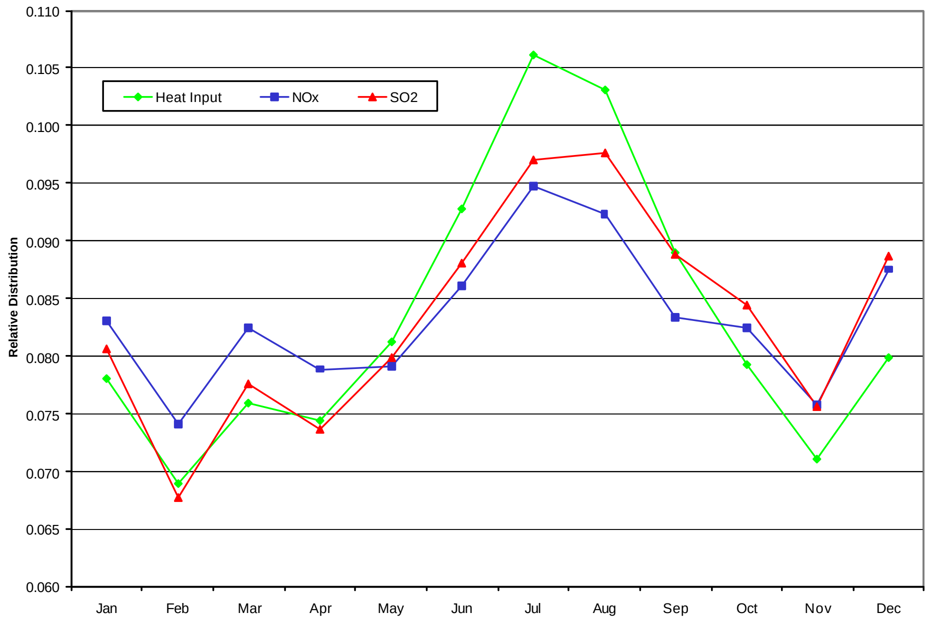
Figure 1. Monthly variation in 2002 of CEM reported heat input, NOx mass, and SO2 mass for VISTAS domain.



When viewed on a State by State basis, the differences in monthly variation are even more pronounced as individual facilities within each State may be affected during any calendar year by extreme temperature variation, shutdowns, or regular maintenance or installation of equipment. As an example, Figure 2 represents CEM data from the State of Mississippi during calendar year 2002 and reveals that SO2 emissions increase throughout the year, NOx emissions stay relatively high during the summer months, and heat input peaks during the month of July. Although Figures 1 and 2 are roughly comparable in shape and monthly distribution, the relative distribution of these values is quite different. In Mississippi's case, close to thirteen percent of the State's CEM-based heat input occurs in July. This compares to the VISTAS average of just over ten percent of CEM-based heat input in July.

Finally, when these data are reviewed at a unit level, the differences become incrementally more distinct due to the unique nature of individual facilities, their operating schedules, pollution regulation, fuel characteristics, and applied technologies. For example, a facility that is complying with summertime NOx regulation may have selective catalytic reduction (SCR) installed on its boiler(s) which in practice may only be run during ozone season months. During this period of time, heat input and SO2 emissions may remain consistent with State or regional monthly profiles, but the NOx emissions may drop significantly relative to the rest of the year.

Figure 3 represents an extreme unit-specific case for monthly differences from State or regional temporal allocation. The unit presented is a Mississippi baseload coal-fired boiler which in 2002 emitted over 4,000 tons of NOx and over 11,000 tons of SO2. This unit would typically run at consistent levels during the entire period, but due to a planned maintenance outage was not in operation in late January through the middle of April in 2002. Given the unique operation of this boiler during this year, the use of a regional or even State-level monthly temporal distribution would introduce significant inaccuracy to air quality modeling in the immediate or downwind area associated with this facility. While this may not be significant at great distance downwind of the source or for annual concentration estimates, more locally, and especially over shorter time scales (daily or weekly), such simplifications would have a noticeable effect on air quality model predictions.

Figure 2. Monthly variation in 2002 of CEM reported heat input, NOx mass, and SO2 mass for Mississippi.

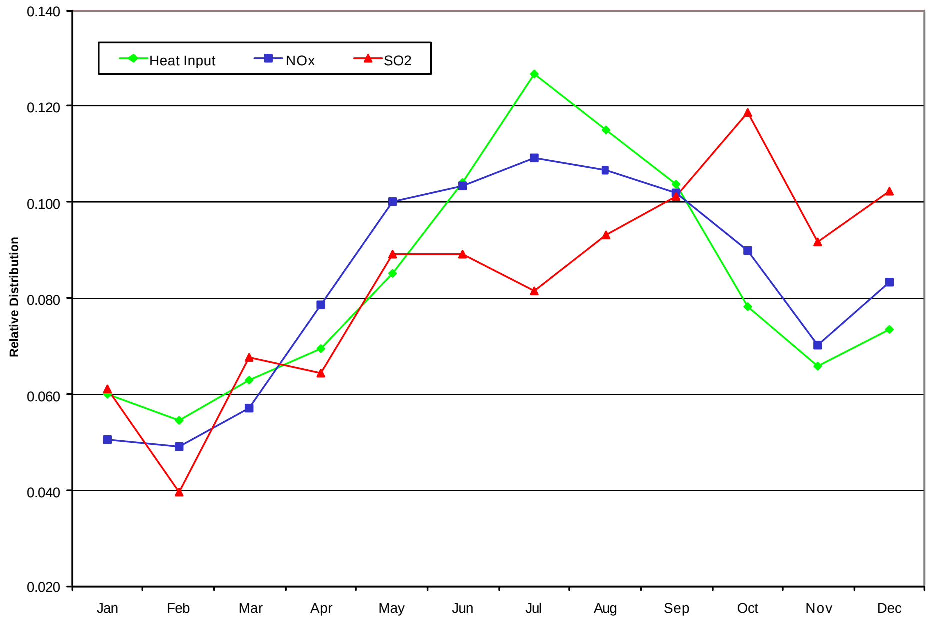


Figure 3. Monthly variation in 2002 of CEM reported heat input, NOx mass, and SO2 mass for specific baseload coal-fired unit in Mississippi with planned outage in late January through mid April.

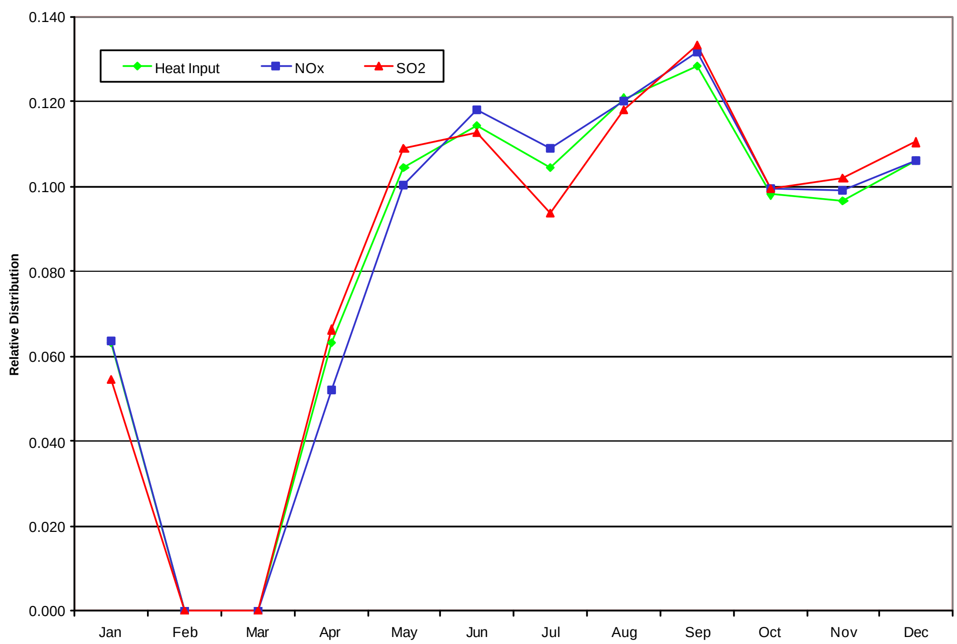
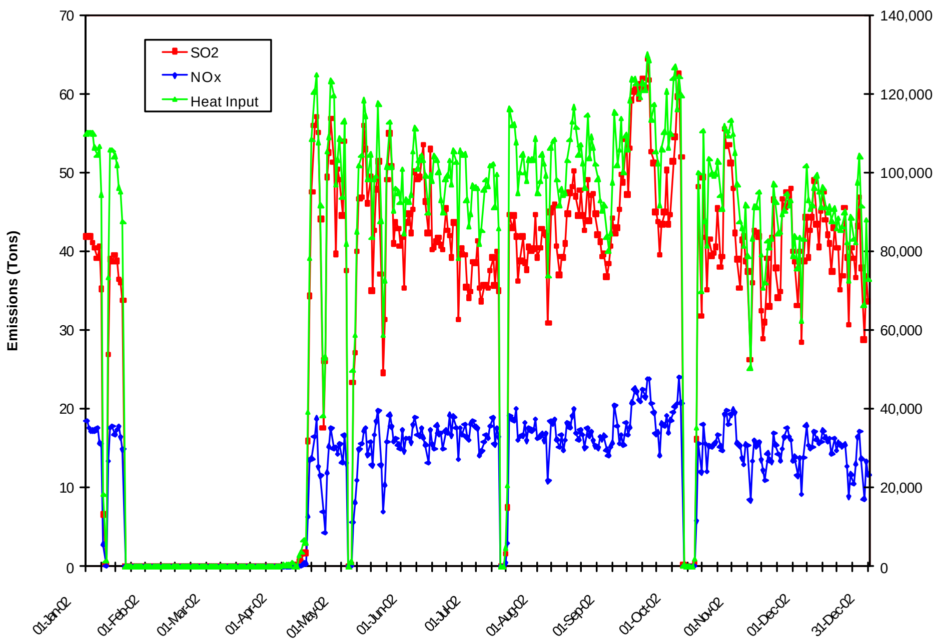


Thus, while improving the representativeness of unit-specific monthly temporal profiles is desirable, providing day and hour-specific values are clearly better. For this reason, during the model performance evaluation process in the VISTAS Phase II modeling, hour-specific temporal ratios were developed for every CEM reporting unit in the VISTAS domain. These ratios allowed for the hour-by-hour accounting of emissions released at each unit at each facility within the VISTAS domain that reported output under the CEM guidelines.

Figure 4 represents the actual daily distribution of SO2 and NOx emissions and heat input from the Mississippi baseload unit from the above example. As can been seen in this figure, not only is the planned January through April outage represented correctly, there are significant peaks and valleys throughout the calendar year which could not be accurately represented with the application of average monthly, day-of-week, or hourly distribution factors. In reality, only the actual operating characteristics of this unit could capture the differences from hour to hour which are potentially quite important in terms of correctly modeling the impact of the source on downwind oxidant and fine particulate concentrations[2].

Figure 4. Actual daily unit-specific 2002 SO2 (tons), NOx, (tons), and heat input (MMBtu) distribution from CEM data.



[2] Stella, G.M., "Development of Hourly Inventories Utilizing CEM-Based Data," presented at the International Emission Inventory Conference, Las Vegas, NV, April, 2005.

4.1.2. Typical EGU Profiles

Hour of day of month specific temporal profiles were developed by calculating the arithmetic mean of each unit's NOx, SO2, and heat input by specific hour of day per month (e.g., Hour 21 of Wednesdays in July) from the data obtained from 2000 through 2004. In order to accomplish this calculation, each record of CEM data was first assigned a day of week. This assignment was based on the actual CEM's date of record and day of week of that record. An example of this assignment is shown in Table 5.

Table 5. Example Day-of-Week per Month Assignment

Date	Day of Week
08/01/02	Thu
08/02/02	Fri
08/03/02	Sat
08/04/02	Sun
08/05/02	Mon
08/06/02	Tue
08/07/02	Wed

Once days of week were assigned to each record in the CEM data base, the arithmetic mean of each unit's NOx, SO2, and heat input were calculated for the ORISPL-UNITID-MONTH-DAY OF WEEK-HOUR combination. Only records where the CEMs were operating for more than half the recorded hour (OPTIME > 0.5) were used in the averaging calculation. An example of the averaged results can be seen in Table 6.

These values were then applied to each unit and hour based on the 2002 calendar to match the meteorological data used in the emissions processing. An example of this application can be seen in Table 7. The date specific hourly averages were then summed to a unit summer (May – Sept) and winter months total and ratios were developed based on each daily hour's average value divided by the average sum total depending on the season of the day. This permitted the appropriate allocation of summertime NOx (as forecasted by IPM) when summer control only was predicted. Using the annual average ratios instead of the seasonal distributions would produce summertime emissions different than what was output from the model.

Equation 2 reflects this calculation for heat input for a summer hour. Ratios were calculated for NOx, SO2, and heat input values. These ratios were then applied to each unit's seasonal (summer or winter) emission value for NOx, SO2, and all other pollutants, respectively.

Equation (2)

$$hi_{ratio,hr,date,sum} = hi_{hr,date,sum} / \sum_{Sep30}^{May1} hi$$

where hi = heat input (MMBtu)

The actual hour-of-day-of-month averages calculated from the CEM data were not used directly as emissions for that hour, but were used only in the calculation of the ratios to be applied to a pre-calculated seasonal (summer or winter) emission value. This allowed for the retention of emission estimates calculated using means other than CEM data, if a State or local agency found them to be more appropriate or if it were derived by other means (e.g., IPM) but an improved distribution of emissions using CEM-based ratios.

As in the actual 2002 profiles calculations, these same calculations were additionally performed for each State so that a hierarchical application of ratios (unit first, State second) could be assigned as necessary. Instead of having variables at the unit level, however, State level values were used. These State value calculations were based on the sum of the unit-level variable averages to the level of aggregation required by the calculation (e.g., State-month. State-month-day-of-week, or State-month-hour). Table 8 shows example ratios calculated for each month by State. Table 9 reflects an example of the State-month-day of week ratio calculation and Table 10 shows a State-month-diurnal ratio calculation example. Each of these ratios were calculated for each State in the VISTAS domain and used in instances where CEM unit matches could not be made to the VISTAS base year emissions inventory.

Again, three parameter values (SO2 mass, NOx mass, heat input) were calculated at each aggregation as NOx and SO2 emissions vary due to fuel blend, sulfur content, or seasonal control and are not necessarily representative of the other variables' seasonal, daily, or even hourly variation.

5.0 Application of Factors

VISTAS chose to prepare its air quality modeling inventories with Version 2.1 of the Sparse Matrix Operating Kernel Emissions (SMOKE) model. For this reason, all emissions were required to be converted to SMOKE's data formats. In particular, because hour specific temporal profiles for each day of a year are not accepted directly by the model, it was necessary to develop a set of hourly emissions inputs to circumvent this limitation. These were generated in the EMS PTHOUR format as described in SMOKE input file documentation[3].

The CEM format for individual hour-specific data files as available in SMOKE was not utilized for VISTAS emissions processing as the emissions allowable by hour would have been limited to NOx, SO2, and CO2. If this file format and optional run configuration were exercised, the NOx, SO2, and CO2 emissions processed by the model would have been accurate for CEM reported emissions, but the remaining pollutants coupled with each CEM unit would have received the monthly, daily, and diurnal temporal profiles associated with the source category codes from the unit. This could lead to potentially displaced emissions if a unit were operating at different times than the default profiles indicated. Additionally, in cases where States may not have reported annual emission estimates directly based on CEMs, these emissions would be slightly different that the original annual inventory.

In VISTAS Phase II modeling, for those EGU sources where CEM data were utilized, NOx, SO2, and heat input-based hour-specific profiles were developed and applied to annual NOx, SO2, and all other emissions, respectively, for both the actual and typical 2002 modeling. Heat input was chosen as a surrogate for non-CEM reported pollutants as the majority of remaining compounds are not as significantly impacted by controls or fuel content, yet the distribution of these emissions would occur during the same times CEM reported pollutants were emitted.

The application of hourly ratios to annual emissions ensured that the annual values provided by States under the CERR were maintained, but distributed using actual hourly to annual profiles. Additionally, for stakeholder sources providing hour-specific data approved by the State in which they operated, data were substituted for State provided emissions and CEM-based distributions.

To temporally allocate the remaining EGU point sources, the NOx, SO2, and heat input data were collected from the 2002 or 2000-2004 CEM datasets, and used to develop State-level temporal distributions. These month-specific hour and day of week temporal profiles were used in conjunction with the emissions inventory to calculate hourly EGU emissions by unit.

Although not as accurate a distribution as the unit-specific factors, the State-based temporal distribution provided improved results to the default profiles provided with the emissions model. Figure 10 represents the monthly distribution comparisons of VISTAS State heat input to the default monthly distribution from Version 2.0 of SMOKE for source category code (SCC) 10100201, representing External Combustion Boilers; Electric Generation; Bituminous/Subbituminous Coal; Pulverized Coal: Wet Bottom (Bituminous Coal), a relatively common boiler type and fuel configuration in the VISTAS domain. This example is for the actual 2002 modeling exercise.

Much like the distinction in month to month variation of the profiles, day of week and diurnal patterns based on CEM data vary from unit to unit. Again, if one were to assign the same day of week or diurnal profile to every unit in the inventory, emissions from these sources would inappropriately be distributed during the episode of interest. In addition to the unique distribution provided by the unit-specific factors based on CEM data, aggregate State level daily and diurnal temporal distribution factors were developed and applied during this process. Figure 11 shows the variance in diurnal distribution from Tennessee's average CEM-based NOx emissions data for each of the twelve months of calendar year 2002 as would have been applied to units unmatched to CEM sources.

ABSTRACT

The most computationally limiting step in emissions modeling is typically the generation of onroad mobile sources. Motor vehicle emissions are influenced by meteorological variability and the processing requirements for daily motor vehicle emissions have been determined to be rate limiting under most modeling schedules. Rather than utilizing averaged meteorological data or pre-calculated motor vehicle emissions, the Visibility Improvement State and Tribal Association of the Southeast (VISTAS) / Association for Southeastern Integrated Planning (ASIP) modeling team developed an emissions processing approach that models a representative week for each month of the year in order to make the SMOKE processing time more manageable and consistent with VISTAS/ASIP modeling schedules. This representative week was selected from mid-month, to try to best represent the average temperature ranges for the month, and also adjusted to exclude holidays that would require atypical processing.

The purpose of this paper is to describe processing options for onroad mobile source emissions using the MOBILE module of the SMOKE emissions processor and to determine, based on air quality predictions and time and resource expenditure, benefits of simulating everyday for onroad mobile emissions to support 8-hr ozone modeling. We will present 12km evaluations of everyday vs. representative week emissions and associated air quality for a number of domains and discuss the benefits and limitations of the various methods relative to ozone, PM and regional haze prediction.

INTRODUCTION

On December 17, 2004, EPA made fine particle ($PM_{2.5}$) nonattainment determinations for at least one area in seven of the states participating in the Visibility Improvement State and Tribal Association of the Southeast (VISTAS) regional haze project. They are Alabama, Georgia, North Carolina, Kentucky, Tennessee, Virginia, and West Virginia. In addition, South Carolina has one three-county area that was designated as unclassifiable in the same action. EPA's Clean Air Interstate Rule (CAIR) modeling indicated that certain nonattainment areas may still be in nonattainment after full implementation of CAIR. These areas include Jefferson County, Alabama and Clayton and Fulton Counties in Georgia.

The $PM_{2.5}$ compliance date is April 2010 unless a state demonstrates that more time is necessary in which case up to five additional years may be granted. The nonattainment designations triggered the requirement for development of state implementation plans (SIPs) that will be due in April 2008. The draft guidance from EPA indicates that a significant requirement of $PM_{2.5}$ SIPs will be attainment demonstrations using, at least in part, modeling analyses to define effective emissions control strategies and confirm that attainment can be achieved after implementation of the strategies. 2009 is the modeling year for the $PM_{2.5}$ attainment demonstration and also is an interim analysis year for the VISTAS regional haze demonstration.

In April of 2004, EPA determined areas that were not meeting the 8-hour ozone standard. States having one or more 8-hour ozone nonattainment areas in the Southeast are Alabama, Georgia, Kentucky, North Carolina, South Carolina, Tennessee, Virginia, and West Virginia. EPA will require attainment of the 8-hour ozone standard in basic nonattainment areas by June 15, 2009 and in moderate nonattainment areas by June 15, 2010. This will require states with basic 8-hour ozone nonattainment areas to model 2008 as the SIP modeling demonstration year while moderate nonattainment areas will require 2009 as the modeling year. Given that North Carolina and Virginia have two year SIP approval processes, there is an immediate need to complete an analysis of ozone attainment using air quality modeling.

The states participating in the VISTAS project (the SESARM EPA Region 4 states plus Virginia and West Virginia from Region 3) have concluded that a collaborative process will be the most efficient approach for the collective states to develop information upon which to base the $PM_{2.5}$ and 8-hour ozone attainment demonstrations. The local air regulatory agencies for Jefferson County, AL, Jefferson County, KY, Mecklenburg County, NC, Forsyth County, NC, Knox County, TN, and Shelby County, TN have also become signatory parties to this collaborative effort. SESARM will coordinate among participating agencies and oversee the performance of the inventory and modeling tasks in parallel with the VISTAS regional haze project tasks.

The name of this collaborative effort is the Association for Southeastern Integrated Planning (ASIP). SESARM was awarded a grant from EPA on February 8, 2005 to conduct what was originally called the fine particle SIP development support project but is now known as ASIP.

These states need to submit their 8-hour ozone State Implementation Plans (SIPs) to EPA by June 2007; the $PM_{2.5}$ SIPs are due by April 2008. Some of the states involved in the ASIP ozone/PM modeling have two-year legislative review processes. Thus, the definition of the SIP control plans is needed in early 2006. Consequently, the ASIP regional ozone and PM modeling has an aggressive schedule.

Figure 1. $PM_{2.5}$ nonattainment counties designed by EPA in December 2004.

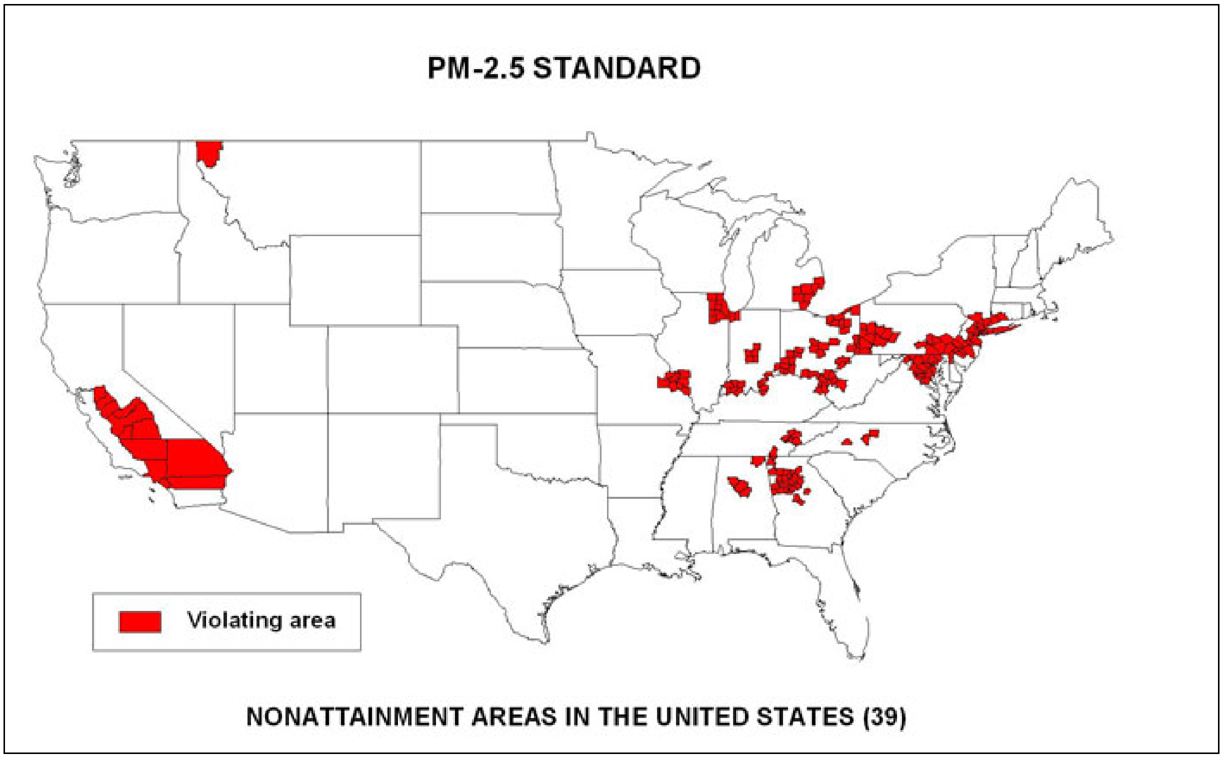

Figure 2. 8-hour ozone nonattainment counties in the US designated by EPA in April 2004.

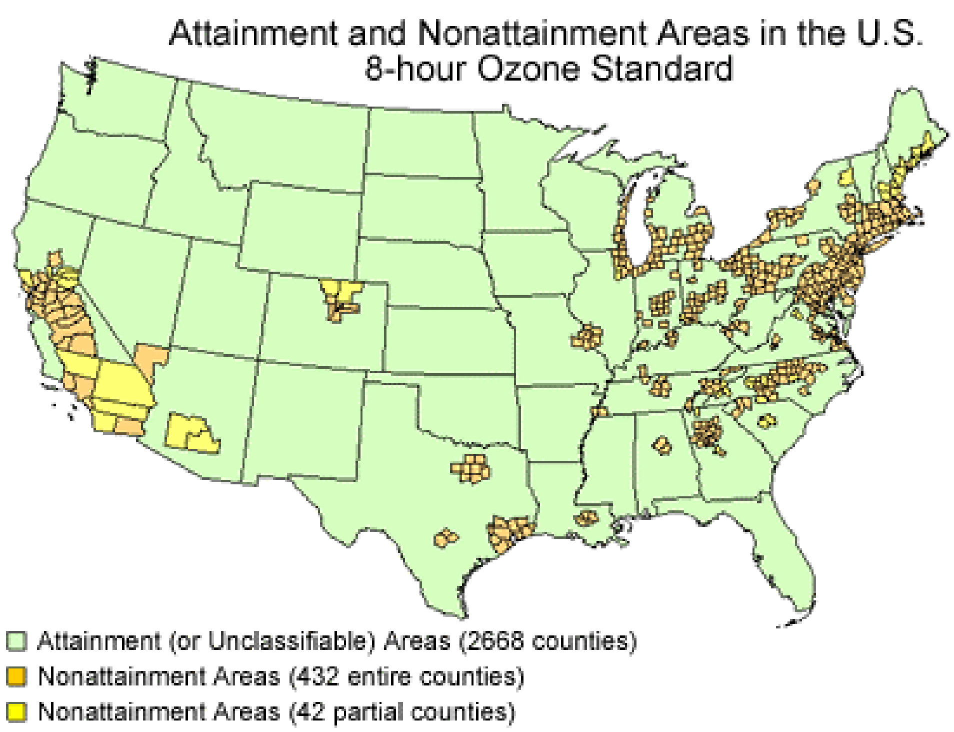


By far the most computationally limiting step in emissions modeling is typically the generation of onroad mobile sources. Motor vehicle emissions are influenced by meteorological variability and the processing requirements for daily motor vehicle emissions have been determined to be rate limiting under most modeling schedules. Rather than utilizing averaged meteorological data or pre-calculated motor vehicle emissions, the VISTAS and ASIP modeling team developed an emissions processing approach that models a representative week for each month of the year in order to make the SMOKE processing time more manageable and consistent with modeling schedule[1]. This representative week was selected from mid-month, to try to best represent the average temperature ranges for the month, and also adjusted to exclude holidays that would require atypical processing.

Based on the findings in the VISTAS Phase I and II modeling activities, ASIP selected the following models for use in modeling 8-hour ozone and particulate matter (PM) of size of 2.5 microns or less ($PM_{2.5}$):

- **MM5[2,3]:** The Pennsylvania State University/National Center for Atmospheric Research (PSU/NCAR) Mesoscale Meteorological Model (MM5) is a nonhydrostatic, prognostic meteorological model routinely used for urban- and regional-scale photochemical, fine particulate and regional haze regulatory modeling studies.

- **SMOKE[4]**: The Sparse Matrix Operator Kernel Emissions (SMOKE) modeling system is an emissions modeling system that generates hourly gridded speciated emission inputs of mobile, nonroad, area, point, fire and biogenic emission sources for photochemical grid models.

- **CMAQ[5,6]:** EPA's Models-3/Community Multiscale Air Quality (CMAQ) modeling system is a 'One-Atmosphere' photochemical grid model capable of addressing ozone, particulate matter (PM), visibility and acid deposition at regional scale for periods up to one year.

The purpose of this paper is to describe processing options for onroad mobile source emissions using the MOBILE module of the SMOKE emissions processor and to determine, based on air quality predictions and time and resource expenditure, benefits of simulating everyday for onroad mobile emissions to support 8-hr ozone modeling. We will present 12km evaluations of everyday vs. representative week emissions and associated air quality for a number of domains and discuss the benefits and limitations of the various methods relative to ozone and regional haze prediction.

MOBILE6 / SMOKE PREPARATION

For the VISTAS/ASIP 2009 annual emissions inventory modeling, SMOKE was configured to generate point, area, nonroad, highway, and biogenic source emissions. In addition, certain subcategories, such as fires and EGUs were maintained in separate source category files in order to allow maximum flexibility in producing alternate strategies. With the exception of biogenic and highway mobile source emissions that are generated using the BEIS and MOBILE6 modules in SMOKE, pre-computed annual emissions will be processed using the month, day, and hour specific temporal profiles of the SMOKE model. Area, nonroad, and point sources were modeled as a block of Thursday, Friday, Saturday, Sunday, Monday one per month (total of 60 days modeled). Biogenics were modeled for each day of the episode.

For this investigation, the onroad mobile source emissions were produced using two approaches:

1) Modeling every day of the annual episode, using the MM5 meteorology files for each model day. When full annual runs were executed, holidays were modeled as Sundays.

2) Modeling selected weeks (seven days) of each month and using these days as representative of the entire month. This selection criterion allows for the representation of day-of-the-week variability in the onroad motor vehicles, and models a representation of the meteorological variability in each month. The modeled weeks were selected from mid-month, avoiding inclusion of major holidays.

The parameters for the SMOKE runs are as follows:

Episodes:

2002 Initial Base Year, and
2009 Future year, using 2009 inventory and modeled using the same meteorology and episode days as 2002.

Episode represented by the following weeks per month:

January 15-21
February 12-18
March 12-18
April16-22
May 14-20
June 11-17
July 16-22
August 13-19
September 17-23
October 15-21
November 12-18
December 17-23

Days modeled as holidays for annual run:

New Year's Day - January 1
Good Friday – March 29
Memorial Day – May 27
July 4th
Labor Day – September 2
Thanksgiving Day – November 28, 29
Christmas Eve – December 24
Christmas Day – December 25

Output time zone:

Greenwich Mean Time (zone 0)

Projection:

Lambert Conformal with Alpha=33, Beta=45, Gamma=-97, and center at (-97, 40).

Domain:

36 Kilometer Grid: Origin at (-2736, -2088) kilometers with 148 rows by 112 columns and 36-km square grid cells.
12 Kilometer Grid: Origin at (108, -1620) kilometers with 168 rows by 177 columns and 12-km square grid cells.

Layer structure:

The CMAQ layer structure will be 19 layers, with specific layer positions defined in the meteorology files to be provided by VISTAS meteorological contractor.

CMAQ model species:

The CMAQ configuration will be for CB-IV with PM. The model species will be: CO, NO, NO2, ALD2, ETH, FORM, ISOP, NR, OLE, PAR, TERPB, TOL, XYL, NH3, SO2, SULF, PEC, PMFINE, PNO3, POA, PSO4, and PMC.

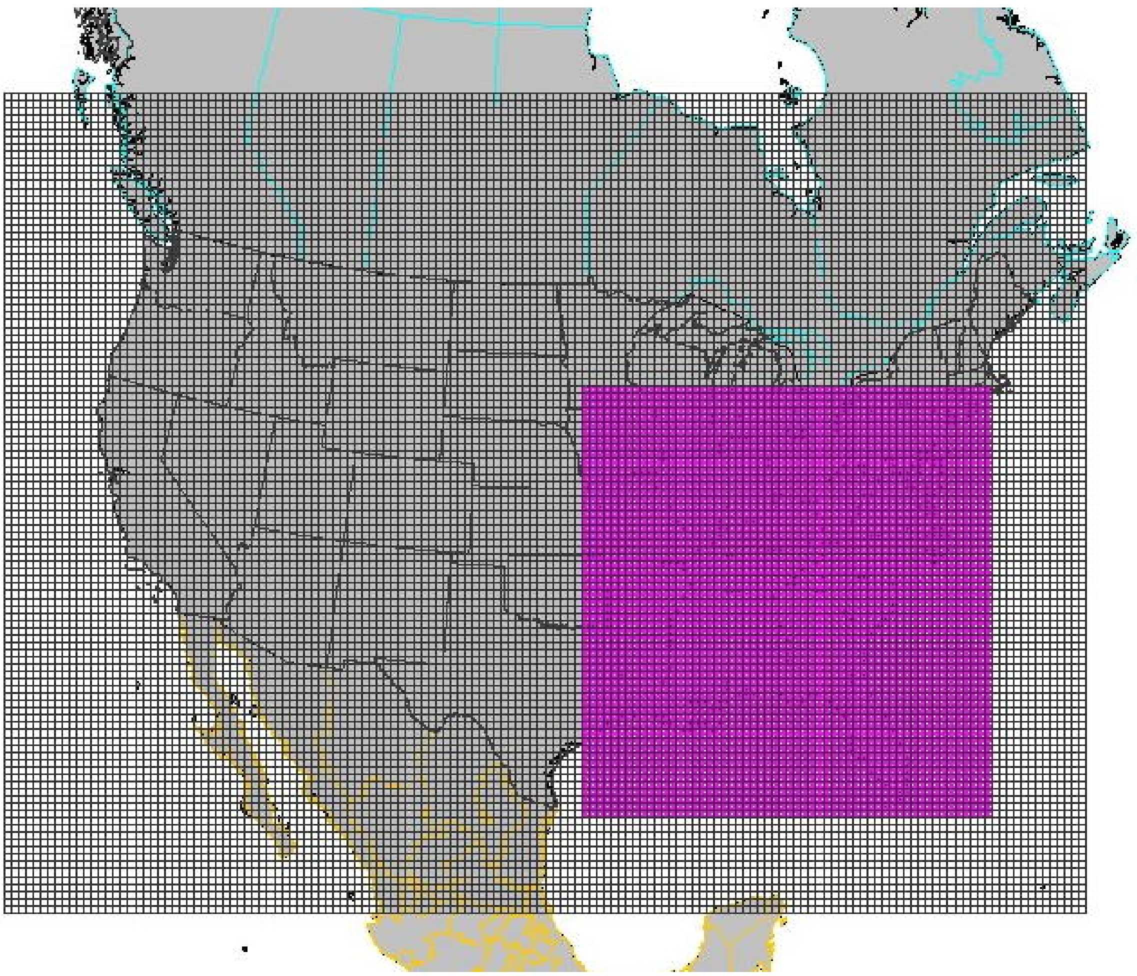
Meteorology data:

Daily (25-hour). SMOKE requires the following five types of MCIP outputs: (1) Grid cross 2-d, (2) Grid cross 3-d, (3) Met cross 2-d, (4) Met cross 3-d, and (5), Met dot 3-d.

Elevated sources:

All sources will be treated by SMOKE as potentially elevated. No plume-in-grid sources will be modeled. Wildfire emissions will be handled as point sources.

Figure 3. 36-km national unified RPO domain and VISTAS 12-km domain.



DEVELOPMENT OF ONROAD MOTOR VEHICLE SOURCE EMISSIONS

The MOBILE6 module of SMOKE was used to develop the onroad mobile source emissions estimates for CO, NOX, PM, and VOC emissions. The MOBILE6 parameters, vehicle fleet descriptions, and VMT estimates are combined with gridded, episode-specific temperature data to calculate the gridded, temporalized emission estimates. The MOBILE6 emissions factors are based on episode-specific temperatures predicted by the meteorological model. Further, the MOBILE6 emissions factors model accounts for the following:

- Hourly and daily minimum/maximum temperatures;
- Facility speeds;
- Locale-specific inspection/maintenance (I/M) control programs, if any;
- Adjustments for running losses;
- Splitting of evaporative and exhaust emissions into separate source categories;
- VMT, fleet turnover, and changes in fuel composition and Reid vapor pressure (RVP).

The primary input to MOBILE6 is the MOBILE shell file. The MOBILE shell contains the various options (e.g. type of inspection and maintenance program in effect, type of oxygenated fuel program in effect, alternative vehicle mix profiles, RVP of in-use fuel, operating mode) that direct the calculation of the MOBILE6 emissions factors. The shells used in these runs were based on VISTAS/ASIP BaseF modeling inputs[7]. The options for all MOBILE6 parameters were held constant between the annual and representative week runs.

Daily results of these model runs for a winter (January 17) and summer (July 18) day are represented in Figures 4 through 6 below. These data provide a comparison of the magnitude difference between ozone and particulate matter precursor species for each of these seasonally different episodes. As can be seen in these figures, the variable inputs (temperature, VMT, seasonal fuels) associated with each month's run have an impact on the overall emissions generated for the onroad mobile source category. It is through modeling these differences with CMAQ for both ozone and PM that we have based our conclusions.

Each of the onroad mobile source emissions runs conducted with the MOBILE6 module of SMOKE were performed on a dual Athlon MP 2600+ with 1.5 G RAM. With this configuration, the modeling team experienced run times of approximately sixty-three (63) minutes per run day on the 12km domain. Using this estimate, the representative week processing would require a total of 5,292 minutes (12 months x 7 days x 63 minutes per run day) or about 88.2 hours (3.5 days) of CPU runtime to generate the files necessary to simulate the annual episode. In comparison, actually running each day's onroad mobile source emissions using the same configuration would require 22,995 minutes (365 days x 63 minutes per run day) or about 383.25 hours (16 days) of CPU run time.

Figure 4. Daily VOC emissions as generated with the MOBILE6 module of SMOKE for a winter (January 17) and summer (July 18) episode day.

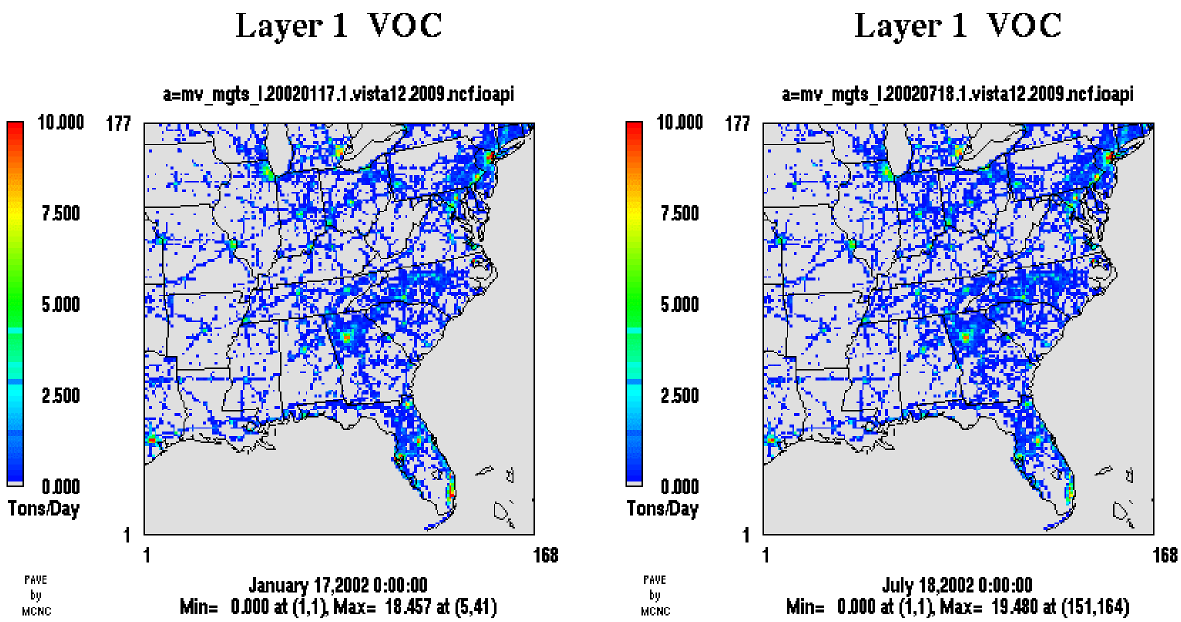


Figure 5. Daily NOx emissions as generated with the MOBILE6 module of SMOKE for a winter (January 17) and summer (July 18) episode day.

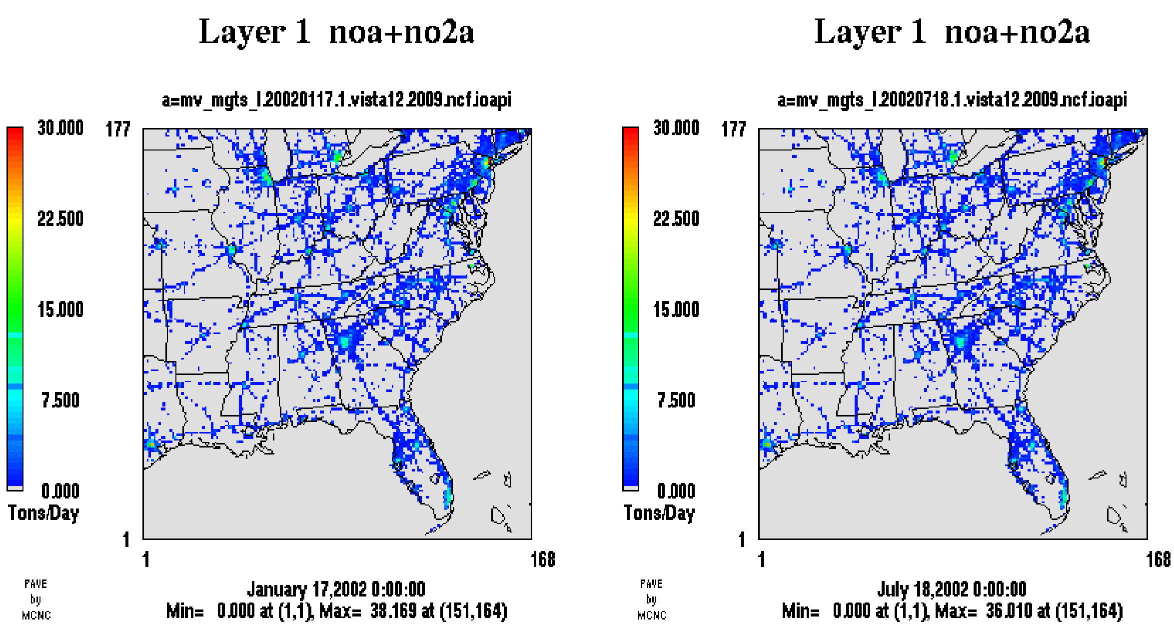

Figure 6. Daily PM-fine emissions as generated with the MOBILE6 module of SMOKE for a winter (January 17) and summer (July 18) episode day.

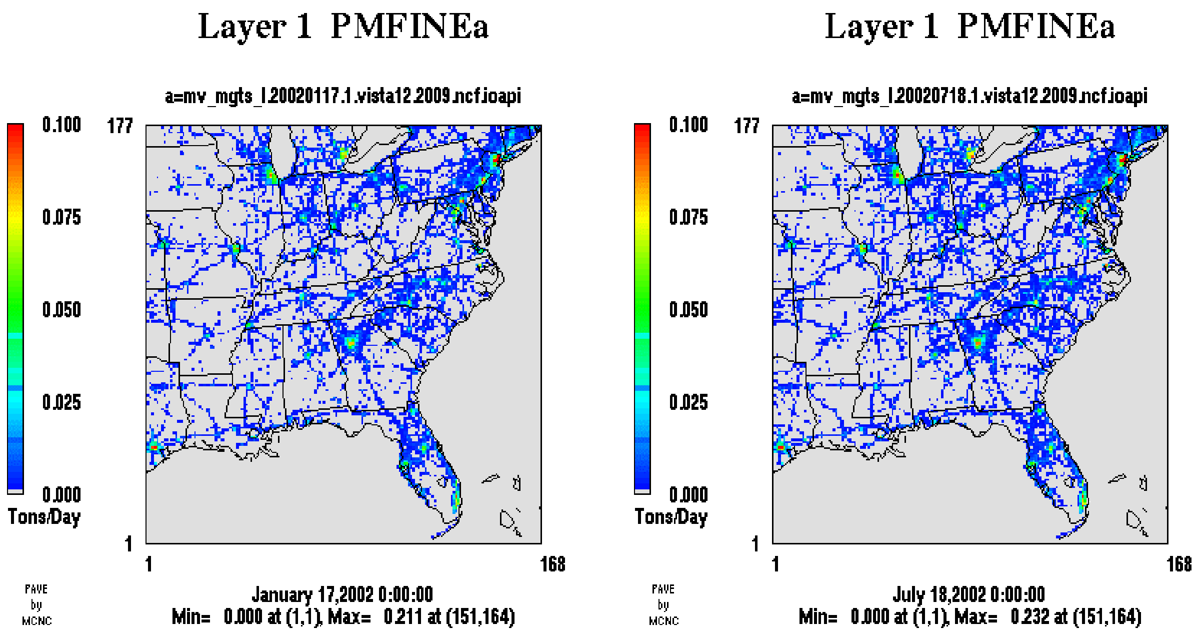

EMISSIONS SUMMARY

The reconstructed emissions based on the representative week run were calculated by mapping each day of week (Mon, Tue, Wed, etc.) from the modeled month to the same day of week generated in the representative week run. In the case of holidays, these days were mapped to representative week Sundays. An example of this mapping for the January episode is presented in Table 1. Note that although the emissions were generated for calendar year 2009, the meteorology is based on 2002. Table 2 presents a comparison of January emissions as generated using the everyday MOBILE6 module run for each VISTAS/ASIP State and these emissions as reconstructed from the representative week MOBILE6 module runs. In comparison, Table 3 presents these emissions for the month of July.

These aggregate emission summaries would lead one to believe that on an extended episode scale (like those required for PM or regional haze modeling), the use of representative week onroad mobile source emissions would be appropriate. However, in modeling either 1-hr or 8-hr ozone, there is enough of a temperature variability and therefore apparent ozone precursor emissions delta on an hour-to-hour basis that this same assumption could not be made without accompanying air quality simulations.

AIR QUALITY MODELING

The VISTAS/ASIP modeling team has applied the CMAQ Version 4.5 O_3/$PM_{2.5}$ photochemical grid modeling system. The VISTAS/ASIP modeling team implemented a comprehensive evaluation of the meteorological[8], emissions and air quality models. The CMAQ model performance evaluation indicated an underestimation of 8-hour ozone maximums during the summer. The model demonstrated reasonably good performance for sulfate, winter overestimation bias and summer underestimation bias for nitrate and reasonably good performance for elemental carbon (EC), albeit with lots of scatter and low correlation. However, organic carbon (OC) was underestimated with the summer OC underestimation bias being quite severe. After an intense focused analysis of the OC underestimation issue, the VISTAS/ASIP modeling team identified processes important to the formation of secondary organic aerosols (SOA) that were not included in the CMAQ SOA module that may be important to OC in the Southeastern U.S.[9] Consequently, VISTAS/ASIP enhanced the CMAQ SOA module by adding several new processes. This enhancement, called "SOAmods", was implemented in CMAQ Version 4.5 and exhibited much improved OC model performance over the standard CMAQ SOA treatment[10]. A complete description of the modeling methods, configurations and performance are described elsewhere[1,7].

CMAQ was applied using both of the mobile emissions modeling methods described above. Recall, all emissions and air quality model inputs and configurations were held constant, with the exception of the mobile source emissions. This will allow us to isolate the air quality impacts of using the representative week mobile emissions versus the "actual" daily modeled mobile emissions. While the VISTAS/ASIP modeling is conducted on both 36-km National RPO and 12-km "VISTAS/ASIP" modeling domains as shown in Figure 3, this study focuses on evaluations of the 12-km air quality modeling results only.

Using each of the mobile emissions databases (daily and the representative week) generated for the January and July study periods, we performed future-year air quality simulations for 2009 using CMAQ. We then post-processed the air quality model results to qualitatively evaluate the magnitude, location, and spatial extent of the differences in predicted ozone and $PM_{2.5}$ concentrations due to the different mobile emissions modeling methodologies. Spatial plots were generated for each day simulated, including:

1) daily maximum 8-hour ozone difference plots;
2) maximum 1-hour ozone maximum difference plots; and,
3) daily $PM_{2.5}$ difference plots.

RESULTS

Our examination of the two air quality simulations began with the daily differences in $PM_{2.5}$ concentrations. Figures 7 and 8 represent the percent difference in the daily $PM_{2.5}$ concentrations between the air quality simulations with representative week mobile emissions and the daily mobile emissions for one winter day (January 22^{nd}) and one summer day (July 9^{th}). No change is seen in either plot indicating daily $PM_{2.5}$ concentrations changed less than one percent. Absolute differences in daily $PM_{2.5}$ concentrations are shown in Figures 9 and 10 for the same two days (January 22^{nd} and July 9^{th}). Again, no change is seen in either plot indicating daily $PM_{2.5}$ concentrations changed less than 0.2 $\mu g/m^3$. In fact, all of the fourteen days modeled (seven winter days and seven summer days) show no differences as high as 0.2 $\mu g/m^3$.

We next examined the results of the two air quality simulations with the daily differences in maximum 8-hour ozone concentrations. Figures 11 and 12 present the percent difference in the daily maximum 8-hour ozone concentrations for one winter day (January 28^{th}) and one summer day (July 15^{th}). In most areas for the winter day, daily maximum 8-hour ozone concentrations changed less than one percent. In a few urban corridors, namely, near Chicago, IL, Atlanta, GA and Baltimore, MD, changes of one percent are noted. Near Philadelphia, PA, changes of up to two percent are noted. However, this was the only day of the seven wintertime days simulated that showed a daily maximum 8-hour ozone difference as high as one percent anywhere in the modeling domain. It should also be noted that predicting wintertime ozone concentrations is not usually an interest because most, if not all high ozone events in the middle latitudes of the northern hemisphere occur during the summertime. Therefore the remainder of the ozone analysis will focus on summertime differences. On the summer day, July 15^{th}, presented in Figure 12, no changes are seen indicating daily maximum 8-hour ozone concentrations changed less than one percent. In fact, all seven of the summer days modeled showed no changes as high as one percent.

Absolute differences in daily maximum 8-hour ozone concentrations are shown in Figure 13 for July 15^{th}. Again, no change as high as 0.5 ppb (0.0005 ppm) was noted on this day or any of the seven summer days modeled. In addition to the 8-hour ozone metrics discussed above, differences in 1-hour ozone maximums were examined. As shown in Figure14 and 15, only two days during the seven day summertime period simulated showed differences in 1-hour ozone maximums as high as 0.5 ppb (0.0005 ppm).

CONCLUSIONS

U.S. EPA attainment demonstration modeling guidance[11,12] notes that in some cases it may be useful to evaluate how the response of an air quality model to emissions changes varies as a function of alternative model inputs or model algorithms. These types of tests can be used to assess the robustness of a base case or control strategy modeling evaluation. As an example, EPA remarks that States/Tribes could consider the effects of assumed boundary conditions on predicted effectiveness of a control strategy. If the model response does not differ greatly over a variety of alternative plausible configurations, this increases confidence in the model results.

The parameters for these sensitivity tests can include, but are not limited to: different chemical mechanisms, finer or coarser grid resolution, meteorological inputs from alternative, credible meteorological model(s), different initial/boundary conditions, and *multiple sets of reasonable emission projections*. Sensitivity tests can and should be applied throughout the modeling process, not just when model performance is being evaluated.

The modeling team's research in using *reasonable alternate sets of onroad emission projections* has determined that the use of representative week onroad mobile emissions for each month of our episodes within our 12km modeling domain predicts ozone and particulate matter concentration differences from annual, everyday onroad mobile modeling which could be considered insignificant from an air quality modeling standpoint. The small differences in the air quality results in combination with the length of time necessary to conduct daily onroad mobile runs using the MOBILE6 module of SMOKE has resulted in the project team's recommendation that representative week onroad mobile emissions methodology be carried forward in the VISTAS regional haze modeling and the ASIP $PM_{2.5}$ and 8-hour ozone modeling.

1. Introduction

The emissions modeling for the Hickory and Greensboro-Winston Salem-High Point, NC PM2.5 nonattainment areas were performed in conjunction with the regional haze modeling being done by the Southeast Regional Planning Organization, Visibility Improvement State and Tribal Association of the Southeast (VISTAS) and the fine particulate matter (PM2.5) and ozone modeling being done by the Association of Southeastern Integrated Planning (ASIP). VISTAS and ASIP are run by the ten Southeast states (Alabama, Florida, Georgia, Kentucky, Mississippi, North Carolina, South Carolina, Tennessee, Virginia and West Virginia. The emissions preprocessing model used to ready the emissions for input into the air quality model was the Spare Matrix Operator Kernel Emissions (SMOKE) modeling system.

2. Deviation From Everyday Modeling

The VISTAS/ASIP modeling was an annual simulation. It would be too resource intensive to process all sources sectors for everyday of the year. Therefore, to produce an emissions inventory to support the annual modeling, representative time periods were selected and modeled.

The area and nonroad mobile sources were modeled as a block of Thursday, Friday, Saturday, Sunday, Monday, one per month (total of 60 days modeled for the annual simulation). Similarly, the on-road mobile sources were represented by an entire single week for each month. This select criteria allows for the representation of day-of-the-week variability in the on-road motor vehicles, and models a representation of the meteorological variability in each month.

The stationary point sources, which include the electric generating units (EGUs) and Non-EGUs, were modeled everyday of the annual simulation. This was due to the plume rise calculations used to parse the emissions into the various layers of the model is different everyday depending on the meteorological inputs. Additionally, VISTAS/ASIP modeled large wild land fires as day specific sources with plume rise incorporated into the emissions modeling. Similar to the stationary point sources, the biogenic emissions were modeled everyday of the annual simulation since the amount of volatile organic compounds emitted is significantly impacted by temperature and solar radiation.

For the area, nonroad mobile and on-road mobile sources, the holidays were modeled as a Sunday. Table 1 describes the representative time period for all source categories.

Table 1. Representative Time Period for Emissions Modeling

Source Category	Emission Modeling frequency of run
Area Sources	5 days per month
Biogenic	Everyday
Canada_area	5 days per month
Canada_point	5 days per month

mms_area	5 days per month
mms_point	Everyday
Non-EGU	Everyday
Nonroad Mobile	5 days per month
On-road Mobile	7 days per month

3. Point Source Deviation

The VISTAS/ASIP emissions modeling used results from the Integrated Planning Model (IPM) to generate future year emissions for the EGU source sector. Duke Energy and Progress Energy updated their plans for complying with North Carolina's Clean Smokestacks Act and the emission projections for the plans varied substantially from the IPM results (Table 2). Therefore, the North Carolina Division of Air Quality (NCDAQ) replaced the IPM emission projections for 2009 with projections from the 2006 Duke Energy and Progress Energy compliance plans. The Clean Smokestacks Act can be found in Appendix M.

Another point source deviation was the temporal profiles used for the typical emissions for the EGU source sector. Instead of using the 2002 continuous emissions monitoring (CEM) profiles for the EGUs, a typical temporal profile was created using data from 2000 through 2004. How the typical temporal profiles were generated is discussed in detail in Appendix F.1.

Table 2. Comparison of 2009 emissions for Duke and Progress compliance plans vs. IPM.

Facility	Compliance Plan 2009 NOx (tpy)	IPM 2009 NOx (tpy)

Meteorological Model Performance

(This page intentionally left blank)

TABLE OF CONTENTS

LIST OF FIGURES

(This page intentionally left blank)

1 INTRODUCTION

The attainment demonstration for the PM2.5 SIP nonattainment areas used the meteorological modeling from the Visibility Improvement State and Tribal Association of the Southeast (VISTAS) regional haze modeling. VISTAS is run by the ten Southeast states: Alabama, Florida, Georgia, Kentucky, Mississippi, North Carolina, South Carolina, Tennessee, Virginia and West Virginia. The meteorological model used for this project was the Pennsylvania State University/National Center for Atmospheric Research Mesoscale Meteorological Model (MM5).

The sections that follow summarize the meteorological model performance for North Carolina on the 12 kilometer (km) grid domain. The overall VISTAS meteorological model development and model performance was documented by the VISTAS contractor Baron Advanced Meteorological Systems, LLC and is attached to this Appendix.

2 12 KM MM5 PERFORMANCE IN NORTH CAROLINA

In general, the MM5 performance for North Carolina was very similar to the performance for the entire VISTAS modeling domain. The temperature bias was negative in the cooler months, reaching a minimum of -.8 K in January and December. The bias approached zero in the summer. Error ranged from 2-2.5 K in the winter to 1.5 K in the summer. The absolute temperature error hovered around 1.5 K from May-September. Figure 2-1 displays the overall temperature, temperature bias and absolute error for North Carolina and the VISTAS modeling domain.

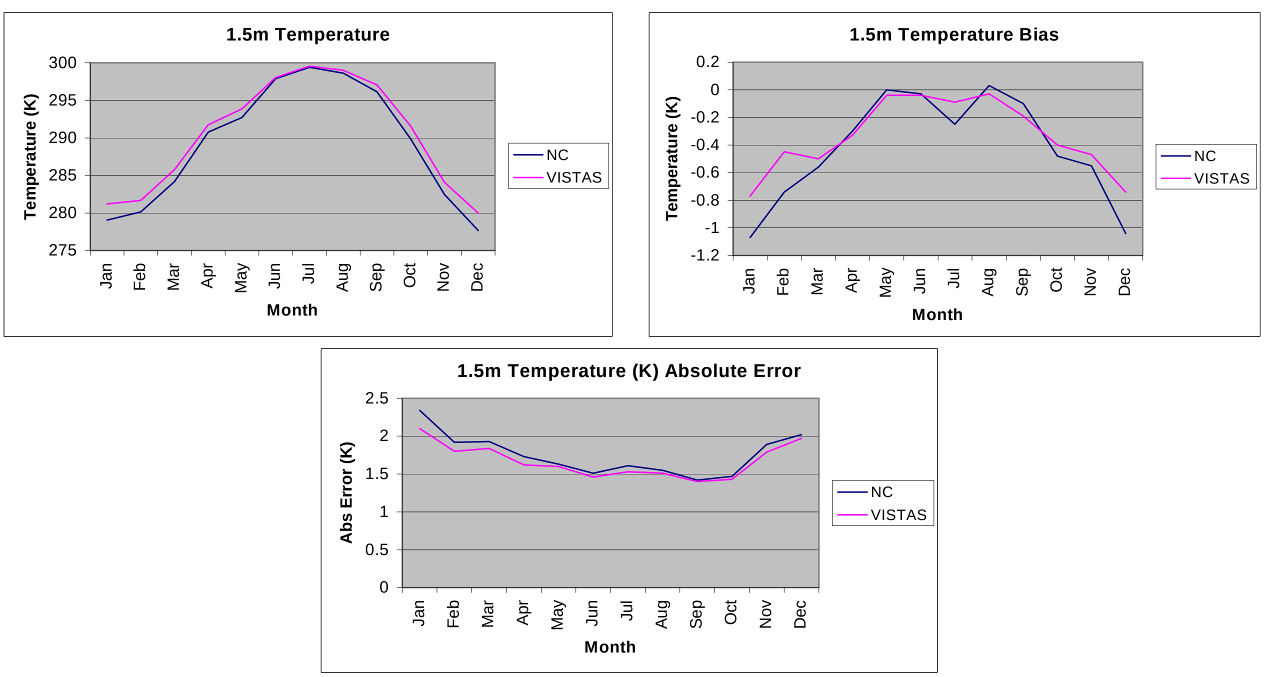

Figure 2-1 Monthly plots of modeled 1.5 meter temperature, bias and absolute error.

The mixing ratio bias in North Carolina was closer to neutral as compared to the entire VISTAS domain, hovering between 0.2 and –0.2 g/kg most of the year.   The worst performance was in September and October, when the negative bias in the MM5 dipped to around 0.6 g/kg. The model was slow to capture the effects of drought-busting rains that fell during those months. The absolute error was only slightly higher in North Carolina than the entire VISTAS domain, peaking at 1.8 g/kg in July, and falling to around 0.7 g/kg during the winter. Figure 2-2 displays the overall mixing ratio, mixing ratio bias and absolute error for North Carolina and the VISTAS modeling domain.

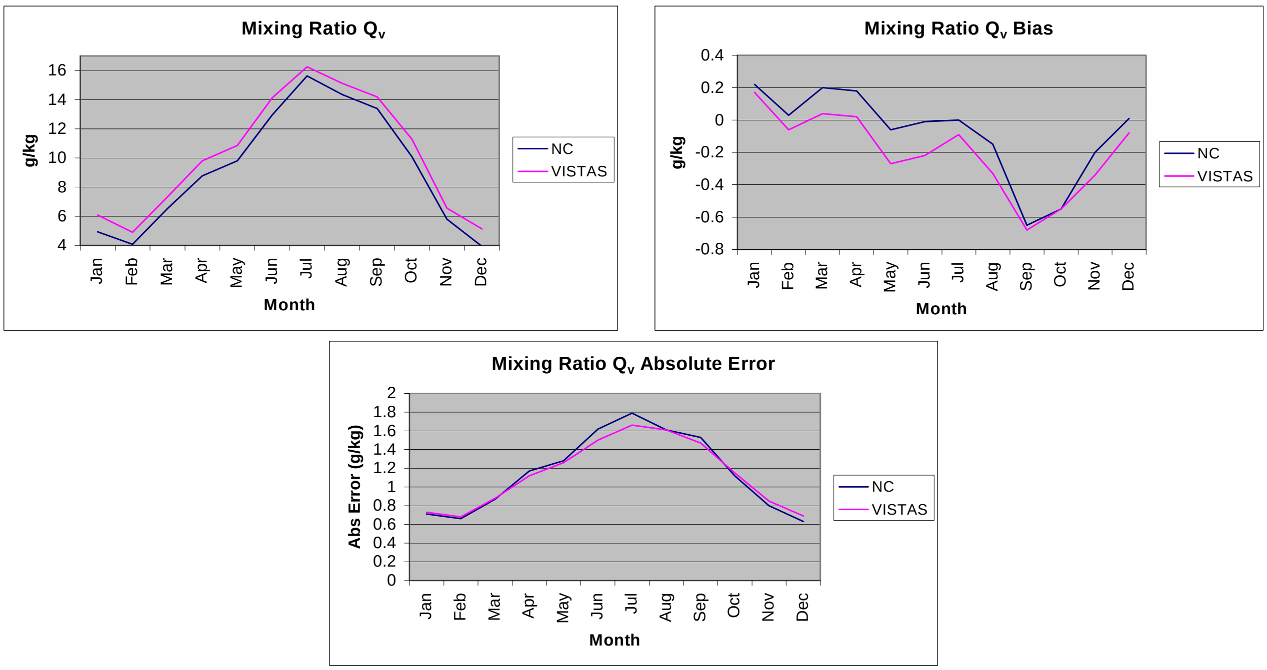

Figure 2-2 Monthly plots of modeled 1.5 meter mixing ratio, bias and absolute error.

The relative humidity bias in North Carolina was about 0.5% higher when compared to the entire VISTAS domain. The relative humidity bias in North Carolina generally hovered around ± 3%. The bias turned negative in September-November due to the models lag in capturing the affects of the drought-busting rains. The absolute error was slightly higher in North Carolina than the entire VISTAS domain, holding steady around 10% during the summer and rising to near 12 % during the winter. Figure 2-3 displays the overall relative humidity, relative humidity bias and absolute error for North Carolina and the VISTAS modeling domain.

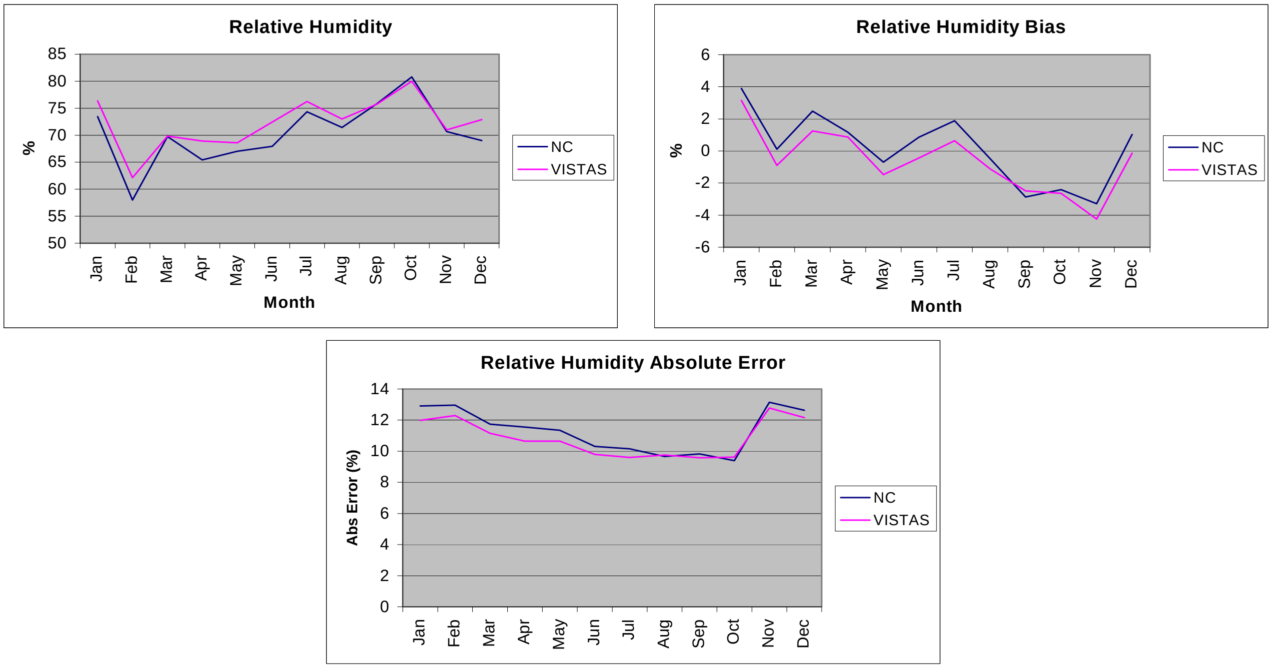

Figure 2-3 Monthly plots of modeled 1.5 meter relative humidity, bias and absolute error

The cloud coverage bias in North Carolina was 2 – 3% higher compared to the entire VISTAS domain. The cloud coverage bias peaked near 10% in July, with all other months with a bias less than 5%. The absolute error was generally 1 – 2% lower than the entire VISTAS domain, peaking at 31% in September and falling to 18-20% in the cooler months. Figure 2-4 displays the overall cloud coverage, cloud coverage bias and absolute error for North Carolina and the VISTAS modeling domain.

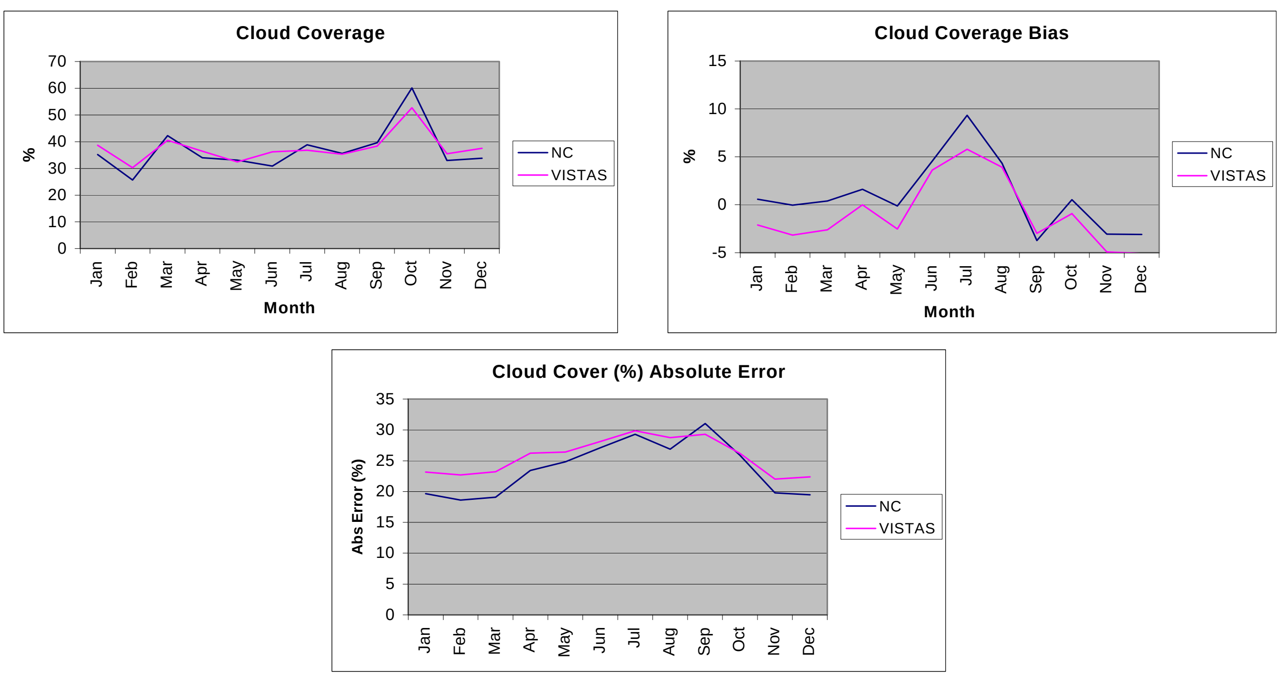

Figure 2-4 Monthly plots of modeled cloud coverage, bias and absolute error.

Wind direction was the most erratic of the measurements. The direction bias in North Carolina was more pronounced, being more negative April through July, and more positive in August and September. The bias during the rest of the year was negligible. The absolute error was close to the entire VISTAS domain, peaking at 35 degrees in July when the lightest winds are experienced. Figure 2-5 displays the overall wind direction, wind direction bias and absolute error for North Carolina and the VISTAS modeling domain.

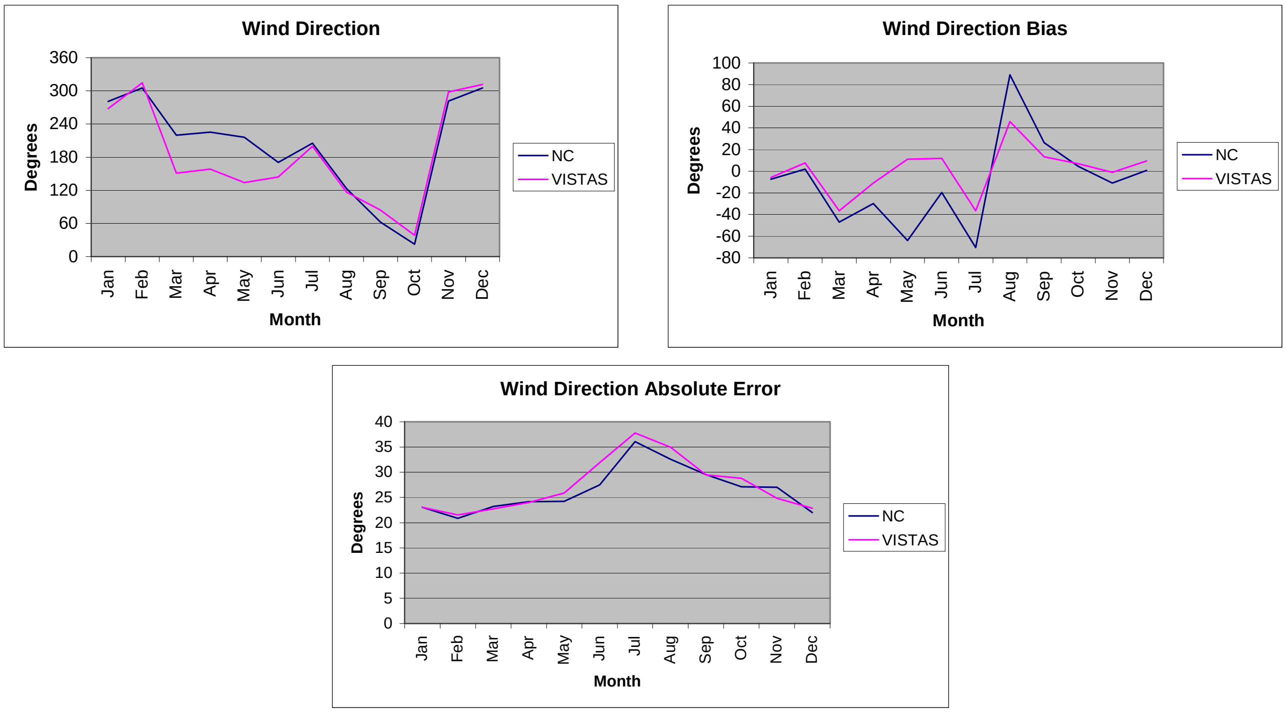

Figure 2-5 Monthly plots of modeled wind direction, bias and absolute error.

The wind speed bias in North Carolina was 0.3 to 0.4 meter/second (m/s) higher than wind speeds across the entire VISTAS domain. When considering all wind measurements, the wind speed was .8 to 1.0 m/s too strong. The absolute error is near 1.2 m/s, just above the entire VISTAS domain. When omitting calm observations, the bias falls to 0.2 to 0.5 m/s. The absolute error is near 1.2 m/s, very close to the entire VISTAS domain. When omitting modeled wind speeds below the threshold of the anemometer (<1.5 m/s), the bias is 0.5 to 0.8 m/s. The absolute error is near 1.3 m/s, just above the entire VISTAS domain. Figure 2-6 displays the overall wind speed, wind speed bias and absolute error for North Carolina and the VISTAS modeling domain. Figure 2-7 displays the wind speed when the calm observations are omitted as well as the bias and absolute error. Figure 2-8 displays the wind speed with modeled wind speeds below 1.5 m/s are omitted.

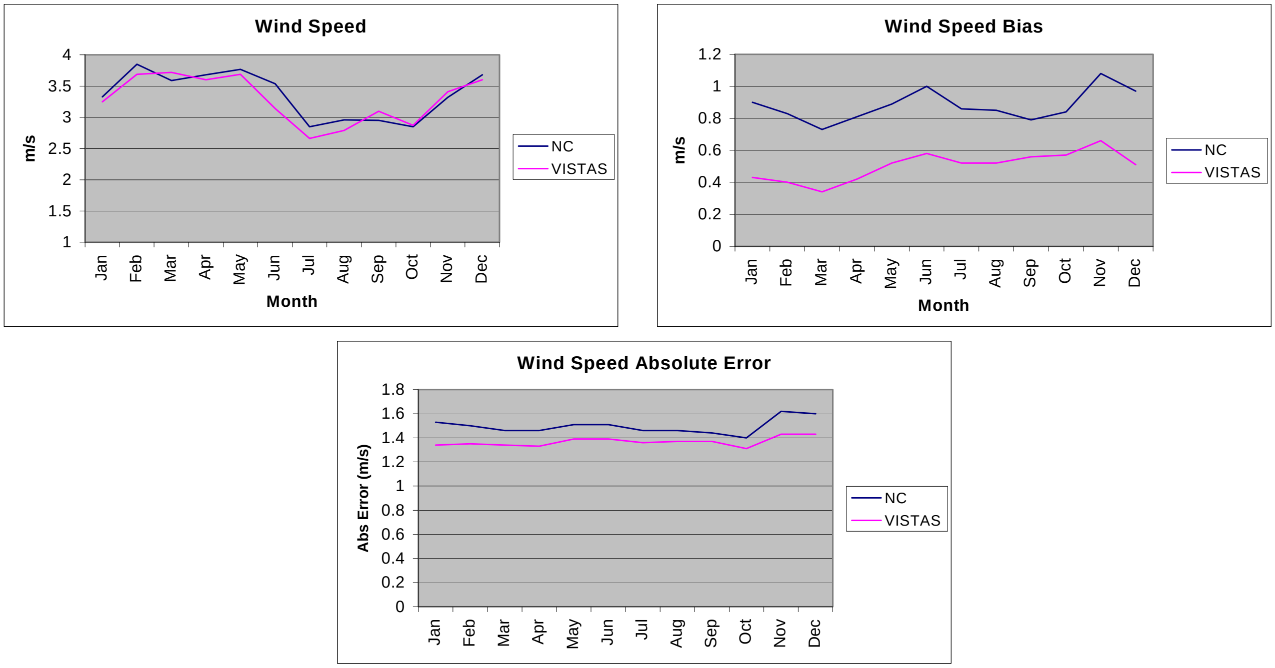

Figure 2-6 Monthly plots of modeled wind speed, bias and absolute error.

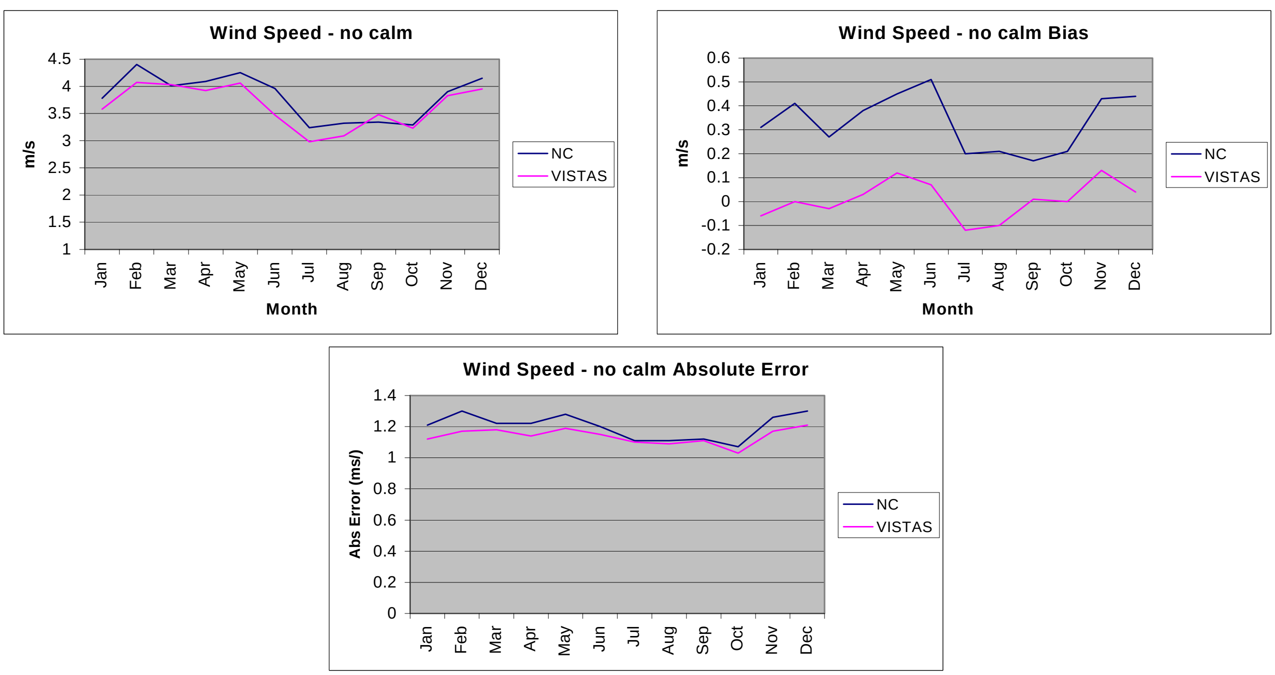

Figure 2-7 Monthly plots of modeled wind speed with calm observations omitted, bias and absolute error.

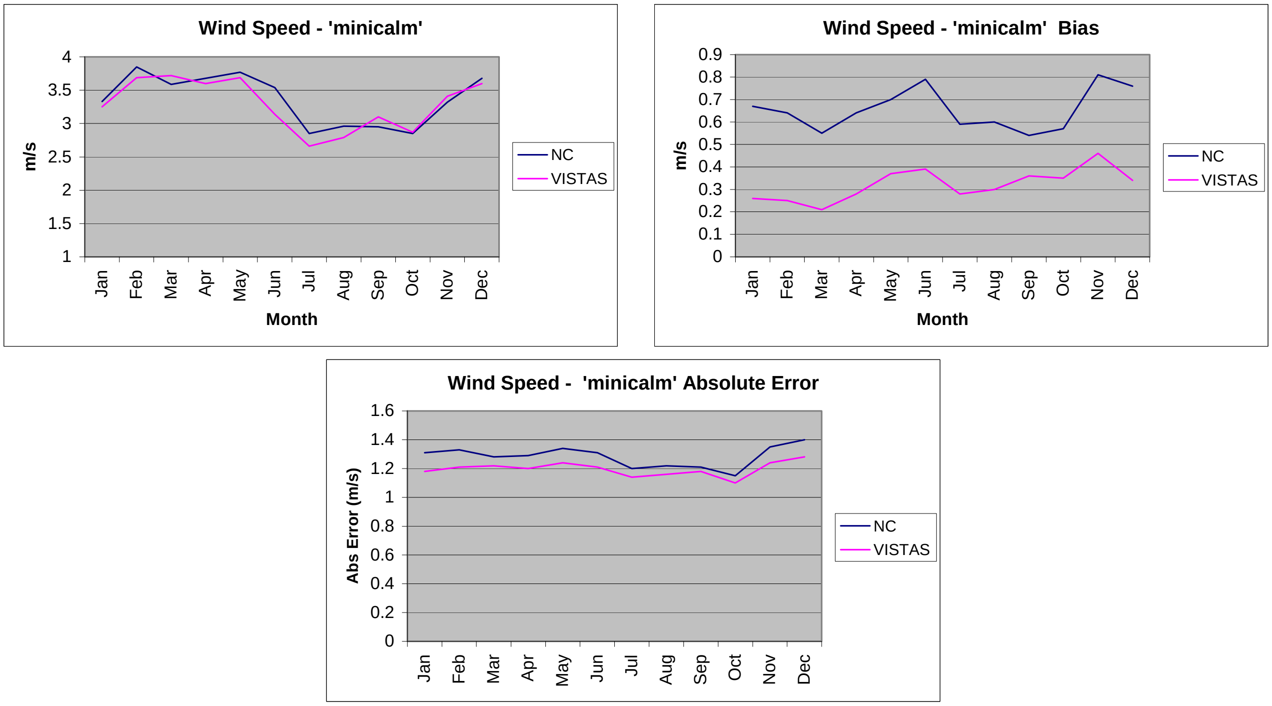

Figure 2-8 Monthly plots of modeled wind speed with modeled wind speed below 1.5 m/s omitted, bias and absolute error.

Overall excess wind speeds, increased relative humidity and cloud cover likely lead to under prediction of the daily maximum peak ozone concentration, which will be discussed in the air quality model performance (Appendix J).

3 MM5 MODEL PERFORMANCE AT GREENSBORO, NC

An additional way to evaluate model performance is to compare the various parameters to surface observations for a site-specific evaluation. Figures 3-1 and 3-2 show a time series of model and observed metrological data for the Greensboro, North Carolina Automated Surface Observing System (ASOS) site (KGSO). The time series include modeled surface values for temperature, mixing ratio, wind speed, wind direction, relative humidity, cloud cover, and precipitation (blue dashed lines). These model predicted values are compared to actual observations from the Greensboro site (solid black lines). Figure 3-1 depicts two different winter weeks (January 15-21 and November 12-18, 2002), while Figure 3-2 depicts two summer weeks (July 20-26 and August 19-25, 2002). It is important to look at both summer and winter events, as the forcing mechanisms for synoptic features can differ from season to season.

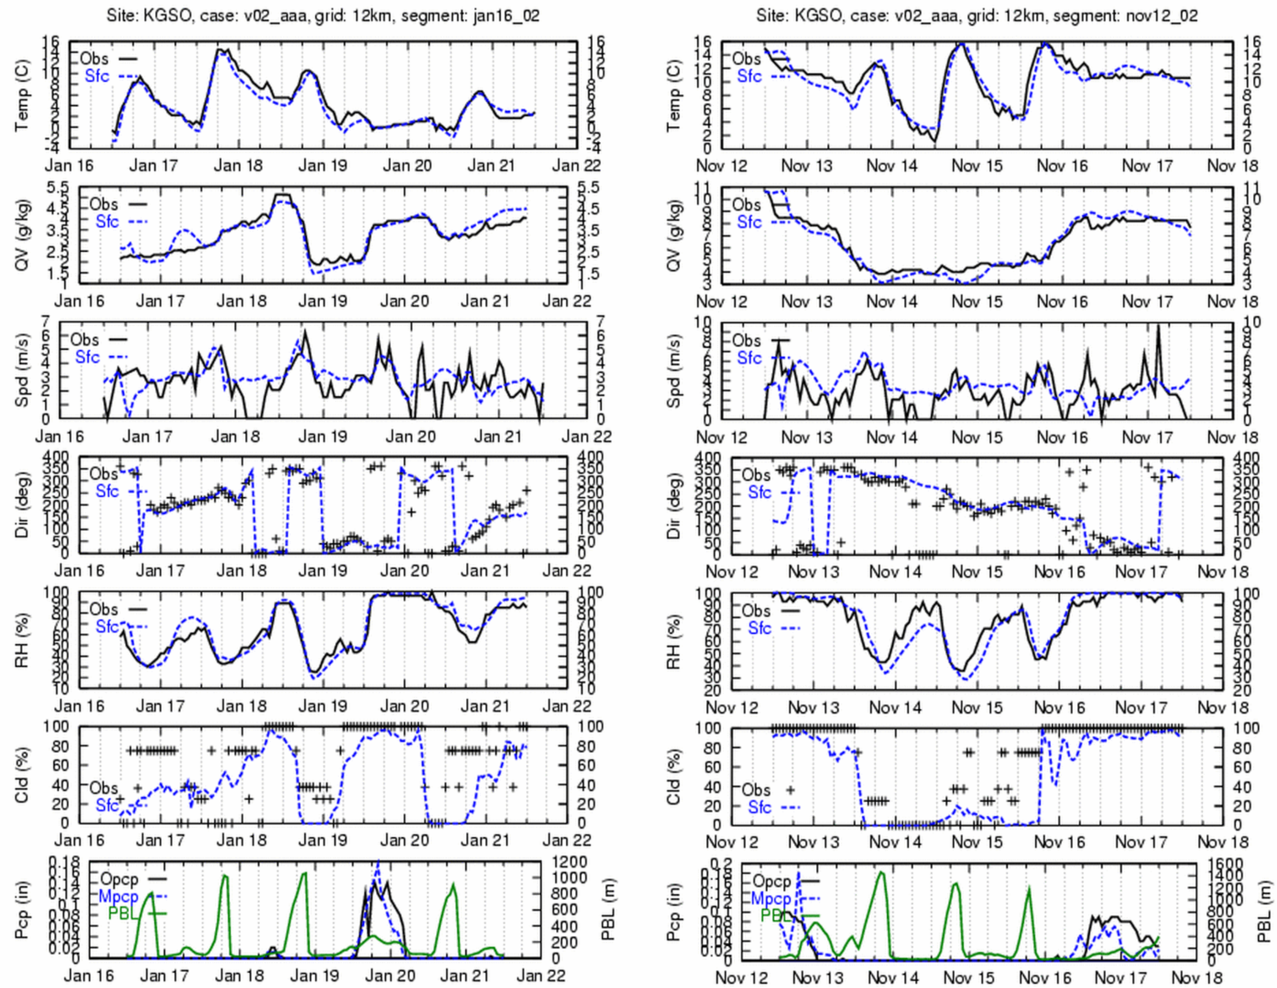

Figure 3-1 Modeled data compared to surface observations at the Greensboro, NC ASOS site (KGSO) for two weeks typical of winter conditions.

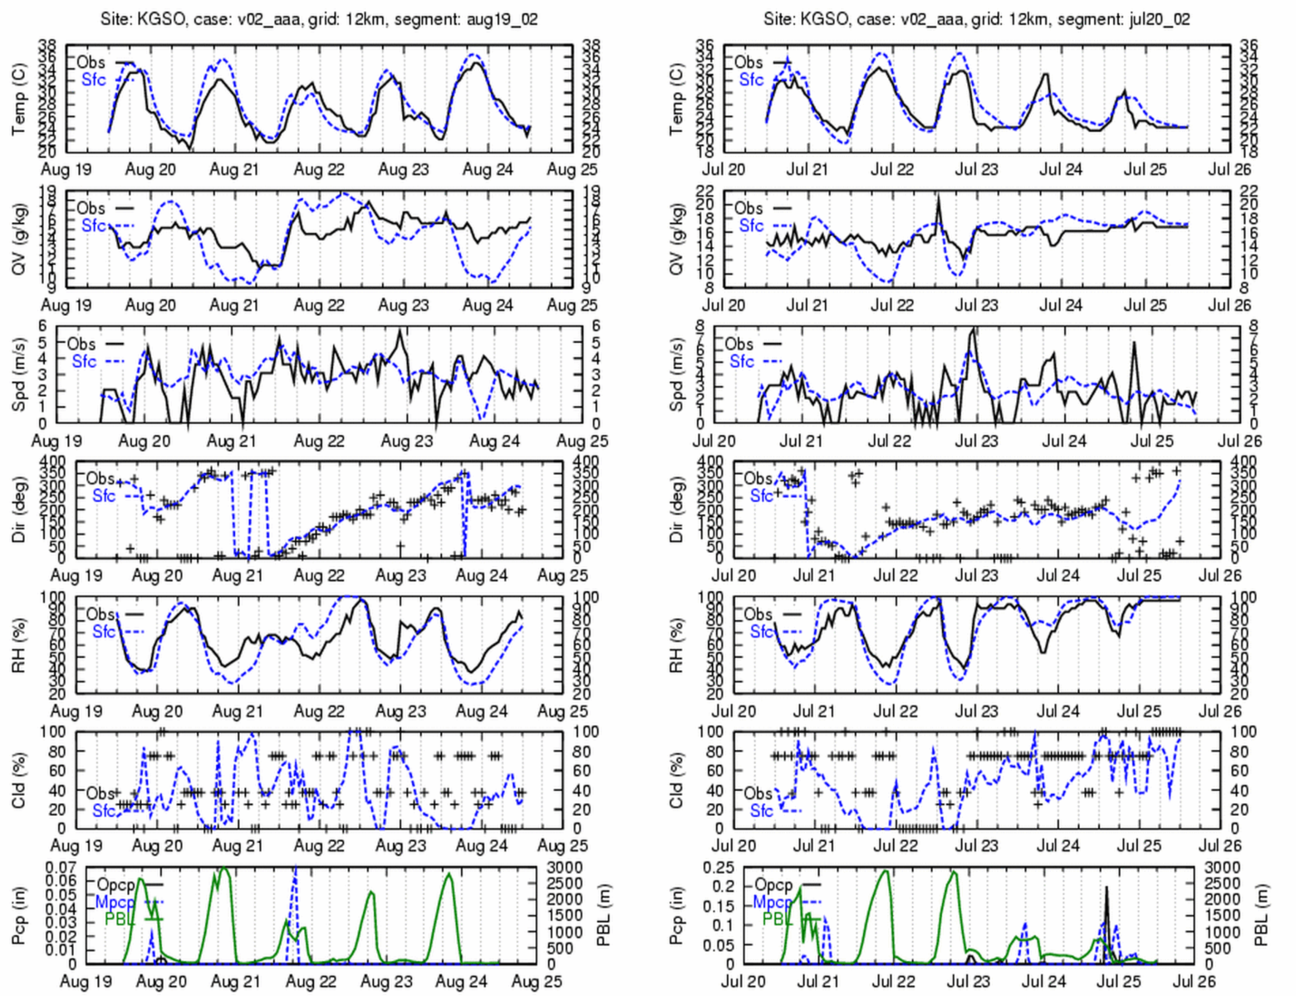

Figure 3-2 Modeled data compared to surface observations at the Greensboro, NC ASOS site (KGSO) for two weeks typical of summer conditions.

Generally the time series reflect what was seen on the monthly plots. Overall the plots reflect good model performance for 2002, when compared to modeling standards. Wind direction was close to observed values, and switched at the appropriate time, when frontal boundaries passed through the area. Wind speeds were captured well by the model during the daylight hours, but were often too strong at night.

Model performance was better at capturing the wintertime diurnal temperature trends than the summertime trends. For the summer temperatures the model was generally too cool with the afternoon high temperatures. Mixing ratio was close to observations in the winter, but, again, the model was more variable in the summertime. The diurnal trends in relative humidity were reasonably well captured, though the diurnal ranges were less in the model than with observations.

4 UPPER AIR MODEL PERFORMANCE

To go further to quantify model performance, upper air data from the model was compared to data from the Charlotte, North Carolina profiler. Figure 4-1 shows a series of profiler plots from the Charlotte, North Carolina profiler. Profilers yield results at a much finer vertical and temporal resolution than do standard rawinsondes (balloons with attached meteorological equipment used to take upper air readings). The profiler data are **not** used to nudge, or correct MM5 modeling results, and in fact cannot effectively be used in that capacity without additional quality control to remove or correct erroneous data. Since the model results will not be artificially biased toward the profiler data because of nudging and the profiler has a high data resolution, it makes an excellent source of data to judge model performance.

Figure 4-1 and 4-2 compare model predicted winds (purple wind barbs) with profiler-derived winds (black wind barbs) over the lowest 2500 meters of the atmosphere. Each plot contains 12 hours of data, with the hour of the observation labeled near the plot bottom, with the hours increasing from left to right. The wind barbs follow the meteorological standard, with a full barb representing a 10-knot (kt) wind, a half barb representing a 5-kt wind, and a full flag representing a 50-kt wind.

Figure 4-1(a) is from the period of 12 to 23 Coordinated Universal Time (UTC) on January 17, 2002, and depicts the typical wind flow pattern prior to frontal passage. Figure 4-1 (b) is 00-11 UTC on January 19, 2002, shows the disruption to the winds field as a cold front passes through the area, with Figure 4-1(c) (00-11 UTC on January 20, 2002) illustrating the northerly flow typically seen after front passage in the region. The model captures the wind direction fairly well through out the atmosphere. The model winds do become disjointed from the observations in the mid levels during the early hours of the frontal passage on the 19^{th} (Figure 4-1(b)).

Figure 4-2(a) represents the time period from 00 UTC to 11 UTC on November 10, 2002, and show the modeling capturing uniform flow through out the atmosphere. Figure 4-2(b) is from seven days later (12-23 UTC on November 17, 2002) and demonstrates the model capturing the disturbance of the uniform flow in the upper levels.

Overall, these Charlotte, North Carolina profiler plots show typical performance in that the model generally matches the profiler winds, but not perfectly. Upper levels winds are captured very well, as are the wind shifts associated with frontal passages. In the subset of days presented here, the model winds are approximately within 20 degrees of the profiler observed winds, and typically are much closer. Unfortunately, it is difficult to know if this slight wind direction bias indicates a model flaw or an issue with the profiler data being representative. It is likely that there are physical mechanisms in the real world of which the model is unaware, which in this case are not being compensated for via nudging.

5 SUMMARY

In general, the meteorological model performed quite well at the 12 km grid resolution. Most of the time the model statistics fell within the expected ranges of error. The NCDAQ believes that the meteorological model performance is adequate for this modeling exercise and should produce credible inputs for the air quality modeling for the attainment demonstration for the Metrolina area.

1 Introduction

In recent years visibility concerns have come to the forefront in the air quality community. Millions of visitors to national parks in the United States have their views obstructed by pollution-induced haze. The USEPA reports that average visibility in the east has been reduced from 90 miles to 15-25 miles (http://www.epa.gov/oar/visibility/what.html). To address this issue, the USEPA in 1999 instituted policies to improve visibility in the national parks. As part of this initiative, five multi-state regional planning organizations (RPO) were formed. The RPO governing visibility issues in the southeastern US is the Visibility Improvement State and Tribal Association of the Southeast (VISTAS) (http://www.vistas-sesarm.org/).

VISTAS recognizes the regional nature of haze, and has therefore set up a modeling approach to address the problem in the southeast US. Ultimately pollution controls will be enacted based upon chemical modeling results over the region of interest. To support this modeling effort, Baron Advanced Meteorological Systems (BAMS) is tasked with conducting the meteorological modeling. A 12-month modeling period is deemed necessary to cover an adequate range of visibility impairment. Prior to investing the resources to produce meteorological results at 36-km and 12-km resolution for the full 12-month period, BAMS executed a series of sensitivity tests to determine the optimal meteorological setup for the annual modeling. This report details the results from this sensitivity testing, leading directly to the protocol we will use for this project.

2 Description of the Meteorological Modeling Approach

The meteorological model used in this study is the PSU/NCAR Mesoscale Model (MM5 version 3.6, Grell et al., 1994, MPP version). In order to build on prior relevant MM5 modeling results funded by the EPA and other RPOs, those studies serve to establish the initial model configuration for this effort, as best can be determined from available reports. Those findings are summarized in Olerud, 2003a. The modeling results indicate that MM5 is most sensitive to the selection of planetary boundary layer (PBL) and soil schemes. Therefore a series of sensitivity tests are recommended in Olerud, 2003b. Given limited time and budget resources, a series of five sensitivity tests are laid out testing primarily the model response to the selection of PBL scheme and soil model. These are the tests:

- **px_acm**: Pleim-Xiu land surface model, asymmetric convective mixing PBL (Xiu and Pleim, 2000), interppx to link runs.
- **px_acm2**: Like px_acm, except no interppx linkage.
- **noah_mrf**: Noah land-surface scheme (Chen and Dudhi, 2001) with the medium range forecast (mrf) PBL (Hong and Pan, 1996).
- **multi_blkdr**: Multi-layer soil scheme with Blackadar PBL and Zilitinkevich thermal roughness length.
- **noah_eta-my**: Noah land-surface scheme with the ETA Mellor-Yamada PBL (IMVDIF=0).

The common options for all sensitivity tests include Kain-Fritsch 2 cumulus parameterization (Kain and Fritsch, 1993; Kain, 2002), mixed phase (Reisner 1) microphysics (Reisner et al, 1998), and Rapid Radiative Transfer Model (RRTM) radiation (Mlawer et al, 1997). Snow effects are turned on (IFSNOW=1). Note that the use of the ETA M-Y pbl scheme necessitates moist vertical diffusion being turned off. The runs are made with analysis nudging coefficients set as follows (36-km and 12-km resolutions):

Winds (aloft):	2.5E-4,1.0E-4,
Winds (surface):	2.5E-4,1.0E-4,
Temp (aloft):	2.5E-4,1.0E-4,
Temp (surface):	Not employed
Moisture (aloft):	1.0E-5,1.0E-5
Moisture (surface):	Not employed

In the cross-sensitivity plots that follow we compare the px_acm2 sensitivity run to the noah_mrf, multi_blkdr, and noah_eta-my sensitivities for episode 1. Episodes 2 and 3 are similar except px_acm will serve as the base configuration.

The runs are executed in 2-way mode with feedback turned off. The five sensitivity runs are executed for three separate episodes listed below:

- Episode 1: January 2-21, 2002
- Episode 2: July 13-28, 2001
- Episode 3: July 13-22, 1999.

Each episode is preceded by a spin-up period (7, 7, and 4 days, respectively) that will not be discussed in this report. The runs are made in 5.5-day segments, each starting at 00 UTC, with the first 12 hours of each segment serving as spin-up. Figure 1 shows the modeling domains used in this study.

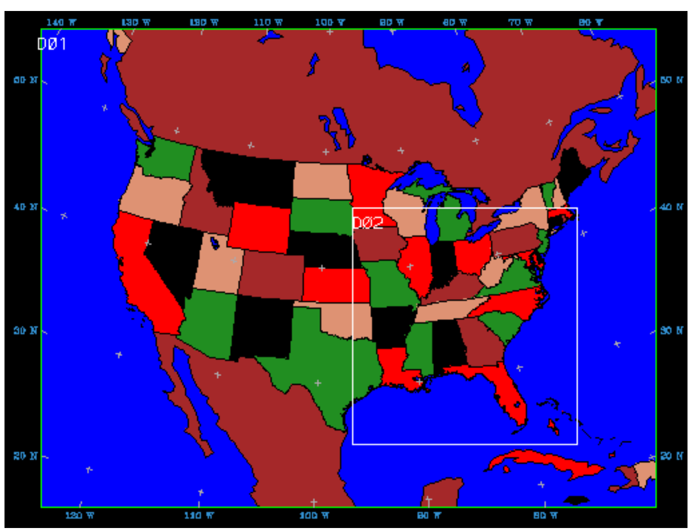

Figure 1. VISTAS 36-km/12-km MM5 modeling domains are shown.

3 Evaluation Approach

It is common in the air quality community to use surface statistics of the base meteorological variables as the dominant metrics to determine acceptable model performance. Often statistics for only temperature, mixing ratio and wind speed are calculated. Obviously it is important for the model to accurately represent these variables, but there are additional variables that also become important when one considers that the results will be used to improve visibility. As such we have added cloud cover, relative humidity, and precipitation to the performance suite. While we calculate metrics separately for wind direction and wind speed, we also calculate the mean error vector as perhaps the single best metric to quantify overall wind performance.

Recognizing that qualitative analyses of the model output are as important as standard quantitative analyses, we enable the systematic visualization of model fields with observations overlaid whenever possible. To do this we process the MM5 output through EPA's MCIP2 program. MCIP2 transforms the data into NetCDF format while also calculating a few fields (e.g. low, middle, and high CFRAC) that are not readily available in the raw MM5 output. MCIP2 also interpolates temperature and wind speed to observation height (1.5m and 10m, respectively) for more accurate evaluation. Even though MCIP2 outputs a total cloud fraction, CMAQ uses this quantity to estimate optical depth. Accordingly its value can be markedly different than what meteorologists typically regard as cloud fraction. To make things as consistent as possible between the model and observations, the cloud fractions presented in this report represent the maximum of the low, middle, and high cloud fractions. We also use MCIP2 to cull a minimum of six cells about the domain periphery to minimize edge effects. The reduced domain precisely matches the domain used in the air quality modeling. The 36-km analysis domain thus contains 148 columns, 112 rows, and 34 layers. The 12-km analysis domain covers 168 columns, 177 rows, and 34 layers.

The observations used for statistics come primarily from UCAR's ds472.0 (TDL) archive (http://dss.ucar.edu/datasets/ds472.0/). These data are quality controlled and converted to NetCDF format, thus allowing the data to be visualized on the model fields via PAVE (http://www.cep.unc.edu/empd/EDSS/pave_doc/index.shtml). Unfortunately the precipitation values in this dataset are not reliable, so we calculate precipitation statistics based on the 24-h gridded accumulations available from the Climate Prediction Center (CPC) (http://www.cpc.ncep.noaa.gov/products/precip/realtime/retro.html). These fields, originally at 0.25- degree resolution, undergo grid transformation to match our 36-km and 12-km domains. Since the CPC analyses are derived primarily from rain gauges, the statistics are only calculated over cells that MM5 deems to be land.

For aloft analyses we process standard sounding observations from the NCEP ds353.4 archive (http://dss.ucar.edu/datasets/ds353.4/). These observations are quality controlled and used to produce model/observation skewT sounding plots for selected sites. Additionally we integrate the observations into sigma levels that match the MM5 specifications, after which we can statistically analyze performance at sigma levels 9, 17, and 22 (~500m, ~1600m, ~3400m, respectively). Qualitative profiler plots showing model/observed hourly winds are also created based upon the data stored at the Forecast Systems Lab (http://www.profiler.noaa.gov/jsp/). These results, along with much more, will not be presented here. The reader is referred to the VISTAS meteorological website (http://www.baronams.com/projects/VISTAS/) for additional evaluation details and results.

The number of analysis plots available on the above website is truly daunting. To keep this report at a somewhat manageable level, we will focus primarily on cross-sensitivity plots and surface statistics. Except for precipitation (as mentioned above), these statistics are calculated at the sites (color-coded by RPO) shown in Figure 2. Statistics are calculated and stored at each observing site, and we routinely aggregate these results to produce statistical time series plots and tables for every appropriate RPO region. This approach also enables us to produce station-specific statistical quantities that can be plotted in a similar manner to Figure 2. The VISTAS web page even shows an animation of how these quantities change throughout an episode-composite day. The results shown in this document focus on statistics aggregated only over the VISTAS portion of the 12-km domain, and the US portion of the 36-km domain. The cross-sensitivity plots are shown only for the 12-km VISTAS domain.

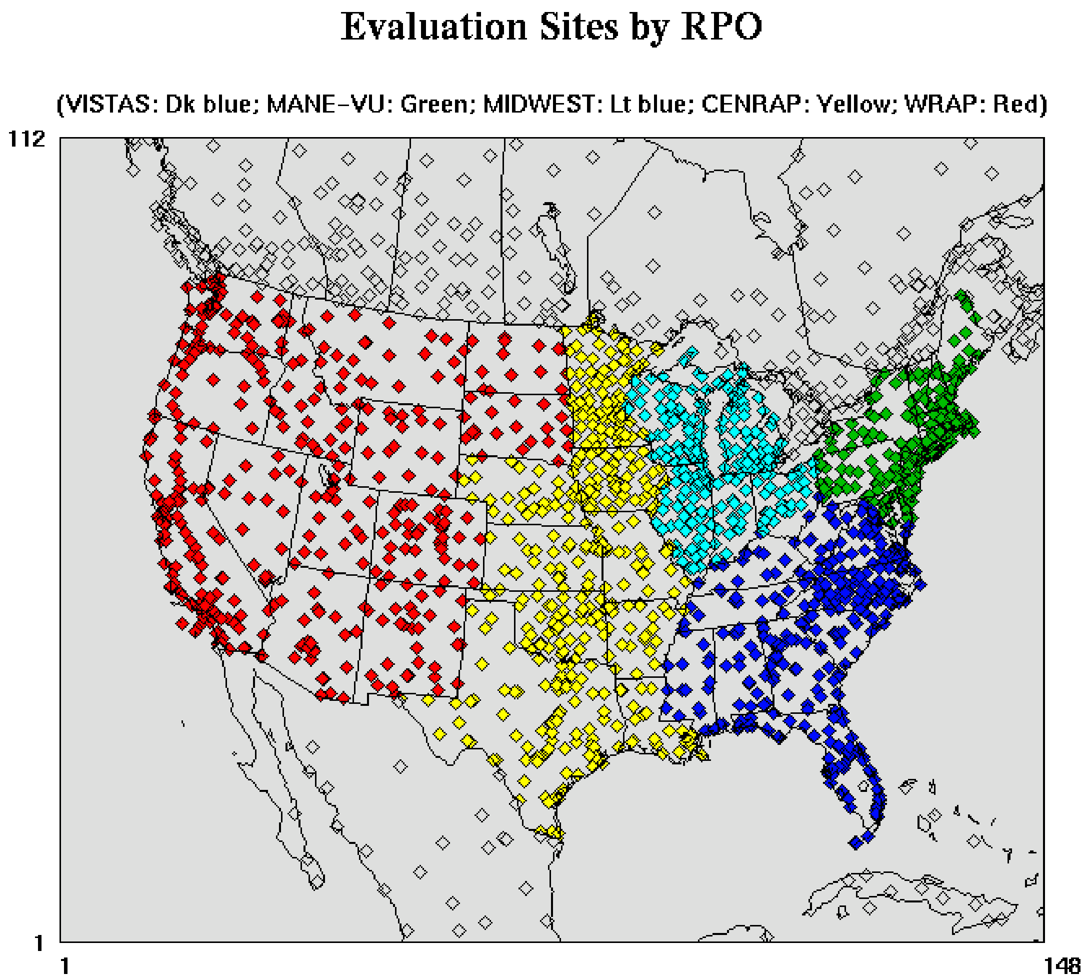

Figure 2. Surface observing network color-coded to represent Regional Planning Organization areas. Dark blue diamonds are in the VISTAS RPO, green diamonds are in the MANE-VU RPO, light blue diamonds are in the MIDWEST RPO, yellow diamonds are in the CENRAP RPO, and red diamonds are in the WRAP RPO.

4 Results

The initial results for the px_acm run for episode 1 are quite discouraging. The run showa a significant cold bias over much of the eastern US, including the VISTAS region as illustrated in figure 3. While mixing ratio, clouds, precipitation, and winds are modeled reasonably well, the large cold bias is unexpected based on prior findings from other RPO's and the EPA. Note in figure 3 that the first couple of days show very little temperature bias, but the bias increases as the mean temperature rises. After much investigation it becomes apparent that the deep soil temperature is initiated during an extreme cold event in the eastern US. Since the model soil temperatures and moisture are passed from one model segment to another via the interppx preprocessor, the cold soil acts as a continuous drag on the atmosphere that the model physics can never quite overcome.

The bias problem is significantly reduced by simply running each model segment independently, thus limiting the cold drag to actual cold conditions. Figure 4 shows the statistical time series for this new case, px_acm2. This px_acm2 configuration will henceforth be considered the base case episode 1 for cross-sensitivity purposes, while px_acm will be used for episodes 2 and 3. For the statistical difference tables that make up the bulk of the table portion of this document, we employ px_acm2 as the de facto base case.

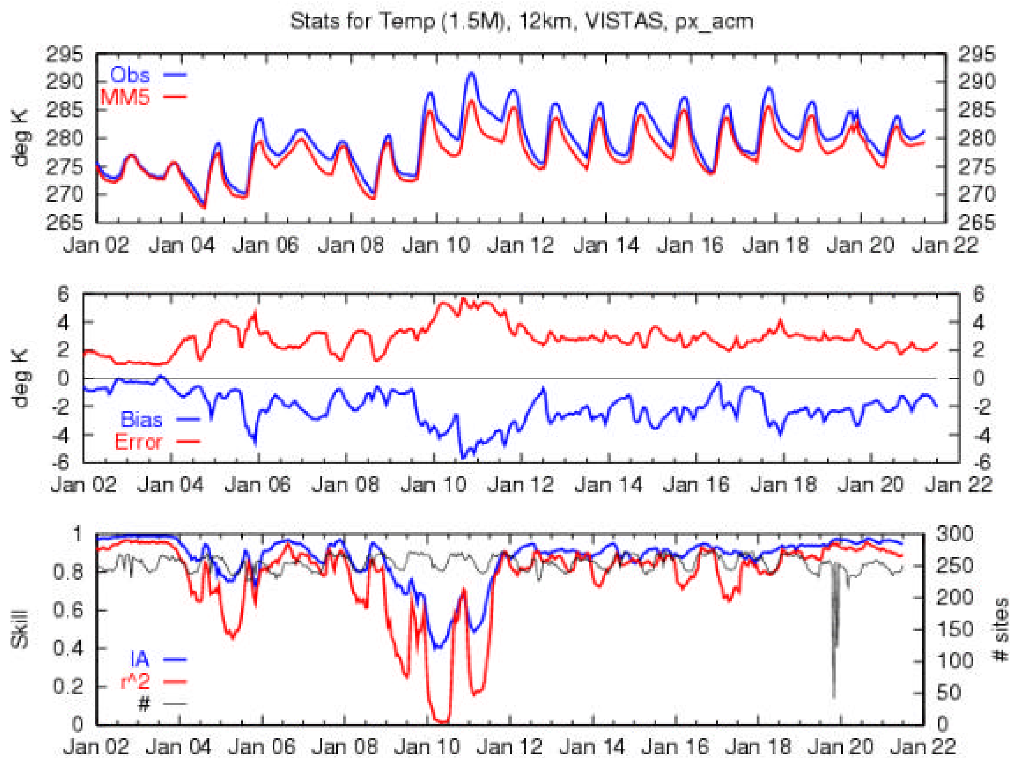

Figure 3. Episode 1 temperature (1.5 m) statistical time series plot for the 12-km VISTAS region, px_acm sensitivity. The top panel shows the mean of the observations (blue) and the model (red), the middle plot shows the model bias (blue) and the absolute error (red), while the bottom plot shows the index of agreement (blue) and coefficient of determination (red).

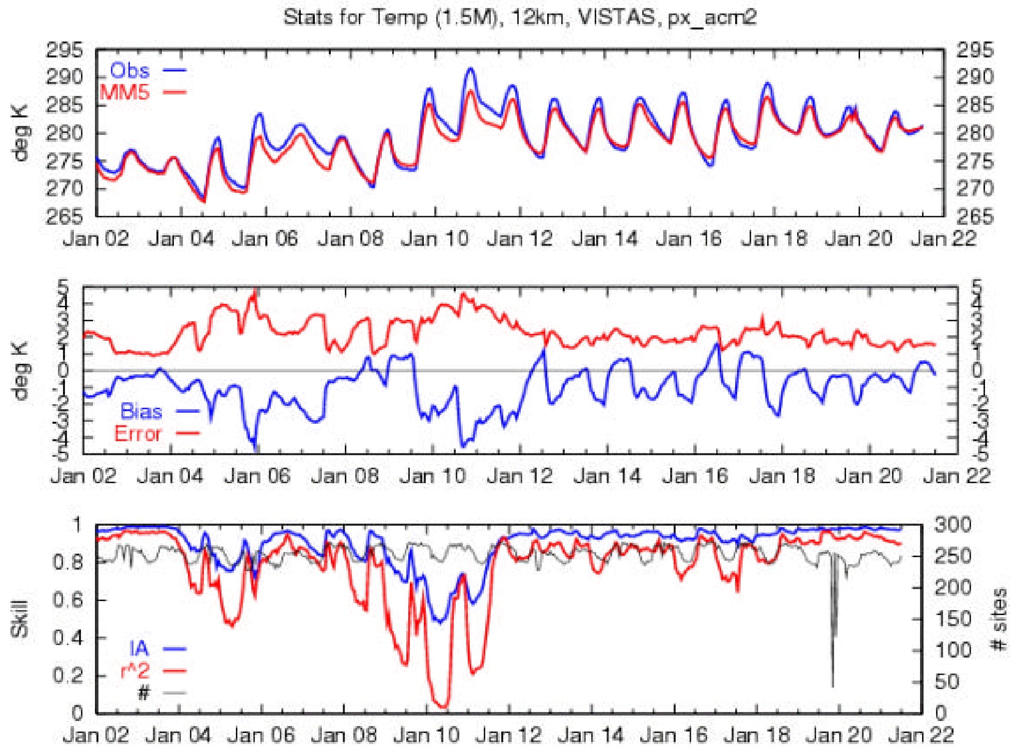

Figure 4. Episode 1 temperature (1.5 m) statistical time series plot for the 12-km VISTAS region, px_acm2 sensitivity. The top panel shows the mean of the observations (blue) and the model (red), the middle plot shows the model bias (blue) and the absolute error (red), while the bottom plot shows the index of agreement (blue) and coefficient of determination (red).

Figure 5 shows the daytime PBL heights for January 10, 2002 at 12-km resolution over the VISTAS region. It should be noted that the noah_eta-my PBL heights can erroneously become negative over small spatial areas; we set all such negative values to zero before averaging. Due to the small areal extent of these negative PBL values, we do not anticipate any qualitative assessments to be affected by those artifacts. The January 10, 2002 PBL heights are rather typical of winter PBL heights. The noah_mrf heights are significantly higher and smoother than those in the other sensitivities. Generally speaking, the noah_eta-my daytime PBL heights are lower than they are in the other sensitivity runs. The px_acm2 heights tend to be more in the middle of those extremes, though they also "bottom out" more than the other runs.

Figure 6 shows the cross-sensitivity daytime precipitation plot for this same day. The low PBL heights in the px_acm2 run are closely correlated to precipitation in the Ohio Valley, while melting snow and clouds (figure 7) might inhibit mixing over the northern Mid-Atlantic States.

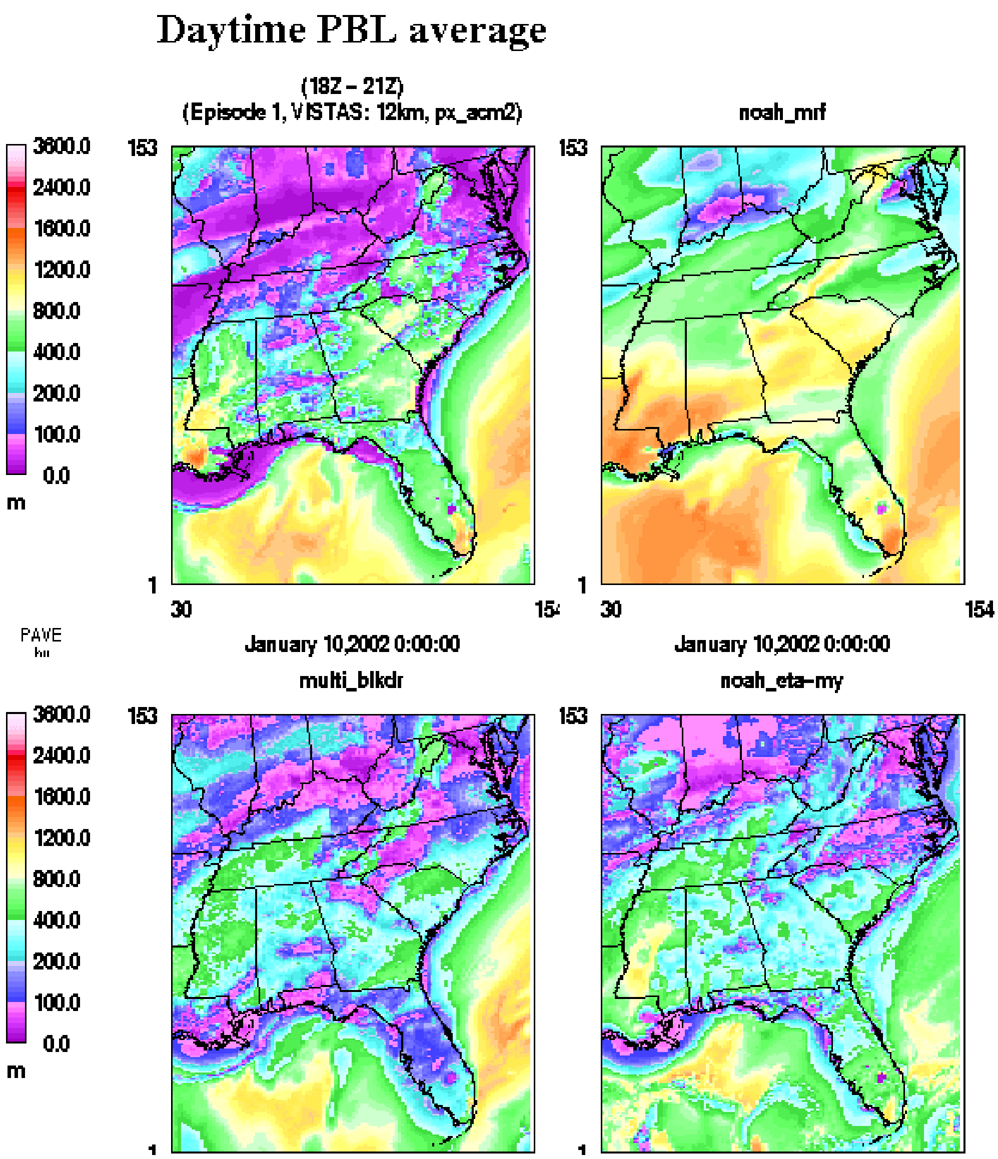

Figure 5. Daytime (18-21 UTC) average PBL heights for the 12-km VISTAS region for January 10, 2002 are displayed. The px_acm2 sensitivity is shown in the upper left, the noah_mrf in the upper right, the multi_blkdr in the lower left, and the noah_eta-my in the lower right. Note that the time value (0:00:00) is only a placeholder and has no physical meaning.

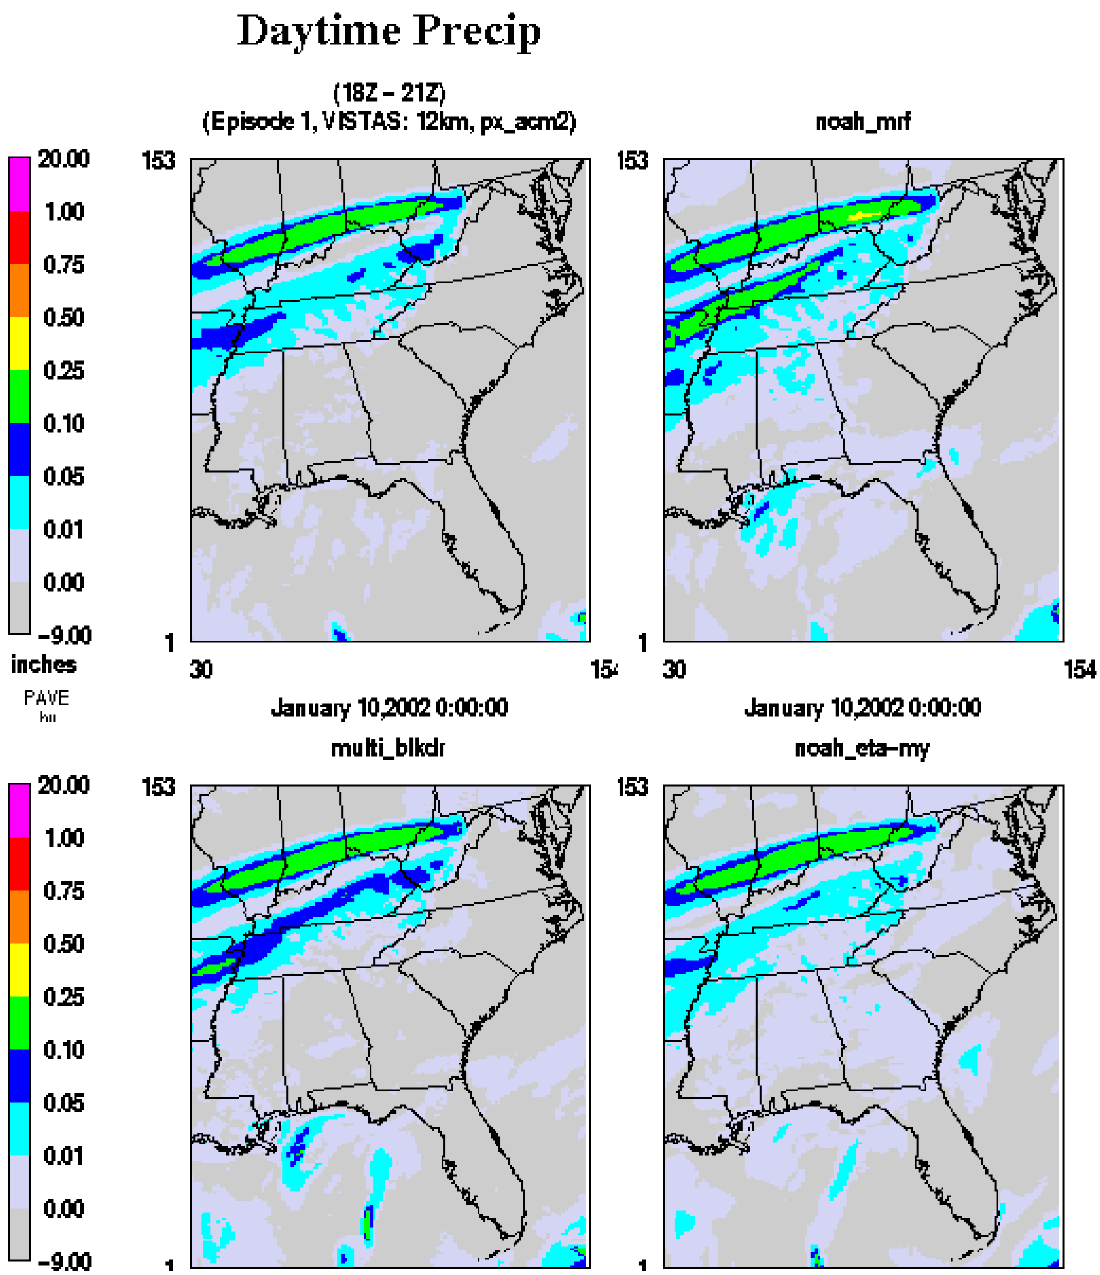

Figure 6. Like figure 5, except for precipitation.

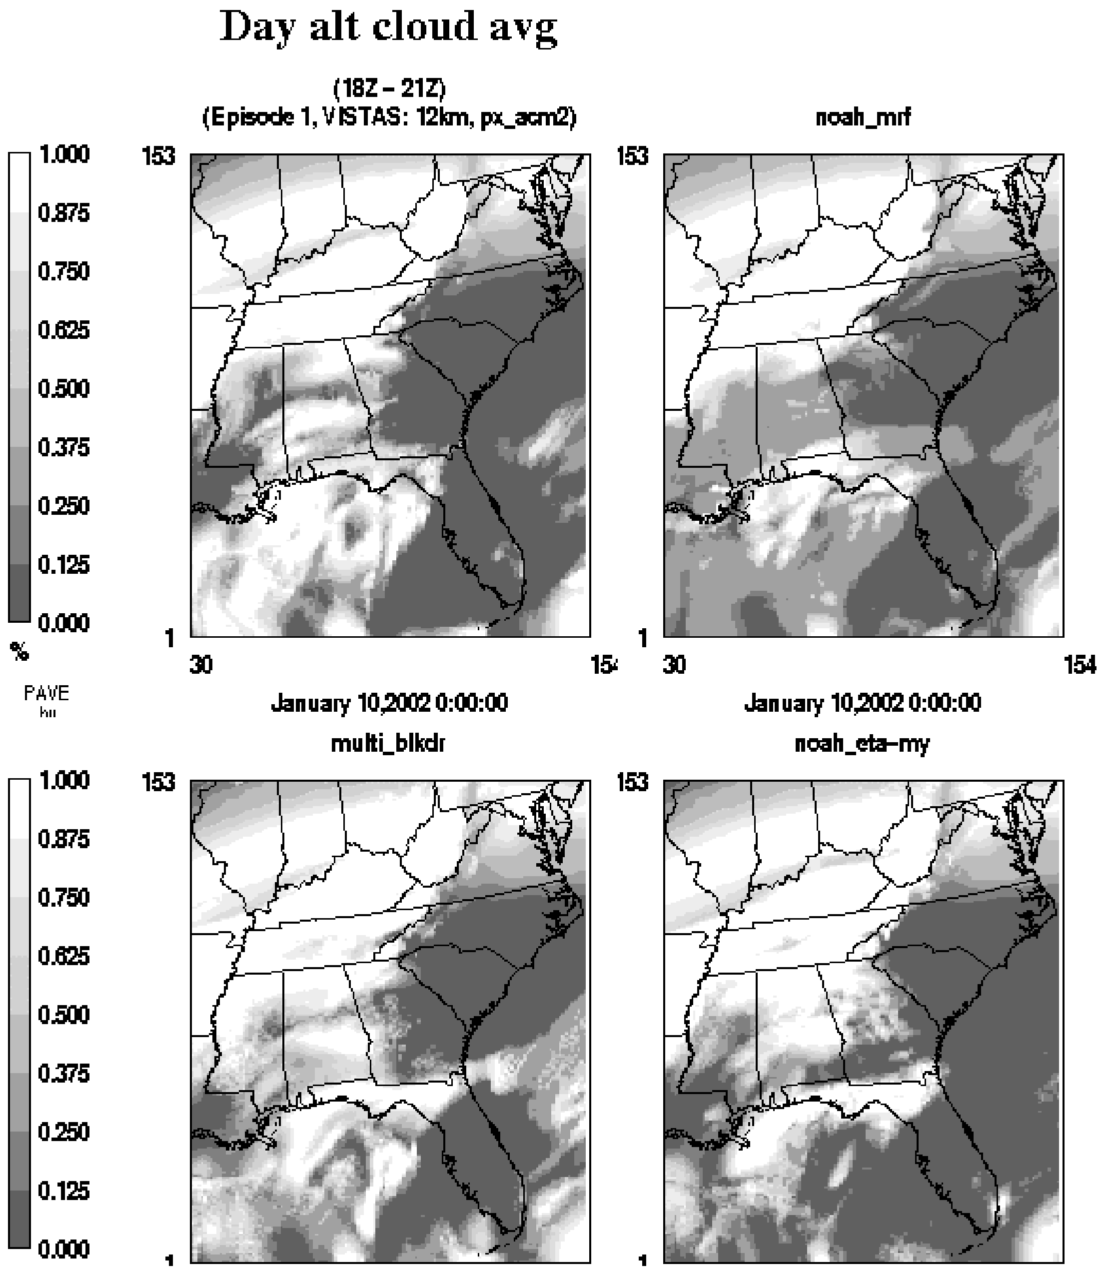

Figure 7. Like figure 5, except for cloud coverage.

Figure 8 shows the daily average temperature for this same day. Note that the px_acm2 case is generally warmer than the other cases, while the noah_eta-my run is the coldest. Figure 9 shows that for daily averaged mixing ratio the patterns are very similar for all runs. The combination of warmer daytime temperatures and similar mixing ratios results in lower daytime relative humidity for the px_acm2 case compared with the other sensitivity runs (figure 10). Finally, figure 11 shows that the daytime wind speeds are similar in all cases.

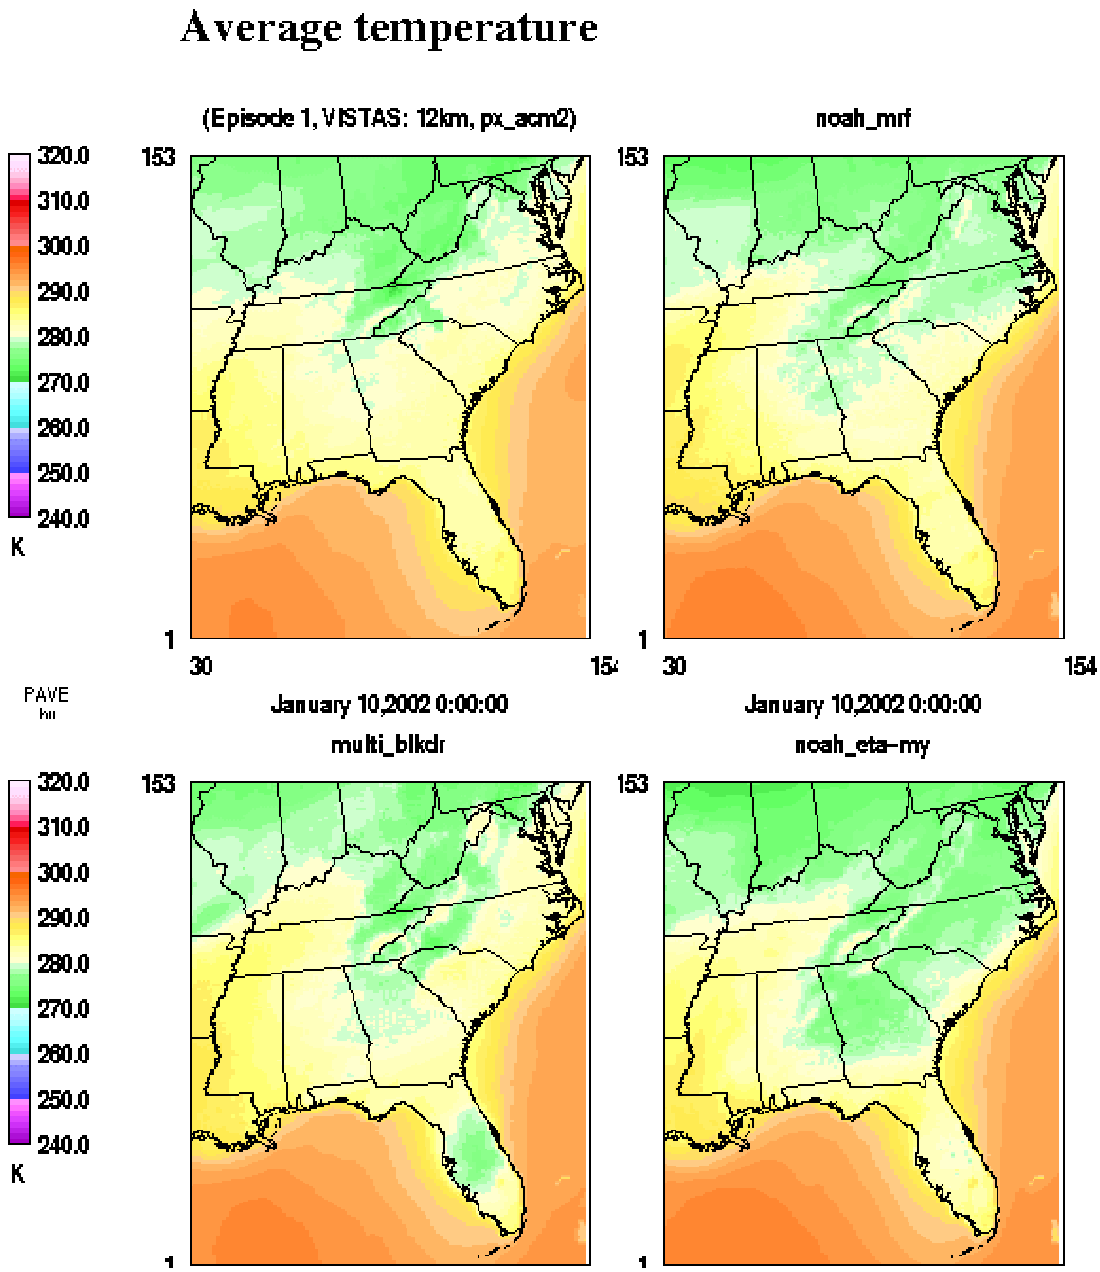

Figure 8. Like figure 5, except for daily average temperature.

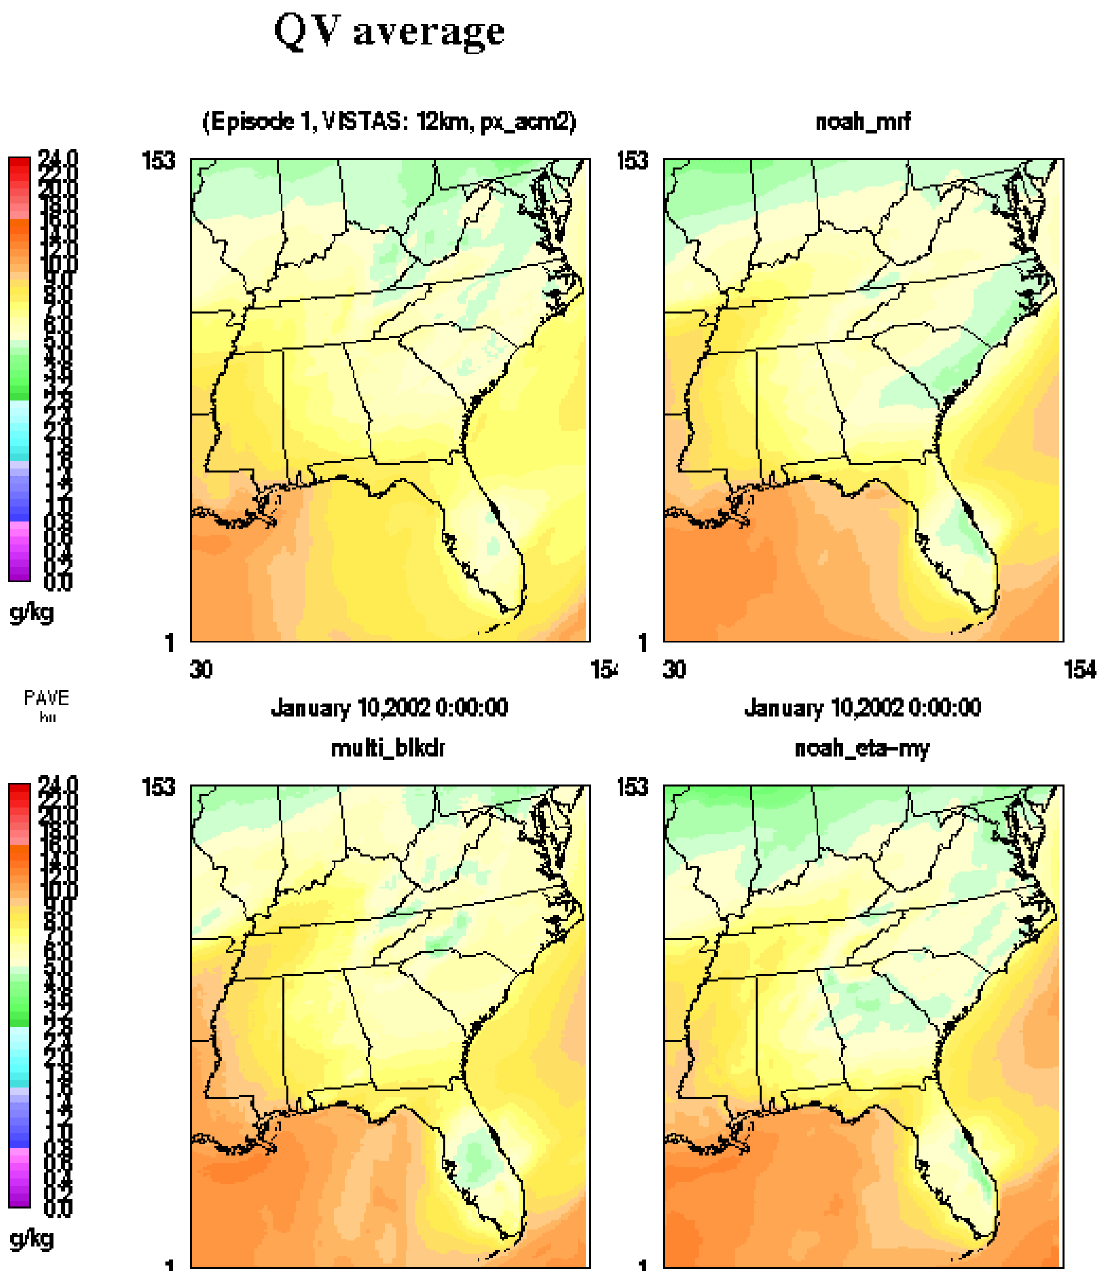

Figure 9. Like figure 5, except for daily average temperature.

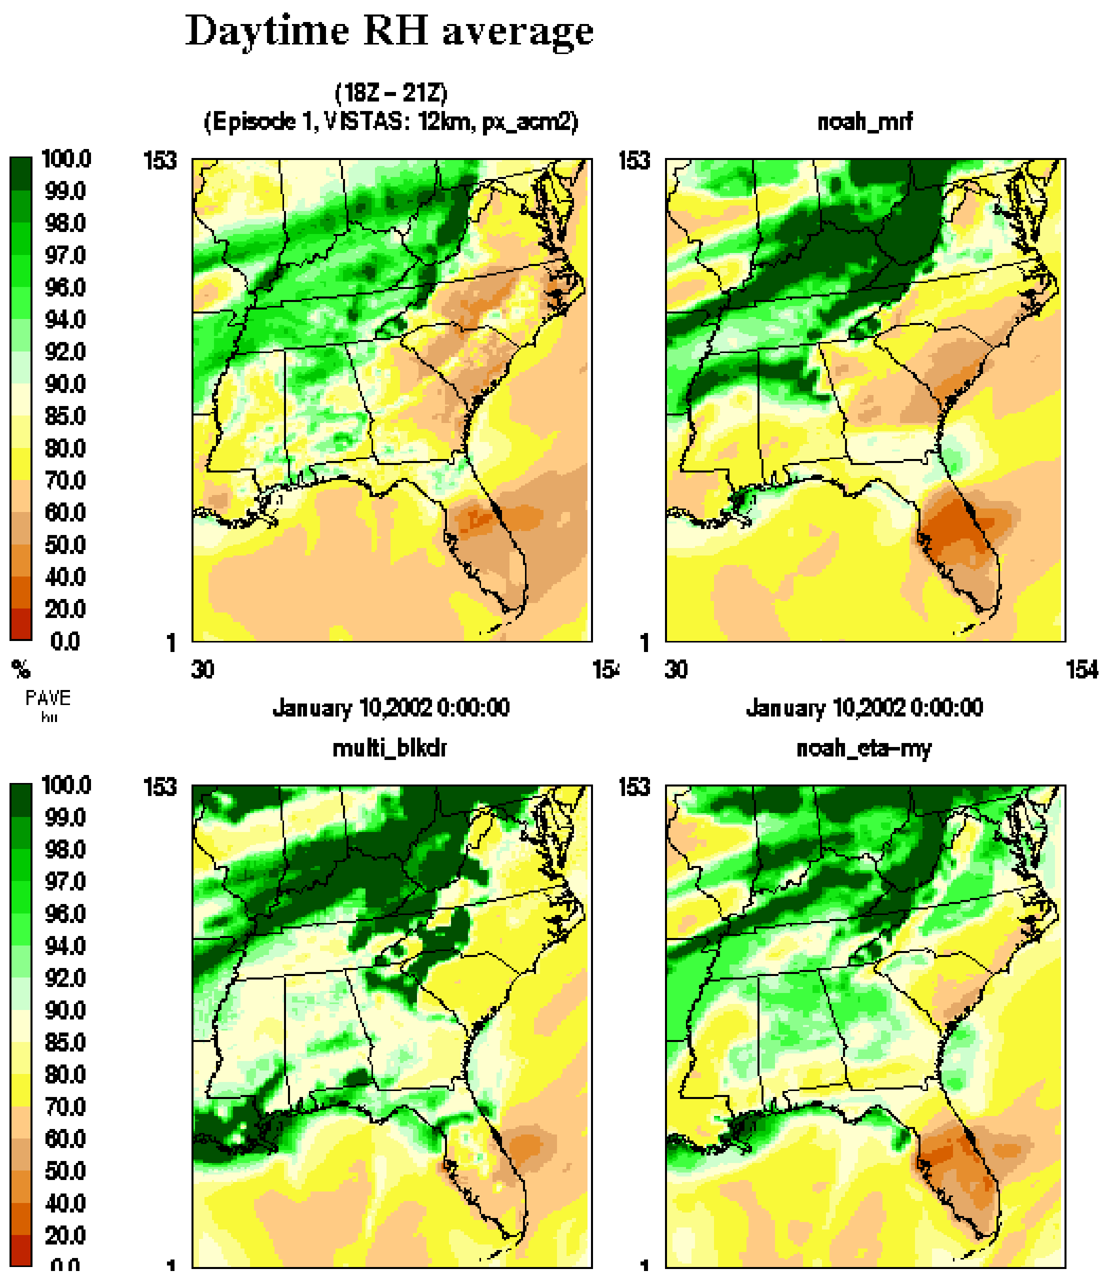

Figure 10. Like figure 5, except for relative humidity.

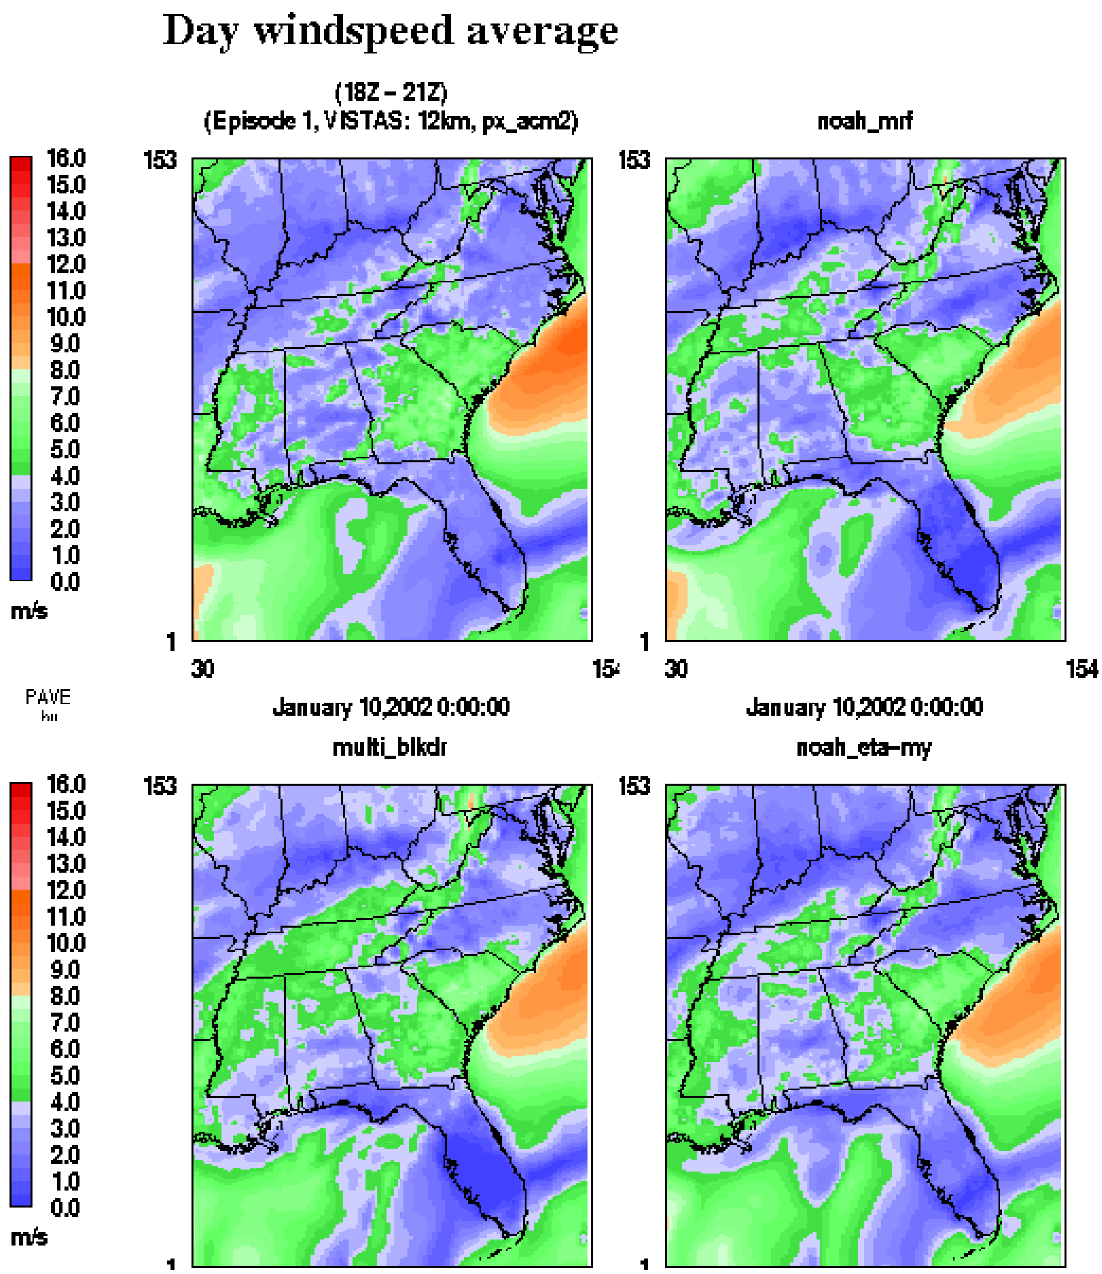

Figure 11. Like figure 5,except for wind speed.

Traditionally nighttime PBL heights have not been considered very important for air quality modeling, but they certainly may be for visibility/particulate modeling. Figure 12 shows the nighttime (07-10 UTC) PBL heights for January 10, 2002. Notice that the px_acm2 produces lower PBL heights than the rest of the sensitivity cases do, thus trapping surface-based emissions in a smaller volume of air than would occur in another MM5 configuration. The noah_mrf run again produces the highest PBL heights at night, while the multi_blkdr and noah_eta-my runs are somewhere in the middle.

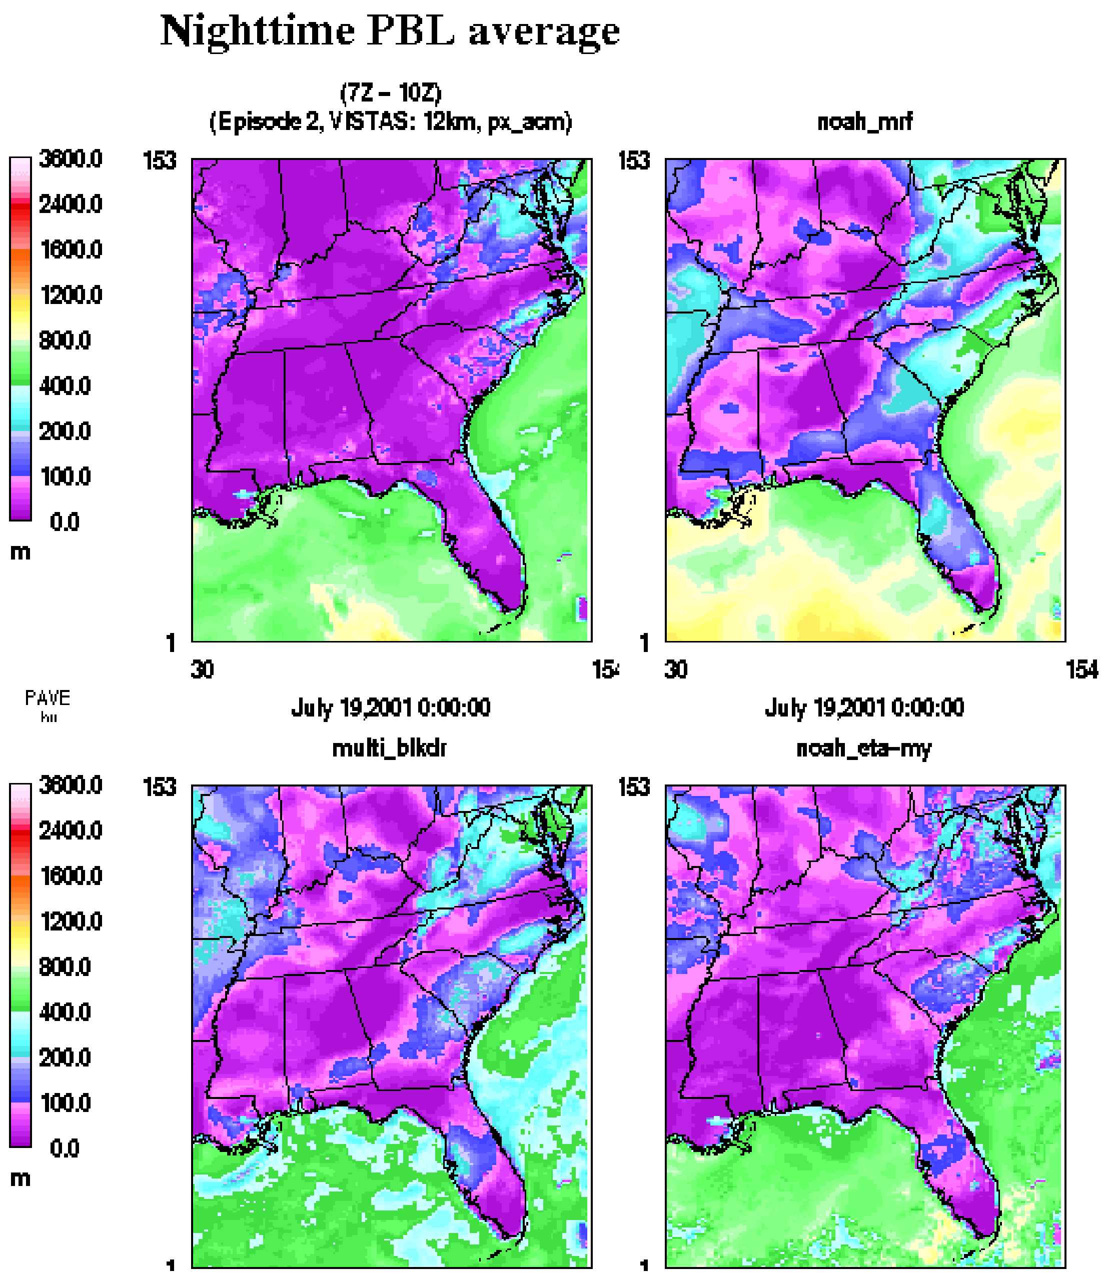

Figure 12. Nighttime (07-10 UTC) average PBL heights for the 12-km VISTAS region for January 10, 2002 are displayed. The px_acm2 sensitivity is shown in the upper left, the noah_mrf in the upper right, the multi_blkdr in the lower left, and the noah_eta-my in the lower right. Note that the time value (0:00:00) is only a placeholder and has no physical meaning.

Nighttime cloud cover is shown in figure 13. The most striking observation from this figure is the cloud deck over Tennessee in the noah_eta-my run that does not exist to the same extent in the other sensitivity runs.

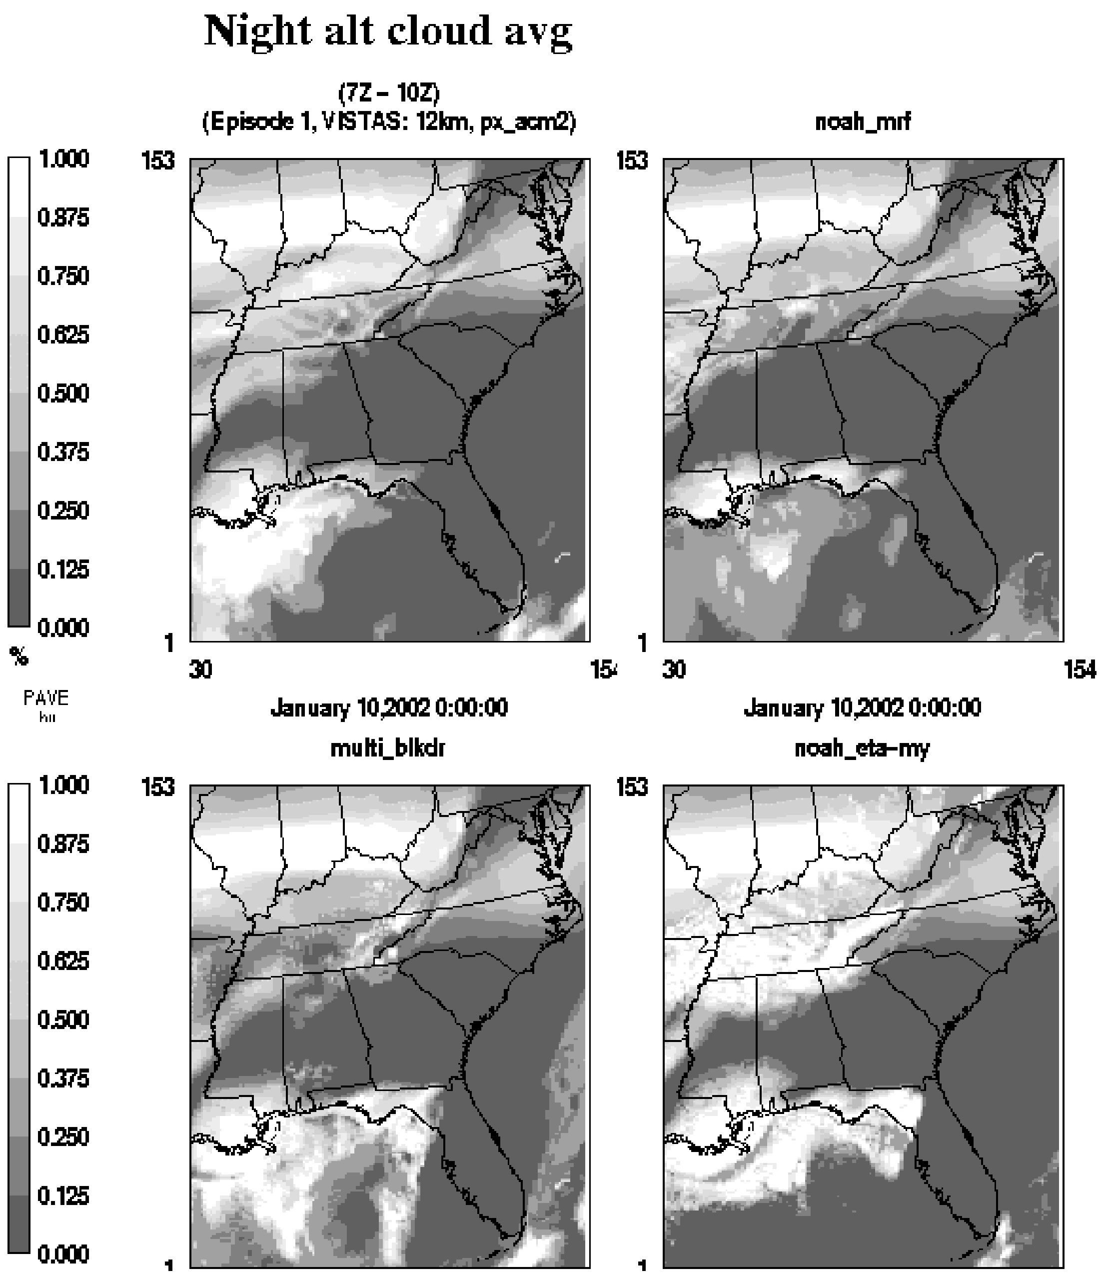

Figure 13. Like figure 12, except for cloud cover.

Figure 14 shows the nighttime relative humidity plot. One might expect that the px_acm2 case would show the highest relative humidity, given the low PBL heights as indicated by figure 12. The opposite is actually the case. The warmer temperatures in this run counteract the increased stability such that the relative humidity values are the lowest of all the runs. The noah_eta-my run easily exhibits the highest relative humidity.

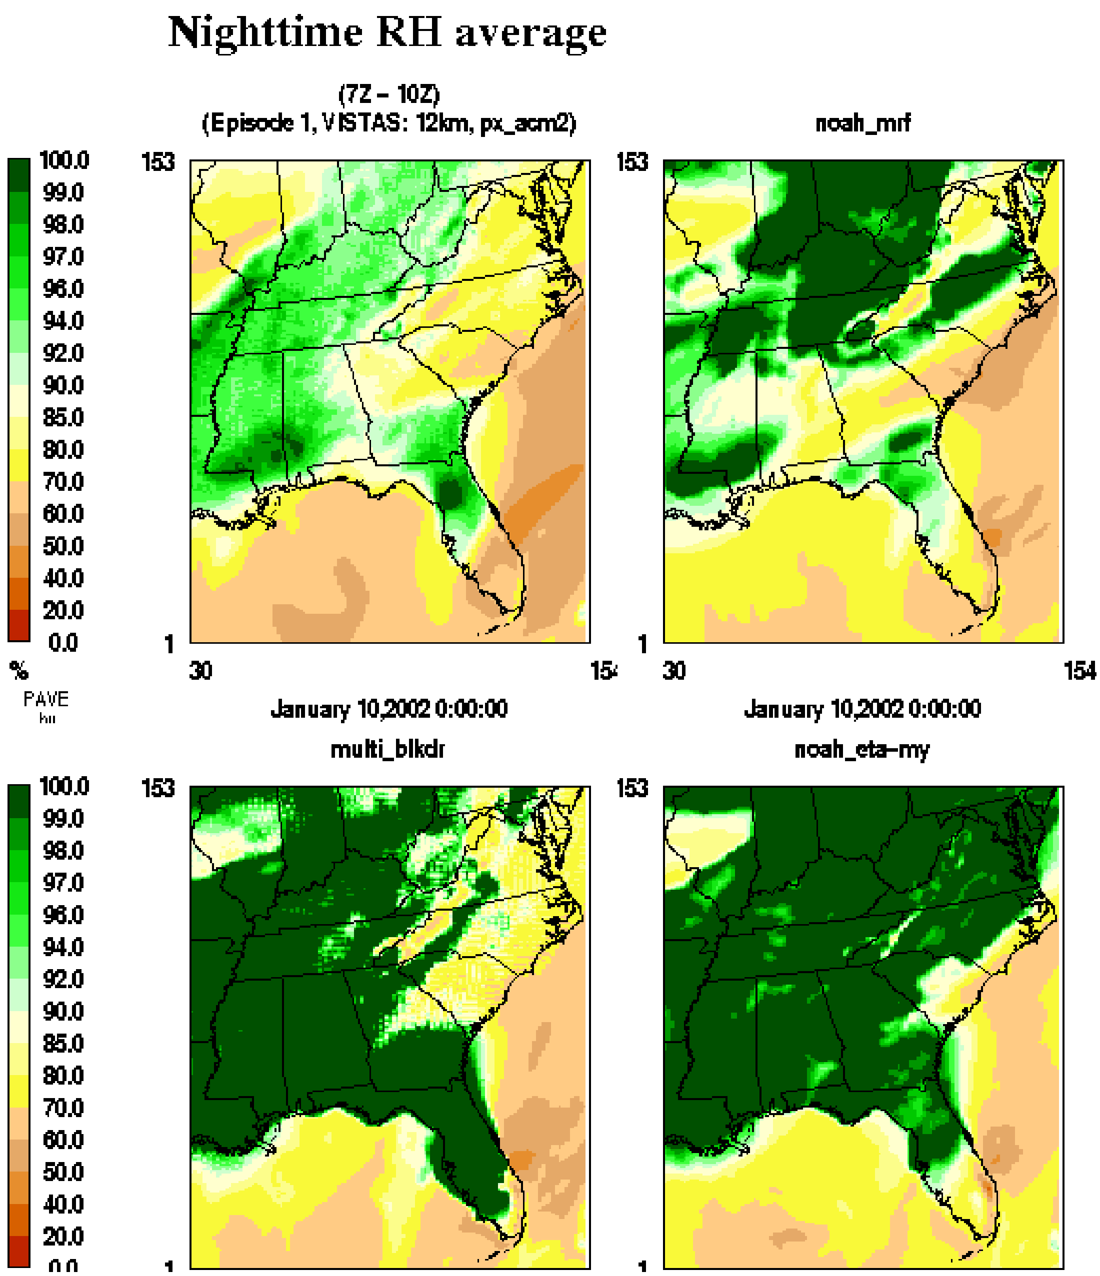

Figure 14. Like figure 12, except for relative humidity.

Figure 15 shows the nighttime wind speed. Speeds are lowest in the noah_eta-my run, followed by px_acm2, noah_mrf, and multi_blkdr. In fact, the latter two cases seem to show an inappropriate diurnal pattern in that their nighttime wind speeds are higher than their daytime wind speeds (figure 12).

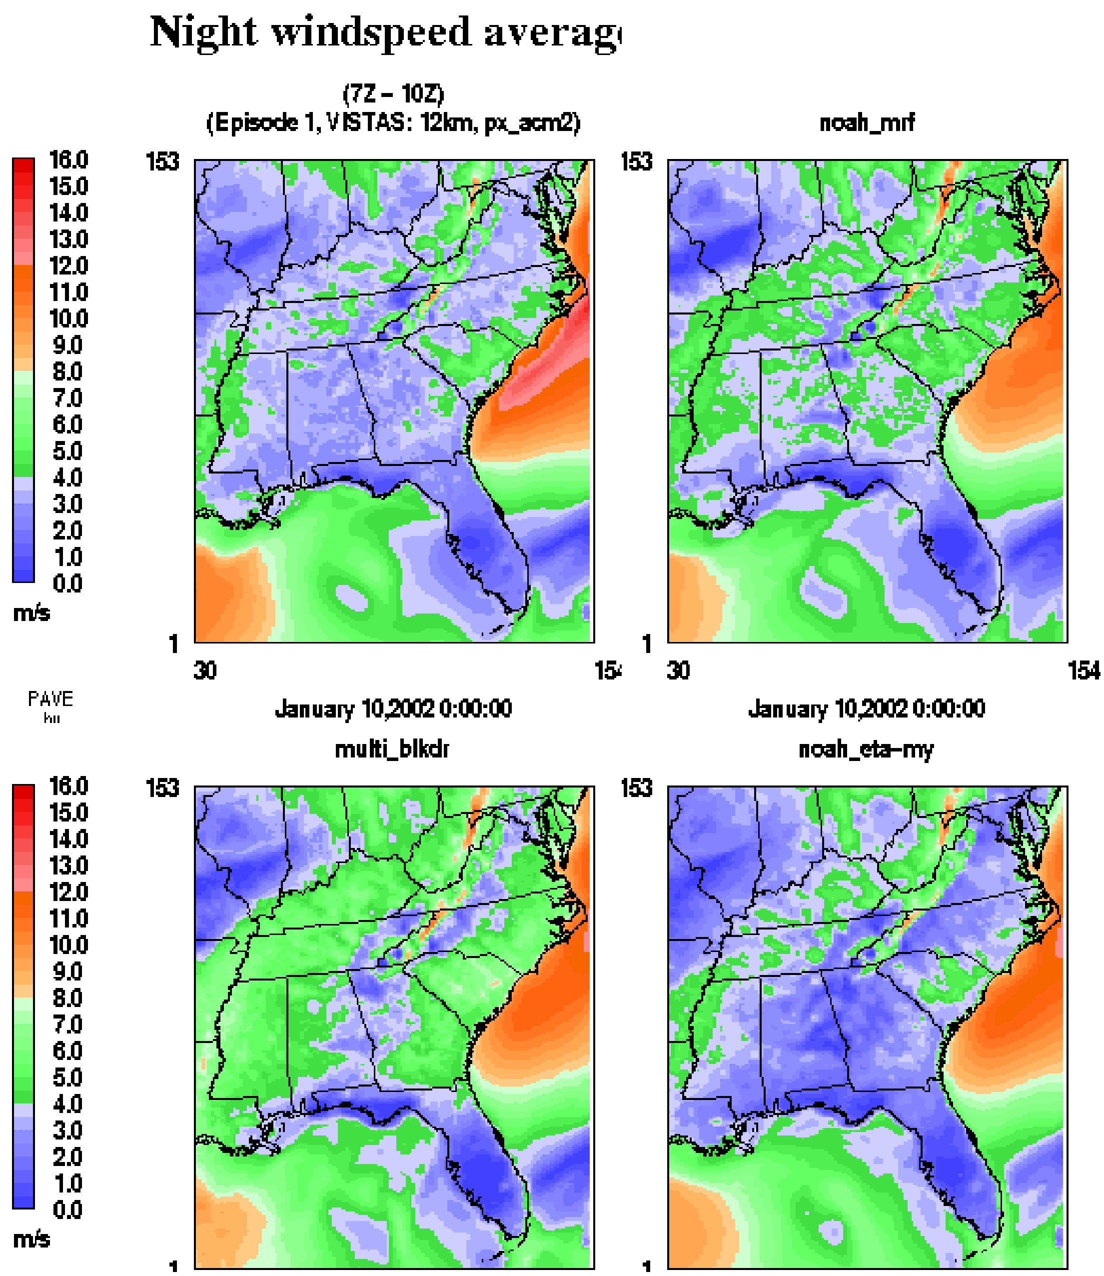

Figure 15. Like figure 12, except for wind speed.

Many of the same observations reported above are also valid for the summer episodes. To save time we will only show spatial 4-panel plots for PBL heights for a sample summer day, July 19, 2001. Figure 16 shows the daytime average, while figure 17 shows the nighttime average.

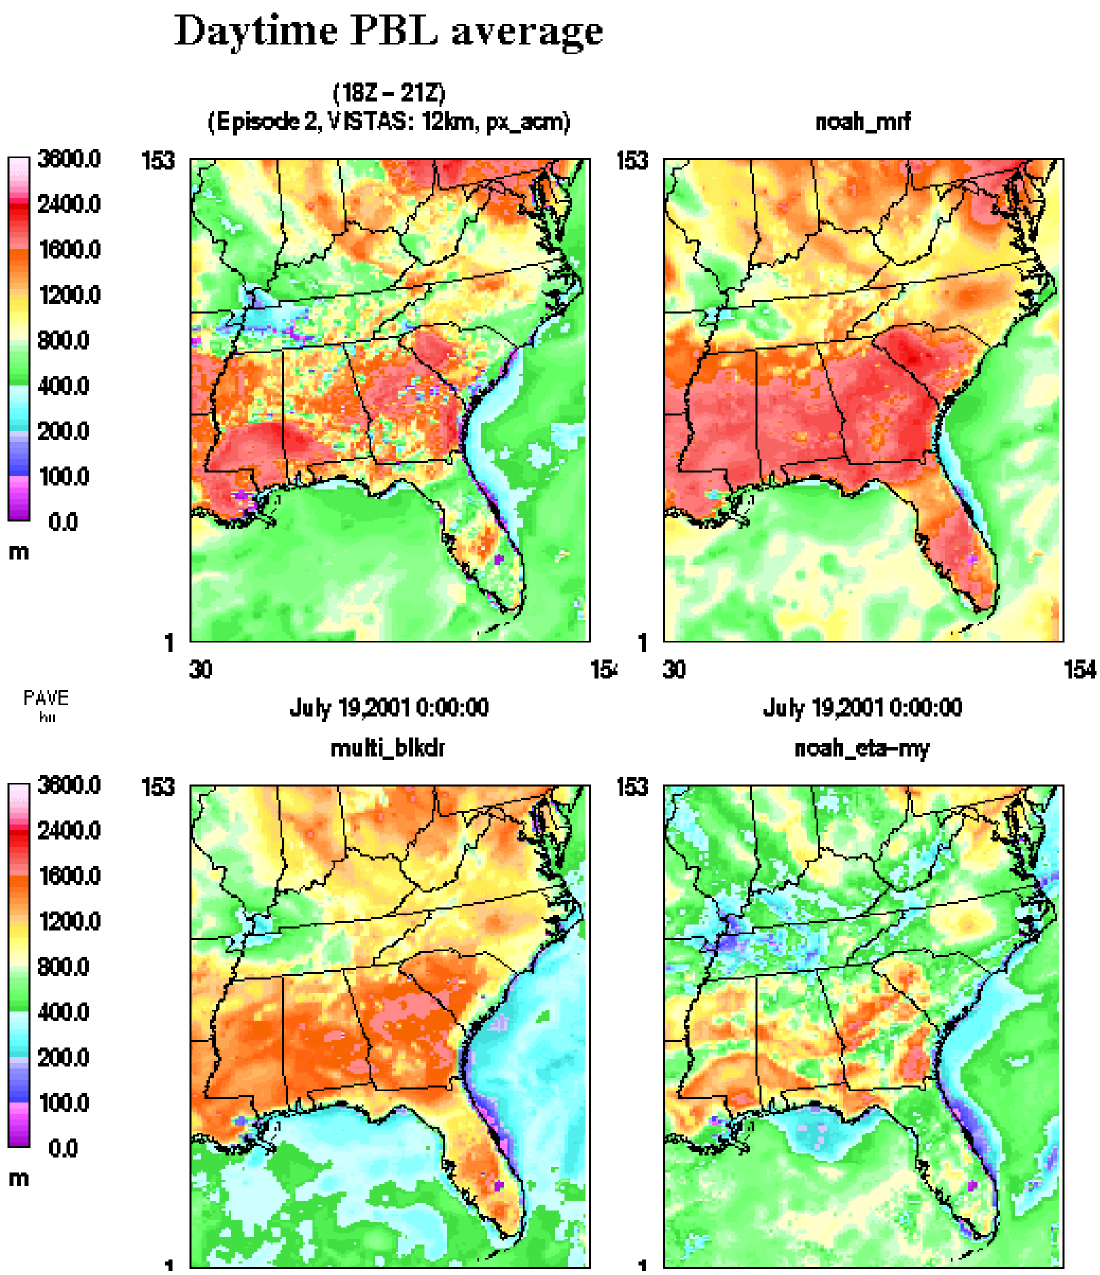

Figure 16. Daytime (18-21 UTC) average PBL heights for the 12-km VISTAS region for July 19, 2001 are displayed. The px_acm sensitivity is shown in the upper left, the noah_mrf in the upper right, the multi_blkdr in the lower left, and the noah_eta-my in the lower right. Note that the time value (0:00:00) is only a placeholder and has no physical meaning.

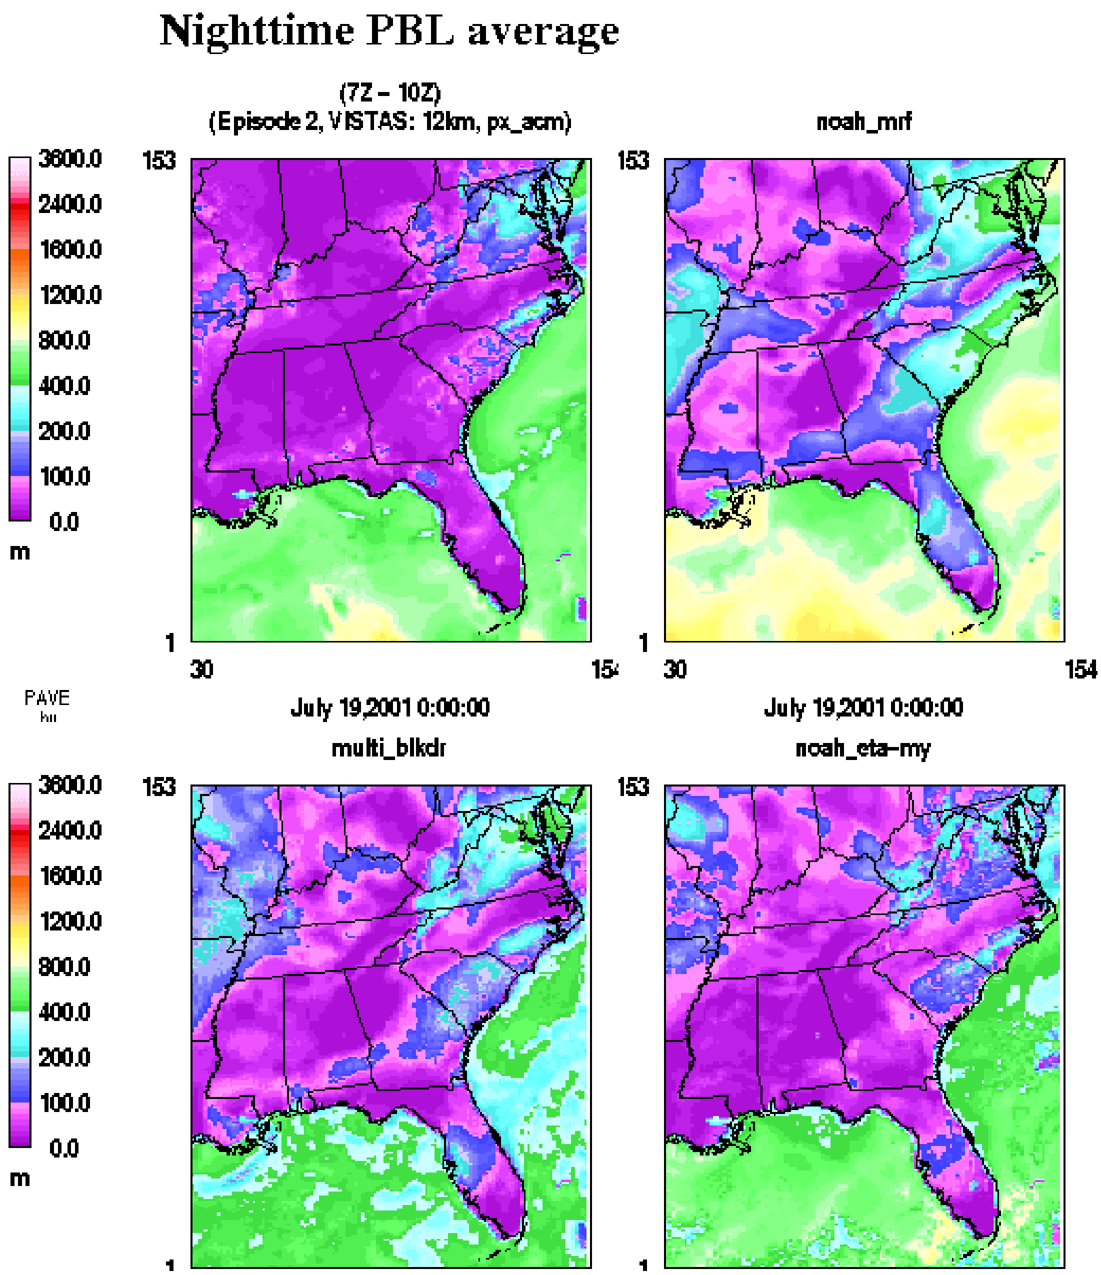

Figure 17. Nighttime (07-10 UTC) average PBL heights for the 12-km VISTAS region for July 19, 2001 are displayed. The px_acm sensitivity is shown in the upper left, the noah_mrf in the upper right, the multi_blkdr in the lower left, and the noah_eta-my in the lower right. Note that the time value (0:00:00) is only a placeholder and has no physical meaning.

Now that a qualitative understanding of these sensitivity runs has been established, the remainder of this report will focus on quantitative comparisons between the sensitivity cases. Figure 18 shows the temperature statistical time series plot for episode 1. While the general performance of the model is very similar across the sensitivity runs, close examination reveals that the px_acm2 case performs the best. Figure 19 shows the corresponding plot for episode 2. The noah_eta-my run clearly performs the worst, while the other sensitivity runs show similar performance. The episode 3 plot (not shown) reveals similar responses.

Figure 20 shows the 12-km mixing ratio statistical time series plot for episode 1 over the VISTAS region. Overall the noah_mrf case performs the best, followed by px_acm2. The multi_blkdr case is clearly the poorest performing. The corresponding episode 2 plot (figure 21) reveals a different result in that the noah_mrf case is negatively biased in mixing ratio. This weakness presumably stems from dry air being mixed down from aloft as the PBL becomes too high. The other cases are relatively similar. The negative mixing ratio bias is also evident for noah_mrf in episode 3 (not shown).

The wind direction plot for episode 1 is shown in figure 22. The direction bias and error plots show similar performance among the sensitivity cases, but the magnitude of the error vector plot (bottom panel) shows that the noah_eta-my is the best performing run, especially at night. The px_acm2 run is generally second best. Figure 23 shows that similar results are seen in episode 2, as well as in episode 3 (not shown).

The cloud cover statistical plots (figures 24-25) show very little difference in performance among the sensitivity runs. Figure 26 reveals that relative humidity for episode 1 is best modeled by either px_acm2 or noah-mrf, with the multi_blkdr case performing the worst. The episode 2 plot (figure 27) shows a strong diurnal signature with the sensitivity runs generally being negatively biased at night and positively biased during the day. The diurnal signature is interestingly the weakest for the noah_eta-my run, leading to that sensitivity possibly performing the best for this quantity. The episode 3 plot (not shown) has the noah_eta-my run displaying the poorest performance, no doubt due to its negative temperature bias.

Figure 28 shows the precipitation statistics for the full 12-km grid for episode 1. The bias blip on January 10 resulted from there being very few grid cells that actually observed measurable precipitation on that day. Sensitivity px_acm2 clearly outperforms the other cases for this episode. Figure 29 shows the corresponding plot for episode 2. Sensitivity noah_eta-my seems to be relatively unbiased, while the other sensitivity runs show a slight low bias. Nevertheless the skill plots show little difference in performance among the runs. The px_acm case appears to show slightly better results than do the other runs. Similar results are found for episode 3 (not shown).

Figure 30 is designed to show which sensitivity case statistically performs the best at each valid observation site. This particular image represents a composite of 1.5m temperatures for all hours, with absolute error being the defining metric. Note that the px_acm2 run performs best for a majority of the sites. The noah_eta-my run appears to do quite well over Florida. Figure 31 shows the corresponding plot for episode 2. Again the px_acm case seems to perform best overall, though noah_eta-my again performs best in Florida and along the southeastern coastline. The results for episode 3 (not shown) reveal no best performing sensitivity.

Figure 32 shows a similar type of plot for mixing ratio. The noah_mrf case appears to perform best for the largest number of sites, followed by the px_acm2 case. The episode 2 results (figure 33) indicate just the opposite, as the noah_eta-my or multi_blkdr cases seem to perform best for most of the sites. The episode 3 plot (not shown) is a mixed bag with the noah_eta-my and px_acm cases seemingly performing best.

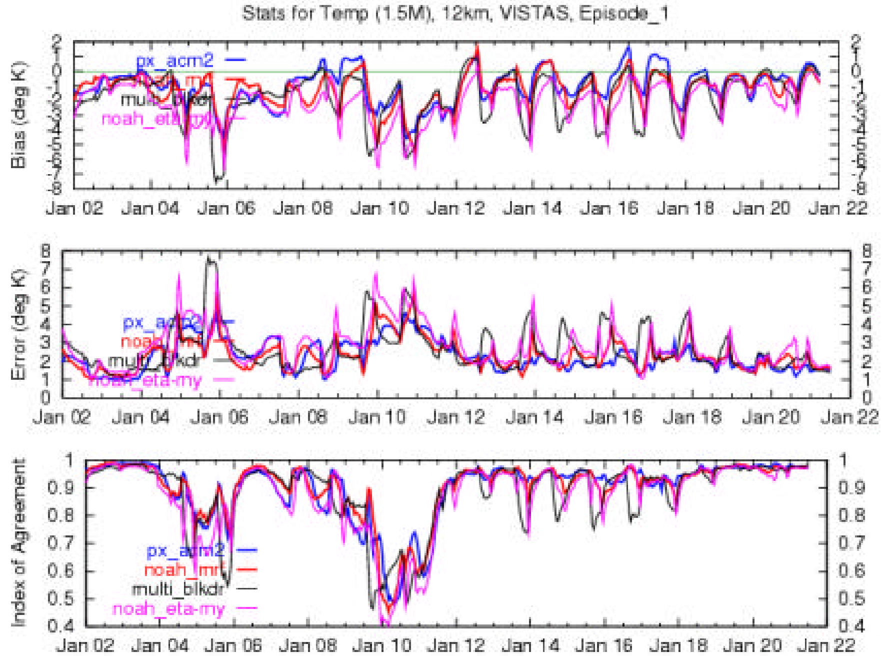

Figure 18. Episode 1 (Jan 2-21, 2002) cross-sensitivity statistical time series plot for temperature is shown. The top panel shows bias, the second panel absolute error, and the bottom panel index of agreement. The px_acm2 case is shown in blue, noah_mrf in red, multi_blkdr in black, and noah_eta-my in purple.

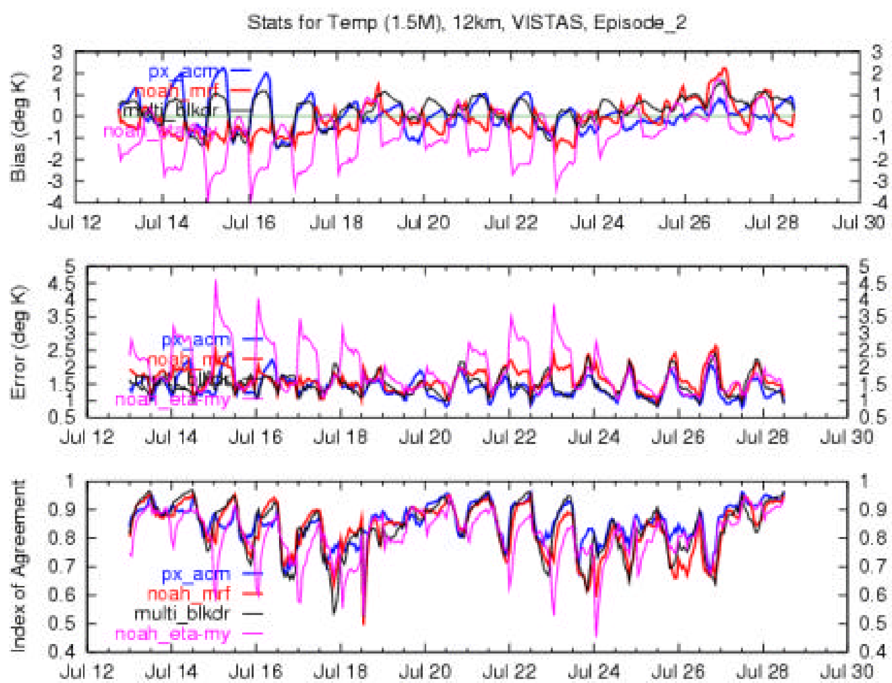

Figure 19. Episode 2 (Jul 13-28, 2001) cross-sensitivity statistical time series plot for temperature is shown. The top panel shows bias, the second panel absolute error, and the bottom panel index of agreement. The px_acm case is shown in blue, noah_mrf in red, multi_blkdr in black, and noah_eta-my in purple.

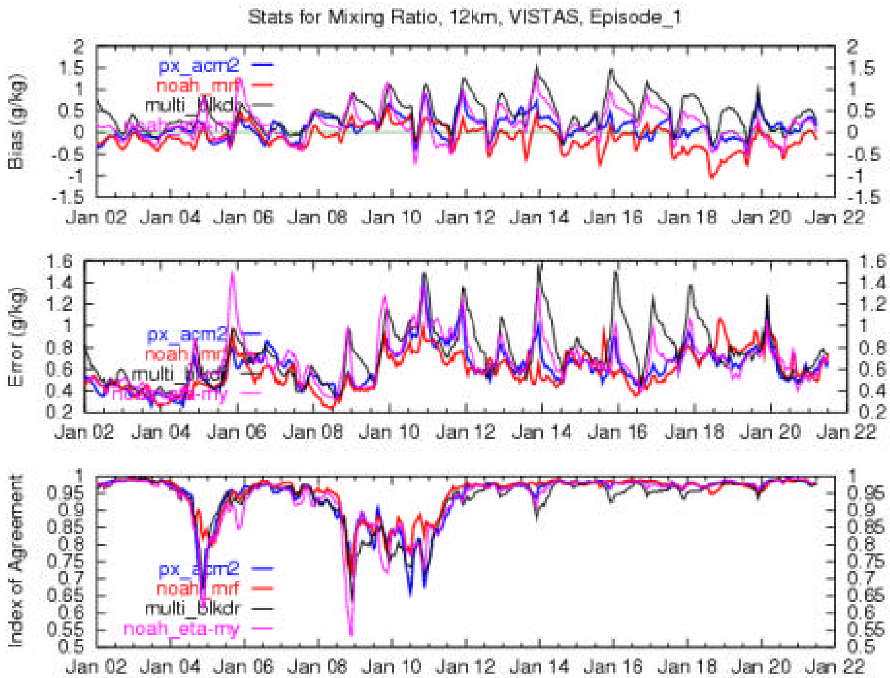

Figure 20. Episode 1 (Jan 2-21, 2002) cross-sensitivity statistical time series plot for mixing ratio is shown. The top panel shows bias, the second panel absolute error, and the bottom panel index of agreement. The px_acm2 case is blue, noah_mrf red, multi_blkdr black, and noah_eta-my purple.

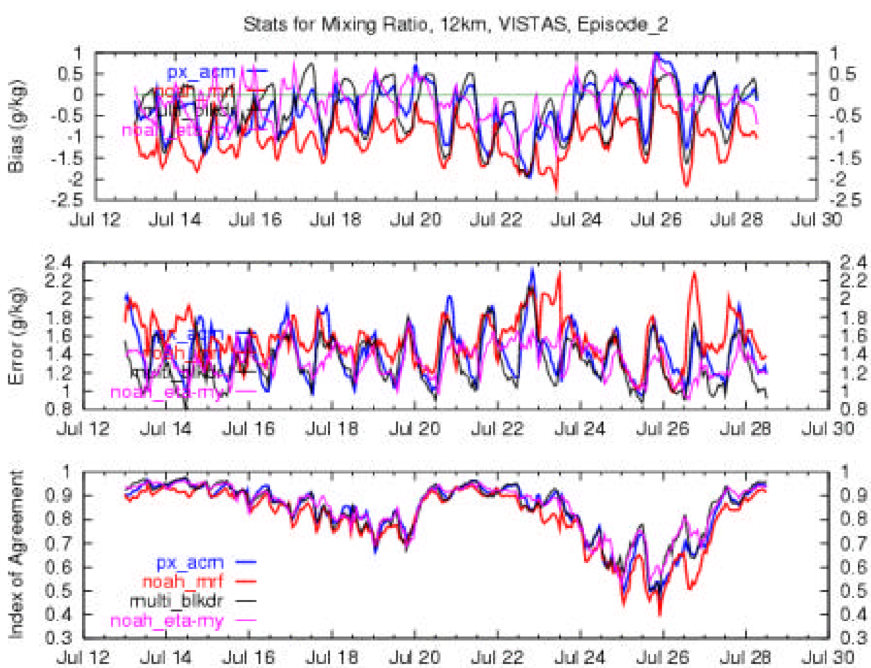

Figure 21. Episode 2 (Jul 13-28, 2001) cross-sensitivity statistical time series plot for mixing ratio is shown. The top panel shows bias, the second panel absolute error, and the bottom panel index of agreement. The px_acm case is blue, noah_mrf red, multi_blkdr black, and noah_eta-my purple.

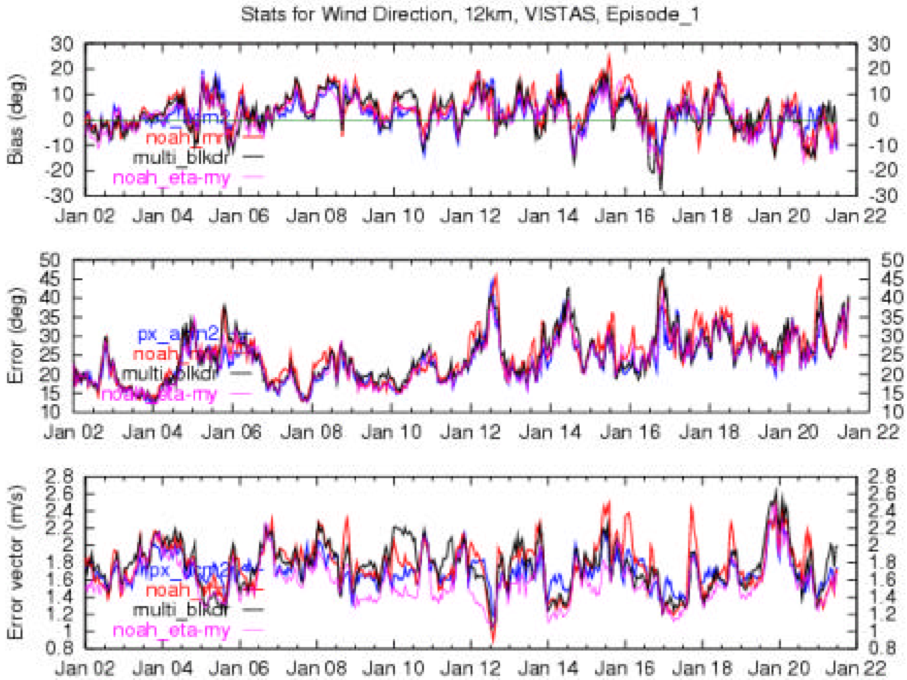

Figure 22. Episode 1 (Jan 2-21, 2002) cross-sensitivity statistical time series plot for winds is shown. The top panel shows wind direction bias, the second panel absolute wind direction error, and the bottom panel the magnitude of the error wind vector. The px_acm2 case is shown in blue, noah_mrf in red, multi_blkdr in black, and noah_eta-my in purple.

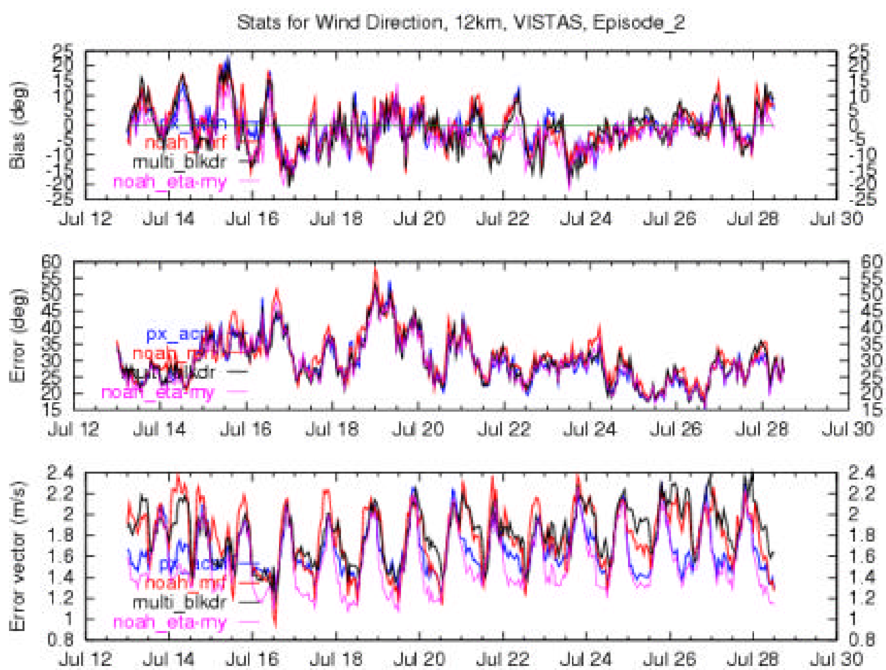

Figure 23. Episode 2 (Jul 13-28, 2001) cross-sensitivity statistical time series plot for winds is shown. The top panel shows wind direction bias, the second panel absolute wind direction error, and the bottom panel the magnitude of the error wind vector. The px_acm case is shown in blue, noah_mrf in red, multi_blkdr in black, and noah_eta-my in purple.

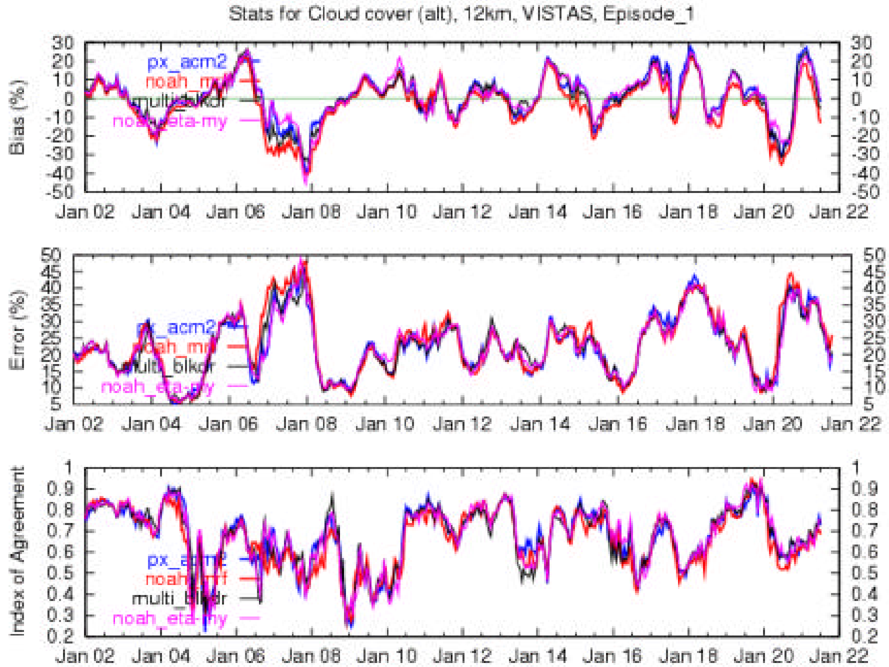

Figure 24. Episode 1 (Jan 2-21, 2002) cross-sensitivity statistical time series plot for cloud coverage is shown. The top panel shows bias, the second panel absolute error, and the bottom panel index of agreement. The px_acm2 case is blue, noah_mrf red, multi_blkdr black, and noah_eta-my purple.

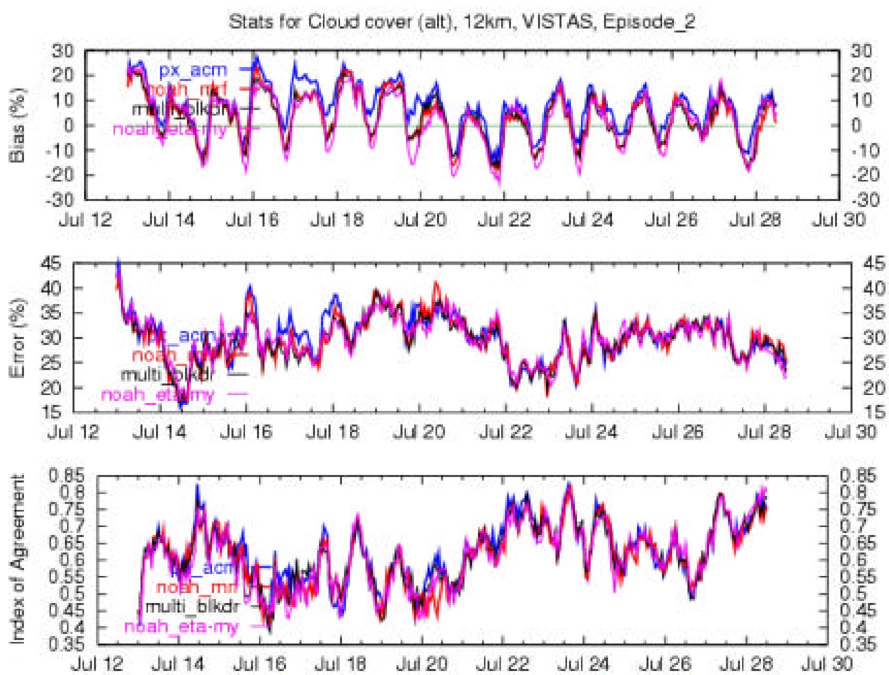

Figure 25. Episode 2 (Jul 13-28, 2001) cross-sensitivity statistical time series plot for cloud coverage is shown. The top panel shows bias, the second panel absolute error, and the bottom panel index of agreement. The px_acm case is blue, noah_mrf red, multi_blkdr black, and noah_eta-my purple.

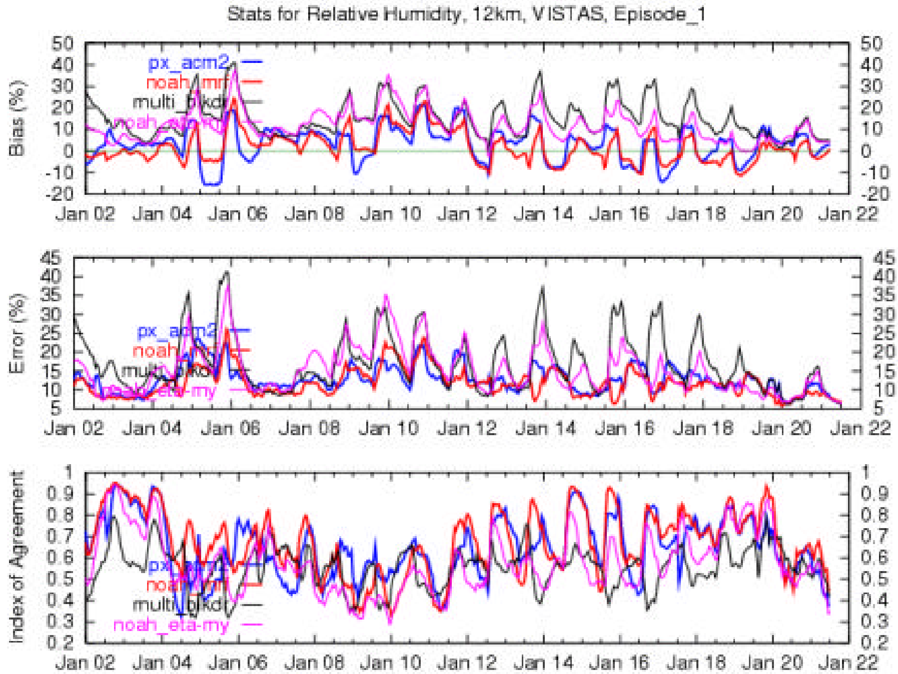

Figure 26. Episode 1 (Jan 2-21, 2002) cross-sensitivity statistical time series plot for relative humidity is shown. The top panel shows bias, the second panel absolute error, and the bottom panel index of agreement. The px_acm2 case is blue, noah_mrf red, multi_blkdr black, and noah_eta-my purple.

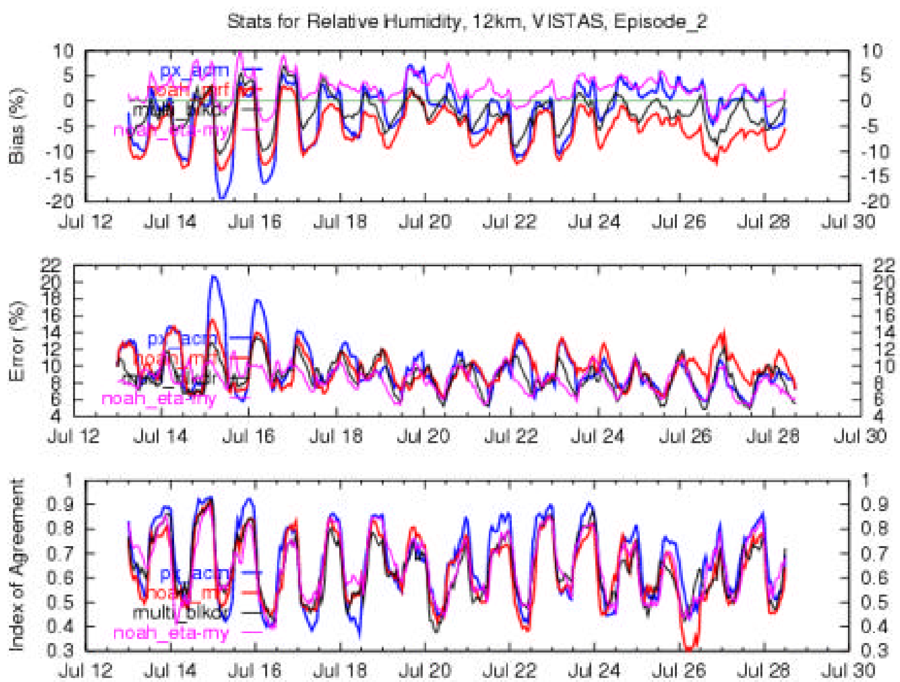

Figure 27. Episode 2 (Jul 13-28, 2001) cross-sensitivity statistical time series plot for relative humidity is shown. The top panel shows bias, the second panel absolute error, and the bottom panel index of agreement. The px_acm case is blue, noah_mrf red, multi_blkdr black, and noah_eta-my purple.

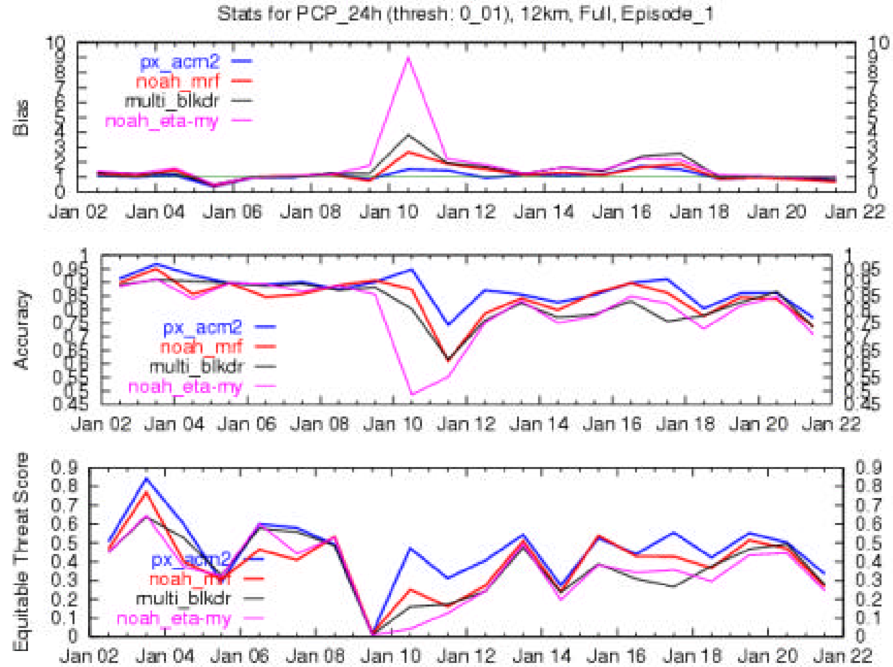

Figure 28. Episode 1 (Jan 2-21, 2002) cross-sensitivity statistical time series plot for 24-h measurable precip is shown. The top panel shows bias, the second panel accuracy, and the bottom panel equitable threat score. The px_acm2 case is blue, noah_mrf red, multi_blkdr black, and noah_eta-my purple.

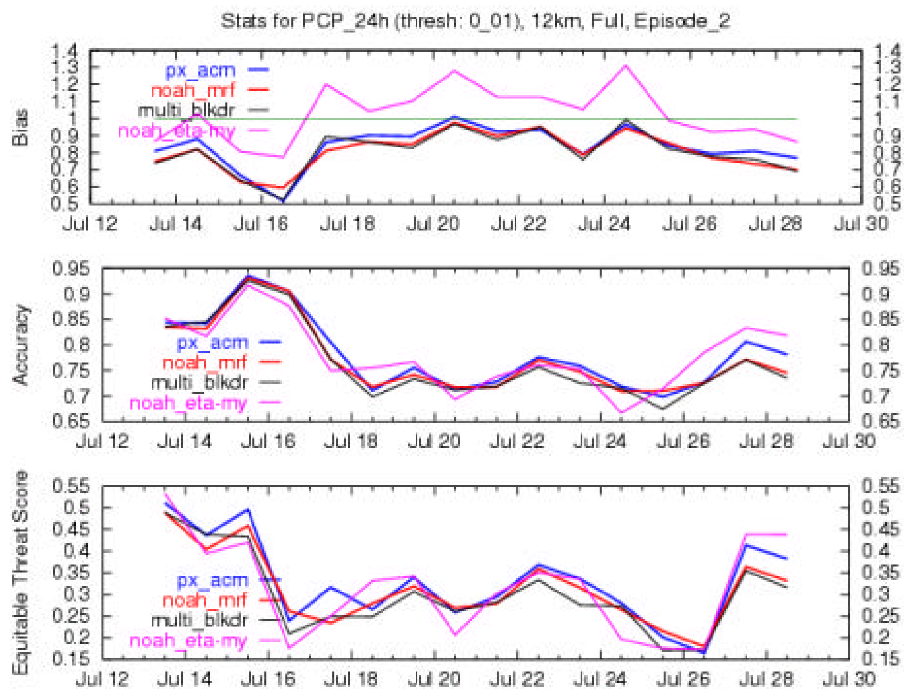

Figure 29. Episode 2 (Jul 13-28, 2001) cross-sensitivity statistical time series plot for 24-h measurable precip is shown. The top panel shows bias, the second panel accuracy, and the bottom panel equitable threat score. The px_acm case is blue, noah_mrf red, multi_blkdr black, and noah_eta-my purple.

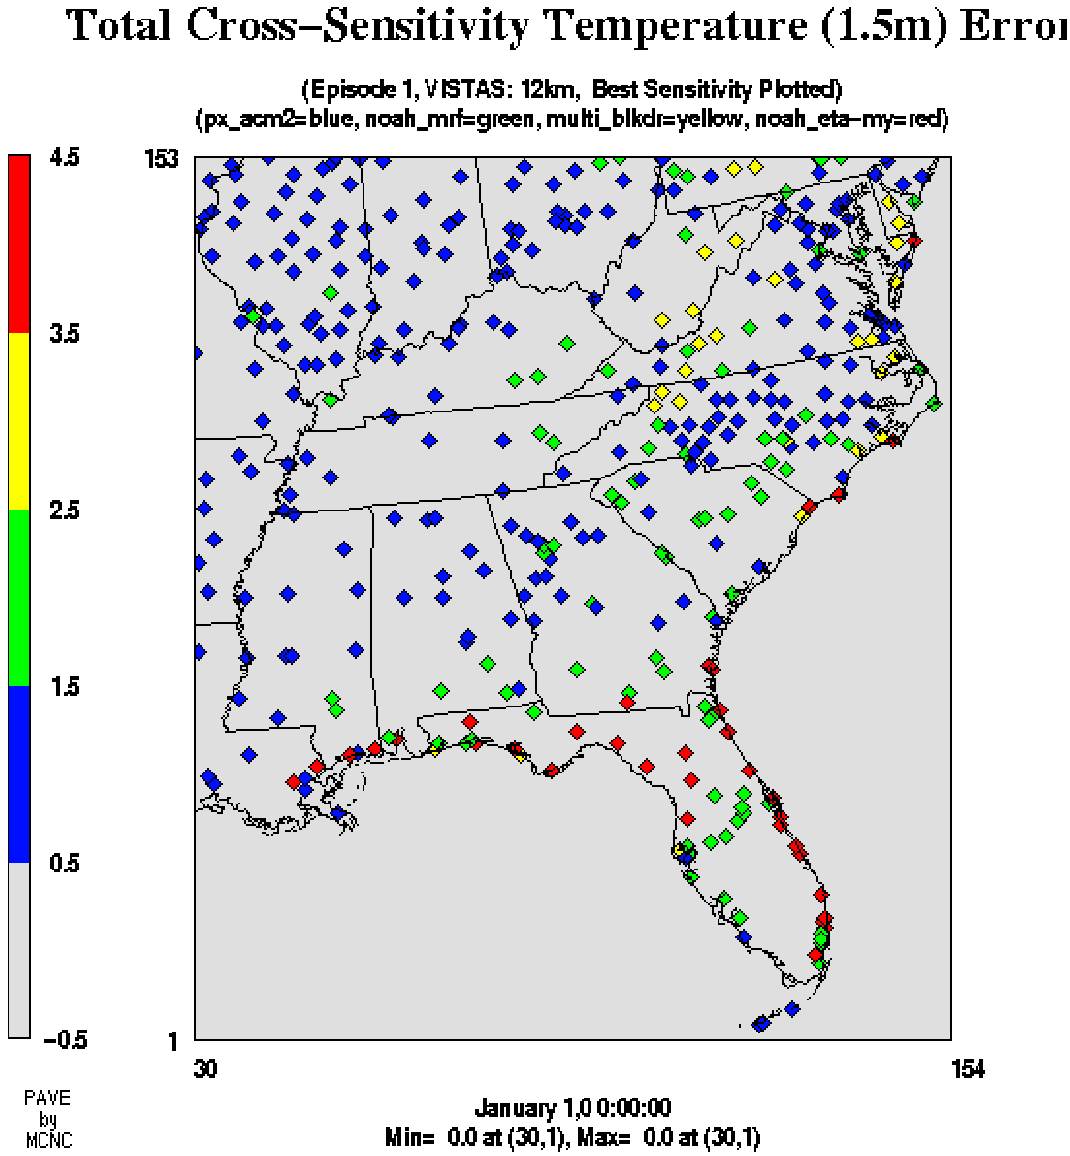

Figure 30. Episode 1 (Jan 2-21, 2002) cross-sensitivity 1.5m temperature absolute error comparison plot is shown. Stations for which px_acm2 show the smallest composite error are plotted in blue, noah_mrf in green, multi_blkdr in yellow, and noah_eta-my in red. The date/time/max/min information at the bottom of the plot serves only as placeholders and should be ignored.

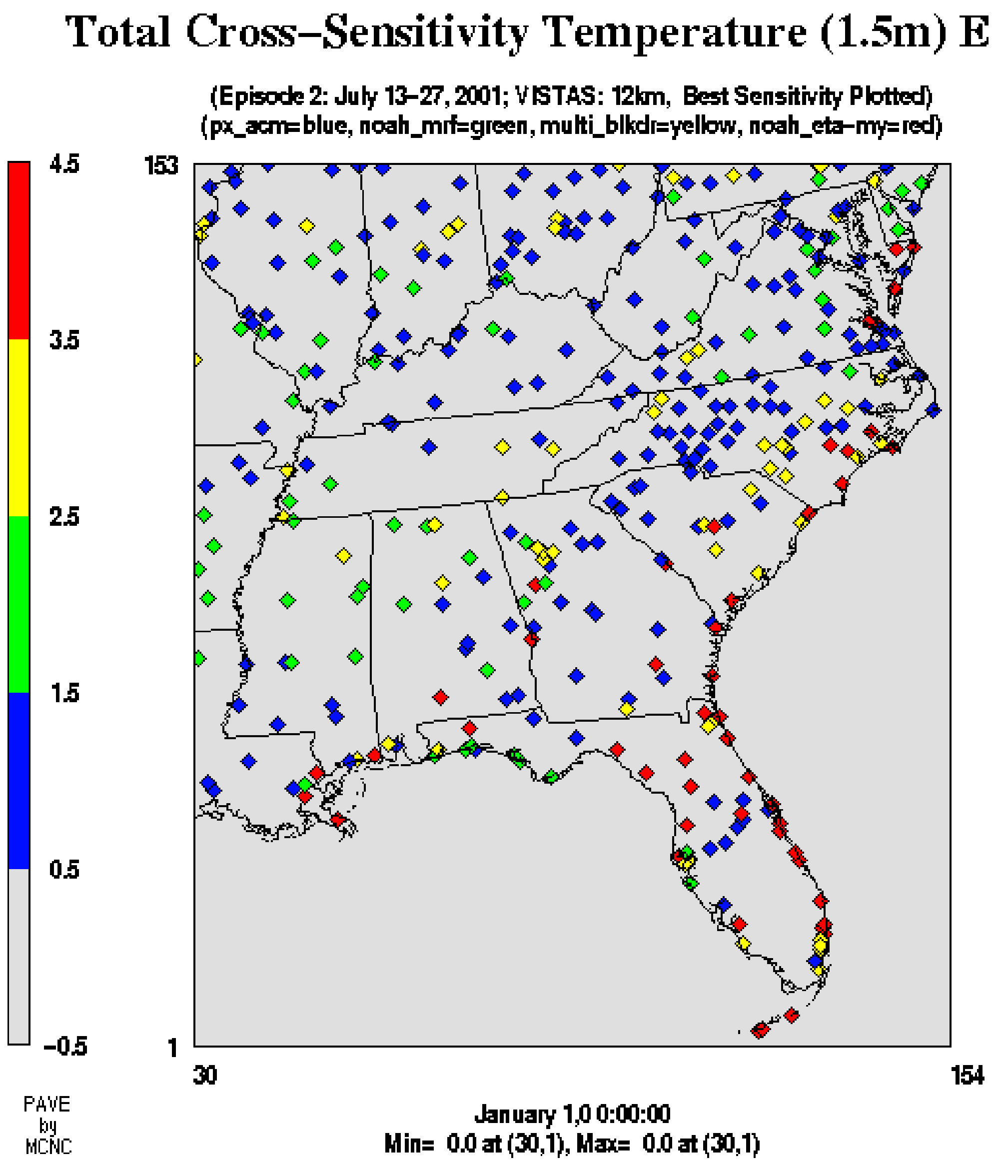

Figure 31. Episode 2 (Jul 13-28, 2001) cross-sensitivity 1.5m temperature absolute error comparison plot is shown. Stations for which px_acm2 show the smallest composite error are plotted in blue, noah_mrf in green, multi_blkdr in yellow, and noah_eta-my in red. The date/time/max/min information at the bottom of the plot serves only as placeholders and should be ignored.

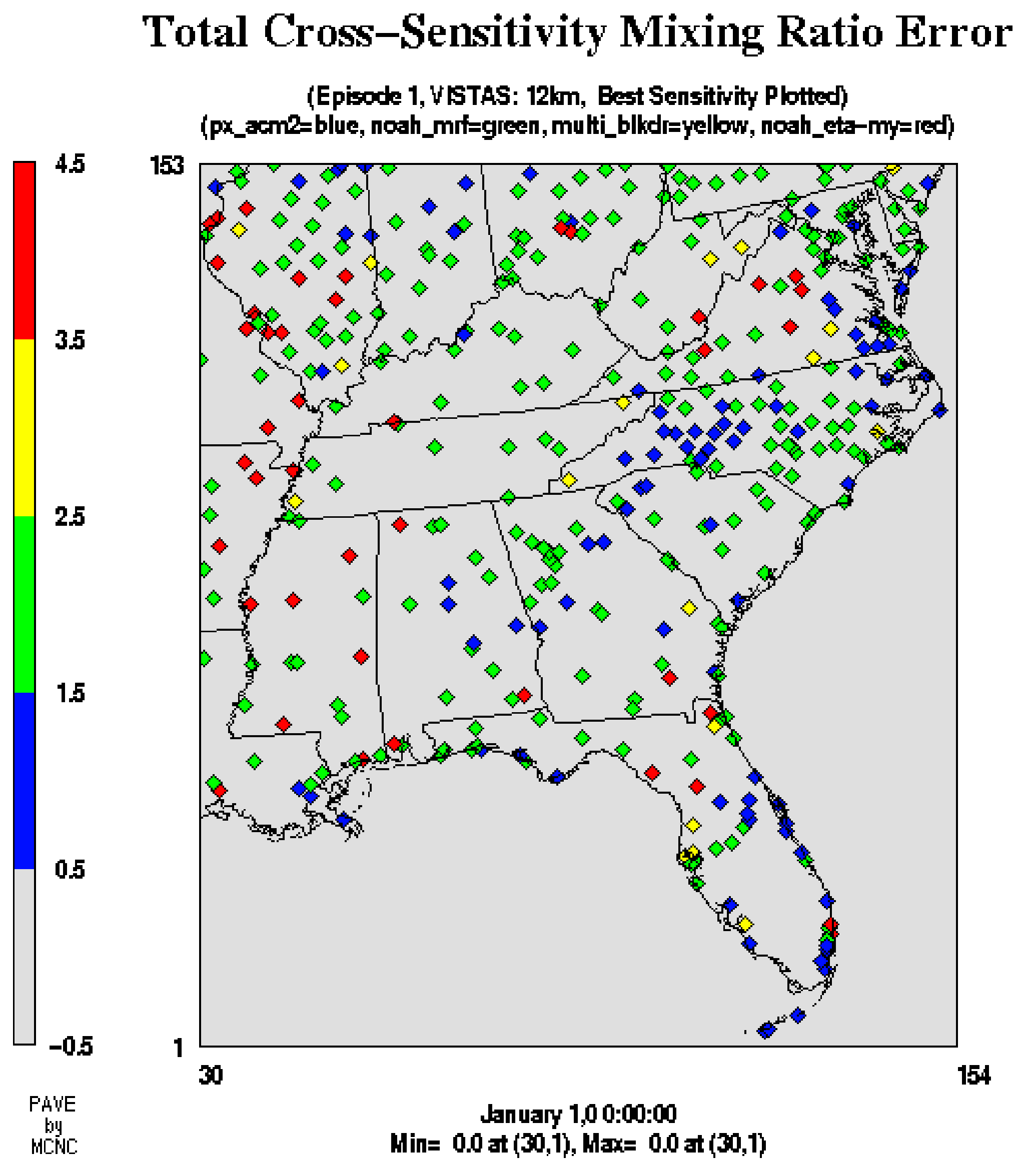

Figure 32. Episode 1 (Jan 2-21, 2002) cross-sensitivity mixing ratio absolute error comparison plot is shown. Stations for which px_acm2 show the smallest composite error are plotted in blue, noah_mrf in green, multi_blkdr in yellow, and noah_eta-my in red. The date/time/max/min information at the bottom of the plot serves only as placeholders and should be ignored.

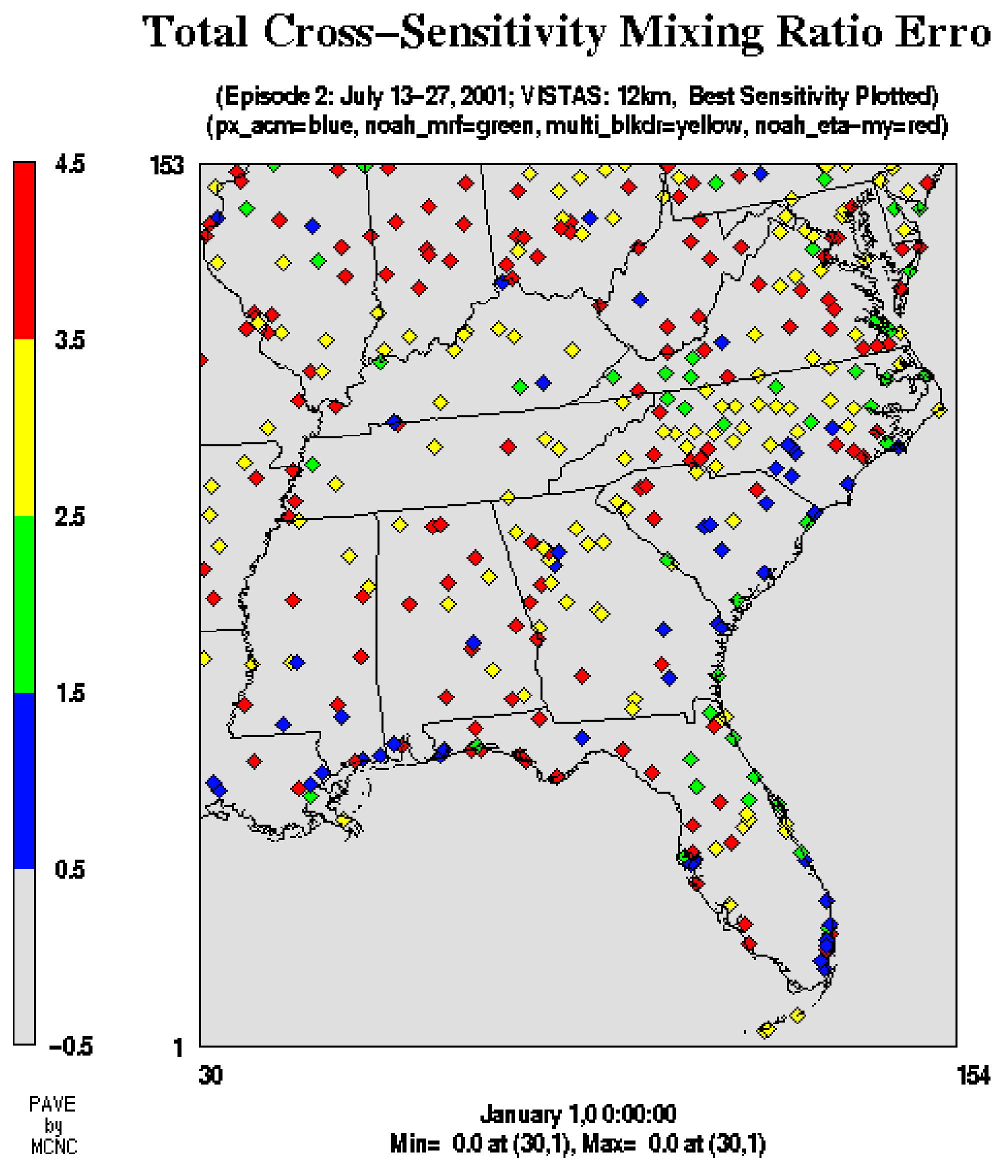

Figure 33. Episode 2 (Jul 13-28, 2001) cross-sensitivity mixing ratio absolute error comparison plot is shown. Stations for which px_acm2 show the smallest composite error are plotted in blue, noah_mrf in green, multi_blkdr in yellow, and noah_eta-my in red. The date/time/max/min information at the bottom of the plot serves only as placeholders and should be ignored.

The corresponding series of plots for the magnitude of the error wind vector (figures 34-35) show the clear superiority of the noah_eta-my runs. The px_acm(2) runs perform a distant second best for all sensitivities. The main reason why noah_eta-my performs so well is its ability to calm its wind speeds at night (figure 15) relative to the other model configurations.

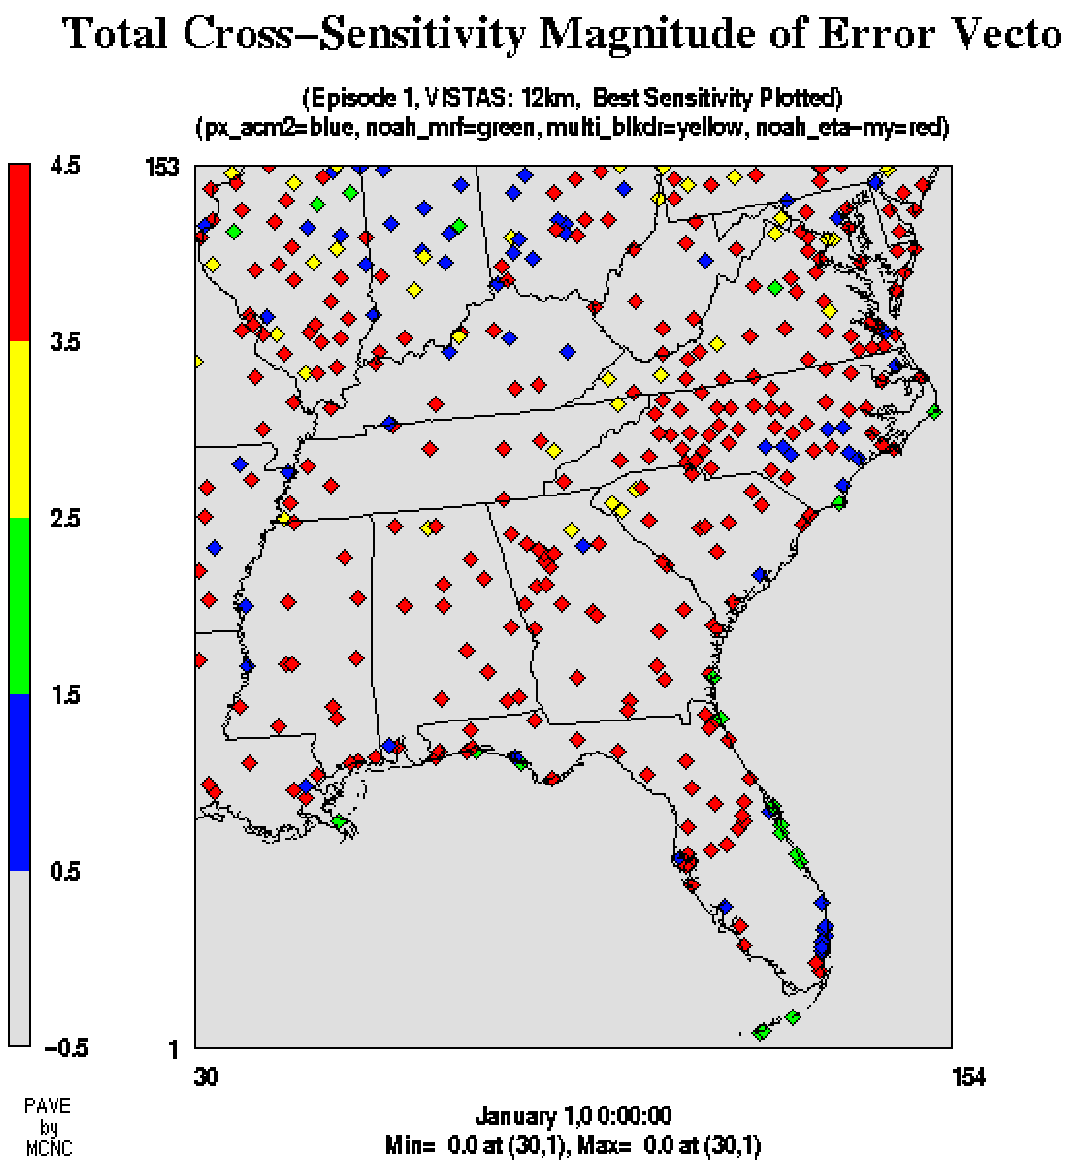

Figure 34. Episode 1 (Jan 2-21, 2002) cross-sensitivity error vector magnitude comparison plot is shown. Stations for which px_acm2 show the smallest composite error are plotted in blue, noah_mrf in green, multi_blkdr in yellow, and noah_eta-my in red. The date/time/max/min information at the bottom of the plot serves only as placeholders and should be ignored.

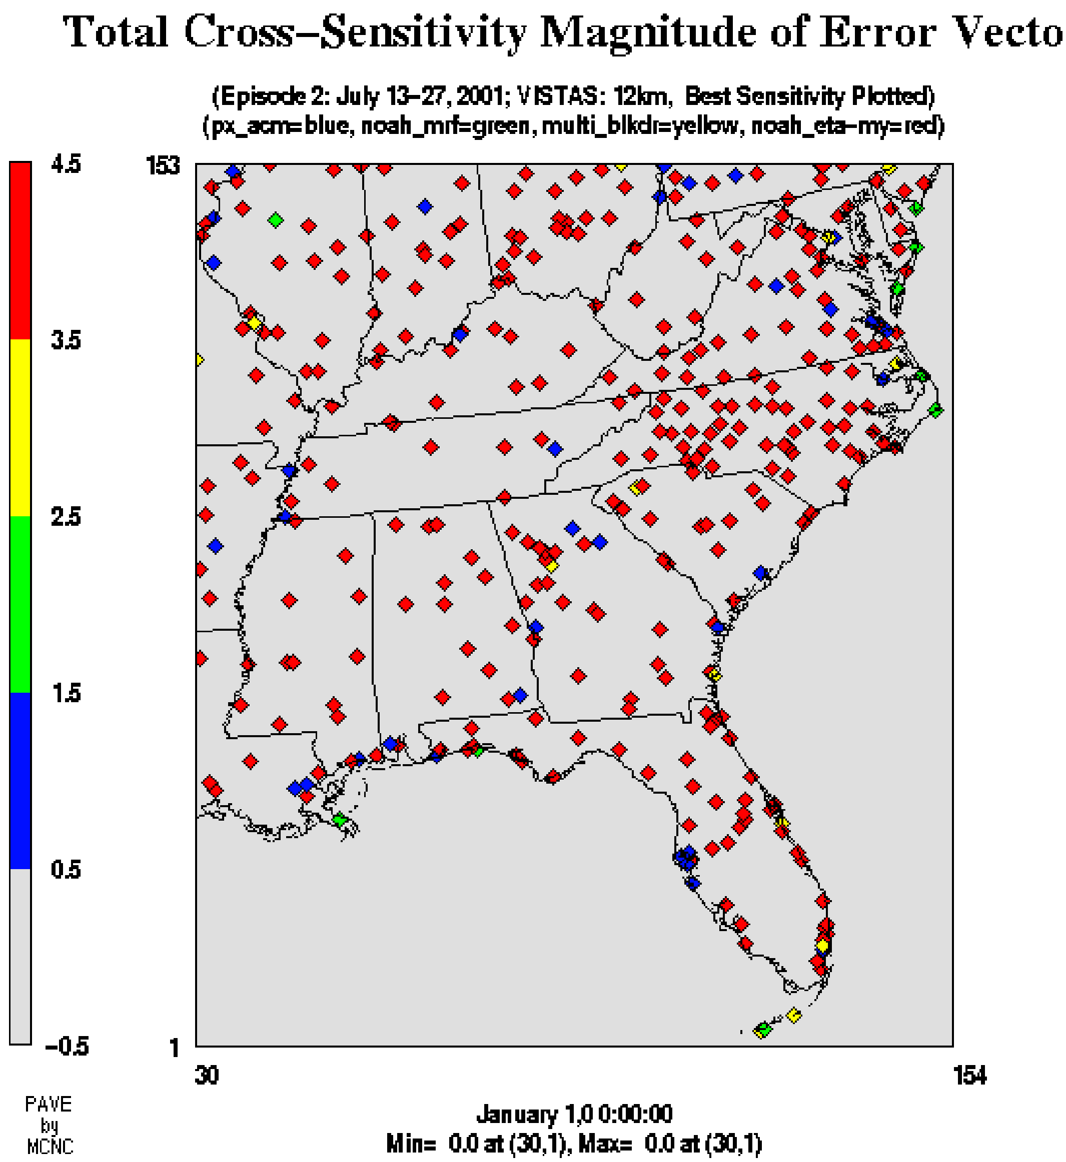

Figure 35. Episode 2 (Jul 13-28, 2001) cross-sensitivity error vector magnitude comparison plot is shown. Stations for which px_acm2 show the smallest composite error are plotted in blue, noah_mrf in green, multi_blkdr in yellow, and noah_eta-my in red. The date/time/max/min information at the bottom of the plot serves only as placeholders and should be ignored.

The remainder of this report will focus primarily on statistical tables. These tables are episode-composites and are divided into three sections. The top section contains bias, absolute error, coefficient of determination (r^2), index of agreement, and root mean square error for temperature (1.5 m), water vapor mixing ratio, relative humidity, wind speed (10 m), and cloud coverage. The second section contains additional statistics for winds, including wind direction bias, absolute wind direction error, U-wind component error, V-wind component error, and the magnitude of the average error wind vector. The latter metric is perhaps the single best means of assessing model wind performance. The final section contains precipitation statistics at various thresholds (0.01, 0.05, 0.10, 0.25, 0.5, and 1.0 inches) for daily precipitation accumulations. The metrics presented are accuracy, bias, false alarm ratio (FAR), probability of detection (POD), critical success index (CSI, i.e. threat score), equitable threat score (ETS), "true skill score" (TSS, i.e. Hanssen and Kuipers score), and Heidke skill score (HSS). These precipitation statistics are only generated for approximately the US portion of the grids; there are no RPO-specific statistics for this variable. Since an RPO-specific statistical summary is incomplete without some sort of precipitation metric, we have decided to use the precipitation statistics described above for every statistical composite we produce. The reader should understand the inconsistencies that this approach entails. Note also that the precipitation observational grids are obtained, in part, by objectively analyzing rain gauge data. This tends to "spread out" the measurable precipitation beyond where it actually occurs. Since a model does not do that, a perfect precipitation forecast might appear to be slightly low biased at the 0.01-inch threshold. At higher thresholds the number of valid occurrences may not reach a robust level.

Sensitivity px_acm2 is the base case for all of the statistical tables that follow. Table 1 shows the base case statistics for the US portion of the 36-km domain for episode 1, while table 2 reports statistics for the VISTAS 12-km domain for episode 1. Recall the meteorological statistical benchmarks reported by Emery (2001):

Wind speed:	RSME	<= 2 m/s,	Bias <= +/- 0.5 m/s,	IA >= 0.6
Wind direction:	Gross Error	<= 30 deg,	Bias <= +/- 10 deg.	
Temperature:	Gross Error	<= 2 K,	Bias <= +/- 0.5 K,	IA >= 0.8
Humidity:	Gross Error	<= 2 g/kg,	Bias <= +/- 1 g/kg,	IA >= 0.6

Note that the only metrics that fail to meet these benchmarks are temperature bias and error. It should be understood that the above benchmarks are based primarily on meteorological modeling of summertime episodes. While ideally we want less temperature bias and error, the results seen here are not unusually bad. Note that the index of agreement temperature statistic easily betters the benchmark value for both domains. No benchmarks exist for relative humidity, cloud cover, and precipitation. It is encouraging that these quantities are all relatively unbiased and appear to show reasonable skill.

Tables 3-4 show the episode 2 statistical tables for px_acm2 for the selected domains. The only base variable that fails to meet the above benchmark is wind direction gross error at 36-km resolution, and that value (32.27^o) is certainly in the ballpark. Given the weak synoptic forcing in this episode, it is likely that sub-synoptic forcing (e.g. terrain flows, thunderstorm outflows, etc…) unresolved adequately at this resolution degrades the wind direction performance. The other variables are modeled reasonably well, with a couple of possible exceptions. Note the positive cloud coverage bias (>7%) in table 4, and the positive precipitation bias at higher thresholds in both table 3 and table 4. The model appears to overestimate the extent and intensity of summertime convection. Similar results are seen for episode 3 (tables 5-6). The cloud biases are less than in episode 2, though the positive precipitation biases at higher thresholds are accentuated at 36-km resolution.

Table 6. Episode 3 composite statistical summary for base case px_acm2 for the VISTAS portion of the 12-km domain is shown.

To augment the statistical tables described above, we have also produced tables of statistical differences from the base case px_acm2. The table setup is precisely the same as above, but the differences reported are not simple differences. Instead we present differences designed to indicate whether the sensitivity produces better results than the base case. For some metrics (e.g. r^2, IA, CSI) larger numbers indicate improved performance. For these metrics we calculate differences: SENS – BASE. Positive results are color-coded green, indicating that the sensitivity improved performance. Negative results are color-coded red, indicating that the sensitivity degraded performance. For some other metrics (e.g. abserr, uverr, FAR) smaller numbers indicate improved performance. Thus the difference table shows BASE – SENS, and the color-coding described above still applies. Similarly the differences for the bias statistics are calculated relative to optimum performance (0 normally, 1 for precipitation). In this manner one can readily ascertain statistical benefits/disbenefits for all sensitivity runs. One should keep in mind that very small non-zero statistical changes are color-coded the same as significant changes, so the actual numerical change should be considered more important than the color-coding.

Tables 7-8 show the statistical difference results for sensitivity px_acm for episode 1. The most significant differences are found in the temperature metrics, revealing that the px_acm configuration is significantly more cold-biased than is px_acm2 for this wintertime episode. Most of the other surface variables also show degraded performance. The px_acm run does seem to very slightly improve cloud coverage and precipitation, but the improvements are very slight and are probably less meaningful than the temperature degradation. These performance patterns hold for both the US 36-km results and the VISTAS 12-km results. Tables 9-10 indicate very little performance difference between the two configurations for episode 2. Precipitation performance is slightly enhanced for this summertime period, while interestingly it actually slightly degrades in the other summertime episode (tables 11-12). Overall px_acm seems to be a less desirable configuration for annual modeling.

Tables 13-14 show the statistical difference results for the noah_mrf sensitivity for episode 1. The performance of mixing ratio and relative humidity for both grids seem to be improved slightly in this configuration. The remaining variables are degraded almost universally. Perhaps the most striking result seen in the episode 2 tables (tables 15-16) is the degraded mixing ratio performance, countermanding the wintertime result. The noah_mrf sensitivity is significantly more low-biased for this variable than is the base case px_acm2, especially for the 12-km VISTAS domain. At 36-km this seems to help the run actually improve its cloud and precipitation performance relative to the base. The 12-km results are more ambiguous for these variables. Generally similar results are found for episode 3 (tables 17-18). These findings, combined with the likelihood that the PBL heights are overestimated under this configuration, lead one to reject this configuration for annual modeling.

The multi_blkdr results for episode 1 are displayed in tables 19-20. With few exceptions this sensitivity shows degraded performance for all variables for both grid resolutions. The low temperature bias is perhaps the most significant issue with this configuration. The summertime tables for multi_blkdr (tables 21-24) show results that are generally degraded from px_acm2. This configuration clearly degrades performance compared with the base case px_acm2.

The noah_eta-my results are found in tables 25-30. As mentioned earlier this configuration tends to improve performance for winds, but the other variables tend to be degraded. Temperature especially is biased low for all grids/resolutions. Still, the superior surface wind performance of the noah_eta-my run deserves additional attention. To compare the performance of this run versus px_acm(2), we computed composite statistics at various sounding locations. These statistics considered only the 00 UTC (or 12 UTC) data in the composite. A plot of this type is shown in figure 36 for Greensboro, NC, episode 1, 00 UTC. Note that at the surface the wind errors are less in the noah_eta-my case than they are in the px_acm2 case, but for the majority of the lower portions of the atmosphere the opposite occurs. The large temperature/dew point biases/errors in the noah_eta-my are expected and corroborate what is seen in the surface statistics. Figure 37 shows that for this site similar results are found in the wind profile for a summer episode. Performance at other upper air stations vary, and for Florida stations the noah_eta-my results appear to be slightly improved over the px_acm results. Generally speaking, though, the improved wind performance for noah_eta-my appears to be relegated to the lowest model layer. For a multitude of reasons, therefore, this configuration is not recommended for the annual modeling.

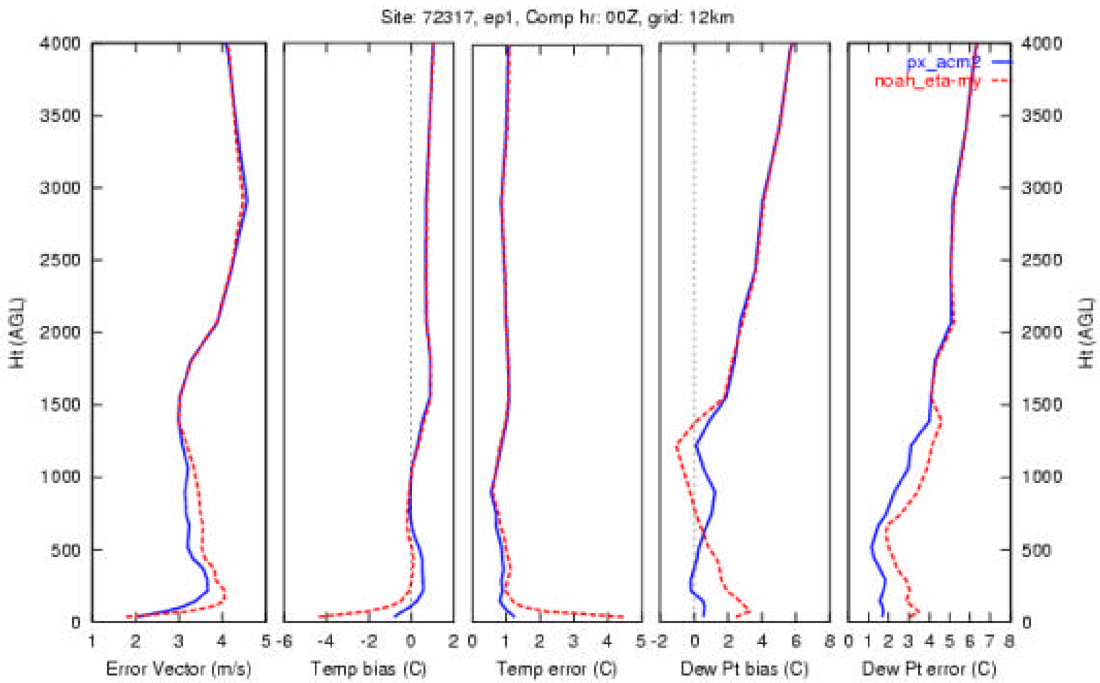

Figure 36. Episode 1 (Jan 2-21, 2002) composite vertical statistics for all 00 UTC times for Greensboro, NC are shown. The magnitude of the error vector is plotted in the leftmost panel, followed by temperature bias and error, then dew point bias and error. Blue represents the px_acm2 case, while dashed red shows the noah_eta-my results.

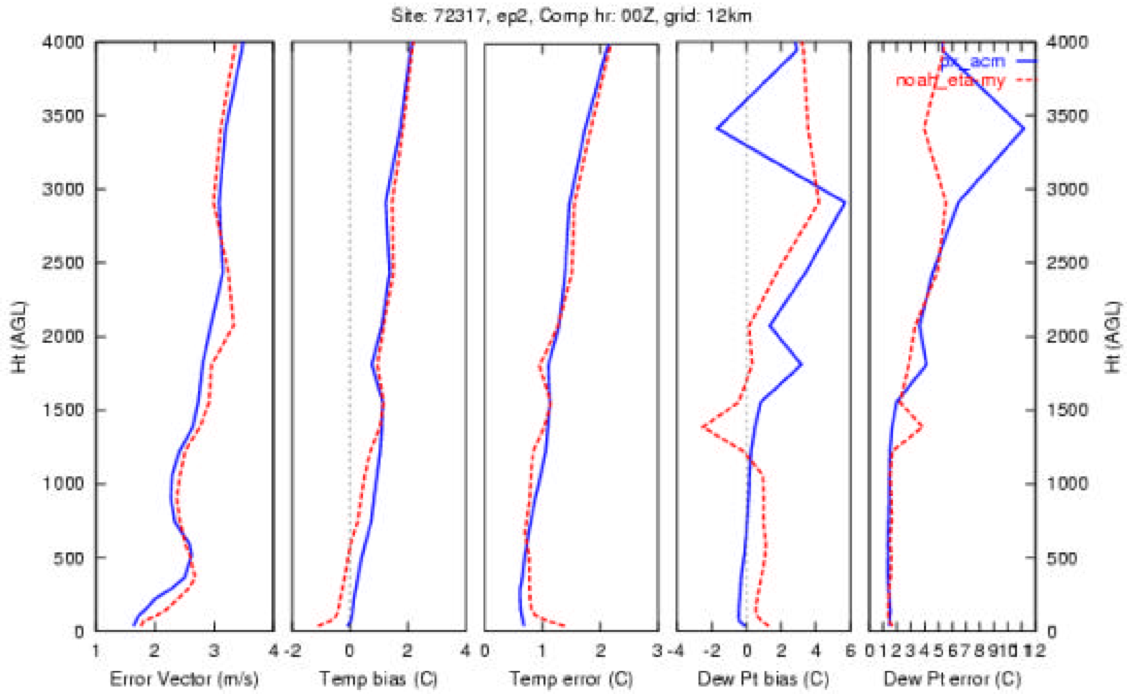

Figure 37. Episode 2 (Jul 13-28, 2001) composite vertical statistics for all 00 UTC times for Greensboro, NC are shown. The magnitude of the error vector is plotted in the leftmost panel, followed by temperature bias and error, then dew point bias and error. Blue represents the px_acm2 case, while dashed red shows the noah_eta-my results.

5 Auxiliary Results

The results from the five main sensitivity runs indicate that the px_acm2 configuration is overall the preferred option for annual modeling. Still there are numerous model options that are not tested in the above configurations. Accordingly we have conducted a variety of auxiliary sensitivity tests with limited analyses. These include:

- **px_acm3**: Like px_acm2, except with soil moisture/temperature initialization for P-X soil layer 2 from EDAS soil layer 3 (40-100 cm).
- **px_acm4**: Like px_acm2, except it uses the SFCFDDA file from RAWINS and MMINPUT files processed using RAWINS data rather than REGRID data.
- **px_acm5**: Like px_acm2, except it uses Reisner 2 microphysics rather than Reisner 1.
- **px_acm6**: Like px_acm2, except analysis nudging strengths aloft for wind/temps are increased from 2.5E-4, 1.0E-4 (36/12 km) to 3.0E-4, 3.0E-4.
- **px_acm7**: Like px_acm2, except the SFCFDDA files from RAWINS are used instead of those from LITTLE_R.
- **px_acm8**: Like px_acm2, except the MMINPUT files are processed using data from LITTLE_R rather than from REGRID.
- **px_acm9**: Like px_acm3, except the initialization for soil temperature/moisture is based on a 25% weighting of EDAS soil layer 1 (0-10 cm) values and a 75% weighting from EDAS soil layer 3 (40-100 cm). Code supplied by Aijun Xiu; executed for episode 3 only.
- **px_acm_n**: Like px_acm2, except surface analysis nudging is turned on for temp/moisture at a strength of 2.5E-4, 1.0E-4 (36, 12 km temps) and 1.0E-4, 1.0E-4 (36, 12 km moisture).
- **px_acm_n2**: Like px_acm_n, except surface analysis nudging for moisture ss reduced to 1.0E-5, 1.0E-5 (36, 12 km). Run only for episode 2.
- **s0px_acm2**: Like px_acm2, except snow cover effects are not considered (IFSNOW=0) as opposed to IFSNOW=1 in px_acm2. Run only for episode 1.
- **s2px_acm2**: Like px_acm2, except the simple snow model is employed (IFSNOW=2) as opposed to IFSNOW=1 in px_acm2. Run only for episode 1.
- **n0_px_acm2**: Like px_acm2, except soil moisture nudging is turned off.

For the most part the analyses of these runs will be statistical and will follow the statistical table format detailed in the prior section. The goal is to quickly determine whether the option being tested proves beneficial. The analyses are limited to the wintertime episode 1 and the longer of the two summertime episodes, episode 2. Recall that the px_acm2 run, while performing the best of the original five sensitivities, failed to meet the statistical "benchmark" for temperature for episode 1. The px_acm3 configuration is an attempt to rectify this bias by initializing the model from the single most appropriate EDAS soil layer (40-100 cm). This run included an error correction pass that reduced the effect of "missing" values in the EDAS data set. Tables 31-32 show the results of this sensitivity for episode 1 for both grid resolutions modeled. Note the vast improvement in temperature bias in both tables. Most of the other variables are relatively unaffected.

Table 32. Like table 31, except for 12-km VISTAS domain.

Unfortunately the improvements noted in the wintertime episode do not translate to the summer episode (tables 33-34). In fact the results indicate a degraded bias result, with the temperatures more significantly cold-biased for both resolutions modeled. The remaining variables tend to be relatively unaffected, generally showing a very slight degradation in performance. If this sensitivity had produced superior results for all episodes, we would recommend further efforts to possibly improve the initialization of the P-X module in MM5. Given the ad hoc nature of this sensitivity test that only yields mixed-bag results at best, we do not recommend applying this approach for the annual modeling.

An alternative approach to using LITTLE_R in the MM5 preprocessing stream is to use RAWINS. Functionally they serve the same purpose, which is to use observations to “improve” the first-guess and analysis fields that drive MM5. NCAR recommends that users employ LITTLE_R, which is a newer, more flexible program, but also somewhat more difficult to implement. (Unfortunately when this project started the documentation for LITTLE_R was less than stellar. The updated documentation indicates that upper air data “probably should” be added to the **sfc_obs** files; we plan to do just that for the annual modeling, but these tests will not have that “benefit”.) Prior modeling results found little difference between using these programs and not using them at all. To use P-X in the recommended manner (i.e. with indirect soil nudging) requires that the SFCFDDA file be available, which necessitates running one of those objective analysis preprocessors. The px-acm2 configuration used LITTLE_R only for that purpose. The px_acm4 configuration is actually a two-fold sensitivity in that it tests the effects of 1) running RAWINS rather than LITTLE_R to generate the SFCFDDA files, and 2) using objective analysis (RAWINS, in this case) output as input to INTERPF, as opposed to using REGRID output. Tables 35-36 show the results for the wintertime episode. In general we see improvement for most of the variables, especially for the VISTAS 12-km domain. Precipitation results are very slightly degraded, but not significantly so. The summertime results for this sensitivity are shown in tables 37-38, and they indicate no clear overall improvement/degradation.

The Reisner 2 microphysics package is sophisticated and computationally expensive, but is believed to incorporate the appropriate science necessary to properly model precipitation over a variety of conditions. Tables 39-40 show the statistical differences for the wintertime episode. Interestingly enough this px_acm5 sensitivity yields improved temperature and cloud coverage performance, but the precipitation skill scores show a very slight degradation. Summertime performance for this sensitivity (tables 41-42) show generally degraded performance. These results do not justify the increased computational/storage cost of implementing Reisner 2 microphysics.

Sensitivity test px_acm6 is designed to show the effects of nudging strength. The very slight increase in nudging strength at 36-km is not expected to have a large effect on the results, and the episode 1 statistical difference table (table 43) bears this out. The 12-km results (table 44) are a little more interesting since the nudging strength aloft is increased more dramatically. The idea is that above the planetary boundary layer synoptic conditions prevail, thus making analysis nudging at a reasonably strong level appropriate. In the boundary layer itself the wind nudging is kept at a relatively weak level. We do note an improvement in the temperature and precipitation metrics, but a slight degradation in mixing ratio and winds. The summer case expectedly reveals little change at 36-km resolution (table 45), while the 12-km results (table 46) show decreased skill for almost all variables, with temperature and winds being the notable exceptions. Overall it is hard to justify this configuration as an improvement over the base case.

Table 46. Like table 45, except for 12-km VISTAS domain.

Recall from the discussion of sensitivity px_acm4 that a slight improvement was found by using RAWINS output to drive both INTERPF and MM5. Since that sensitivity involved changing two variables at once, we do not know which change (or both) led to the improvement. Sensitivities px_acm7 and px_acm8 are designed to answer that question. In px_acm7 we change only the SFCFDDA file that MM5 reads in, using the RAWINS output rather than LITTLE_R output. Tables 47-50 show the results for both grids and for both episodes. Very slight performance degradation is seen in all tables. Tables 51-54 show the results for px_acm8, a sensitivity in which LITTLE_R outputs are used as inputs both to MM5 and INTERPF. While the wintertime tables show very slight performance degradation for precipitation, the remaining variables show universal improvement. Similar improvements are seen in the summertime cases with no performance degradation in the precipitation statistics. This configuration appears to be an improvement over the base case and should be incorporated into the annual modeling protocol.

The MM5 (http://www.mmm.ucar.edu/mm5/documents/MM5_tut_Web_notes/MM5/mm5.html) documentation states that the IFSNOW option applies when the LSM is not used. So this flag was not deemed to be important for P-X applications. Of course when MM5 documentation refers to the LSM it normally means the NOAH LSM, not the P-X LSM. So we performed a couple of wintertime only sensitivities to determine the effect the IFSNOW flag may have on a P-X run. Table 55 shows the results for the 36-km domain if the IFSNOW flag is set to 0. Note the bias improvement of 0.07 ^{o}C for temperature for this sensitivity s0px_acm2. Perhaps snow effects are being double-counted in P-X if this flag is turned on? The other variables are relatively unaffected, though it is interesting to note the almost universal slight degradation of precipitation skill. Since snow is a relatively rare occurrence in the VISTAS domain, little change is seen at 12-km resolution for the VISTAS domain, as illustrated in table 56.

Tables 57-58 show the statistical difference tables for the s2px_acm2 configuration. This sensitivity turns the simple snow model on. These runs are very cold-biased, even for the 12-km VISTAS domain. Clearly this configuration is not recommended for annual modeling.

Tables 59-60 show the shorter summertime episode (episode 3) results for the px_acm9 sensitivity. The idea for this test is to see if an integration of EDAS soil temperature/moisture might yield similar wintertime benefits that we saw in the px_acm3 sensitivity, while not showing the degraded summertime performance that prior sensitivity showed. Admittedly more work could be done along these lines, but the results for this px_acm9 sensitivity show the summertime performance degradation we had hoped would not exist. This configuration is not recommended for annual modeling.

The next few sensitivity runs quantify the effects of nudging temperature/moisture near the surface. One advantage of the P-X module is that it allows indirect soil moisture nudging to be applied, thereby in essence "nudging" the lowest layers of the atmosphere without the instabilities that might result from directly applying surface analysis nudging of temperature/moisture. To quantify the effects this indirect soil nudging has on the results, we turned it off in sensitivity n0px_acm2 and applied the model only for episode 2 at 36-km resolution (table 61). Not surprisingly we see general performance degradation, though the character of the simulation is not changed dramatically. For example, the temperature error metric still shows better performance than what we saw in the noah_mrf, multi_blkdr, and noah_eta-my runs (tables 15, 21, and 27, respectively).

Table 61. Episode 2 composite statistical comparison of sensitivity n0px_acm2 with base case px_acm2 for the US portion of the 36-km domain is shown.

As mentioned above instabilities can sometimes result when the thermodynamic variables (t, q) are nudged in the boundary layer. In a test performed years ago using Blackadar mixing we saw checkerboard daytime PBL height patterns that were obviously wrong. Heights varied in adjacent cells from ~2500 m to ~40 m to ~2500 m and so on. The warning against nudging temperature/moisture in the boundary layer appears to be only passed down by word of mouth; no warning appears to exist in the MM5 documentation. In fact, the sample deck in the documentation has FDDA turned off completely, but if it were turned on the default would be for surface analysis nudging of temperature/moisture to be enabled. Might the warnings against this be outdated? To test this we have conducted two sensitivities. Both tests have temperature nudging at the same strength as wind nudging in the boundary layer. The first test (px_acm_n) has moisture nudged at 1.0E-4 for both 36-km and 12-km resolutions, while the second test (px_acm_n2) reduces the moisture nudging strength to the default value of 1.0E-5 for both grids. Aloft we keep the nudging strengths the same as in the base case. Note that the low values for moisture nudging aloft make sense given the discontinuous nature of moisture aloft. There is no guarantee that the moisture from an observed sounding is actually representative of the synoptic conditions. At the surface, however, mixing ratio is a much more continuous quantity and theoretically could be nudged at a higher strength.

With the daytime checkerboard PBL pattern in mind, we checked the PBL heights from px_acm_n to see if similar instabilities exist. We could find not find them. Tables 62-63 show the statistical difference results for this sensitivity for the wintertime episode 1. Note the general improvement in the surface statistics, especially the temperature bias for both grids. Precipitation skill is relatively unaffected. The episode 2 results (tables 64-65) show a different story. This sensitivity improves the error statistics for temperature, mixing ratio, and relative humidity, and the winds are only slightly affected. But look at the precipitation statistics! The runs are significantly biased high at all thresholds, especially in the 36-km grid. Accordingly all of the precipitation skill metrics, with the exception of course of probability of detection, show degraded performance. Apparently the surface nudging is causing some sort of convective instabilities that are not evident to a significant extent in the winter.

Perhaps the convective instabilities might go away if the moisture nudging coefficients are reduced to the default values. Tables 66-67 show the results for the px_acm_n2 sensitivity for episode 2. The bias overestimation improves over px_acm_n, but it still shows a significant degradation compared with our original base case. It should be noted that if we did not consider precipitation statistics we would probably consider these last two sensitivities to be the most appealing of all the sensitivities tested. Fortunately that is not the case here. We should also note that the precipitation instabilities are relatively subtle and might not be found by simply looking at a PAVE/RIP animation of model precipitation.

To further investigate the precipitation patterns of all the sensitivities tested, we have developed a 4-panel episode-composite approach. The upper left panel contains the total observed precipitation for the episode. The upper right panel shows the total modeled precipitation for the sensitivity being examined, while the lower left panel shows the difference between the total modeled precipitation and the observed. Finally, for all non-base case runs, the lower right panel shows the difference between the sensitivity and the base case px_acm2. Figure 38 shows the episode 1 36-km precipitation composite plot for the base case. The general precipitation patterns are captured nicely by the px_acm2 configuration, though there are places where the model underestimates total precipitation (e.g. northwest coastline) and places where the model overestimates total precipitation (e.g. eastern South Carolina). Figure 39 shows the corresponding plot for the 12-km grid. Again the model does a decent job in the general placement and magnitude of the precipitation, though certain precipitation bands are slightly displaced.

Figures 40-41 show the px_acm total precipitation plots for the px_acm case. The results are similar to the px_acm2 case, though less precipitation falls in this sensitivity, presumably due to the cold bias seen in this run. Figures 42-43 show the episode 1 plots for noah_mrf. The results are different from the base case but not particularly striking. Figures 44-45 show that the corresponding plots for the multi_blkdr runs exhibit large areas of slightly increased precipitation compared with the base case. This is very similar to the noah_eta-my results shown in figures 46-47.

The base case results for episode 2 (figures 48-49) are less encouraging. The px_acm2 run shows a clear positive accumulation bias at both grid resolutions. The bias is probably manageable, but it is certainly something to consider when analyzing air quality runs driven by this meteorology. The px_acm (figures 50-51), noah_mrf (figures 52-53), multi_blkdr (figures 54-55), and noah_eta-my (figures 56-57) results all are qualitatively similar. Perhaps the model triggers convection a little too easily.

The Reisner 2 (px_acm5) plots are shown in figures 58-61. This sensitivity tends to produce slightly less total precipitation than the base case, though the character of the run is essentially unchanged. The same can be said for the px_acm8 results shown in figures 62-65. The wintertime plots for px_acm_n (figures 66-67) are also very similar to the base case. The summertime px_acm_n plots (figures 68-69) are another matter entirely!

Table 67. Like table 66, except for 12-km VISTAS domain.

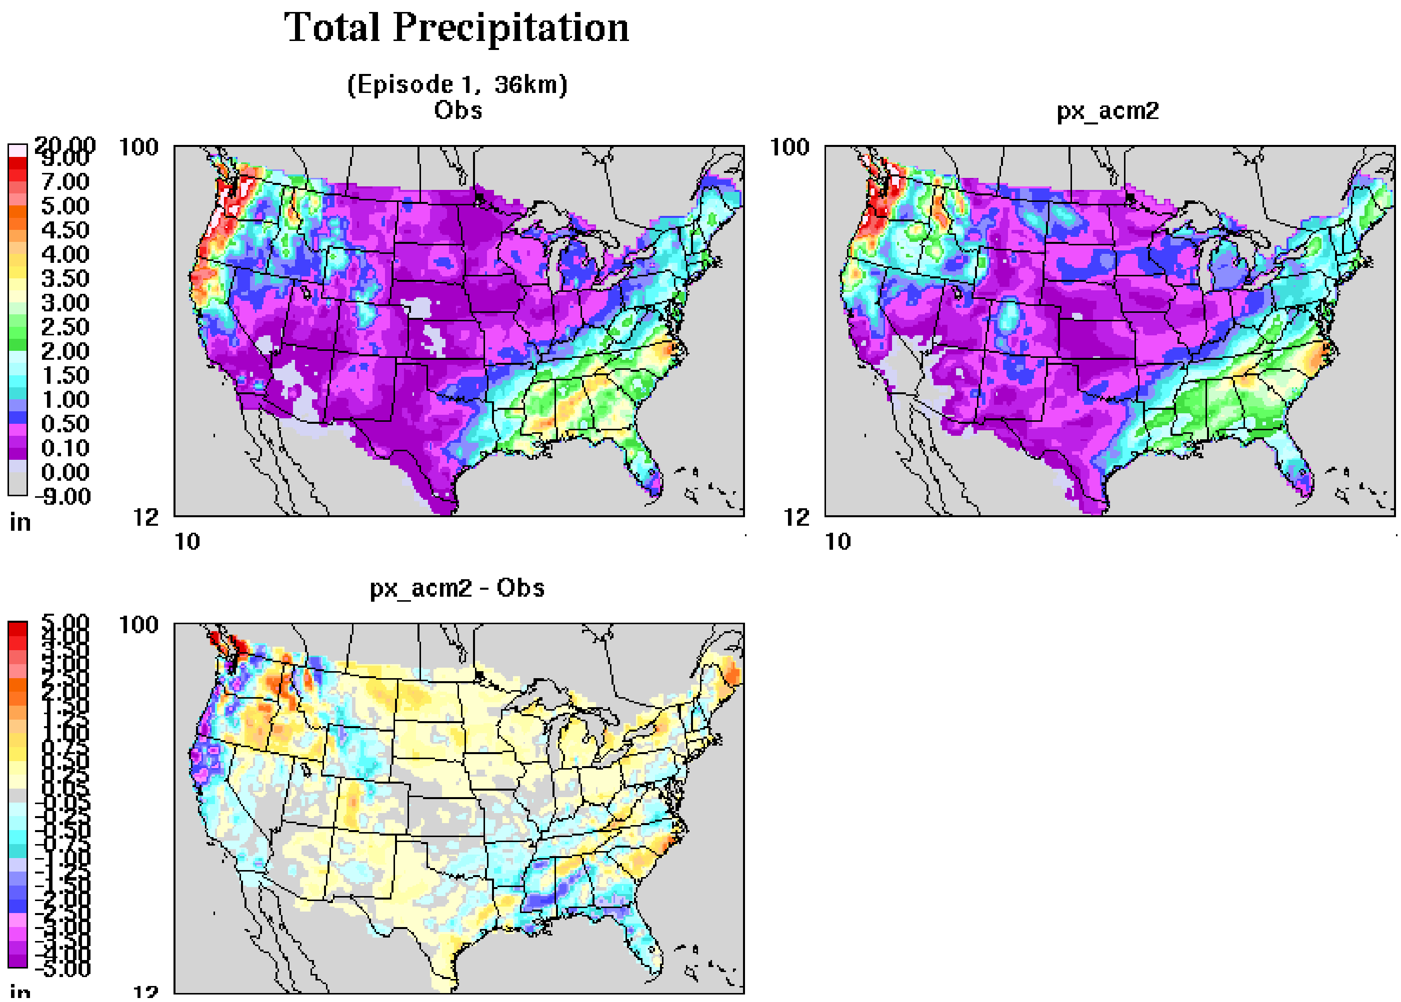

Figure 38. Episode 1 (Jan 2-21, 2002) composite precipitation for the US land-portion of the 36-km domain is shown. The top left panel displays the accumulated precipitation generated from the Climate Prediction Center gridded precipitation datasets. The top right panel shows the corresponding plot for the base case px_acm2 model configuration. The lower left plot shows the difference plot of the top panels.

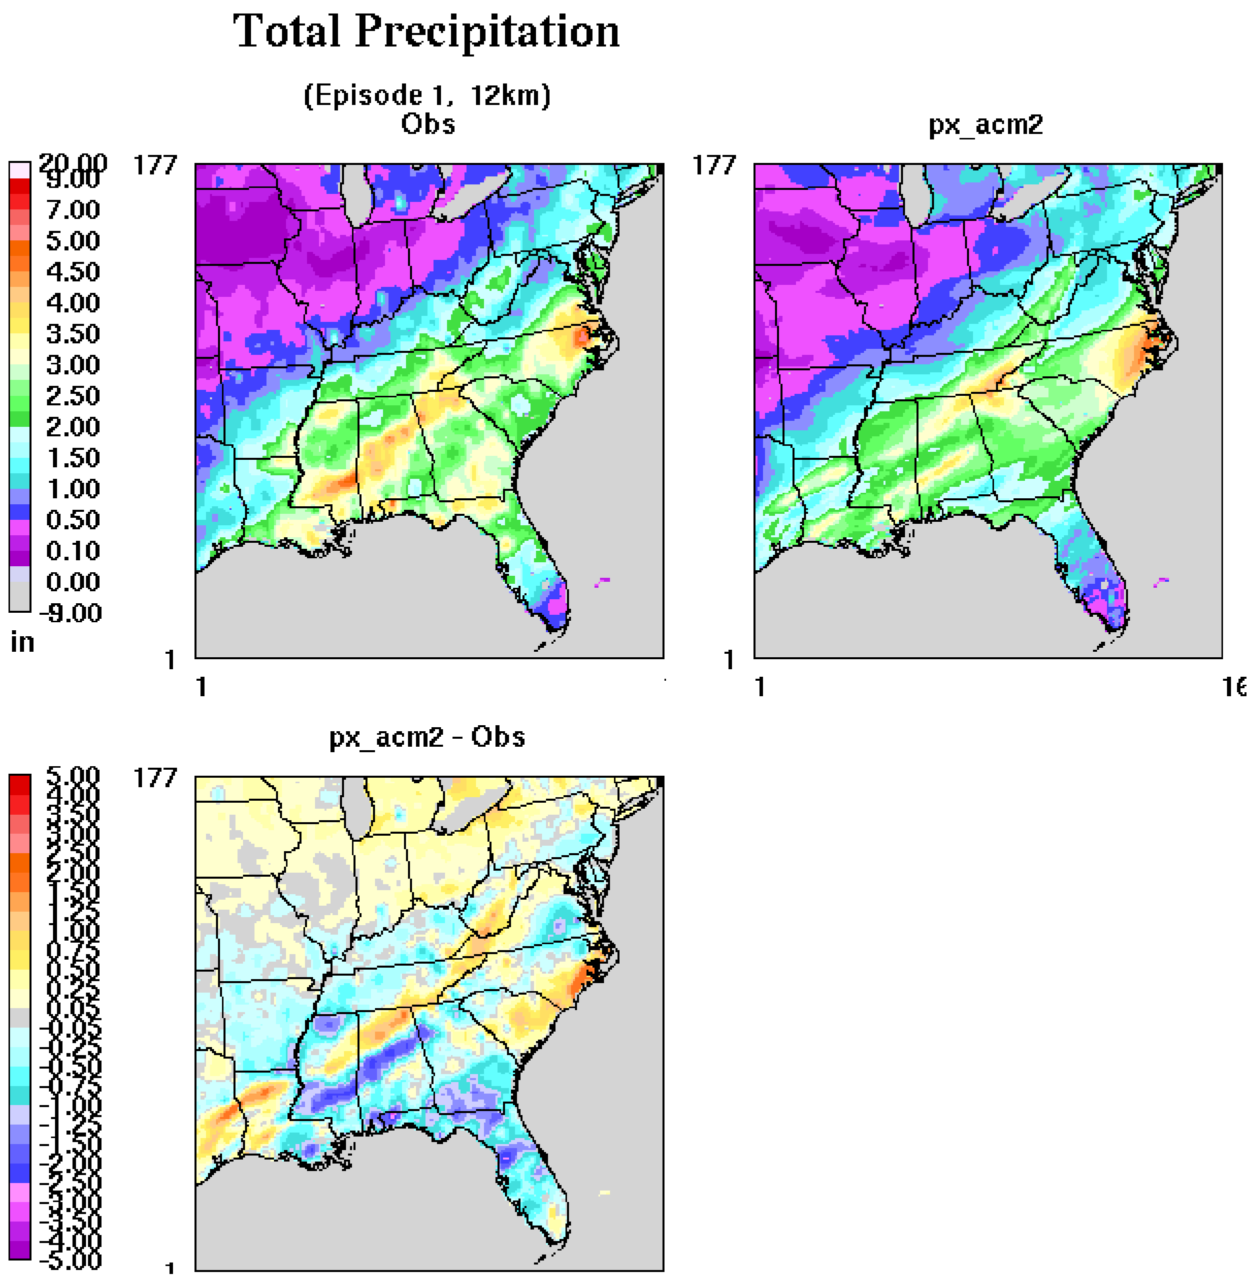

Figure 39. Episode 1 (Jan 2-21, 2002) composite precipitation for the US land-portion of the 12-km domain is shown. The top left panel displays the accumulated precipitation generated from the Climate Prediction Center gridded precipitation datasets. The top right panel shows the corresponding plot for the base case px_acm2 model configuration, and the lower left plot shows the difference plot between the model and the observations.

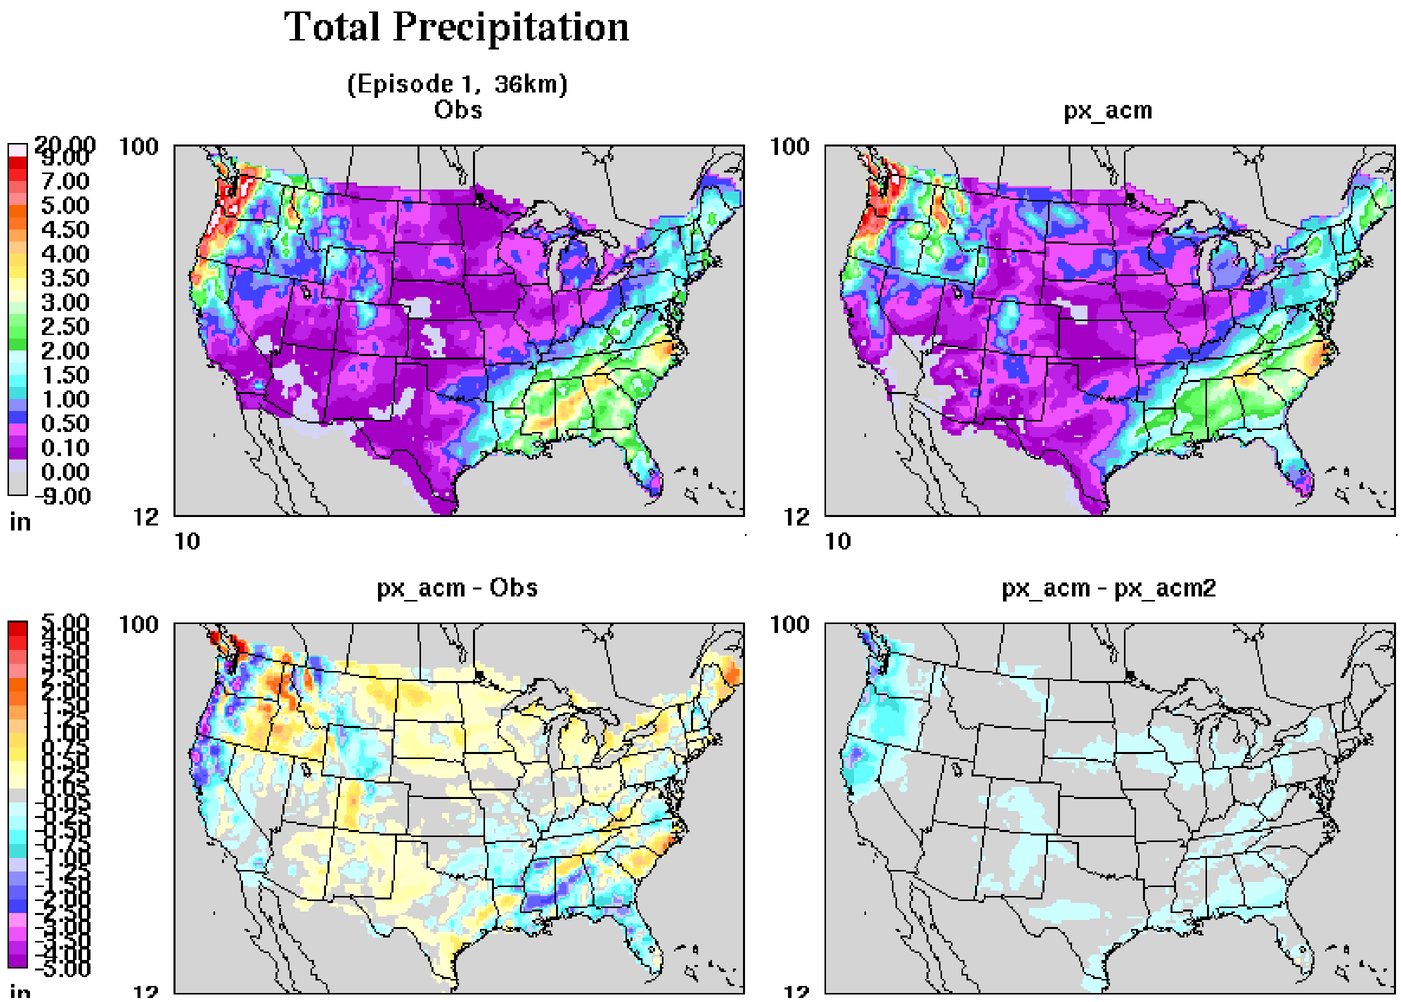

Figure 40. Episode 1 (Jan 2-21, 2002) composite precipitation for the US land-portion of the 36-km domain is shown. The top left panel displays the accumulated precipitation generated from the Climate Prediction Center gridded precipitation datasets. The top right panel shows the corresponding plot for the px_acm model configuration, and the lower left plot shows the difference plot between the model and the observations. The bottom right plot shows the difference between the px_acm sensitivity and the px_acm2 base case.

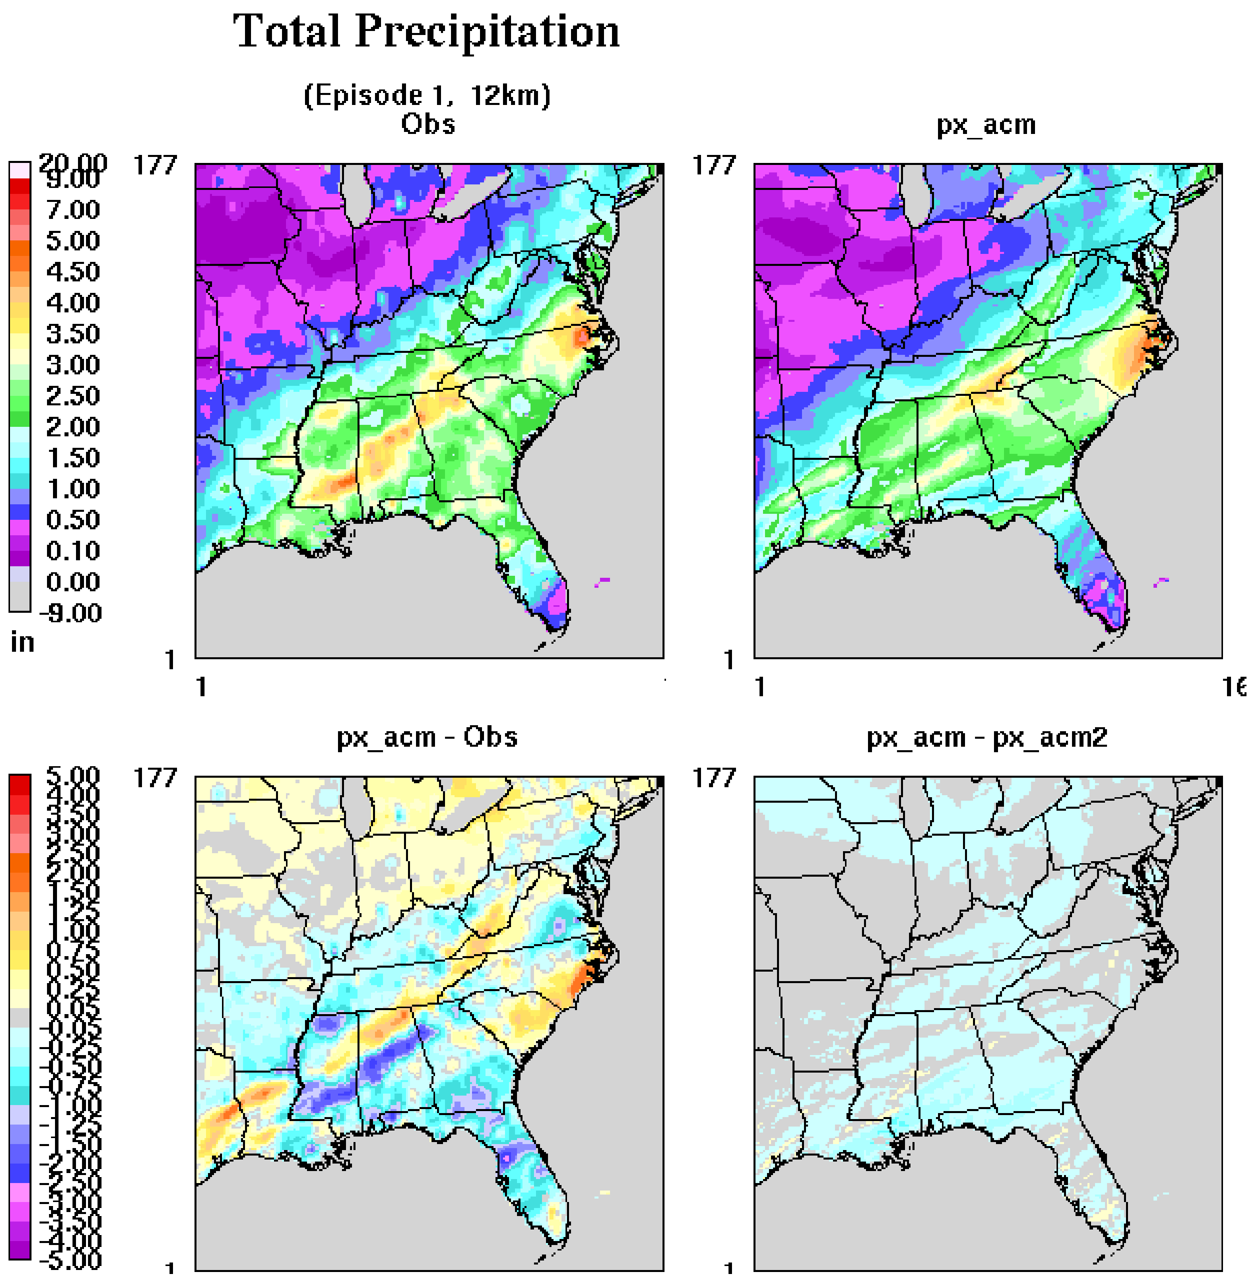

Figure 41. Episode 1 (Jan 2-21, 2002) composite precipitation for the US land-portion of the 12-km domain is shown. The top left panel displays the accumulated precipitation generated from the Climate Prediction Center gridded precipitation datasets. The top right panel shows the corresponding plot for the px_acm model configuration, and the lower left plot shows the difference plot between the model and the observations. The bottom right plot shows the difference between the px_acm sensitivity and the px_acm2 base case.

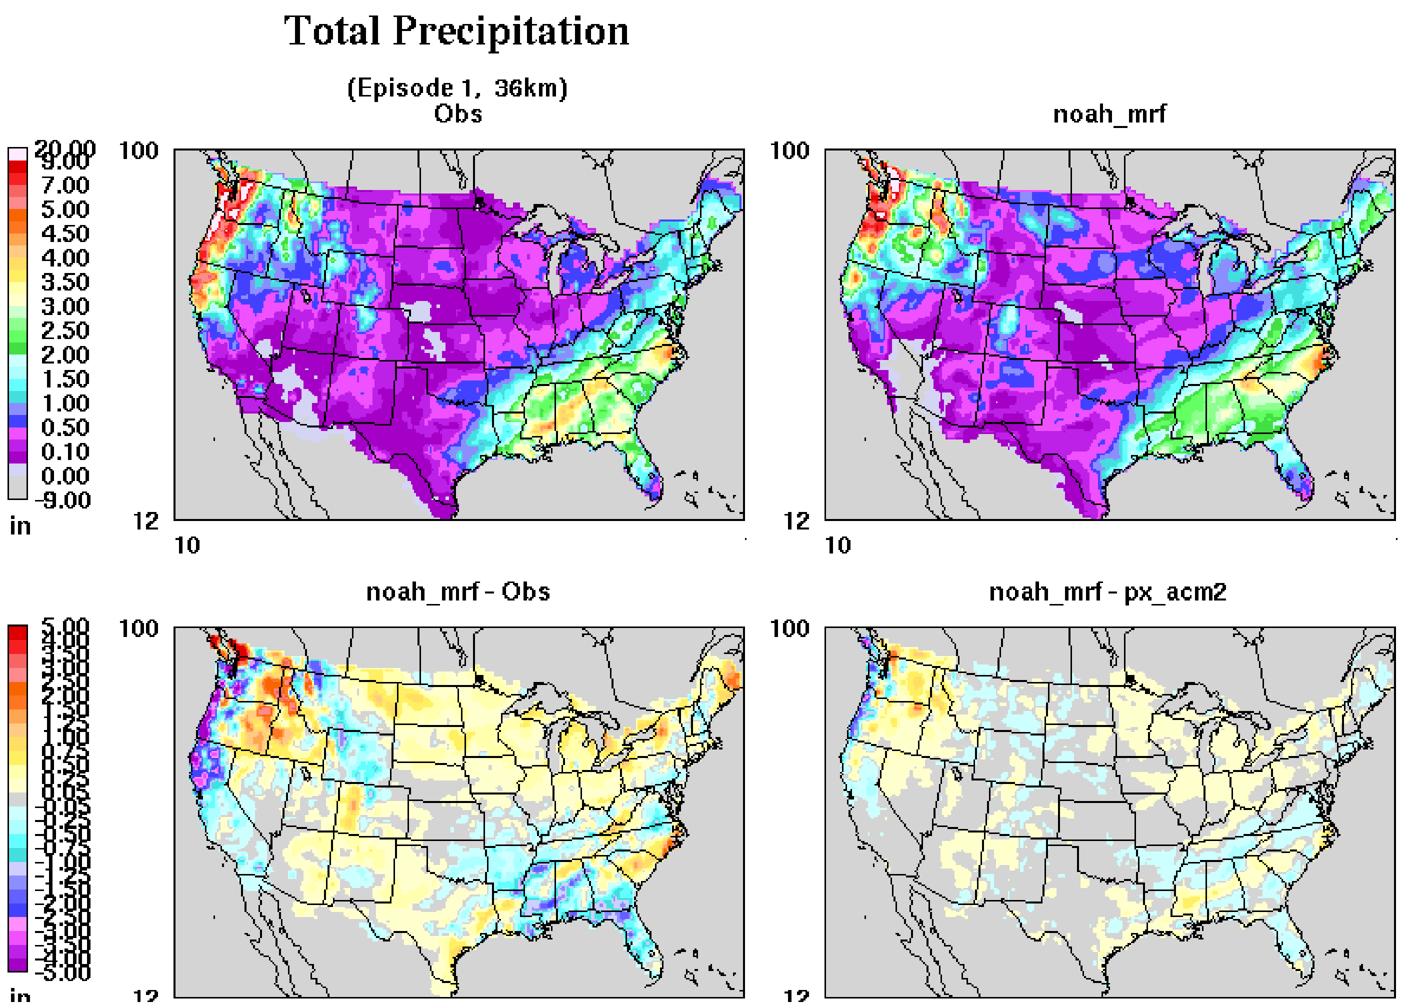

Figure 42. Episode 1 (Jan 2-21, 2002) composite precipitation for the US land-portion of the 36-km domain is shown. The top left panel displays the accumulated precipitation generated from the Climate Prediction Center gridded precipitation datasets. The top right panel shows the corresponding plot for the noah_mrf model configuration, and the lower left plot shows the difference plot between the model and the observations. The bottom right plot shows the difference between the noah_mrf sensitivity and the px_acm2 base case.

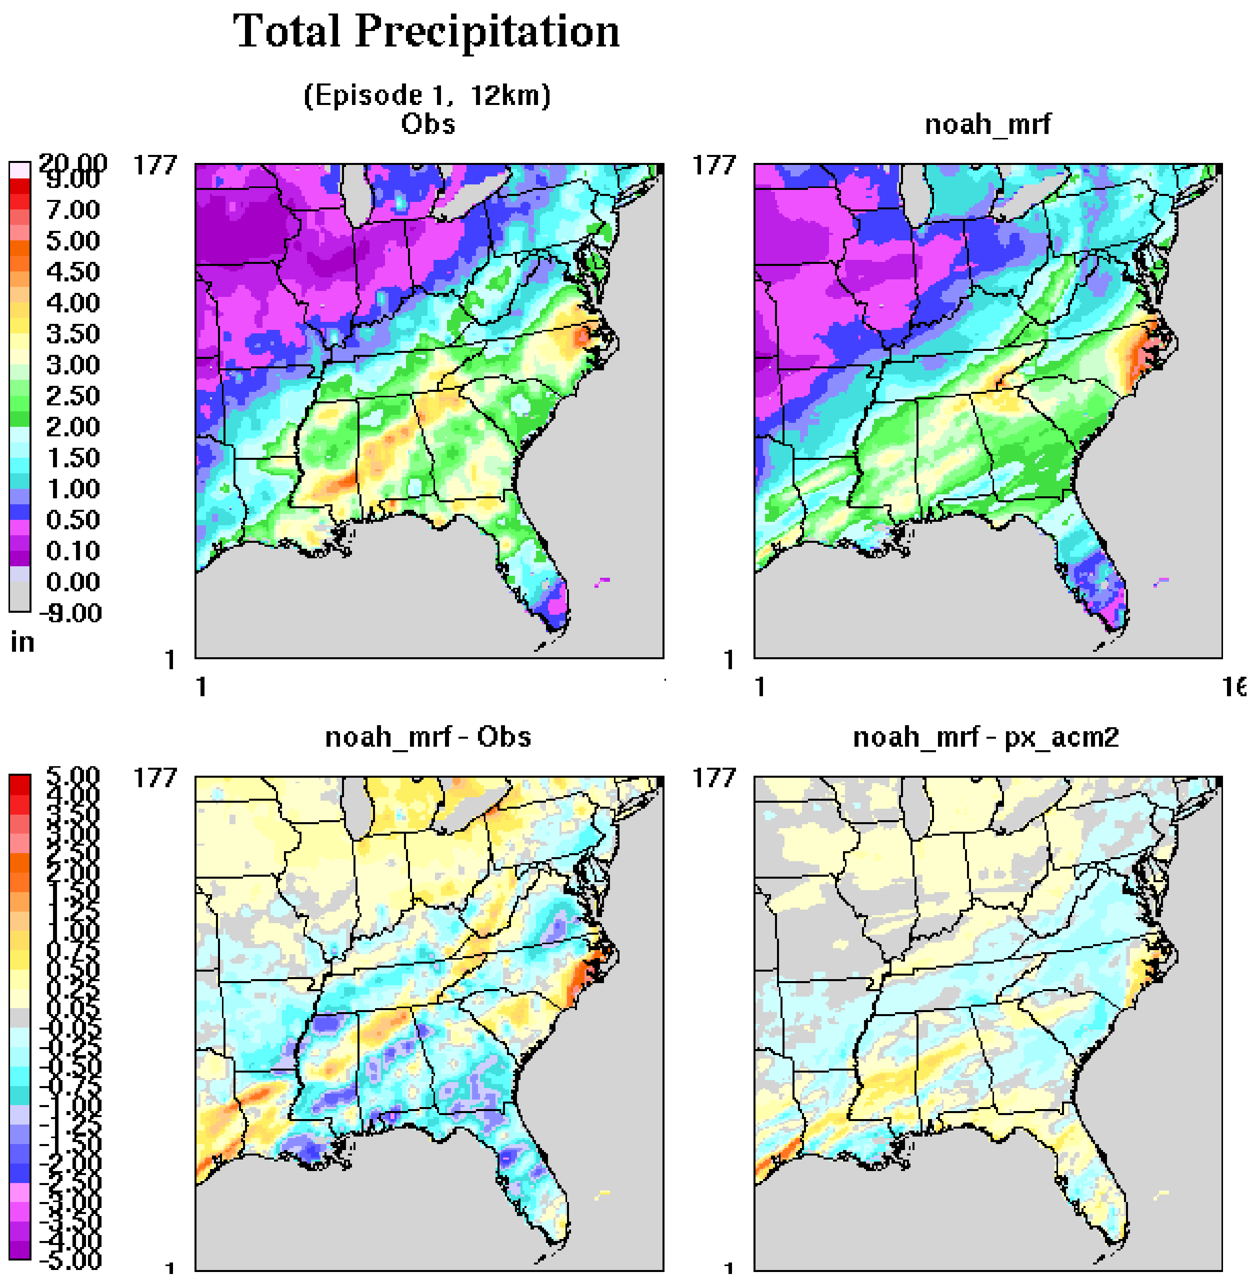

Figure 43. Episode 1 (Jan 2-21, 2002) composite precipitation for the US land-portion of the 12-km domain is shown. The top left panel displays the accumulated precipitation generated from the Climate Prediction Center gridded precipitation datasets. The top right panel shows the corresponding plot for the noah_mrf model configuration, and the lower left plot shows the difference plot between the model and the observations. The bottom right plot shows the difference between the noah_mrf sensitivity and the px_acm2 base case.

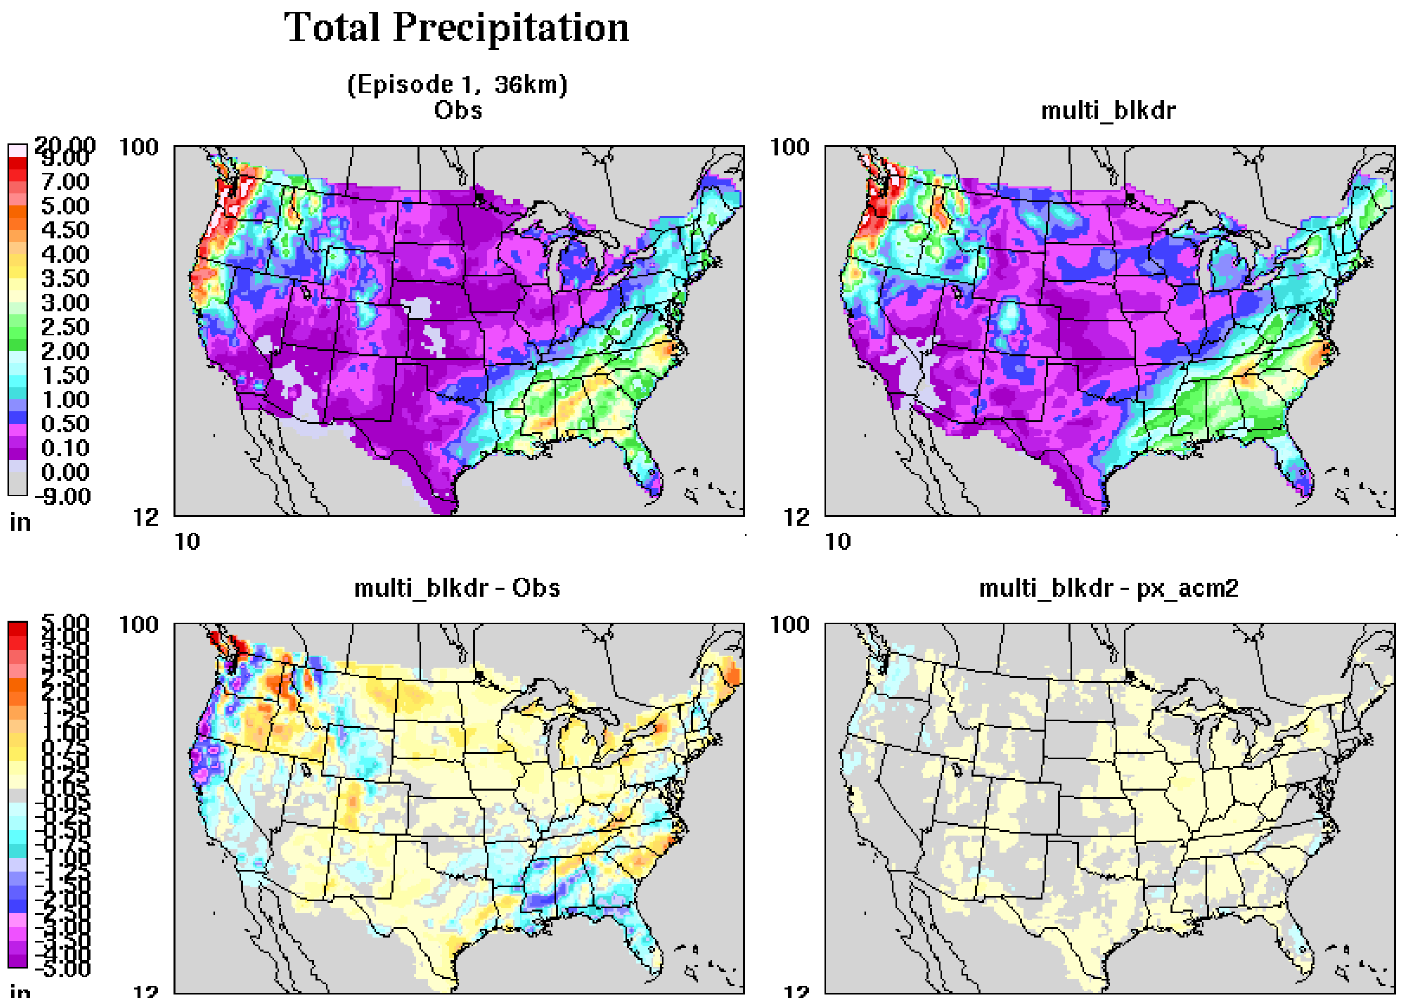

Figure 44. Episode 1 (Jan 2-21, 2002) composite precipitation for the US land-portion of the 36-km domain is shown. The top left panel displays the accumulated precipitation generated from the Climate Prediction Center gridded precipitation datasets. The top right panel shows the corresponding plot for the multi_blkdr model configuration, and the lower left plot shows the difference plot between the model and the observations. The bottom right plot shows the difference between the multi_blkdr sensitivity and the px_acm2 base case.

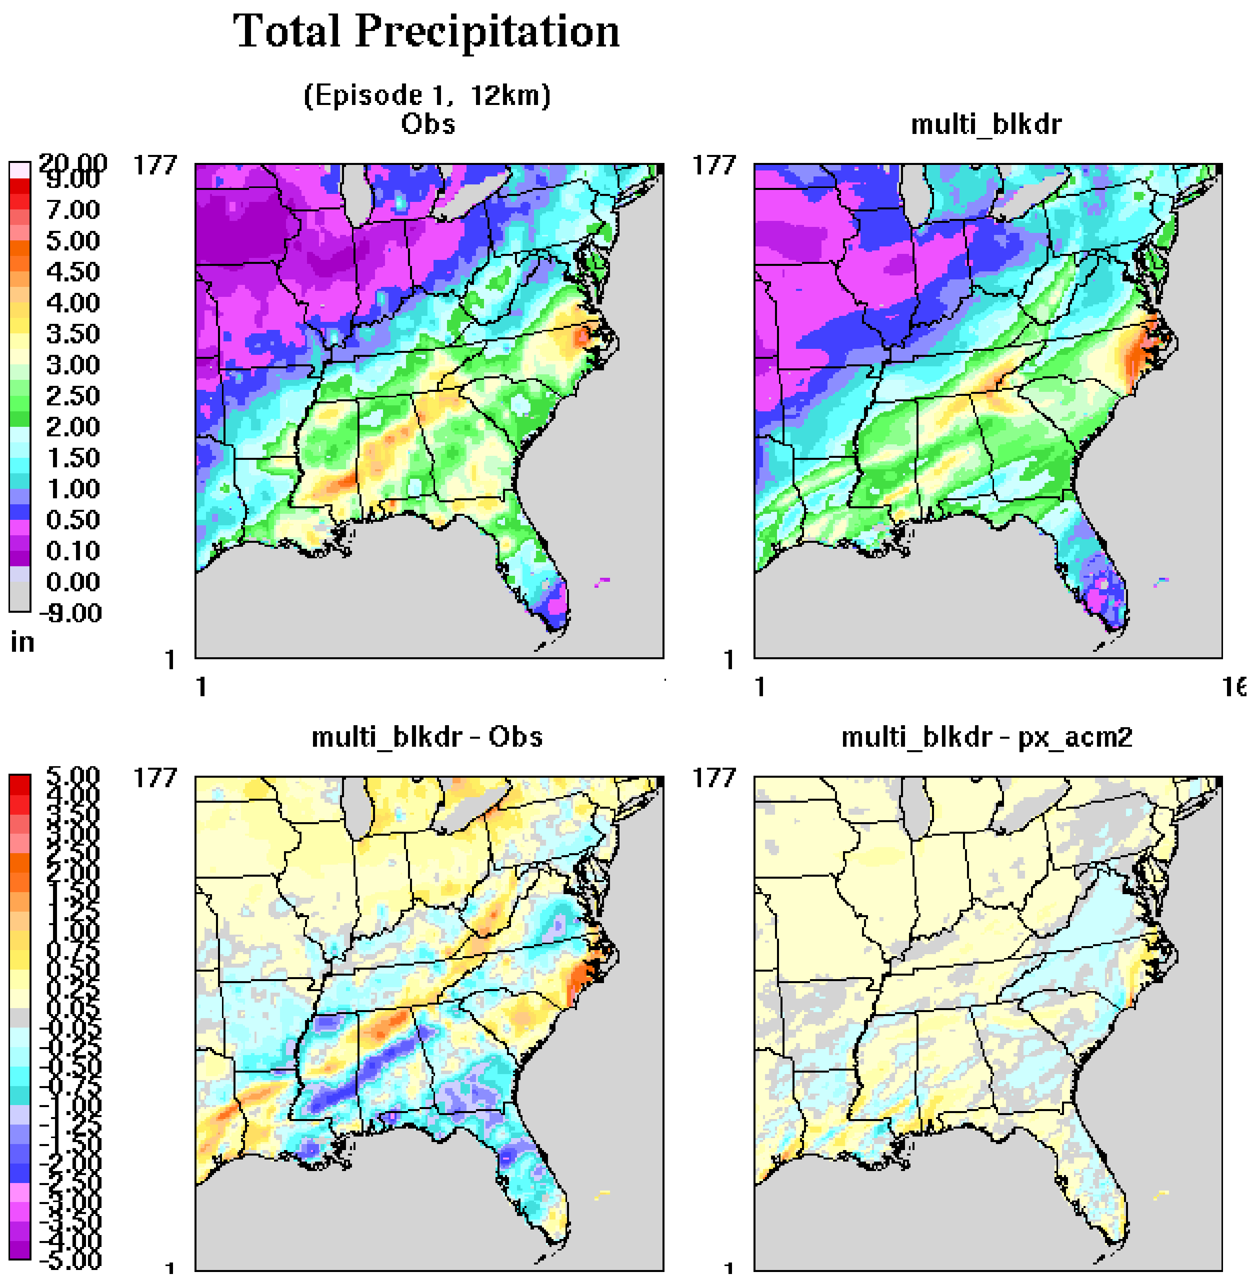

Figure 45. Episode 1 (Jan 2-21, 2002) composite precipitation for the US land-portion of the 12-km domain is shown. The top left panel displays the accumulated precipitation generated from the Climate Prediction Center gridded precipitation datasets. The top right panel shows the corresponding plot for the multi_blkdr model configuration, and the lower left plot shows the difference plot between the model and the observations. The bottom right plot shows the difference between the multi_blkdr sensitivity and the px_acm2 base case.

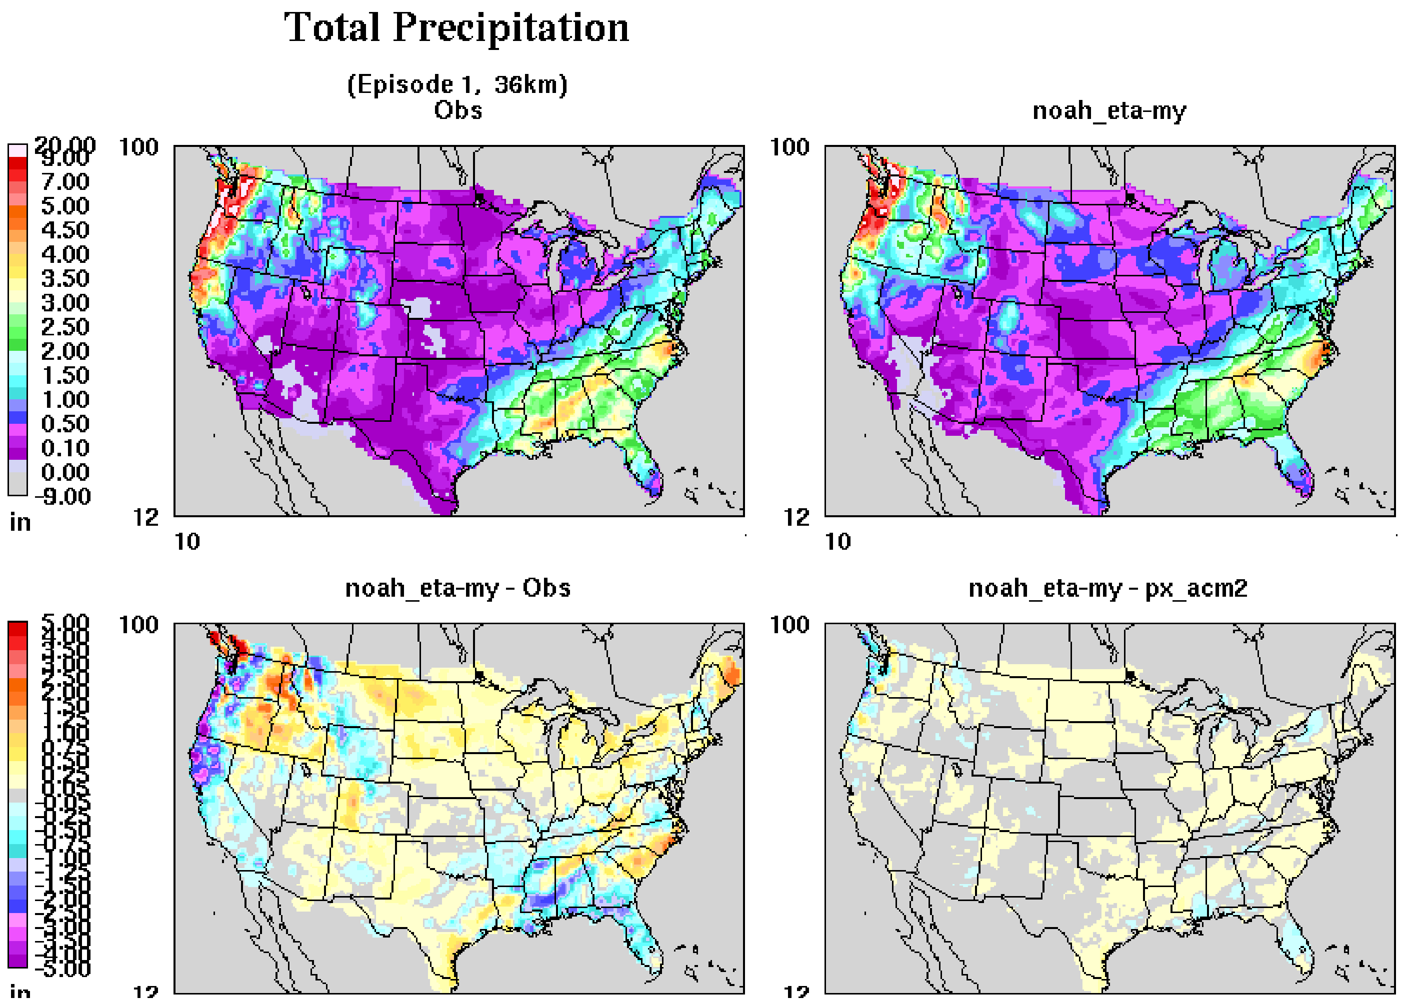

Figure 46. Episode 1 (Jan 2-21, 2002) composite precipitation for the US land-portion of the 36-km domain is shown. The top left panel displays the accumulated precipitation generated from the Climate Prediction Center gridded precipitation datasets. The top right panel shows the corresponding plot for the noah_eta-my model configuration, and the lower left plot shows the difference plot between the model and the observations. The bottom right plot shows the difference between the noah_eta-my sensitivity and the px_acm2 base case.

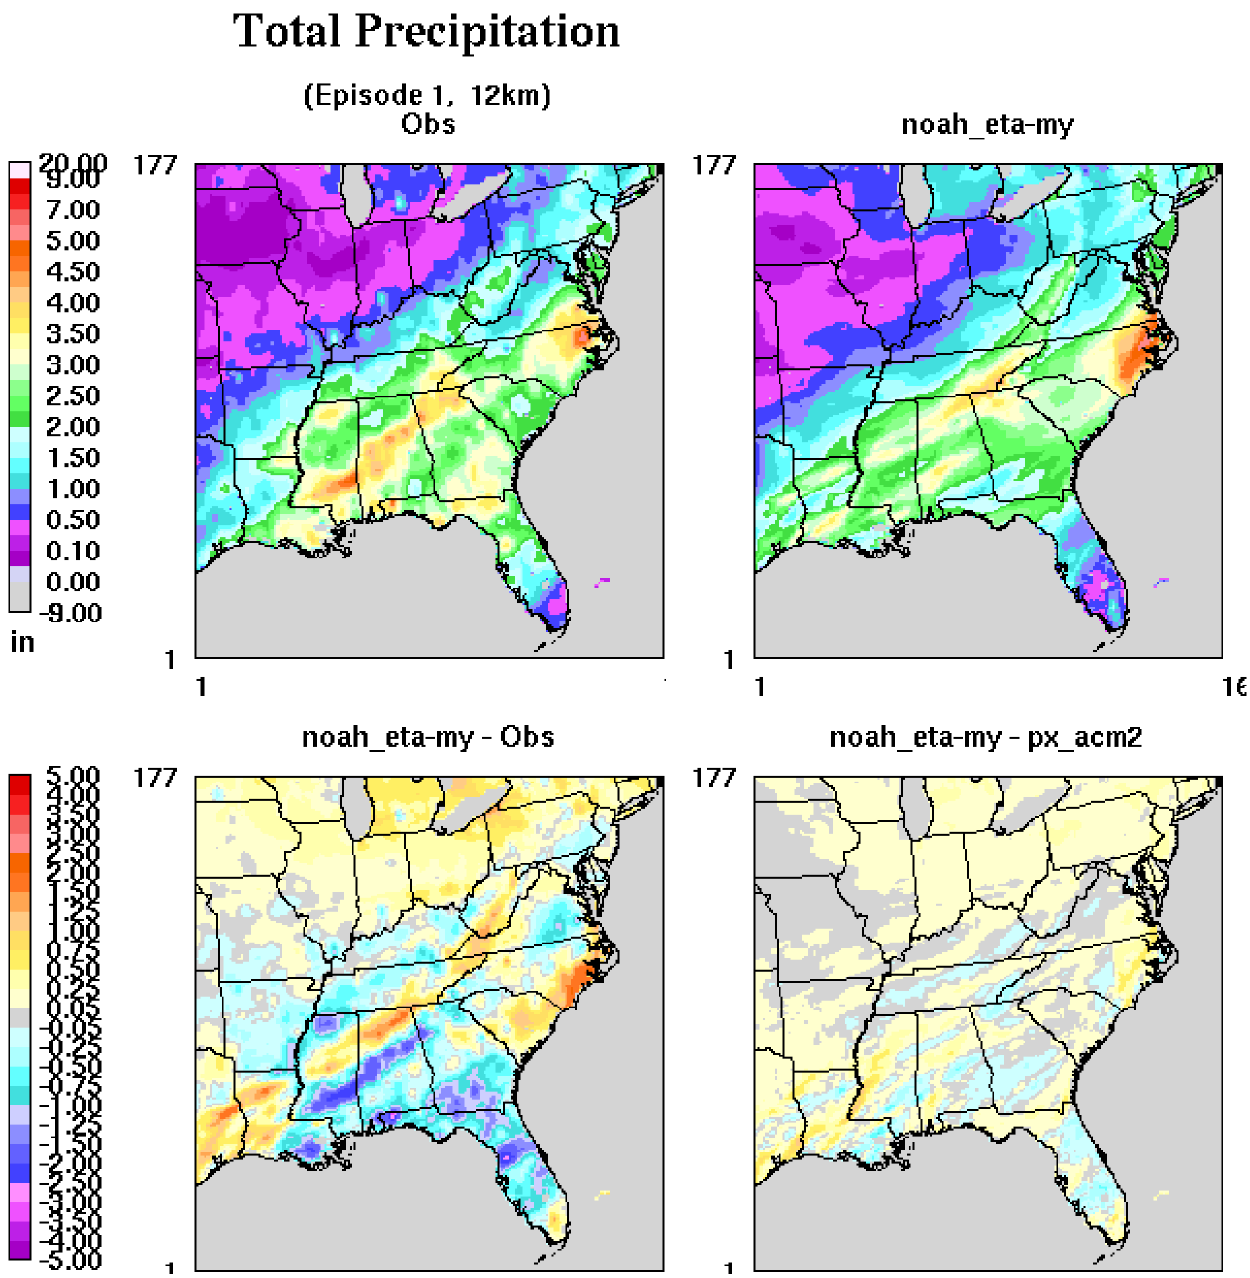

Figure 47. Episode 1 (Jan 2-21, 2002) composite precipitation for the US land-portion of the 12-km domain is shown. The top left panel displays the accumulated precipitation generated from the Climate Prediction Center gridded precipitation datasets. The top right panel shows the corresponding plot for the noah_eta-my model configuration, and the lower left plot shows the difference plot between the model and the observations. The bottom right plot shows the difference between the noah_eta-my sensitivity and the px_acm2 base case.

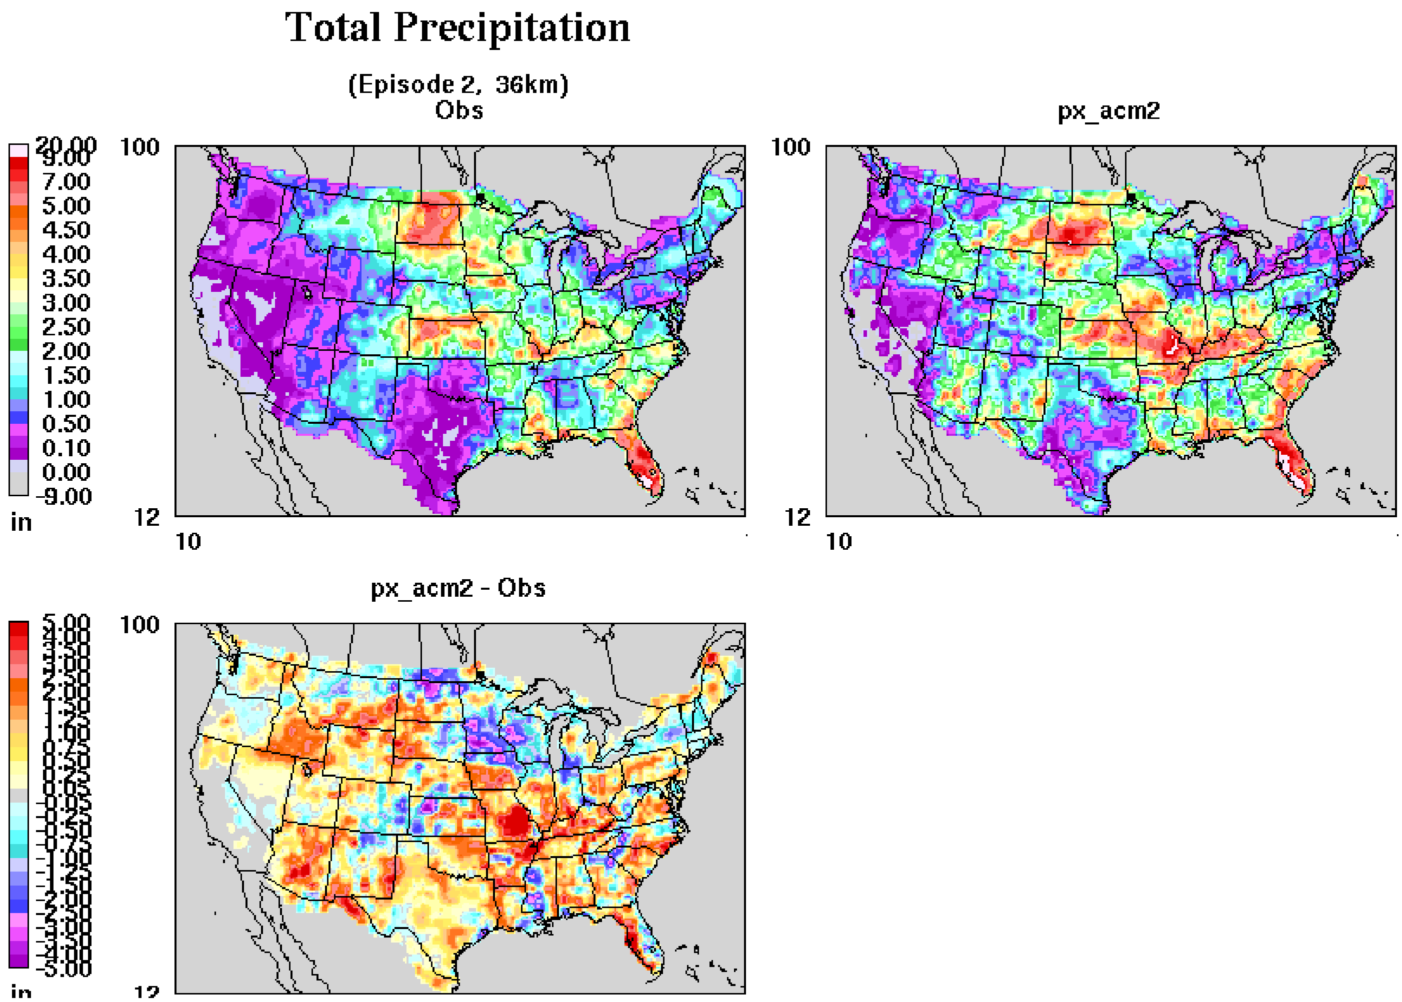

Figure 48. Episode 2 (Jul 13-28, 2001) composite precipitation for the US land-portion of the 36-km domain is shown. The top left panel displays the accumulated precipitation generated from the Climate Prediction Center gridded precipitation datasets. The top right panel shows the corresponding plot for the base case px_acm2 model configuration. The lower left plot shows the difference plot of the top panels.

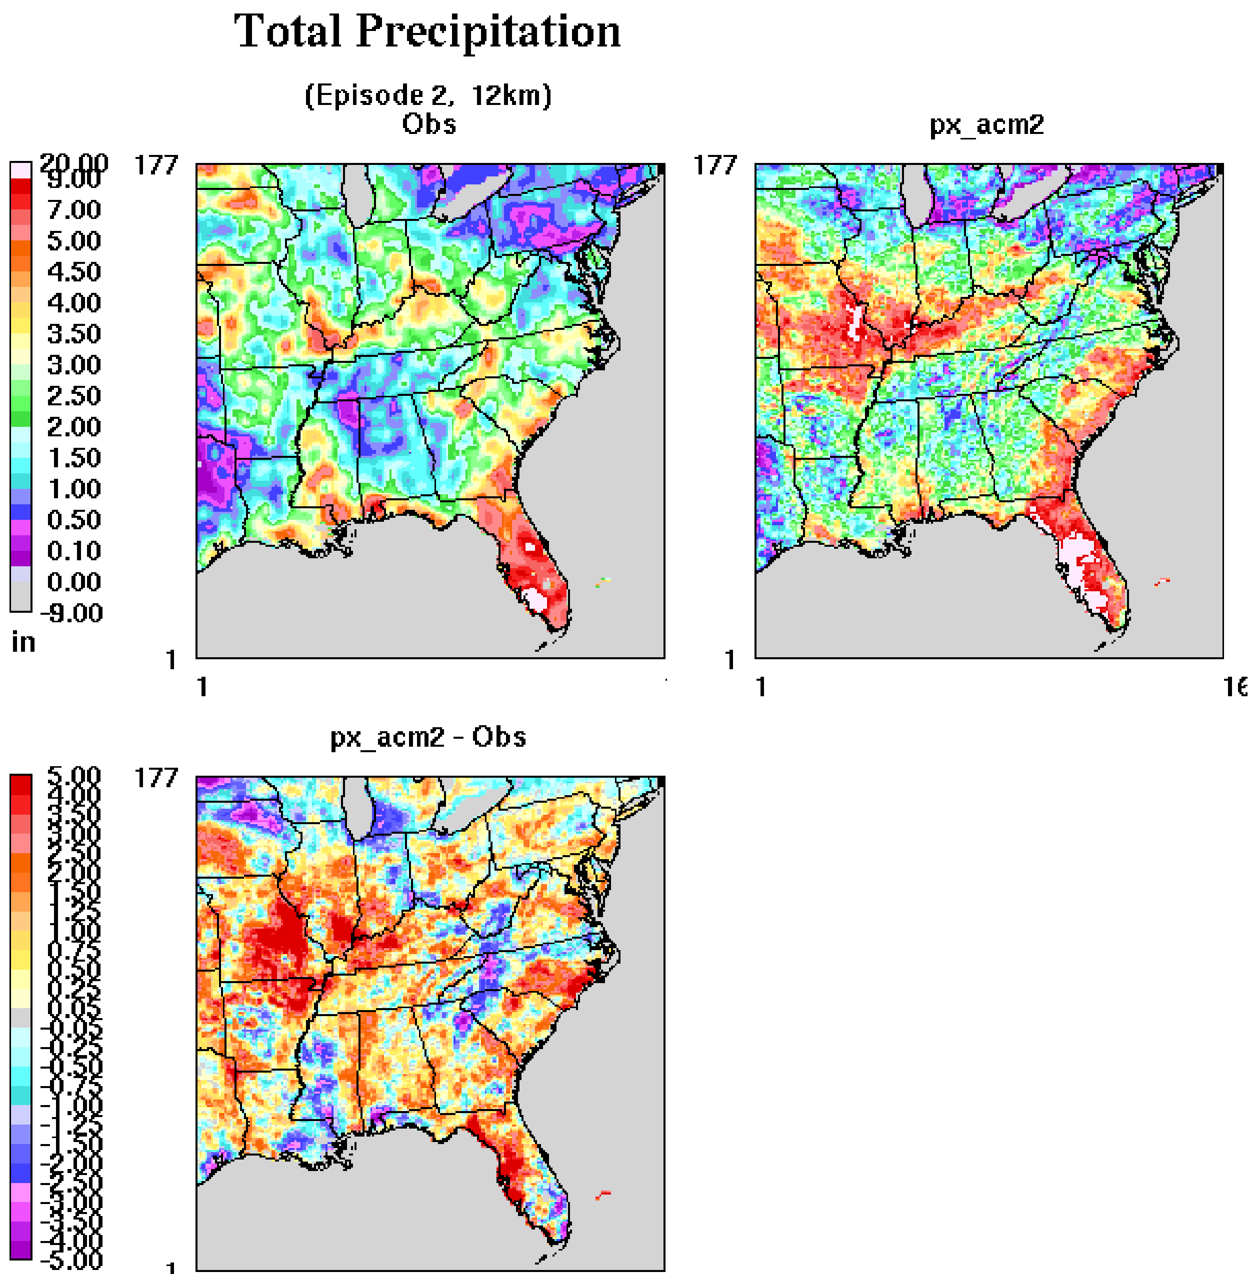

Figure 49. Episode 2 (Jul 13-28, 2001) composite precipitation for the US land-portion of the 12-km domain is shown. The top left panel displays the accumulated precipitation generated from the Climate Prediction Center gridded precipitation datasets. The top right panel shows the corresponding plot for the base case px_acm2 model configuration. The lower left plot shows the difference plot of the top panels.

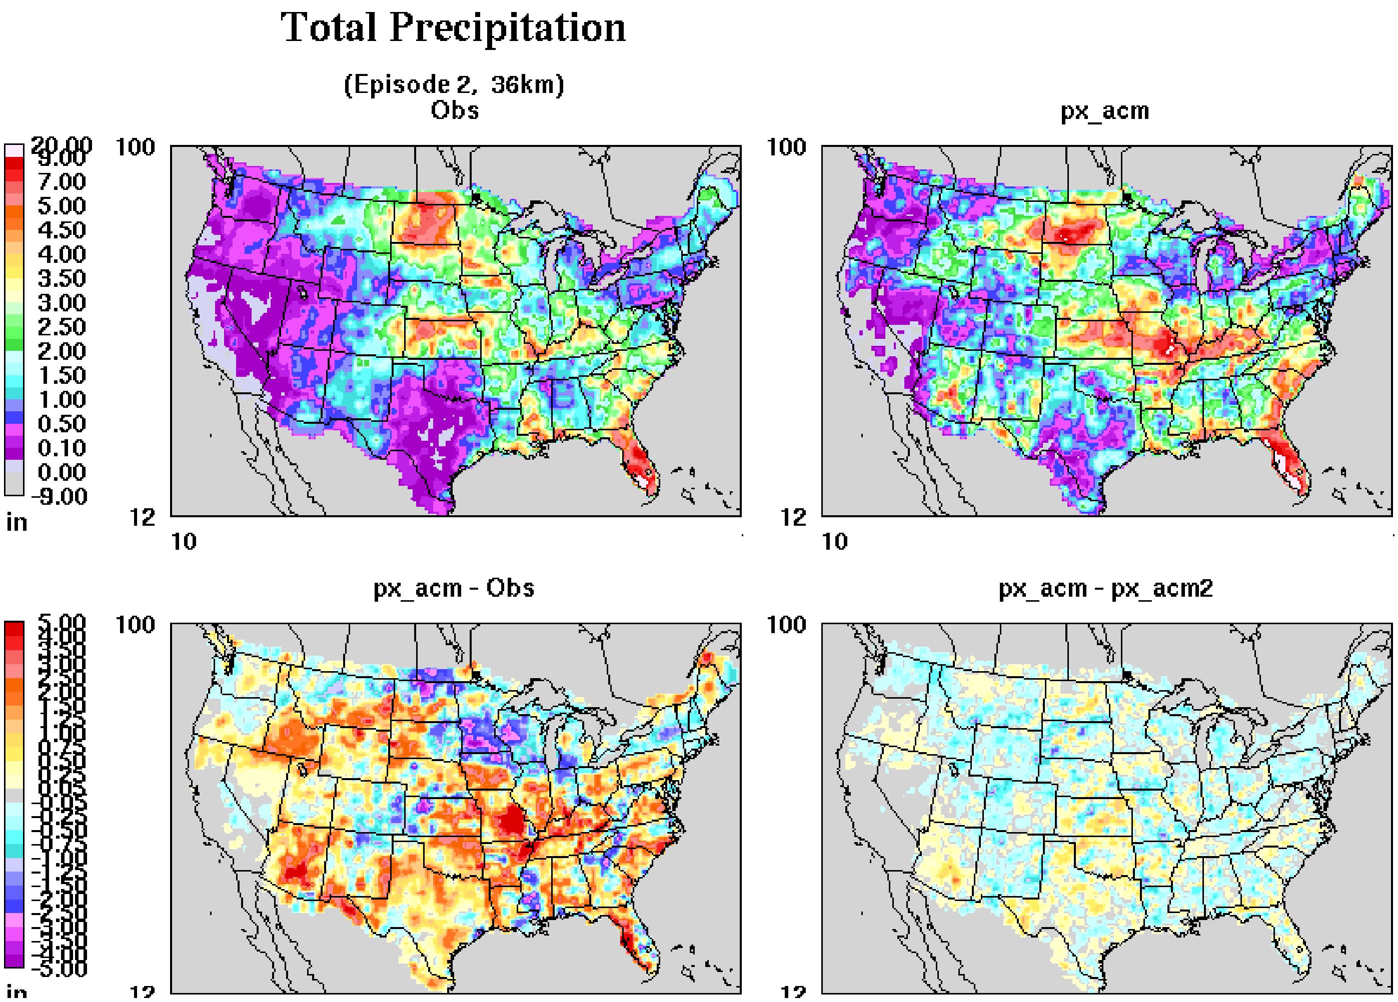

Figure 50. Episode 2 (Jul 13-28, 2001) composite precipitation for the US land-portion of the 36-km domain is shown. The top left panel displays the accumulated precipitation generated from the Climate Prediction Center gridded precipitation datasets. The top right panel shows the corresponding plot for the px_acm model configuration, and the lower left plot shows the difference plot between the model and the observations. The bottom right plot shows the difference between the px_acm sensitivity and the px_acm2 base case.

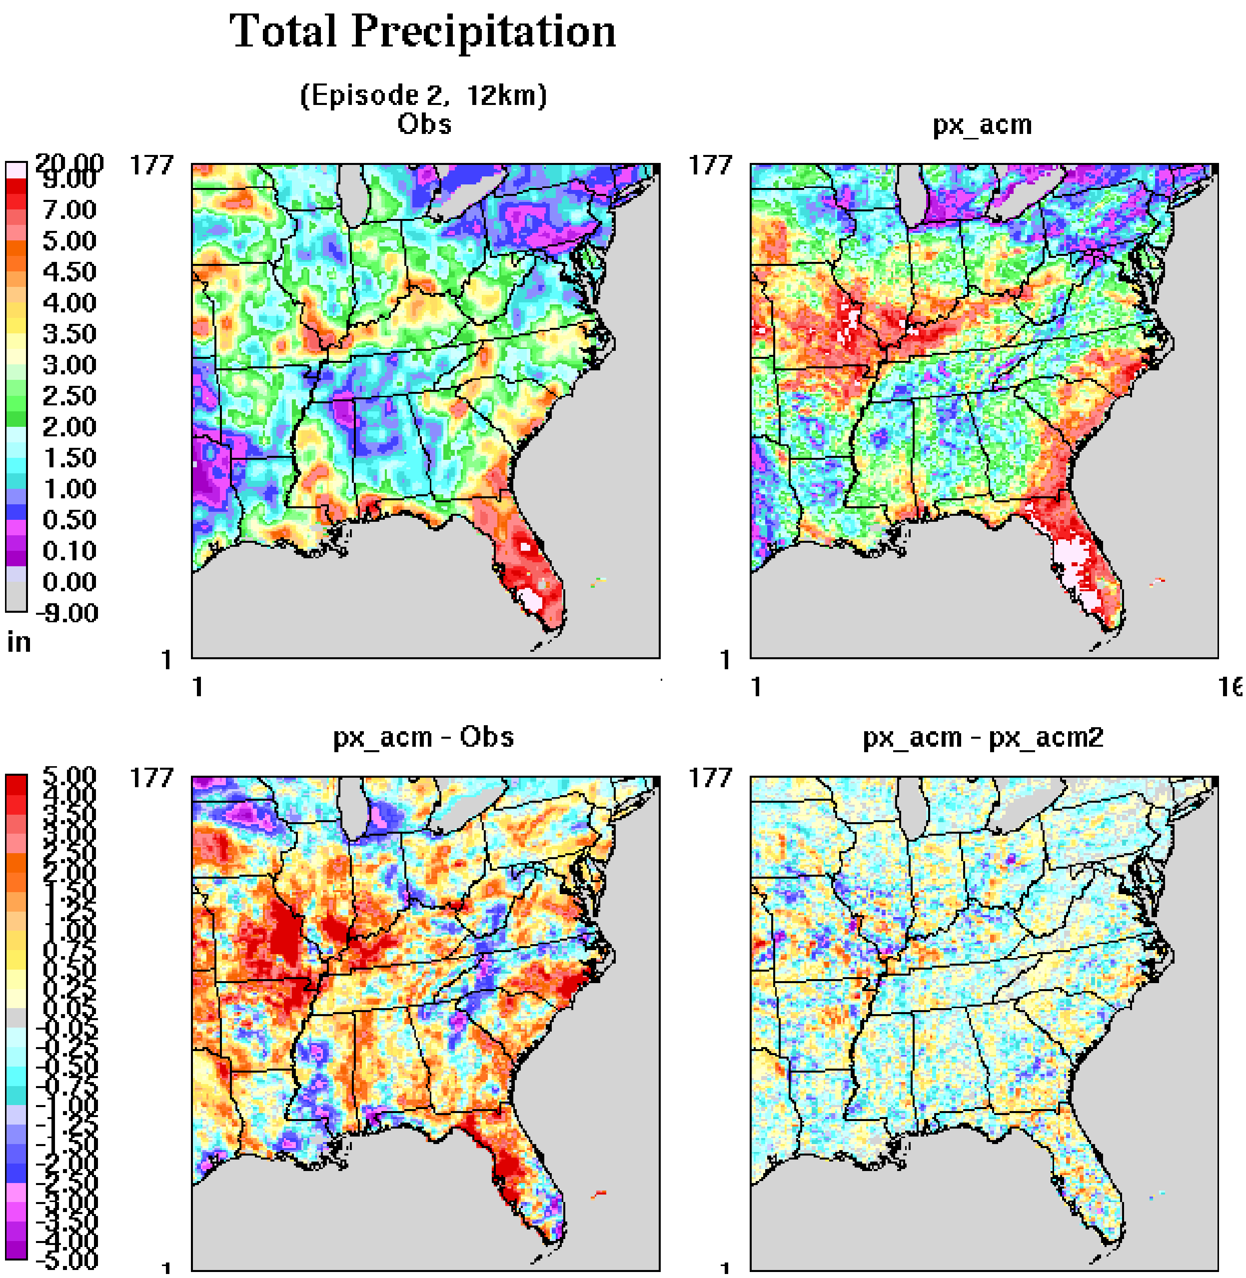

Figure 51. Episode 2 (Jul 13-28, 2001) composite precipitation for the US land-portion of the 12-km domain is shown. The top left panel displays the accumulated precipitation generated from the Climate Prediction Center gridded precipitation datasets. The top right panel shows the corresponding plot for the px_acm model configuration, and the lower left plot shows the difference plot between the model and the observations. The bottom right plot shows the difference between the px_acm sensitivity and the px_acm2 base case.

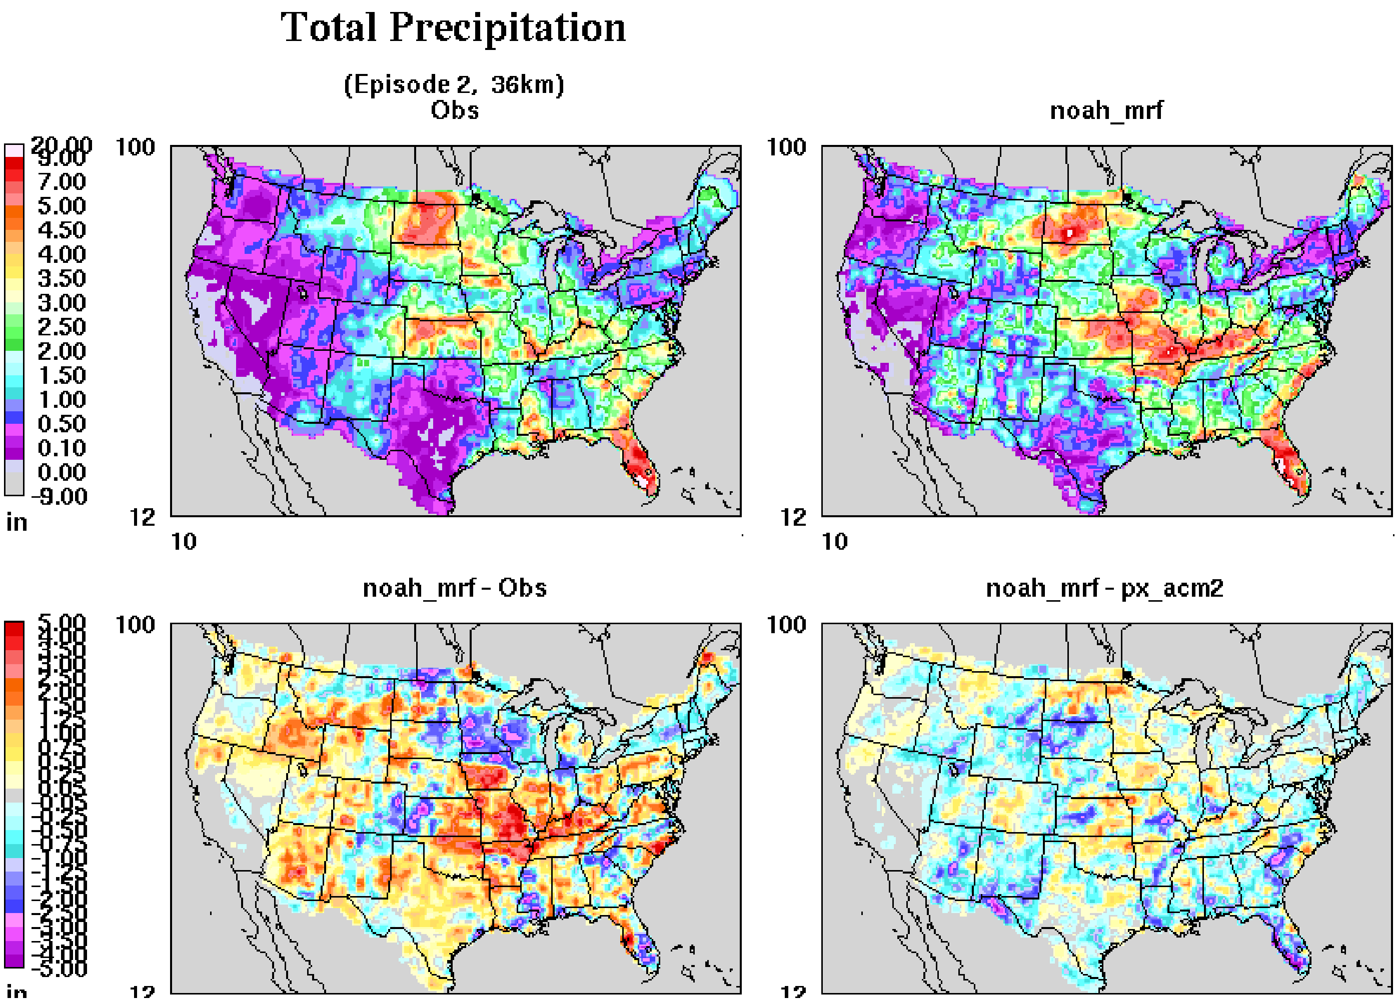

Figure 52. Episode 2 (Jul 13-28, 2001) composite precipitation for the US land-portion of the 36-km domain is shown. The top left panel displays the accumulated precipitation generated from the Climate Prediction Center gridded precipitation datasets. The top right panel shows the corresponding plot for the noah_mrf model configuration, and the lower left plot shows the difference plot between the model and the observations. The bottom right plot shows the difference between the noah_mrf sensitivity and the px_acm2 base case.

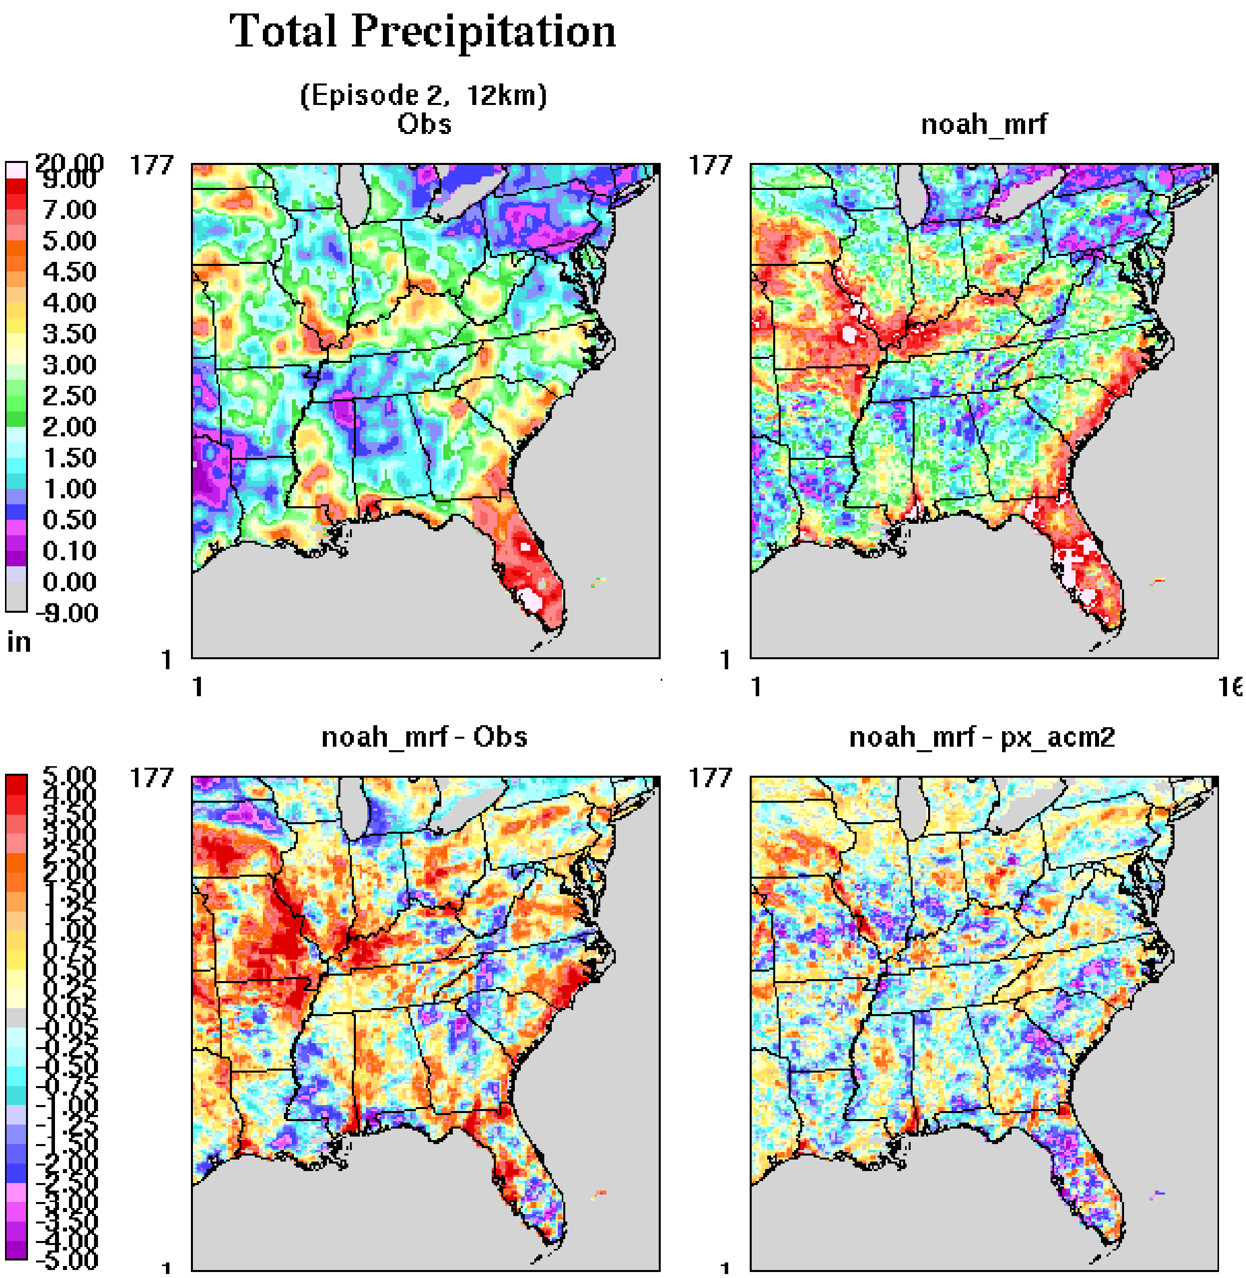

Figure 53. Episode 2 (Jul 13-28, 2001) composite precipitation for the US land-portion of the 12-km domain is shown. The top left panel displays the accumulated precipitation generated from the Climate Prediction Center gridded precipitation datasets. The top right panel shows the corresponding plot for the noah_mrf model configuration, and the lower left plot shows the difference plot between the model and the observations. The bottom right plot shows the difference between the noah_mrf sensitivity and the px_acm2 base case.

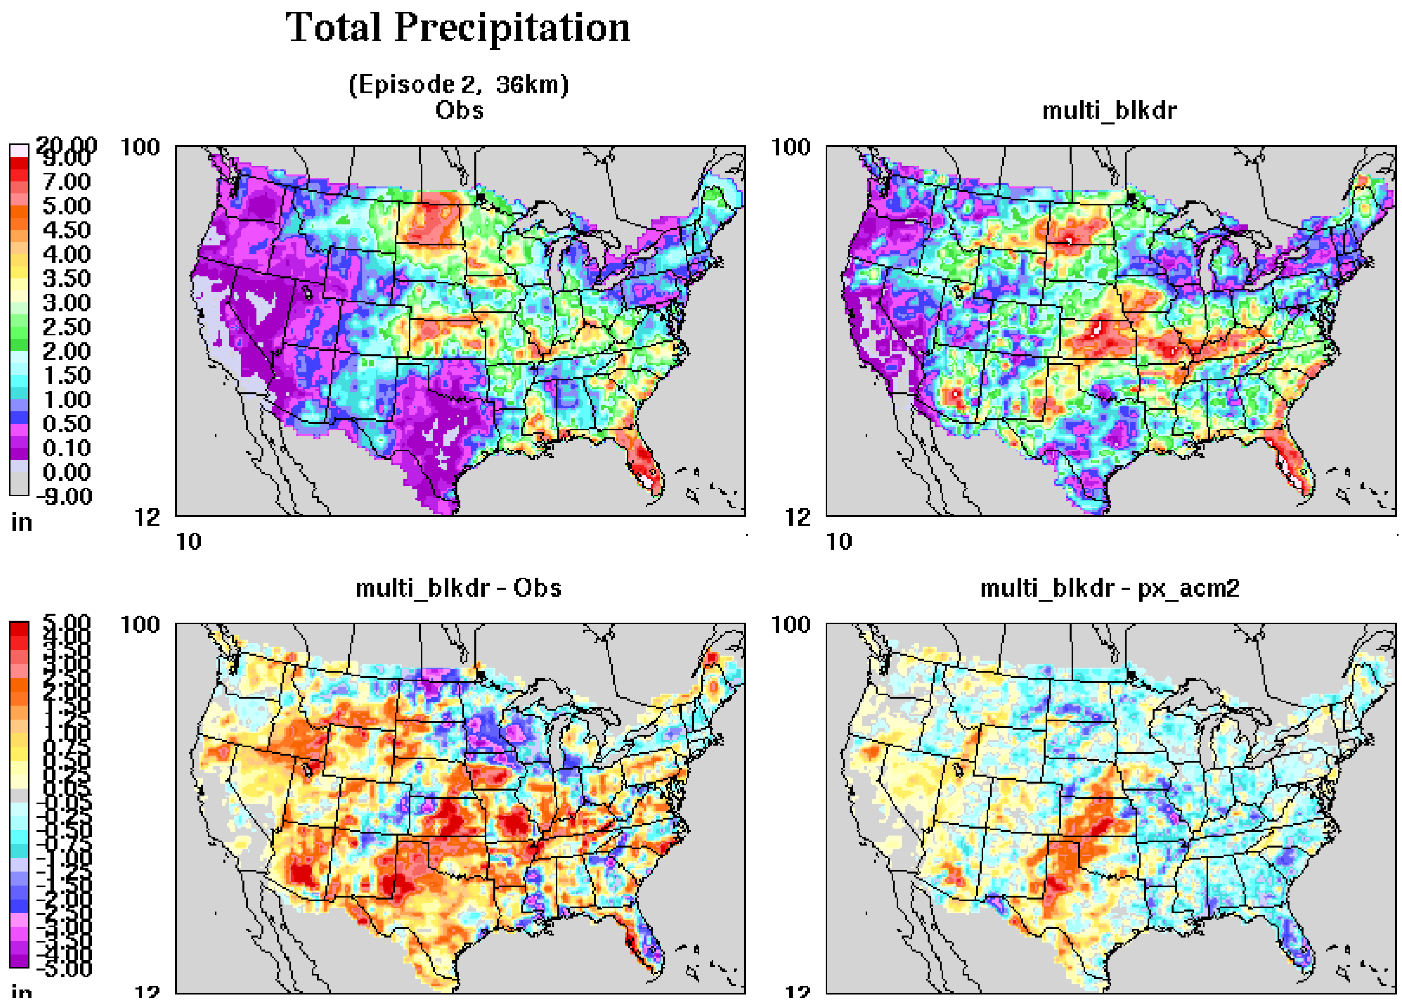

Figure 54. Episode 2 (Jul 13-28, 2001) composite precipitation for the US land-portion of the 36-km domain is shown. The top left panel displays the accumulated precipitation generated from the Climate Prediction Center gridded precipitation datasets. The top right panel shows the corresponding plot for the multi_blkdr model configuration, and the lower left plot shows the difference plot between the model and the observations. The bottom right plot shows the difference between the multi_blkdr sensitivity and the px_acm2 base case.

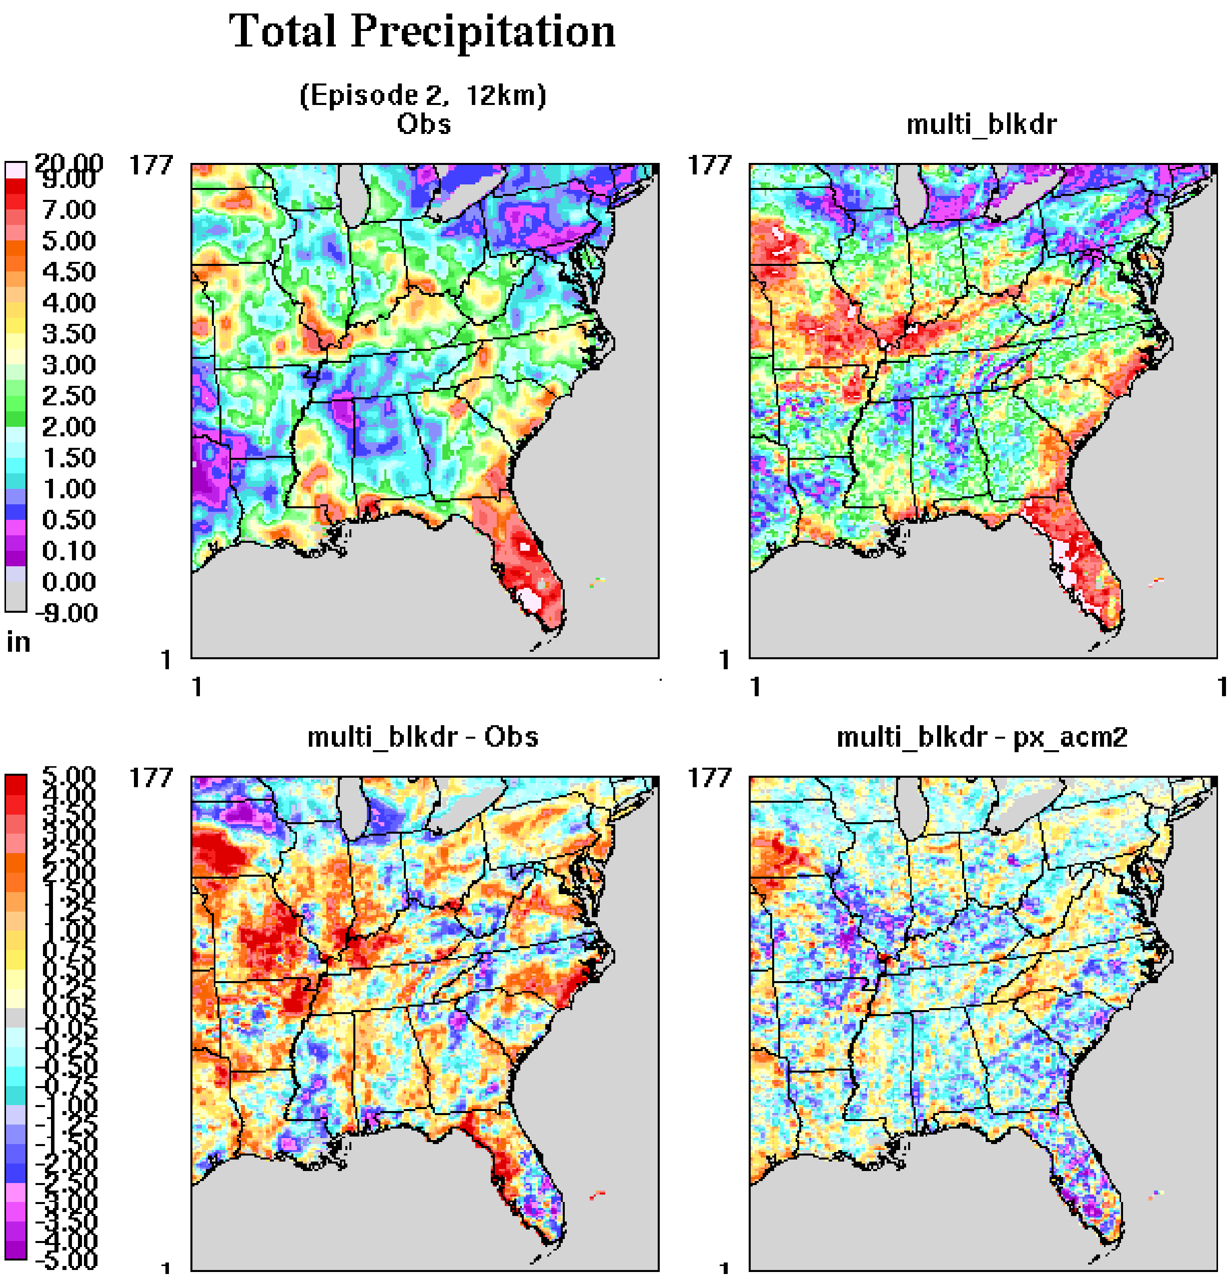

Figure 55. Episode 2 (Jul 13-28, 2001) composite precipitation for the US land-portion of the 12-km domain is shown. The top left panel displays the accumulated precipitation generated from the Climate Prediction Center gridded precipitation datasets. The top right panel shows the corresponding plot for the multi_blkdr model configuration, and the lower left plot shows the difference plot between the model and the observations. The bottom right plot shows the difference between the multi_blkdr sensitivity and the px_acm2 base case.

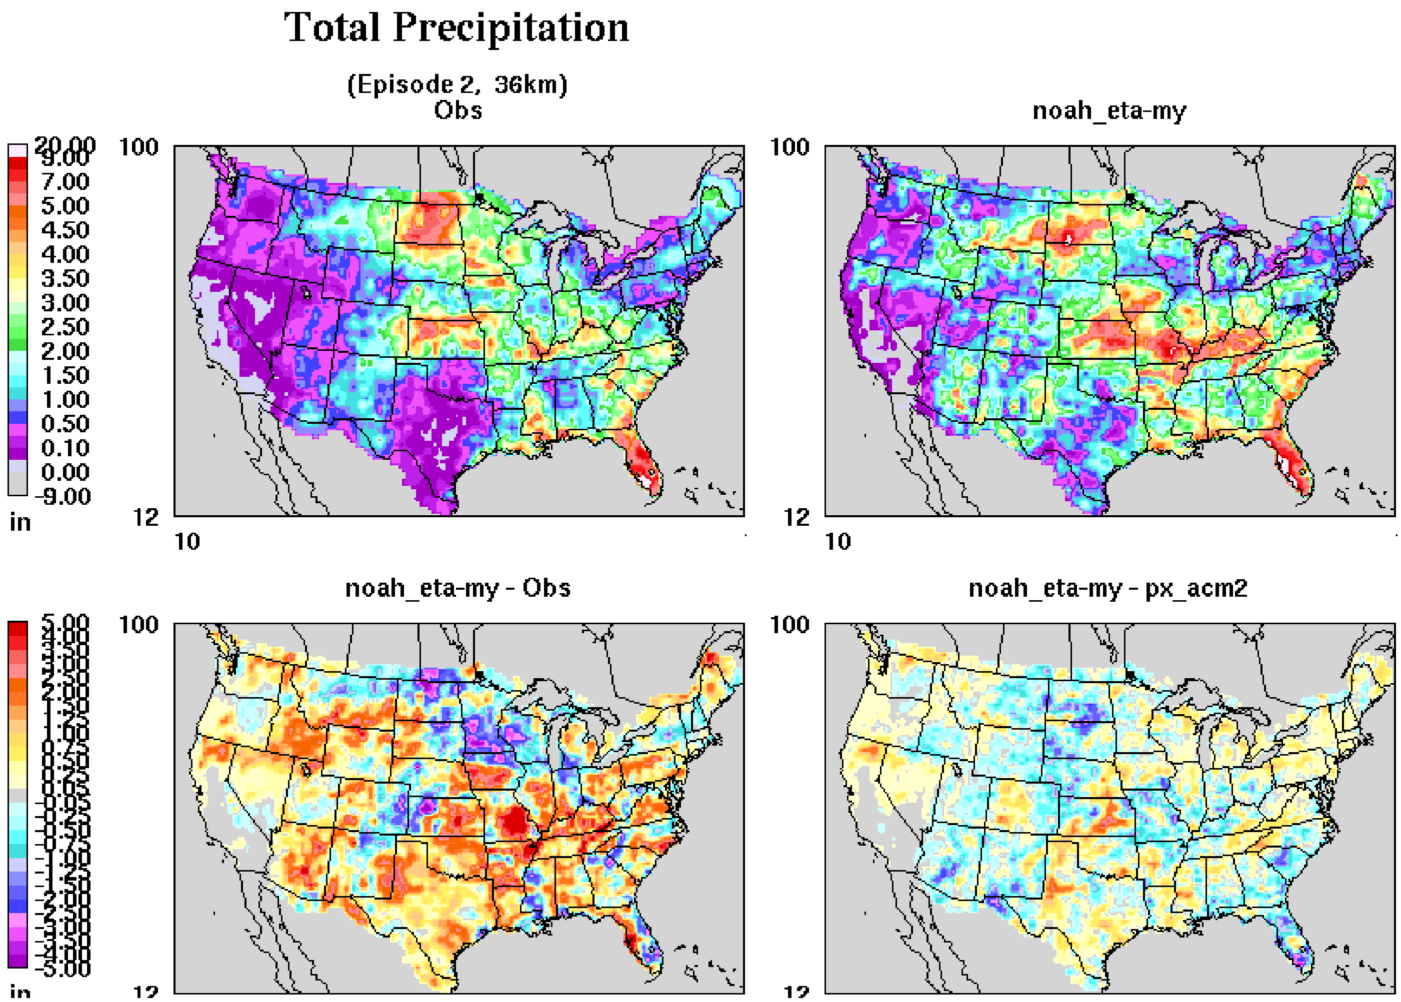

Figure 56. Episode 2 (Jul 13-28, 2001) composite precipitation for the US land-portion of the 36-km domain is shown. The top left panel displays the accumulated precipitation generated from the Climate Prediction Center gridded precipitation datasets. The top right panel shows the corresponding plot for the noah_eta-my model configuration, and the lower left plot shows the difference plot between the model and the observations. The bottom right plot shows the difference between the noah_eta-my sensitivity and the px_acm2 base case.

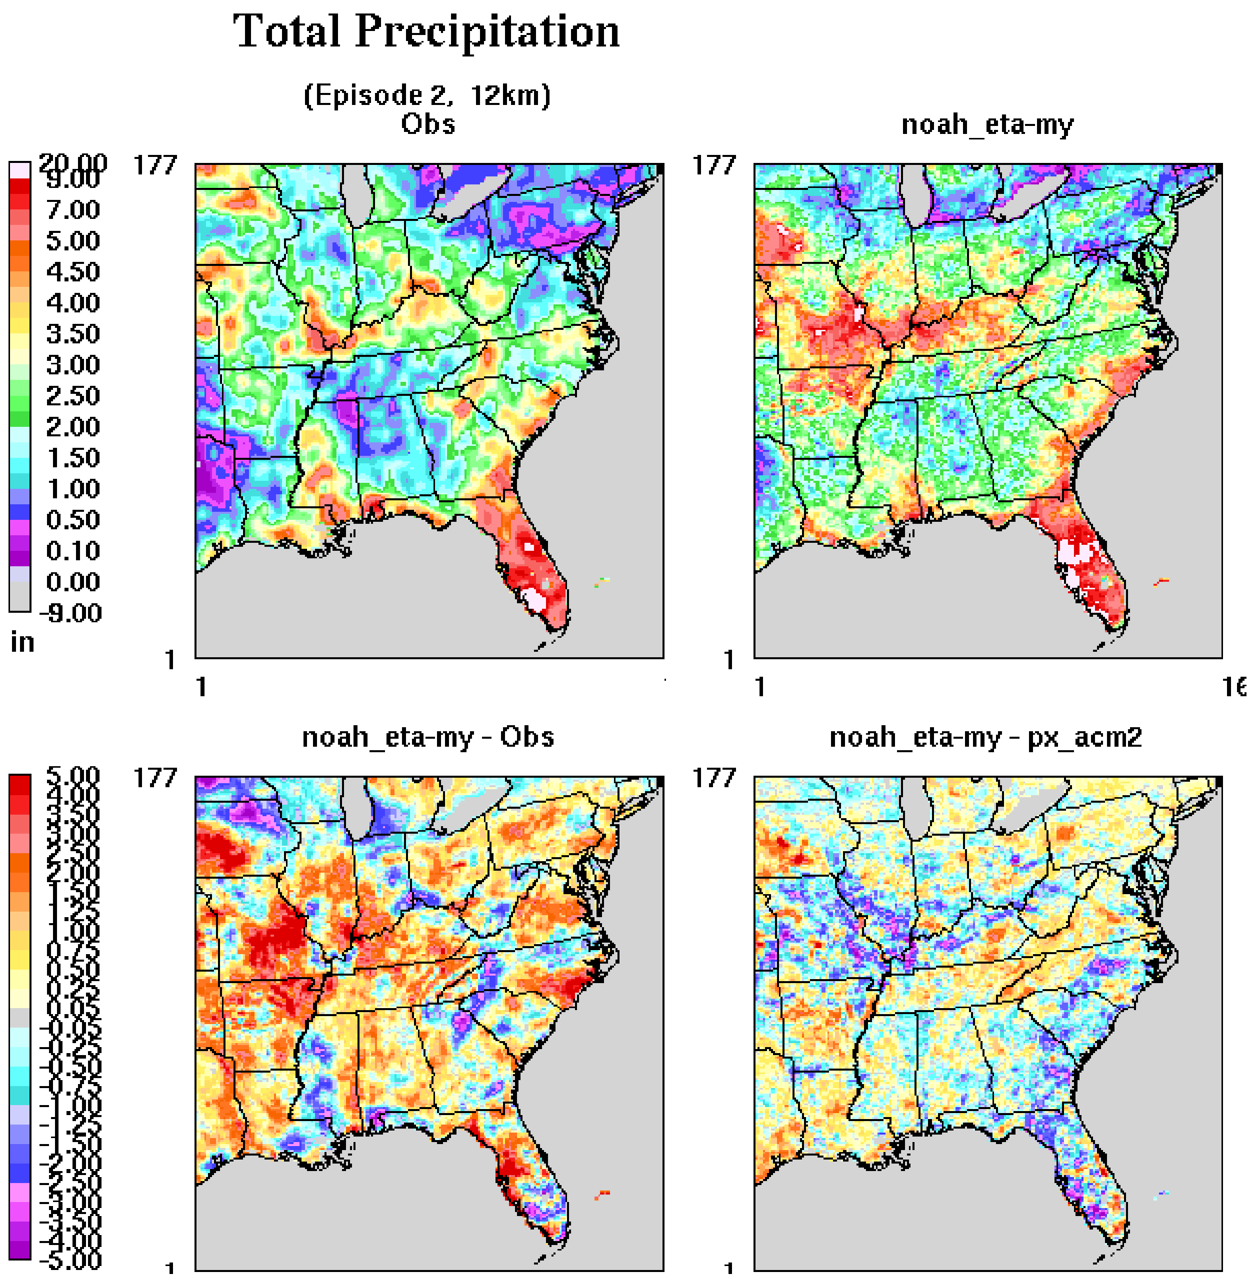

Figure 57. Episode 2 (Jul 13-28, 2001) composite precipitation for the US land-portion of the 12-km domain is shown. The top left panel displays the accumulated precipitation generated from the Climate Prediction Center gridded precipitation datasets. The top right panel shows the corresponding plot for the noah_eta-my model configuration, and the lower left plot shows the difference plot between the model and the observations. The bottom right plot shows the difference between the noah_eta-my sensitivity and the px_acm2 base case.

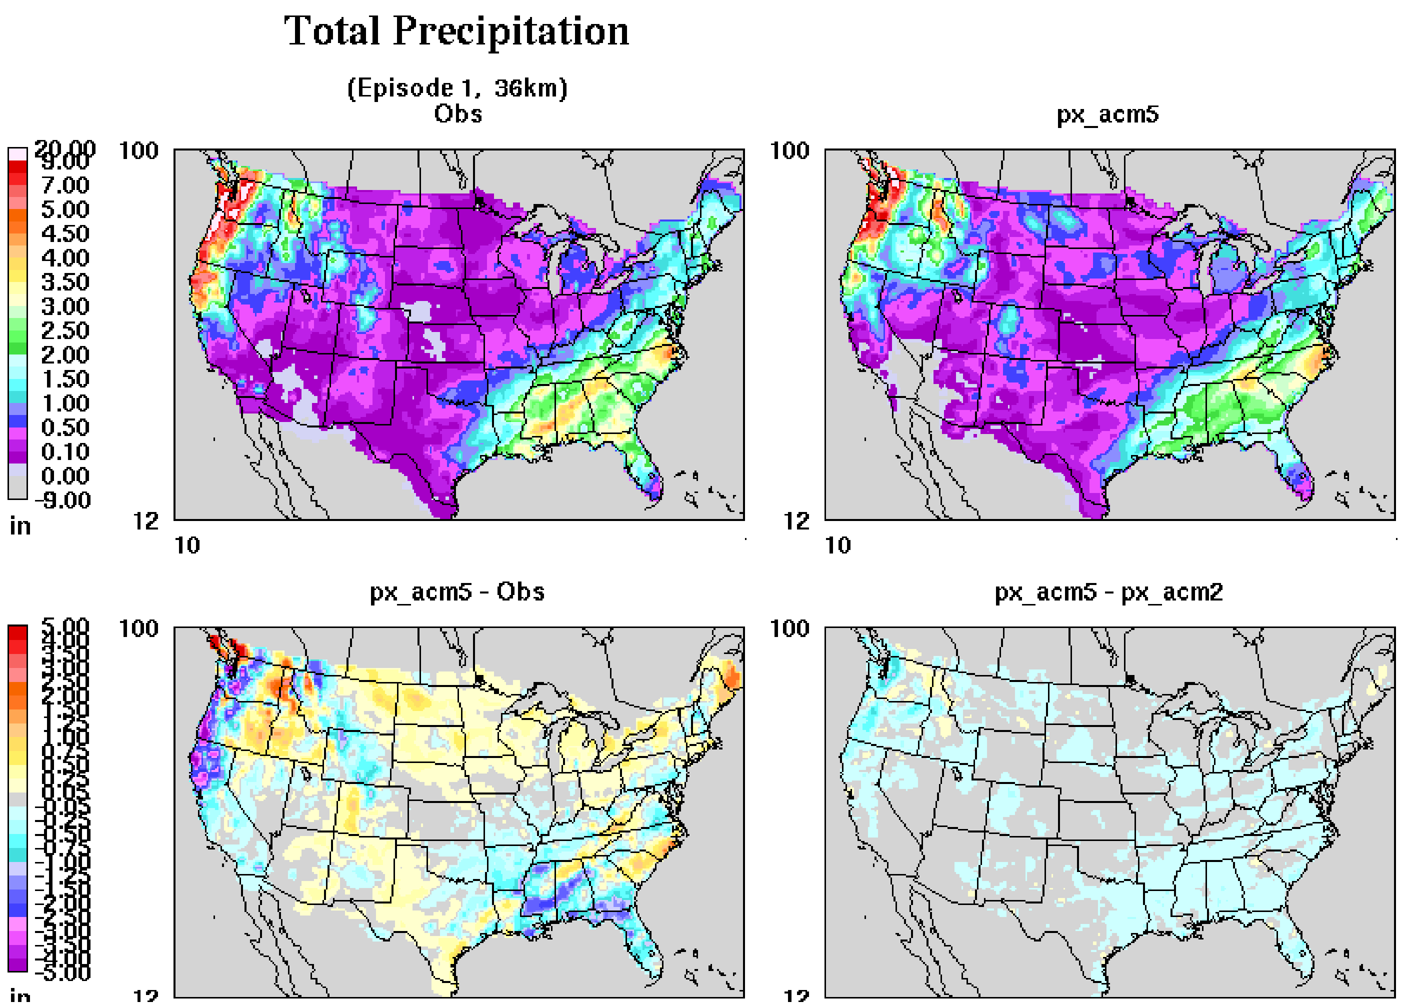

Figure 58. Episode 1 (Jan 2-21, 2002) composite precipitation for the US land-portion of the 36-km domain is shown. The top left panel displays the accumulated precipitation generated from the Climate Prediction Center gridded precipitation datasets. The top right panel shows the corresponding plot for the px_acm5 model configuration, and the lower left plot shows the difference plot between the model and the observations. The bottom right plot shows the difference between the px_acm5 sensitivity and the px_acm2 base case.

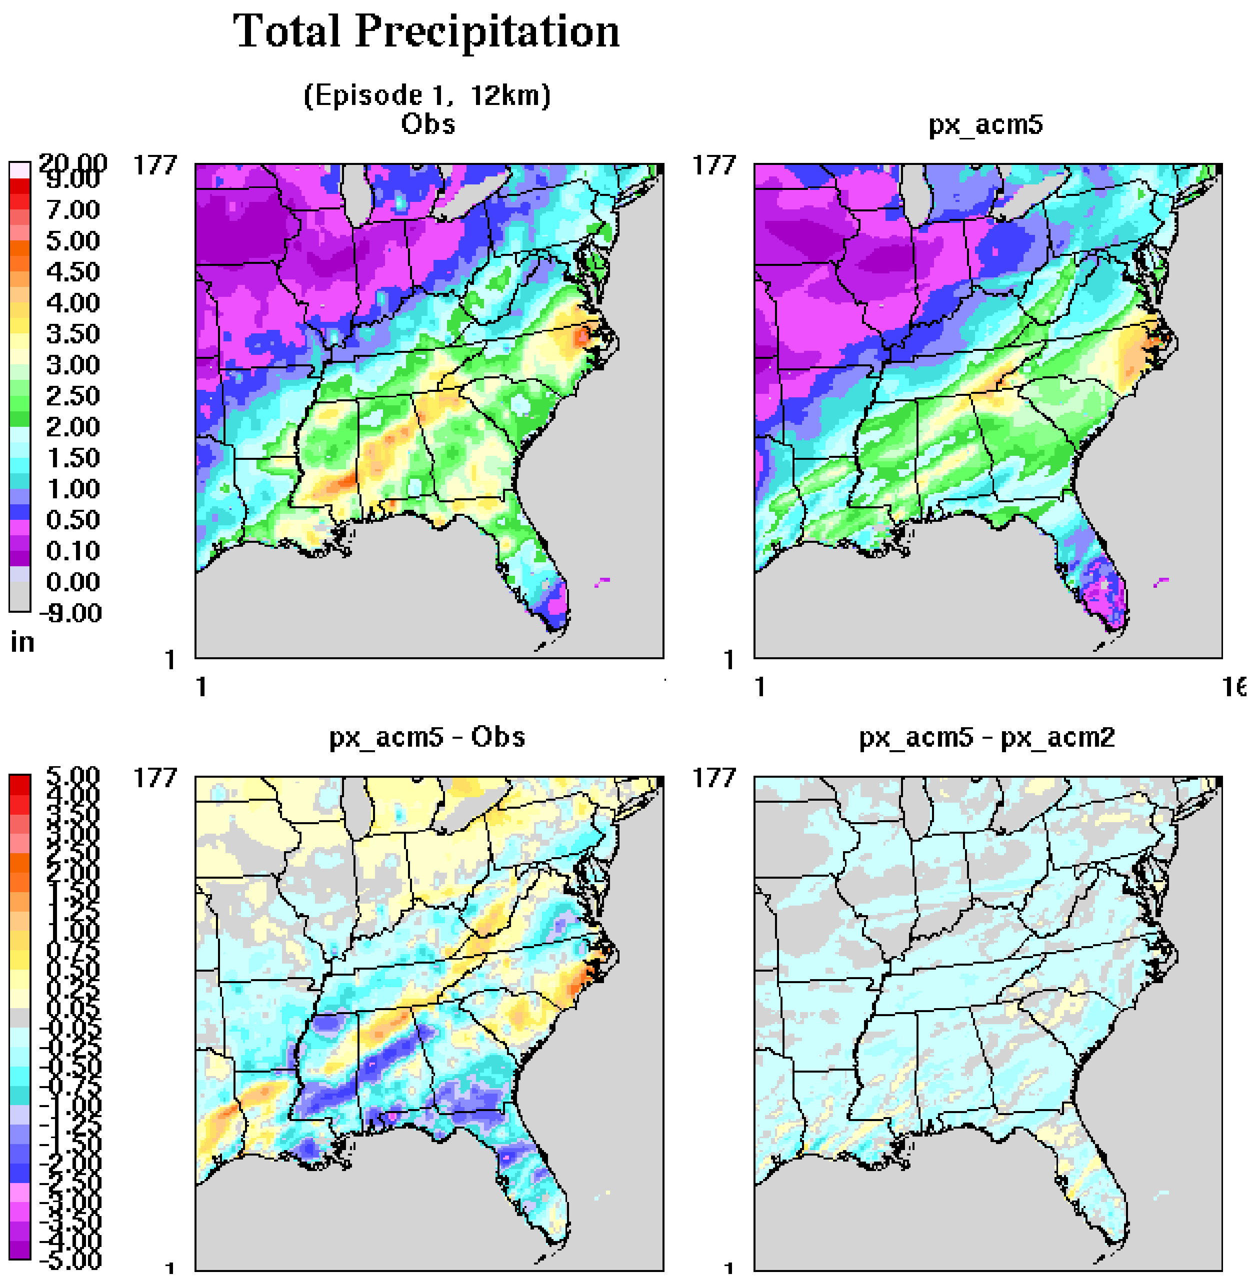

Figure 59. Episode 1 (Jan 2-21, 2002) composite precipitation for the US land-portion of the 12-km domain is shown. The top left panel displays the accumulated precipitation generated from the Climate Prediction Center gridded precipitation datasets. The top right panel shows the corresponding plot for the px_acm5 model configuration, and the lower left plot shows the difference plot between the model and the observations. The bottom right plot shows the difference between the px_acm5 sensitivity and the px_acm2 base case.

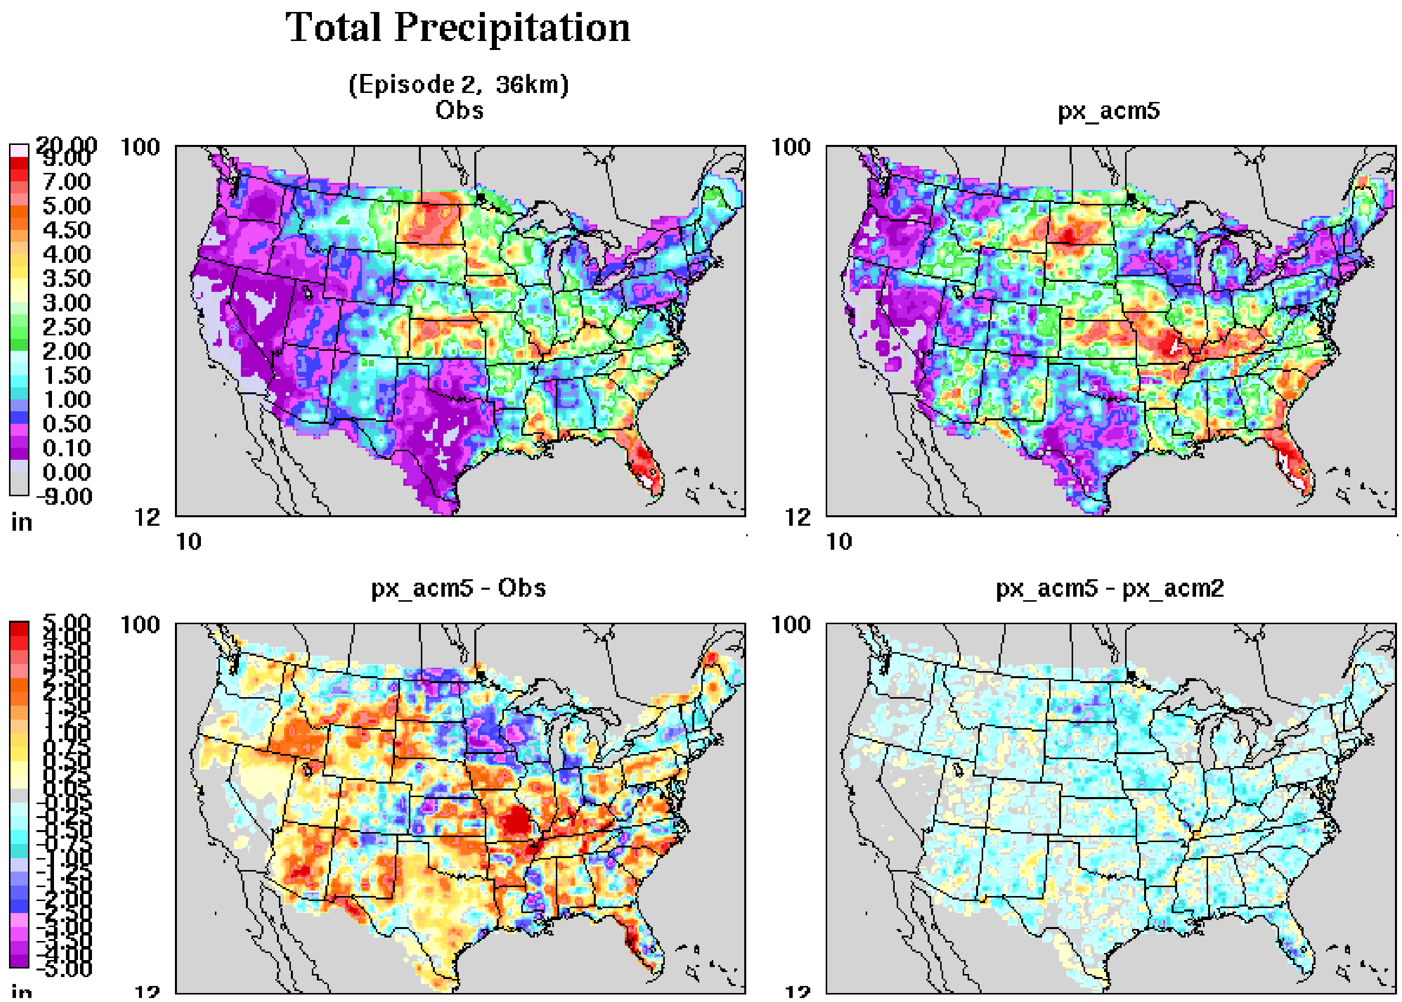

Figure 60. Episode 2 (Jul 13-28, 2001) composite precipitation for the US land-portion of the 36-km domain is shown. The top left panel displays the accumulated precipitation generated from the Climate Prediction Center gridded precipitation datasets. The top right panel shows the corresponding plot for the px_acm5 model configuration, and the lower left plot shows the difference plot between the model and the observations. The bottom right plot shows the difference between the px_acm5 sensitivity and the px_acm2 base case.

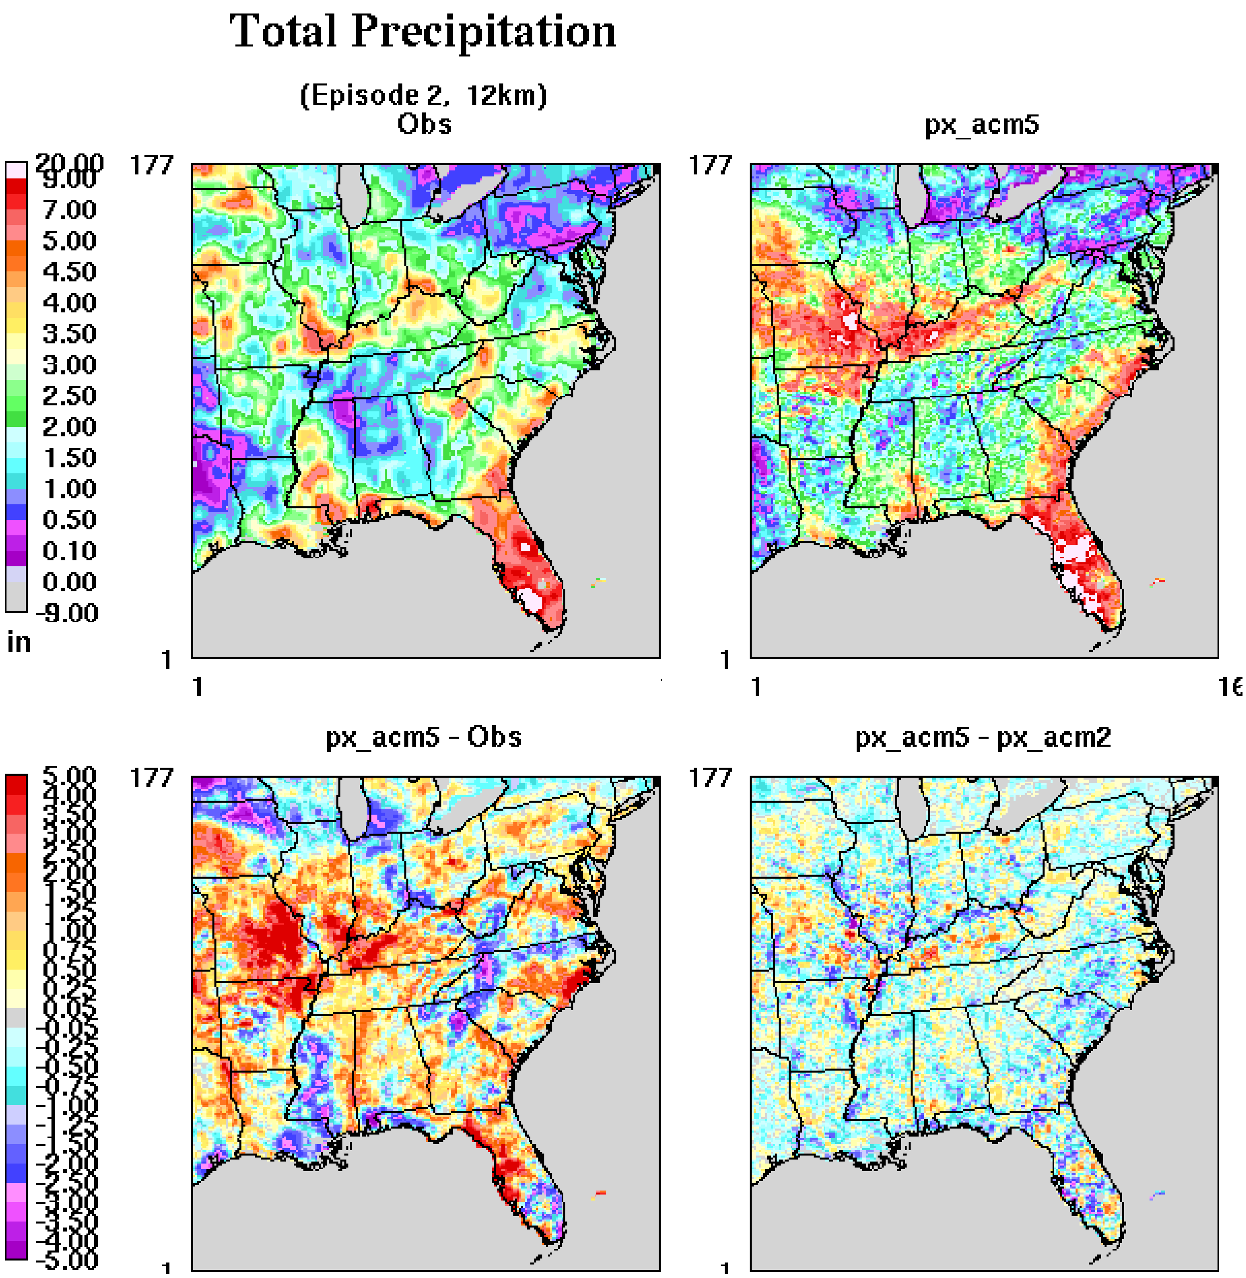

Figure 61. Episode 2 (Jul 13-28, 2001) composite precipitation for the US land-portion of the 12-km domain is shown. The top left panel displays the accumulated precipitation generated from the Climate Prediction Center gridded precipitation datasets. The top right panel shows the corresponding plot for the px_acm5 model configuration, and the lower left plot shows the difference plot between the model and the observations. The bottom right plot shows the difference between the px_acm5 sensitivity and the px_acm2 base case.

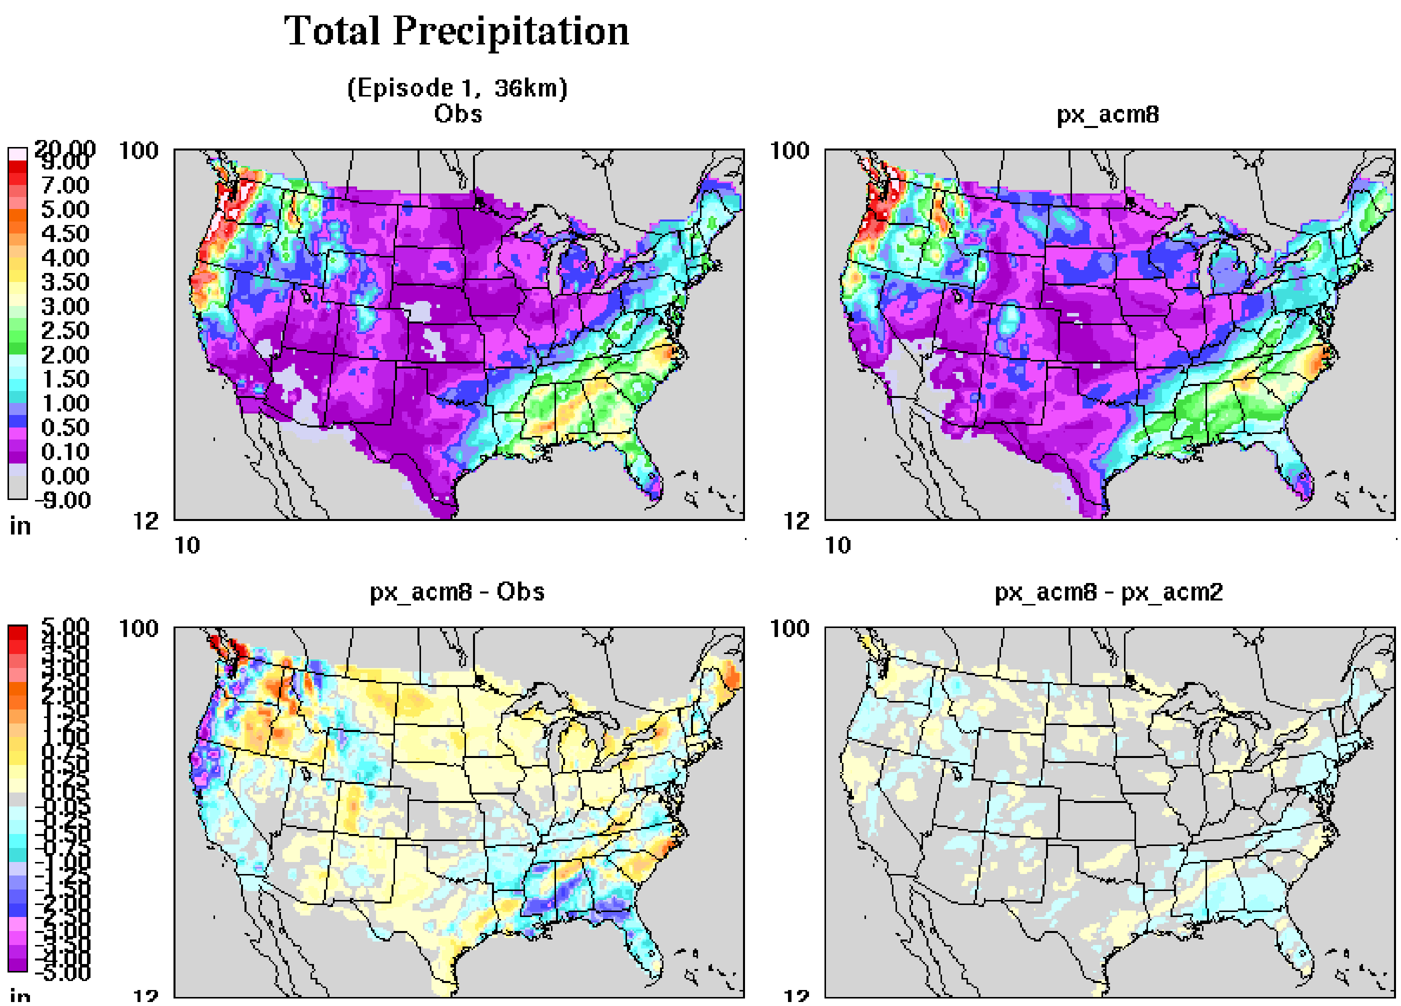

Figure 62. Episode 1 (Jan 2-21, 2002) composite precipitation for the US land-portion of the 36-km domain is shown. The top left panel displays the accumulated precipitation generated from the Climate Prediction Center gridded precipitation datasets. The top right panel shows the corresponding plot for the px_acm8 model configuration, and the lower left plot shows the difference plot between the model and the observations. The bottom right plot shows the difference between the px_acm8 sensitivity and the px_acm2 base case.

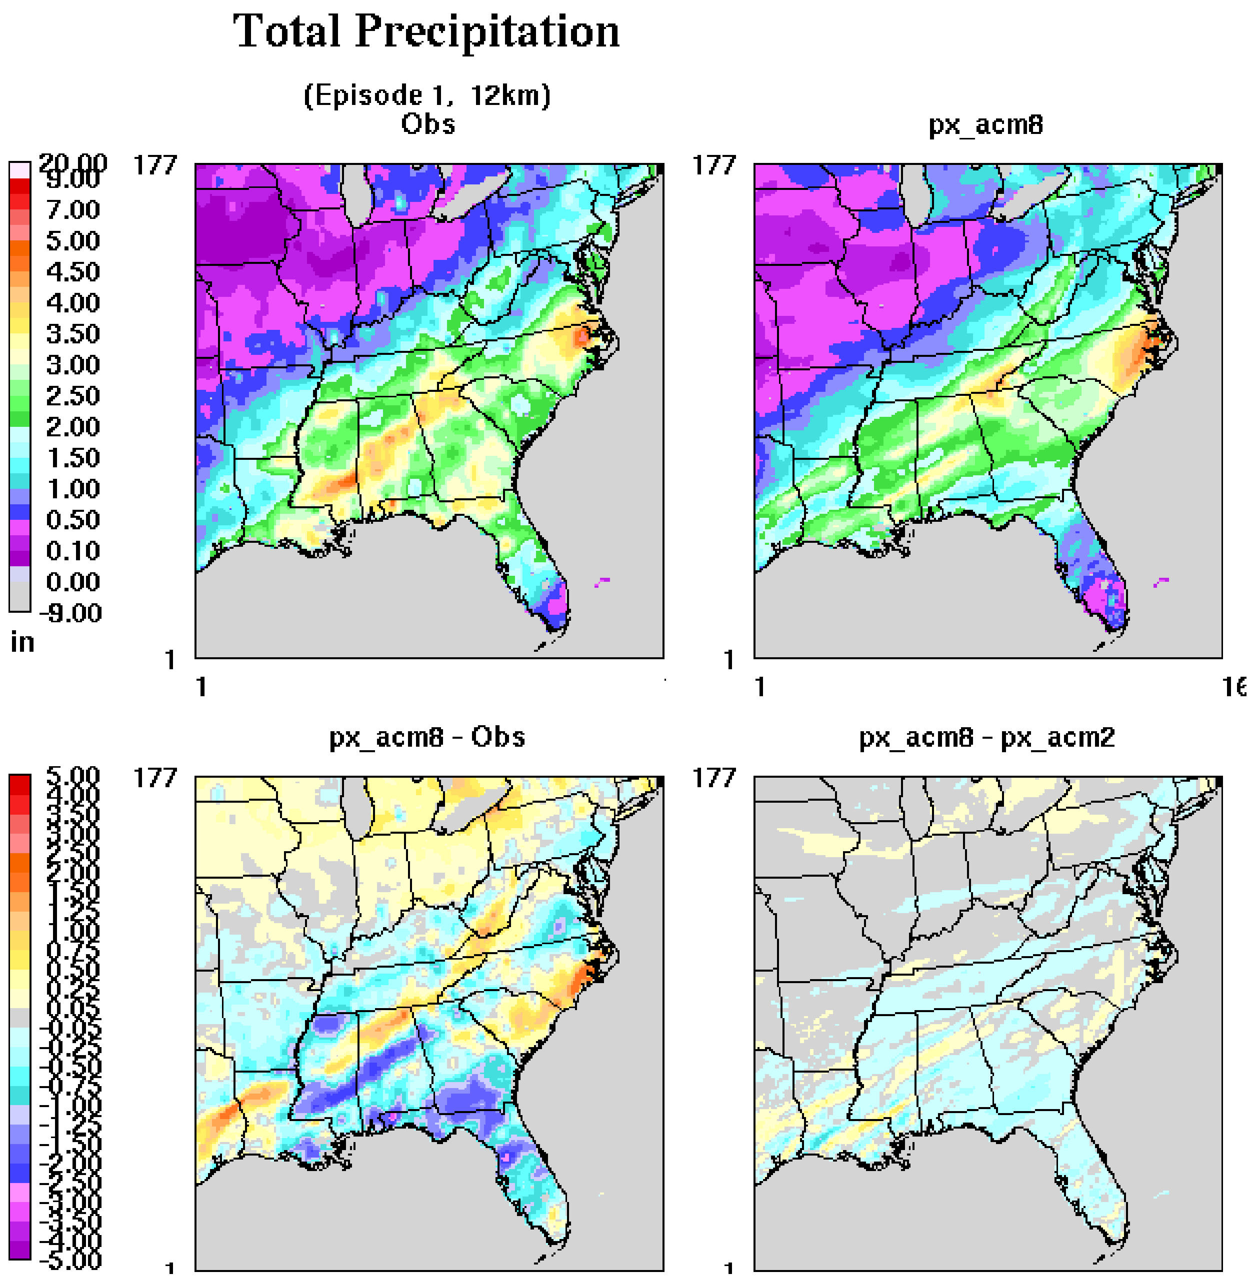

Figure 63. Episode 1 (Jan 2-21, 2002) composite precipitation for the US land-portion of the 12-km domain is shown. The top left panel displays the accumulated precipitation generated from the Climate Prediction Center gridded precipitation datasets. The top right panel shows the corresponding plot for the px_acm8 model configuration, and the lower left plot shows the difference plot between the model and the observations. The bottom right plot shows the difference between the px_acm8 sensitivity and the px_acm2 base case.

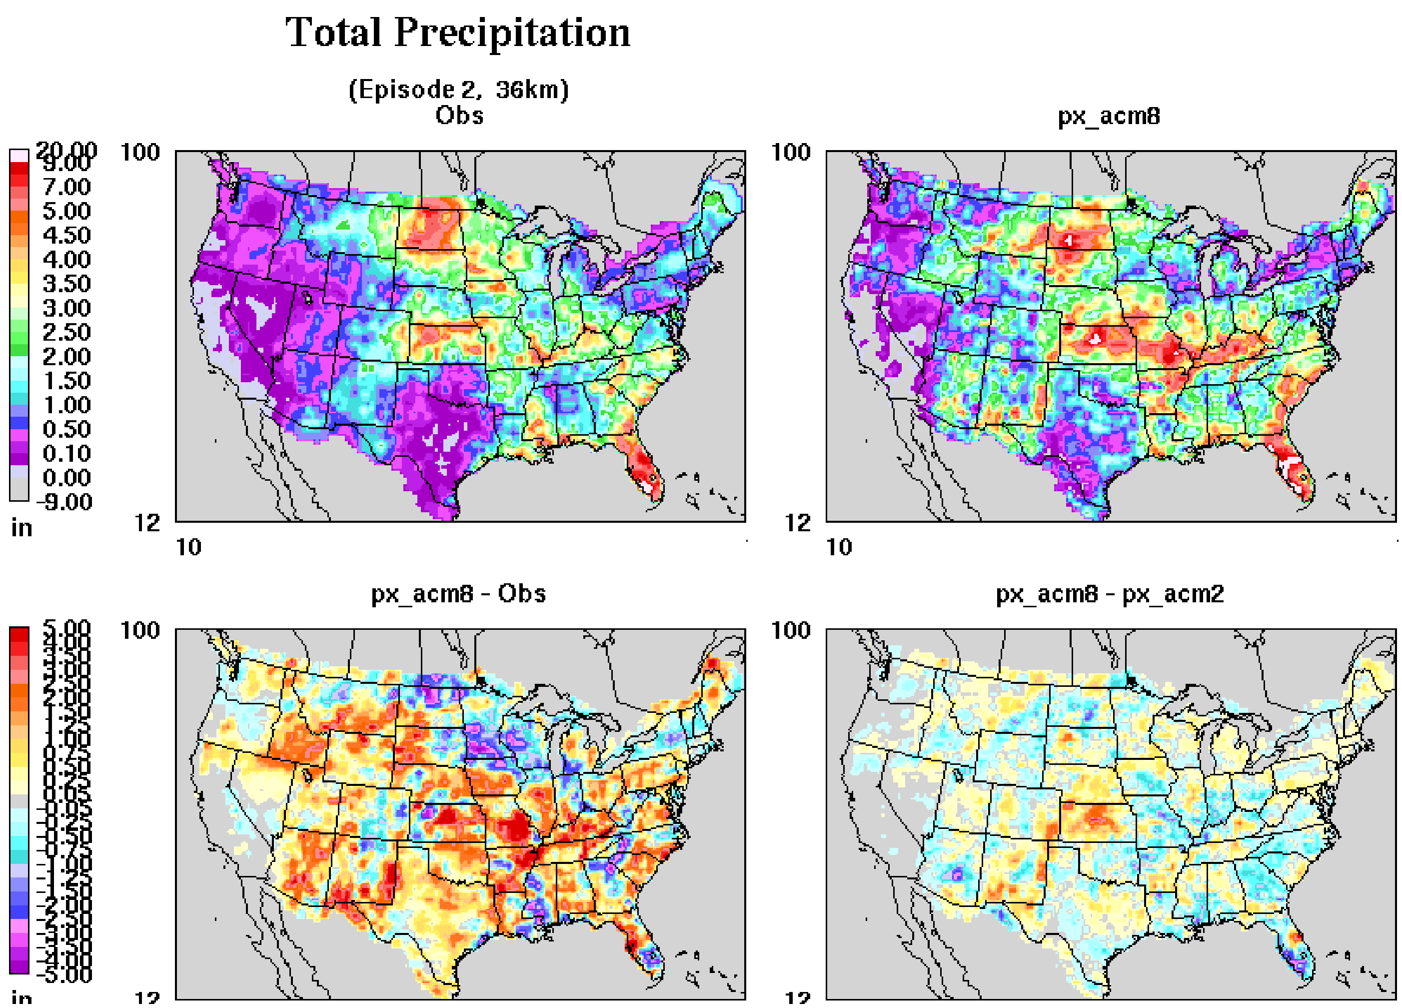

Figure 64. Episode 2 (Jul 13-28, 2001) composite precipitation for the US land-portion of the 36-km domain is shown. The top left panel displays the accumulated precipitation generated from the Climate Prediction Center gridded precipitation datasets. The top right panel shows the corresponding plot for the px_acm8 model configuration, and the lower left plot shows the difference plot between the model and the observations. The bottom right plot shows the difference between the px_acm8 sensitivity and the px_acm2 base case.

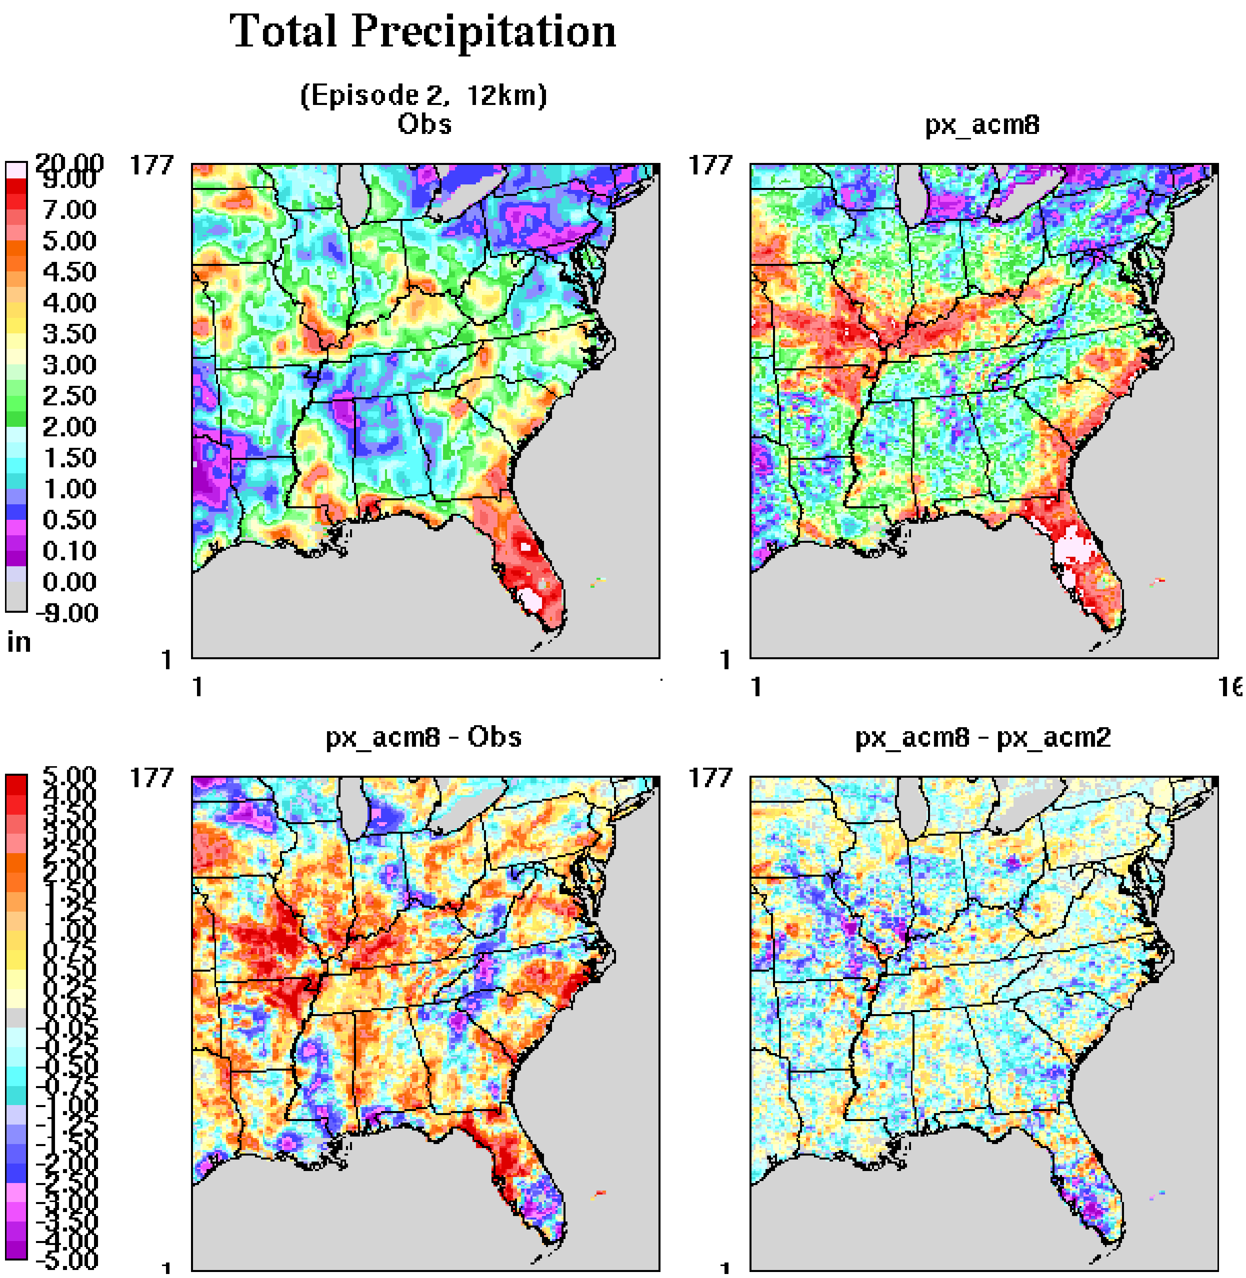

Figure 65. Episode 2 (Jul 13-28, 2001) composite precipitation for the US land-portion of the 12-km domain is shown. The top left panel displays the accumulated precipitation generated from the Climate Prediction Center gridded precipitation datasets. The top right panel shows the corresponding plot for the px_acm8 model configuration, and the lower left plot shows the difference plot between the model and the observations. The bottom right plot shows the difference between the px_acm8 sensitivity and the px_acm2 base case.

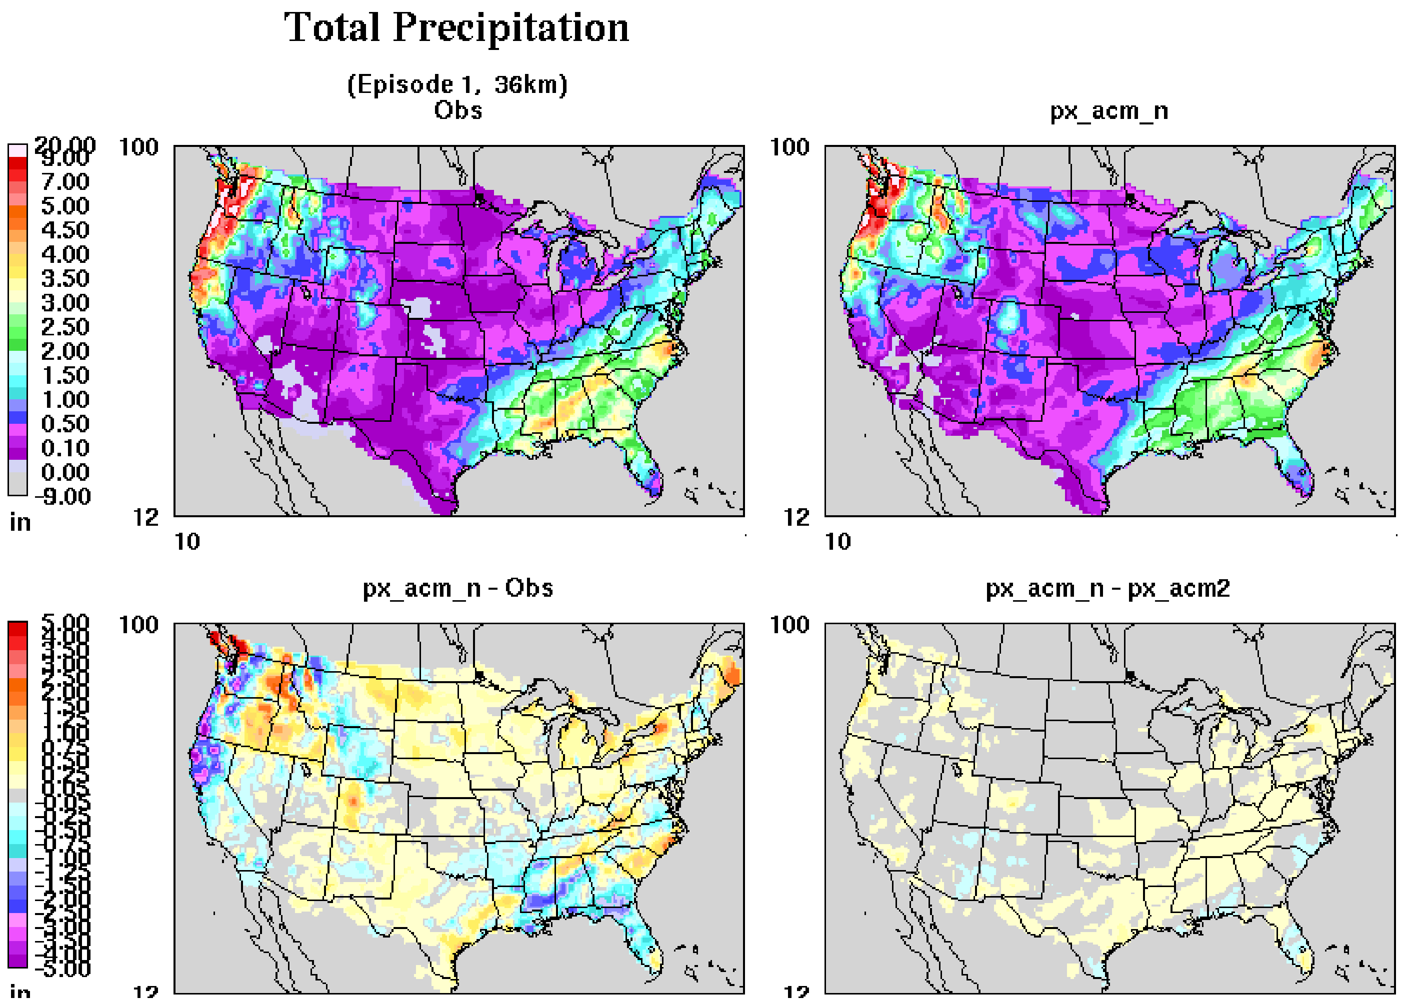

Figure 66. Episode 1 (Jan 2-21, 2002) composite precipitation for the US land-portion of the 36-km domain is shown. The top left panel displays the accumulated precipitation generated from the Climate Prediction Center gridded precipitation datasets. The top right panel shows the corresponding plot for the px_acm_n model configuration, and the lower left plot shows the difference plot between the model and the observations. The bottom right plot shows the difference between the px_acm_n sensitivity and the px_acm2 base case.

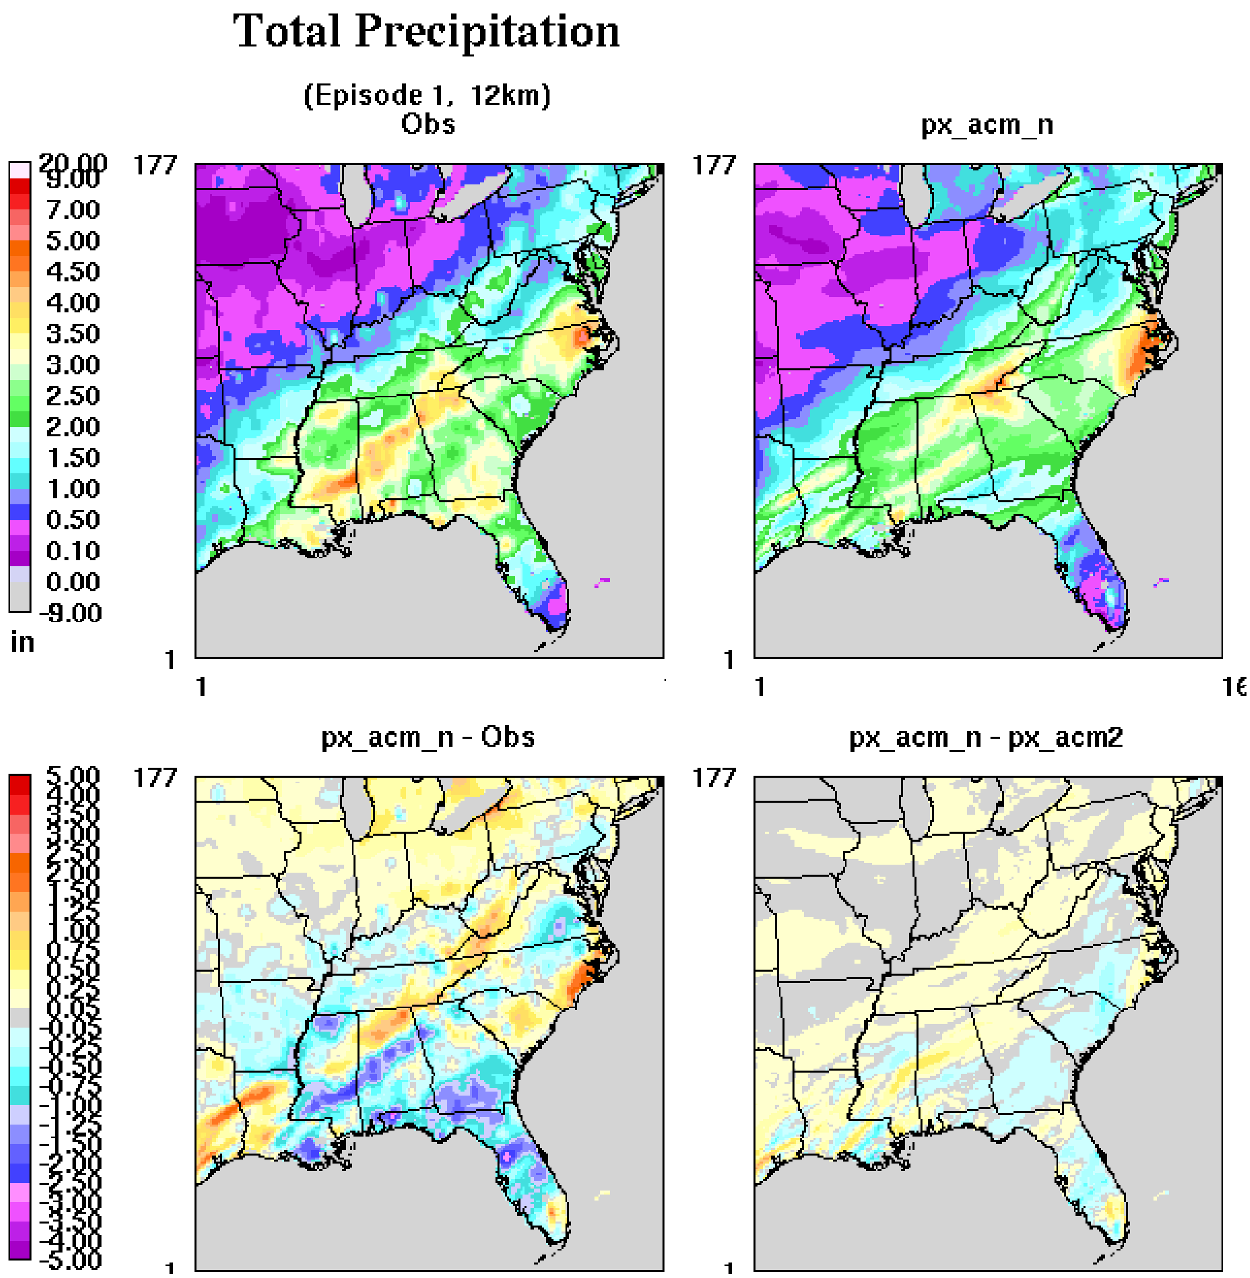

Figure 67. Episode 1 (Jan 2-21, 2002) composite precipitation for the US land-portion of the 12-km domain is shown. The top left panel displays the accumulated precipitation generated from the Climate Prediction Center gridded precipitation datasets. The top right panel shows the corresponding plot for the px_acm_n model configuration, and the lower left plot shows the difference plot between the model and the observations. The bottom right plot shows the difference between the px_acm_n sensitivity and the px_acm2 base case.

Note the explosion of precipitation that nudging temperature/moisture in the boundary layer produces in figures 68-69. The problem is lessoned somewhat by reducing the nudging strength of moisture (px_acm_n2, figures 70-71), but the accumulation bias already evident in the base case is exacerbated nonetheless. We might be able to get away with a px_acm_n or px_acm_n2 configuration in the winter, but definitely not in the summer. To avoid these potential precipitation artifacts altogether, we recommend not nudging temperature or moisture in the boundary layer at all.

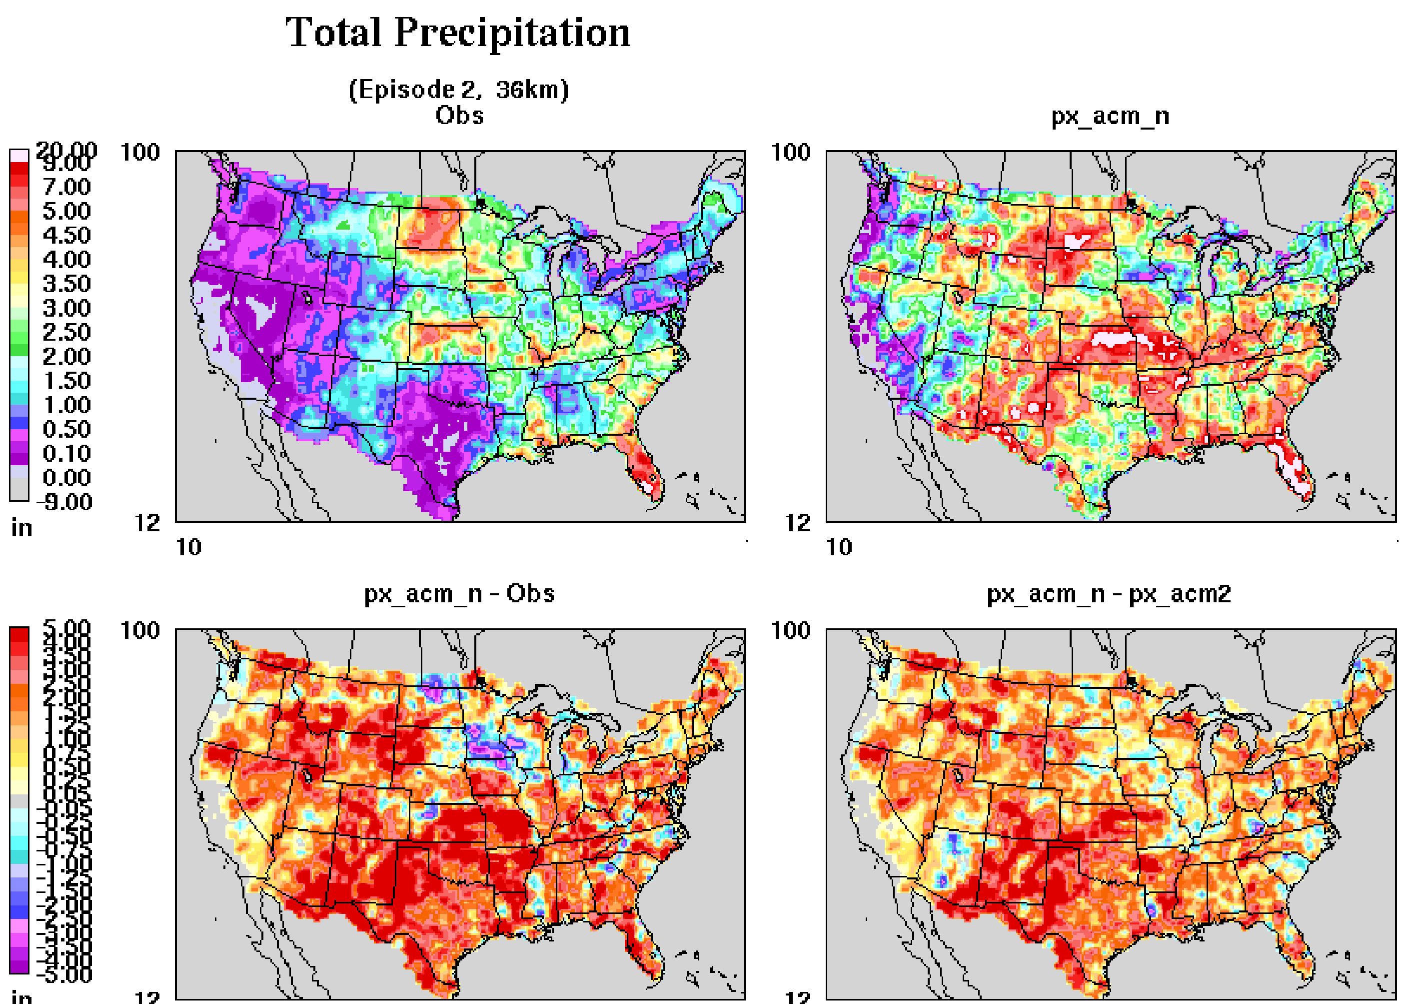

Figure 68. Episode 2 (Jul 13-28, 2001) composite precipitation for the US land-portion of the 36-km domain is shown. The top left panel displays the accumulated precipitation generated from the Climate Prediction Center gridded precipitation datasets. The top right panel shows the corresponding plot for the px_acm_n model configuration, and the lower left plot shows the difference plot between the model and the observations. The bottom right plot shows the difference between the px_acm_n sensitivity and the px_acm2 base case.

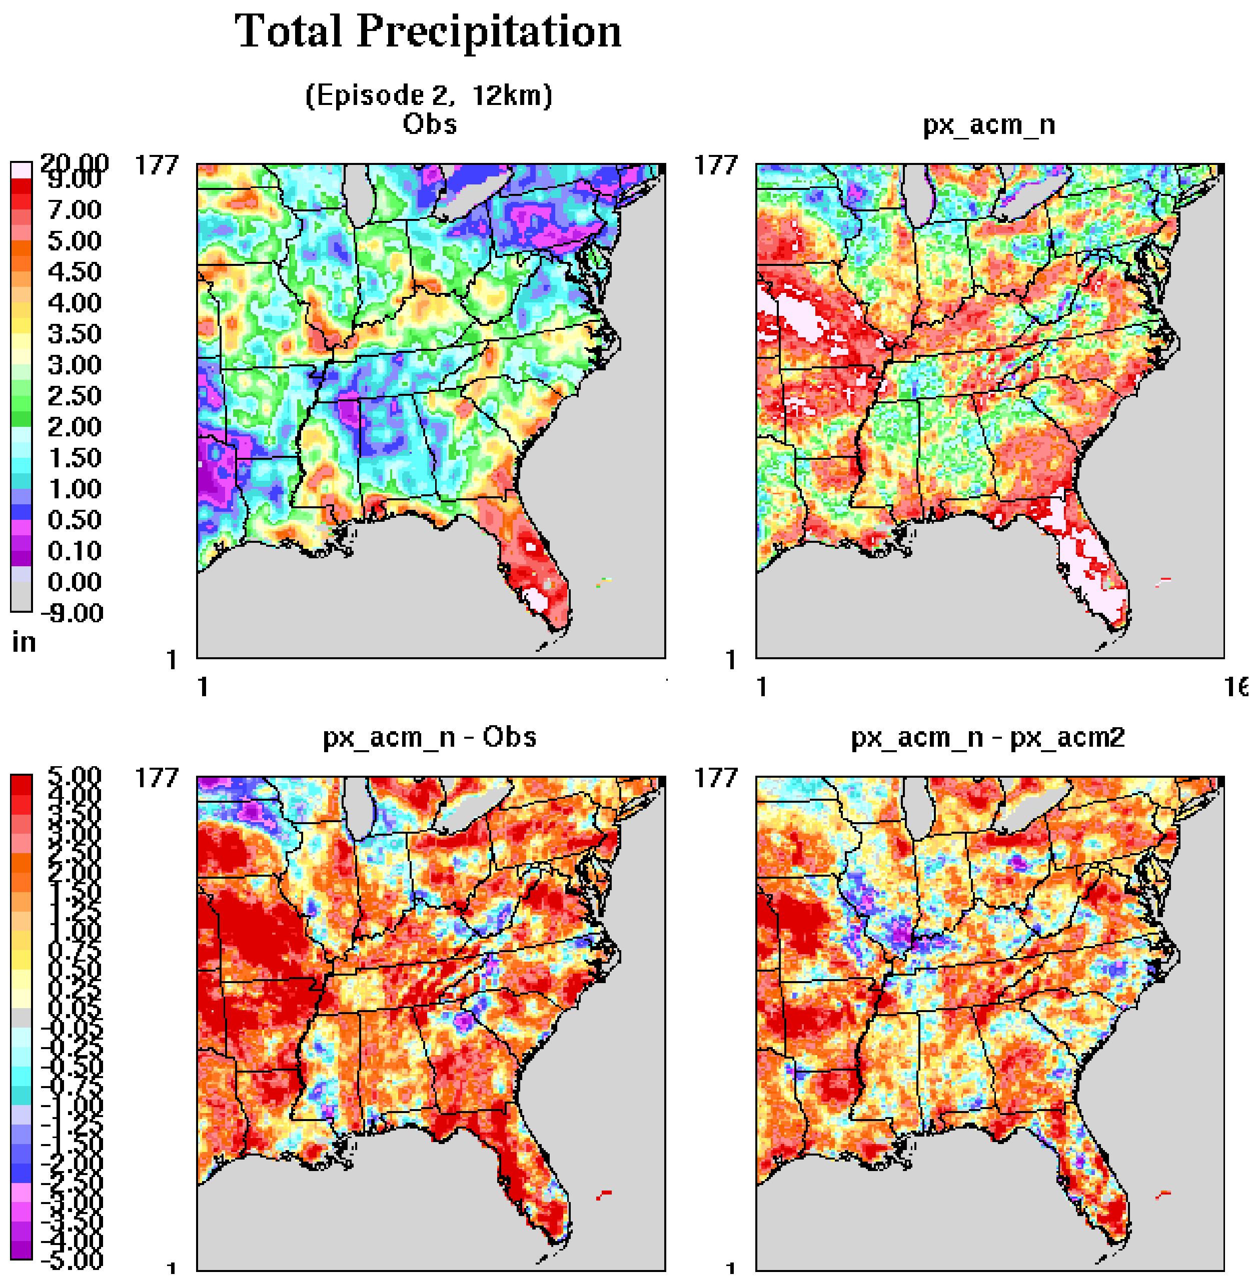

Figure 69. Episode 2 (Jul 13-28, 2001) composite precipitation for the US land-portion of the 12-km domain is shown. The top left panel displays the accumulated precipitation generated from the Climate Prediction Center gridded precipitation datasets. The top right panel shows the corresponding plot for the px_acm_n model configuration, and the lower left plot shows the difference plot between the model and the observations. The bottom right plot shows the difference between the px_acm_n sensitivity and the px_acm2 base case.

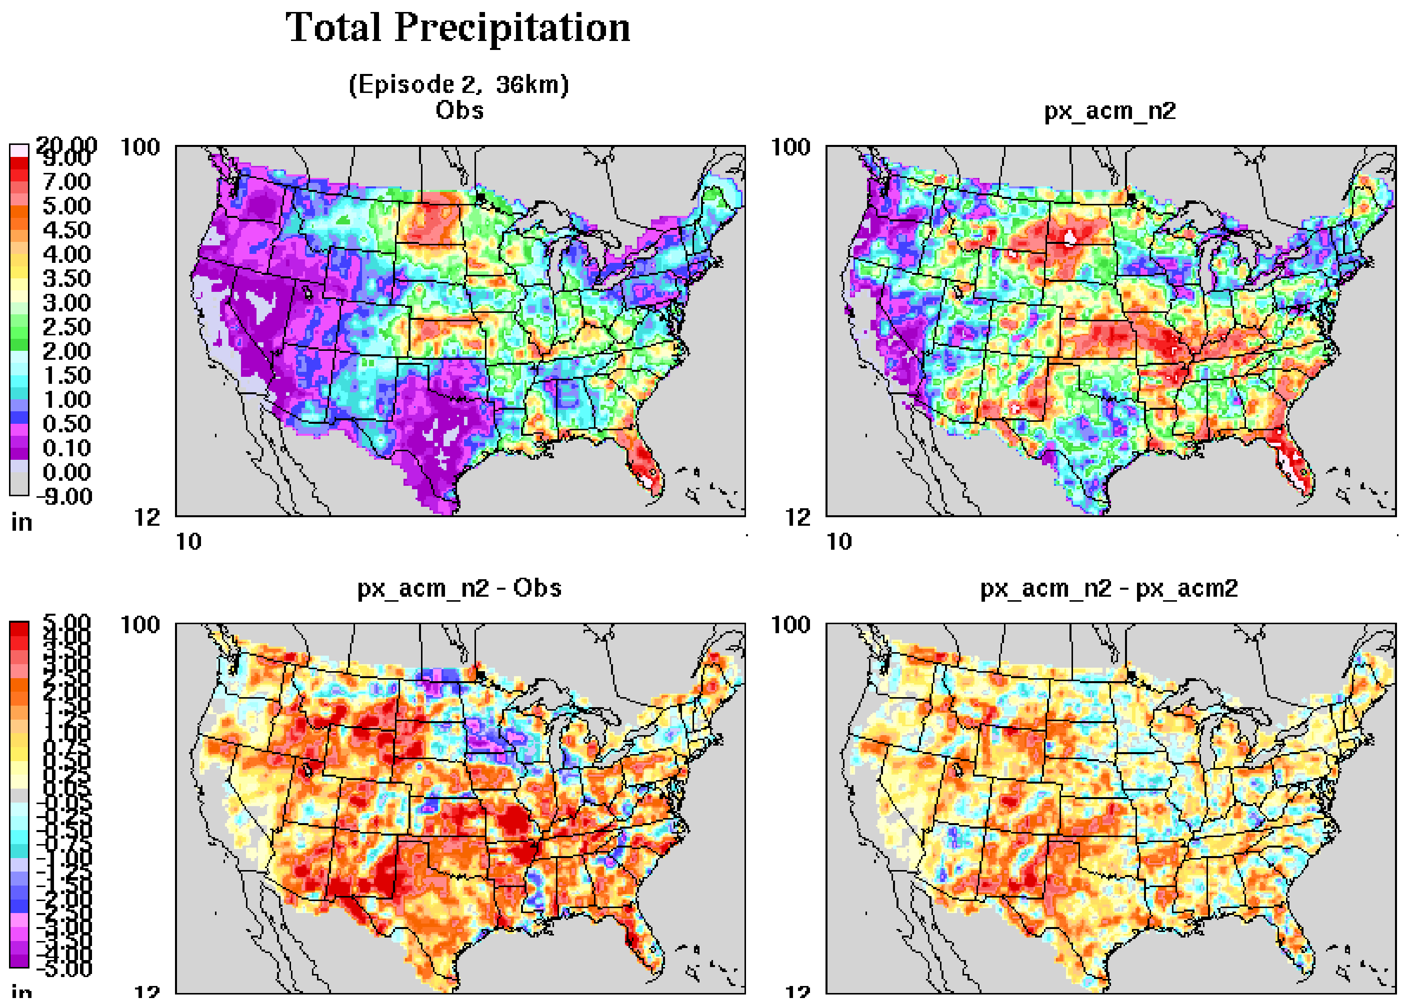

Figure 70. Episode 2 (Jul 13-28, 2001) composite precipitation for the US land-portion of the 36-km domain is shown. The top left panel displays the accumulated precipitation generated from the Climate Prediction Center gridded precipitation datasets. The top right panel shows the corresponding plot for the px_acm_n2 model configuration, and the lower left plot shows the difference plot between the model and the observations. The bottom right plot shows the difference between the px_acm_n2 sensitivity and the px_acm2 base case.

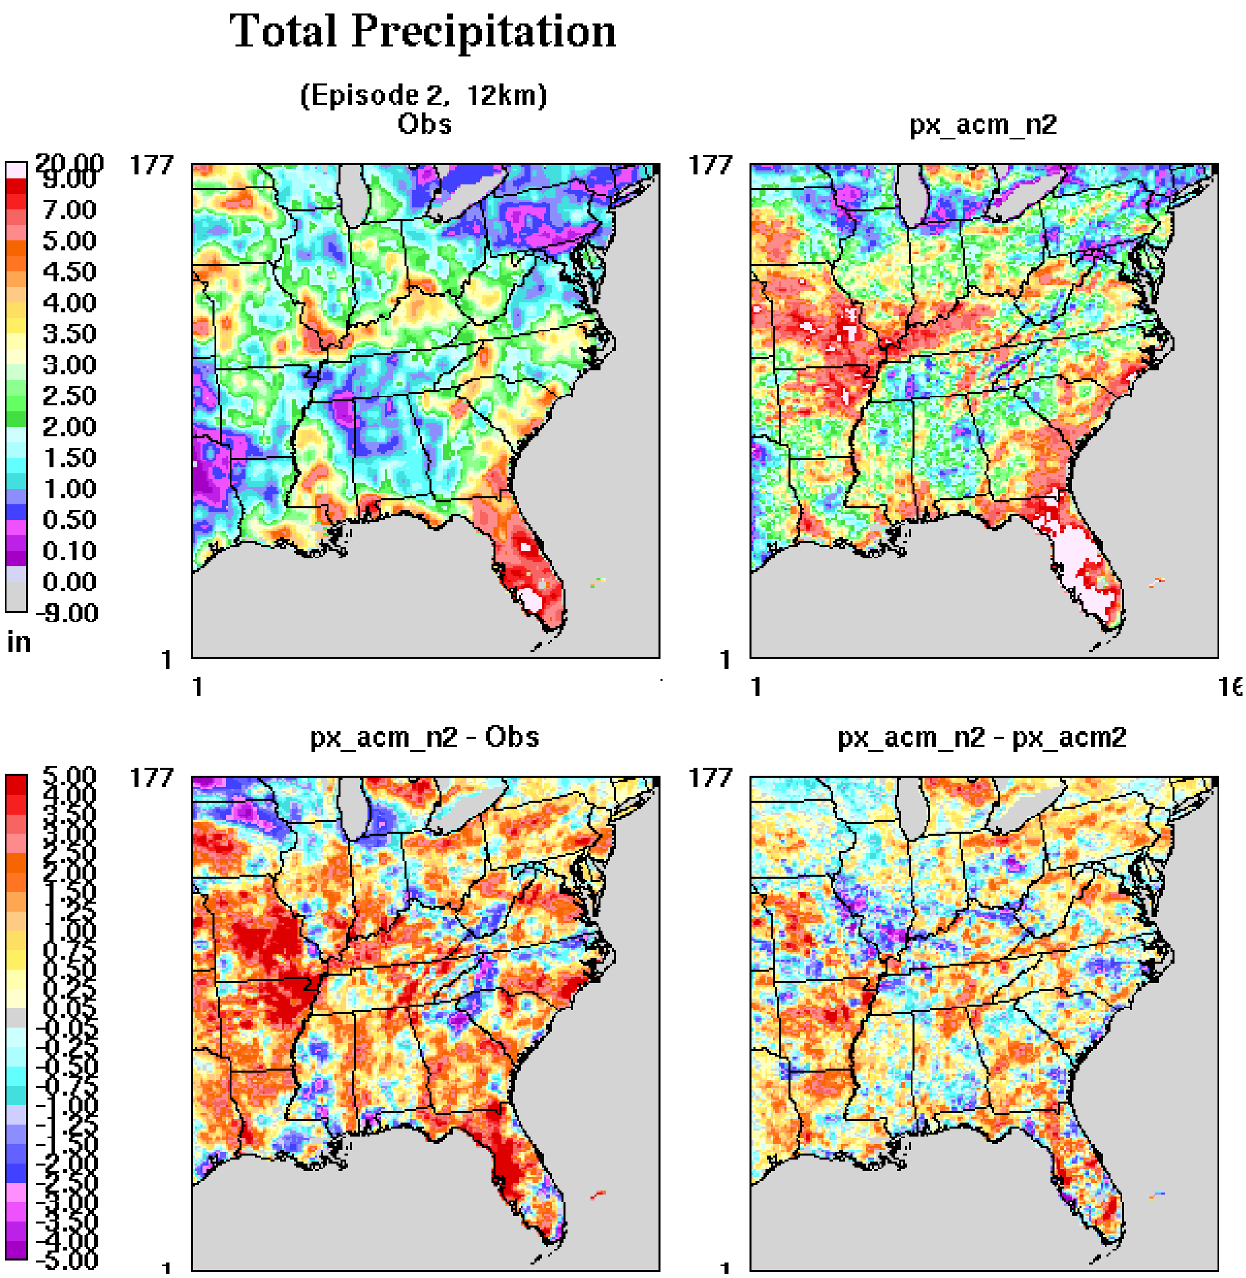

Figure 71. Episode 2 (Jul 13-28, 2001) composite precipitation for the US land-portion of the 12-km domain is shown. The top left panel displays the accumulated precipitation generated from the Climate Prediction Center gridded precipitation datasets. The top right panel shows the corresponding plot for the px_acm_n2 model configuration, and the lower left plot shows the difference plot between the model and the observations. The bottom right plot shows the difference between the px_acm_n2 sensitivity and the px_acm2 base case.

6 Conclusions from Sensitivity Modeling

Considering only the original four (five, including px_acm2) sensitivity runs mandated under VISTAS Met task 2d, the px_acm2 run performs best overall. This conclusion is the result of a rather exhaustive quantitative and qualitative assessment of these sensitivity runs over three episodes. While the statistical performance for px_acm2 for certain quantities might be surpassed by other model configurations (e.g. noah_eta-my winds), it seldom performs the poorest of the five original sensitivities tested.

A few general conclusions can be drawn about these initial sensitivity tests. They are:

- PBL heights are consistently highest in the noah_mrf simulations, while the noah_eta-my runs consistently produce the lowest daytime PBL heights. At night the px_acm(2) PBL heights are usually lowest.
- Surface winds are consistently best represented by the noah_eta-my runs, in large part because that configuration appropriately produces the calmest winds at night.
- The px_acm2 temperatures are modeled better than all other configurations for the winter episode, including px_acm. The noah_eta-my runs consistently show the most extreme low temperature bias of all configurations for all episodes.
- All configurations other than noah_eta-my exhibit similar performance in modeling measurable 24-h precipitation. The noah_eta-my runs produce more precipitation coverage and are generally slightly less skilled than the other sensitivities, especially for the winter episode. The runs all seem to produce too much accumulated precipitation in the summer.

The auxiliary tests show that using LITTLE_R output to drive INTERPF (px_acm8) produces slightly beneficial results. In essence px_acm8 is the "best and final" configuration. Our recommendation for the annual modeling effort, therefore, is to implement the px_acm8 configuration. These tests also reveal that MM5 seems to suffer from a wintertime cold bias. All of our configurations yielded that signature. While the px_acm8 set-up produces the best results of the credible configurations, the cold bias still remains. The problem seems to be most acute whenever the temperature changes significantly over the course of a 5-5 day segment. More effort from the MM5 community at large needs to be made to correct this bias, but at present it appears that these transient cold bias signatures are unavoidable.

7 Methodology for Annual Modeling Effort

With the sensitivity runs completed, we can establish the procedures we will use to execute/analyze MM5 for the annual modeling study period.

A. Modeling Approach

For the sensitivity modeling we used the MPP implementation of MM5 version 3.6.1. It is important to note that considerable effort was expended to port EPA's MPP version of the Pleim-Xiu LSM into the 3.6.1 MM5 code. A few other modifications were made to the code to allow MPP, most notably modifications to the Kain-Fritsch 2 cumulus parameterization module. This version was kept frozen throughout the course of the sensitivity testing. Since then a new minor-release version of MM5 (v3.6.2) has been released. According to NCAR's release notes, the only changes in the actual MM5 code that could possibly affect our modeling results involve seasonal vegetative adjustments and sea ice treatments. The vegetative adjustments have already been implemented in our version of the code, and the sea ice issue is likely to have negligible effects on our results. Considering the resources required to test the v3.6.2 code with all of our modifications added, and considering the expected negligible effects of these modifications, for the annual modeling effort we will implement the v3.6.1 code used in the sensitivity modeling. The preprocessor code, however, could affect results positively. Therefore we will use the latest v3.6.2 releases of those codes.

In the sensitivity modeling we generally executed MM5 in 5.5-day segments starting at 00Z, and we will continue this approach for the annual modeling. Though our modeling period is all of 2002, we will begin our simulations at 00Z December 17, 2001. This allows the air quality team to "spin-up" CMAQ (or another air quality model) for up to two weeks before our period of interest. It requires 76 5.5-day segments to process the entire year, assuming a 12-hr overlap between runs. Realizing that new runs may at some point be needed, we will assign a "case" tag to each file associated with a particular segment. This tag includes the start date/year of the segment, as well as "v02_aaa" ("v" for VISTAS, "02" for 2002, and "aaa" indicating the first meteorological run). The segments align as follows:

Date tag	Duration		Date Tag	Duration
dec17_01	00Z Dec 17, 2001 – 12Z Dec 22, 2001		jun25_02	00Z Jun 25, 2002 – 12Z Jun 30, 2002
dec22_01	00Z Dec 22, 2001 – 12Z Dec 27, 2001		jun30_02	00Z Jun 30, 2002 – 12Z Jul 5, 2002
dec27_01	00Z Dec 27, 2001 – 12Z Jan 1, 2002		jul05_02	00Z Jul 5, 2002 – 12Z Jul 10, 2002
jan01_02	00Z Jan 1, 2002 – 12Z Jan 6, 2002		jul10_02	00Z Jul 10, 2002 – 12Z Jul 15, 2002
jan06_02	00Z Jan 6, 2002 – 12Z Jan 11, 2002		jul15_02	00Z Jul 15, 2002 – 12Z Jul 20, 2002
jan11_02	00Z Jan 11, 2002 – 12Z Jan 16, 2002		jul20_02	00Z Jul 20, 2002 – 12Z Jul 25, 2002
jan16_02	00Z Jan 16, 2002 – 12Z Jan 21, 2002		jul25_02	00Z Jul 25, 2002 – 12Z Jul 30, 2002

B. Model Execution

To prepare the MM5 input files we execute the MM5v3.6.2 preprocessor system. The general flow stream is as follows:

Processor	Function	Execution Schedule
TERRAIN	Prepare time-independent grid information	Once
REGRID (Pregrid)	Extract files from EDAS analyses at 3-hr (sfc) and 12-hr (3D) temporal resolution	Monthly
REGRID (Regridder)	Translates pregrid output onto TERRAIN grids	6 days
FETCH (adp_sfc)	Creates surface/ship data at 3-hr resolution	Monthly (nominal 3-day chunks)
FETCH (adp_upa)	Creates upper air data (cat with sfc data) at 3-hr resolution	Monthly (nominal 15-day chunks)
LITTLE_R	Uses FETCH output to "improve" REGRID output	6 days
INTERPF	Translates LITTLE_R output to MM5 vertical coordinate system	6 days
MM5	Creates hourly gridded meteorological files	5.5 days

Terrain

Terrain is processed using the 2 min (~4 km) global land-use data set for both the 36-km and 12-km domains. The 36-km grid is the national RPO domain, and the 12-km domain is identical to what was used in the sensitivity modeling. Note that we have selected the "BotSoil" option per EPA's example. The exact details are found in the terrain.namelist file that is included in the Appendix 9A.

REGRID (pregrid)

Since the EDAS files (ds609.2 from NCAR) are archived in month chunks (half month 3D analyses files), we process these files through pregrid at monthly intervals. We use the standard GRID vtables to process four types of files: 1) FILE*, 2) SNOW*, 3) SOIL*, and 4) SST*, each at 3-hourly resolution. An example pregrid namelist file is shown in Appendix 9B.

REGRID (regridder)

The output of pregrid is interpolated to the MM5 grids for each modeled segment by regridder. Note that these input grids cover 6 days rather than 5.5 days due to an INTERPF requirement. Separate regridder runs are made for both the 36-km and 12-km grids, and the temporal resolution is 3 hours. An example regridder namelist file is shown in Appendix 9C. We have implemented one minor change from the methodology used in the sensitivity tests, that being that the climatological albedo file (used by the NOAH LSM) is not processed for the annual run.

FETCH (adp_sfc)

The adp_sfc preprocessor converts surface and ship data files (ds464.0) into a format that can be read by LITTLE_R (Objective Analysis). The surface data are stored in five or six day chunks so that a month of data is always included in six data sets, while the ship data are in monthly chunks. We have discovered that adp_sfc might not work correctly if we try to process too long a time span, so we limit our processing to 3 or 4 day periods. So we execute adp_sfc ten times for both the surface data and the ship data. Hourly output files are produced, though we only use the 3-hourly files. The surface and ship data are concatenated, and eventually the upper air data are also concatenated at the end of the data file. The preprocessing for the sensitivity runs did not include upper air data in the surface_obs files. An example namelist for adp_sfc is shown in Appendix 9D.

FETCH (adp_upa)

The adp_upa preprocessor converts upper air data files (ds353.4) into a format that can be read by LITTLE_R. The upper air data are stored in monthly segments, and we process the data in half-month intervals one after the other. The output interval is typically 6-hourly. We concatenate the surface/ship data into these data sets, so the output upper-air_obs files are actually at 3-hour intervals. An example namelist for adp_upa is shown in Appendix 9E.

LITTLE_R (Objective Analysis)

LITTLE_R performs internal quality control on the observational data produced by FETCH and uses these data to “improve” the REGRID output fields. Our auxiliary sensitivity tests indicate that this provides a discernable improvement in the MM5 predictions, so unlike the base sensitivity runs we will use the LITTLE_R output as input to INTERPF. LITTLE_R needs to be executed for both the 36-km and 12-km grids. This processor produces SFCFDDA files that directly feed into MM5. An example LITTLE_R namelist file is shown in Appendix 9F.

INTERPF

INTERPF converts the LITTLE_R output into the 34-sigma layers that have become the RPO standard. Because the LOWBDY files require a full day (00Z-21Z) to produce output, this preprocessor, as well as REGRID and LITTLE_R, needs to be run for a full six days to allow MM5 to execute the desired 5.5 days. An example INTERPF namelist is included in Appendix 9G.

MM5

The sensitivity tests described earlier in this document enables us to define the likely optimal model configuration we will implement for the annual run. One expected minor change from px_acm8 is that the RADFRQ interval is decreased from 30 minutes to 15. In summary here are the key parameters:

36-km domain: 129x165x34 (N-S dot cells, W-E dot cells, vertical levels)
12-km domain: 190x181x34 (N-S dot cells, W-E dot cells, vertical levels)
2-way nesting, no feedback, 90-second outer grid time step, 7920 minutes total, hourly output

LSM:	Pleim-Xiu (independent segments initiated from EDAS soil quantities)
PBL:	Asymmetric Convective Model (ACM)
Radiation scheme:	Rapid Radiative Transfer Model (RRTM)
Cumulus scheme:	Kain-Fritsch 2
Snow:	Snow effects on (IFSNOW=1)
SST:	Varying (ISSTVAR=1)
Analysis nudging:	2.5E-4 (36-km sfc/aloft winds, temps aloft only)
	1.0E-4 (12-km sfc/aloft winds, temps aloft only)
	1.0E-5 (36-km/12-km mixing ratio, aloft only)

Appendix 9H shows an example mmlif file.

The MM5 output files are broken down into daily chunks to keep the output files from becoming too large. The default is for MM5 to name the outer 36-km grid as domain "1", while the 12-km grid is referred to as domain "2". This is what the 36-km files are named by default:

MMOUT_DOMAIN1_00	(initial hour 0 only)
MMOUT_DOMAIN1_01	(hours 1-24, inclusive)
MMOUT_DOMAIN1_02	(hours 25-48, inclusive)
MMOUT_DOMAIN1_03	(hours 49-72, inclusive)
MMOUT_DOMAIN1_04	(hours 73-96, inclusive)
MMOUT_DOMAIN1_05	(hours 97-120, inclusive)
MMOUT_DOMAIN1_06	(hours 121-132, inclusive)

When the model files are sent to the air quality team they will have the date/case tag added as previously described. So for the model run that initiates on March 17, 2002, a file might be named MMOUT_DOMAIN2_04.mar17_02.v02_aaa. This file contains 12-km MM5 output data for the time period 01Z March 20, 2002 through 00Z March 21, 2002 from the run that started at 00Z March 17, 2002.

C. Model Evaluation Procedures

A variety of evaluation procedures have been established for this project (see http://www.baronams.com/projects/VISTAS/reports/VISTAS_TASK1.pdf). The results will be transmitted to the TAWG and other interested parties via the VISTAS meteorological web page (http://www.baronams.com/projects/VISTAS/select_annual_product.html). Here is a summary of the evaluation products that will be available on that web site:

1) Surface Products
    a. Spatial Plots
    b. Timeseries Plots
    c. Combination Plots
2) Aloft Products
    a. Spatial Plots
    b. Sounding Plots
    c. Profiler Plots
3) Statistical Products
    a. Surface Statistical Timeseries
    b. Aloft Statistical Timeseries
    c. Statistical Tables
4) Monthly Products
    a. Spatial Statistical Plots
    b. Spatial Summary Plots
    c. Monthly "Bakergram" Plots
    d. Annual "Bakergram" Plots
    e. Monthly Summary Statistics

In many of the web forms the user is asked to select options from a few drop-down menus. Here is a summary of the most common menus:

1) Region, or areal extent of results
    a. VISTAS (VISTAS RPO, valid for both 36-km and 12-km grids)
    b. Full (Entire grid, valid for both grids)
    c. US (All US stations, 36-km stats only)
    d. MANE-VU (MANE-VU RPO, 36-km only)
    e. MIDWEST (MIDWEST RPO, 36-km only)
    f. CENRAP (CENRAP RPO, 36-km only)
        i. CENRAP_N (Northern portion of CENRAP)
        ii. CENRAP_S (Southern portion of CENRAP)
    g. WRAP (WRAP RPO, 36-km only)
        i. WRAP_N (Northern portion of WRAP)
        ii. WRAP_S (Southern portion of WRAP)

2) Sensitivity
    a. v02_aaa (for Vistas '02, initial met/emis/air_quality)

3) Scale
    a. 12km (12-km grid)
    b. 36km (36-km grid)

4) 5-day segment (Segment identifier, MonDD_YY)
    a. dec17_01 (Segment from Dec 17, 2001, 12Z to Dec 22, 2001, 12Z)
    b. dec22_01 (Segment from Dec 22, 2001, 12Z to Dec 27, 2001, 12Z)

c. …
d. dec27_02 (Last segment, Dec 27, 2002, 12Z to Jan 1, 2003, 12Z)

A brief summary of each product type is given below.

Surface Products (Spatial Plots)

Spatial plots of key surface variables are available at 6-hrly intervals. Variables include:

1) Temperature (1.5 m), with TDL obs overlaid.
2) Mixing Ratio, with TDL obs overlaid.
3) Winds, vectors (with a very light wind speed background) at an MCIP2-derived 10 meter (observational) height. Not available for 36-km Full region (too busy).
4) Cloud fraction (CFRAC in MCIP2.1). The overlaid obs come from the TDL surface reports and represent the maximum of the low-, middle-, and high- observed cloud coverage. The black and white color scale is designed to mimic (sort of) satellite imagery.
5) Cloud fraction (alt). Like the above cloud fraction, except we take the maximum of the MCIP2.1 low, middle, and high clouds to represent the total model cloud fraction. This is the preferred variable from a meteorological perspective.
6) 6-hrly accumulated precipitation, with TDL obs overlaid. Be warned that in the TDL obs it is impossible to differentiate "missing" precipitation values from "No precip" reports. So use these images qualitatively with that realization.
7) Relative humidity, with TDL obs overlaid.
8) Temperature (layer 1), with TDL obs overlaid.
9) PBL heights.

Surface Products (Timeseries Plots)

Time series plots of key meteorological variables are available for a number of important sites. Note that no 12-km plots are available for stations outside of the 12-km grid. Plots are available for the following scales:

1) 12KM: 12-km grid (includes aloft trace where applicable)
2) 36KM: 36-km grid (includes aloft trace where applicable)
3) 36_12KM: 36-km/12-km results co-plotted. (no aloft traces)

Surface Products (Combination Plots)

Model/observed (or analyzed) fields are plotted next to each other. These animations are region independent. Here are the available fields:

1) pcp24: 24-hr accumulated precipitation ending at 12Z daily. Observed values derive from the Climate Prediction Center.
2) ir_sat: Model cfrac (alt) is compared with GOES 8 infrared imagery at 00Z and 12Z.

3) slp: The Unisys surface analyses are compared with a RIP-generated analyses. Note that the plotted precipitation is qpr, the total precipitation hydrometeor mixing ratio. The scale for this variable does **not** match the analyzed precipitation, and in fact there are times, especially in the summer, in which actual modeled precipitation falls below the lower range of the qpr scale.

4) vis_sat: Model cfrac (alt) is compared with GOES 8 visible imagery daily at 18Z.

Aloft Products (Spatial Plots)

This product shows spatial plots for the basic meteorological variables at layers 9 (sigma 0.94-0.93, midpoint ~500m), 17 (sigma 0.82-0.80, midpoint ~1600m), and 22 (sigma 0.65-0.60, midpoint ~3400m). The observations are integrated through the depth of the sigma layers. Note that only full grid images are produced. Here are the available variables:

1) Temperature
2) Mixing ratio
3) Winds

Aloft Products (Sounding Plots)

This product shows sounding plot animations for selected upper air observing sites. Observations are co-plotted, and soundings are available from the surface to 100 mb as well as from the surface to 500 mb.

Aloft Products (Profiler Plots)

This product shows profiler plot wind animations for selected profiler sites in the southeastern US up to a height of 2500 AGL. Individual images show 12 hours of data, from 00-11Z or 12-23Z.

Statistical Products (Surface Statistical Timeseries)

Statistical metrics are plotted on a three-panel image. For most variables the top panel shows the mean obs (blue) and the mean model (red), the second panel shows the bias (blue) and absolute error (red), while the third panel shows the Index of Agreement (IA, in blue), the coefficient of determination (r^2, in red), and the number of valid obs/model pairs (#, thin black, right axis). Wind direction plots differ from the above paradigm in that the number of valid obs/model pairs appears in the top panel, and more importantly in that the third panel shows the U/V wind component absolute error and bias. The three-panel precipitation plots are vastly different in description from the other variable. The top panel shows precipitation accuracy (“Acc”, in blue), false alarm ratio (“FAR”, in red), probability of detection (“POD”, in black), and bias (“Bias”, right axis, in magenta). A thin green line marks the 1.0 level (right axis), the “perfect” precipitation bias level. The second panel shows the following skill measures: Threat score (“Threat”, in blue), the Equitable Threat Score (“ETS”, in red), the True Skill Score (or Hanssen and Kuipers score, “TSS”, in black), and Heidke Skill Score (“HSS”, in magenta). Before describing the third panel, we need to define a few terms. Measurable precipitation, by definition, matches or exceeds 0.01 inches. A “Hit” means that the model predicted measurable precipitation and measurable precipitation actually occurred. A “Miss” means the model failed to predict measurable precipitation when measurable precipitation occurred. A “False” means that the model predicted measurable precipitation when none actually occurred. Finally, a “Zero” means that the model and observations both indicated no measurable precipitation. The third panel thus shows the number of “Hits” (blue), “Misses” (red), and “Falses” (black) plotted using the left axis, and the number of “Zeroes” (magenta) plotted using the right axis. All of the metrics plotted in the first two panels are calculated based on the numbers plotted in this third panel. A final note about precipitation metrics needs to be made. It is possible to calculate these metrics using a threshold other than 0.01, which we indeed will do. A higher threshold can yield insight into the ability of the model to accurately handle more significant precipitation events. The downside of using higher thresholds is that some of the metrics (especially “Bias”) may end up being calculated with smallish numbers in its denominator, thus enabling the metric to at times reach very high numbers, essentially blowing the scale for other time periods. The third panel plot then becomes a useful surrogate to gauge model performance.

Here are the available statistical time series variables:

1) Temperature (1.5m)
2) Mixing Ratio
3) Wind Speed (10m)
4) Wind Direction
5) Cloud Fraction (orig): (From MCIP2.1 CFRAC)
6) Cloud Fraction (alt): (preferred)
7) Relative Humidity
8) Temperature (layer 1)
9) Wind Speed (layer 1)
10) 24-hr precipitation (0.01 in threshold):
    i. These stats are calculated using the Climate Prediction Center (CPC) gridded precipitation fields (0.25x0.25 degree resolution) regridded to match our 36km and 12km grids. The stats are then calculated on a cell by cell basis. Since the CPC fields are mainly for the US, we applied a mask (Figure 72) to only consider grid points near the US, and another mask to only consider land points in the calculations.
11) 24-hr precipitation (0.05 in threshold)
12) 24-hr precipitation (0.10 in threshold)
13) 24-hr precipitation (0.25 in threshold)
14) 24-hr precipitation (0.50 in threshold)
15) 24-hr precipitation (1.00 in threshold)

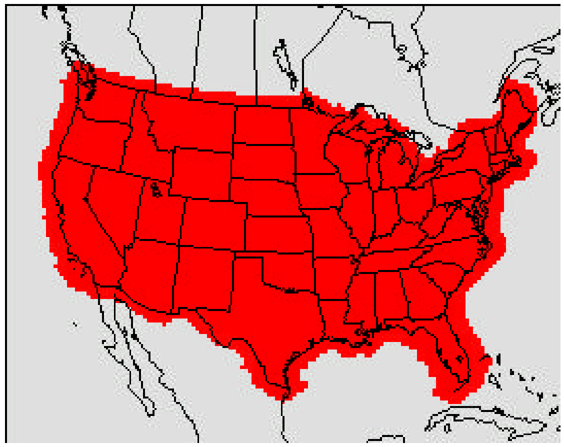

Figure 72. Mask for precipitation stats (36km).

Statistical Products (Aloft Statistical Timeseries)

This product shows the 3-panel statistical time series plots for our three aloft sigma layers (09, 17, and 22). Here are the available variables:

1) Temperature (K)
2) Mixing Ratio (g/kg)
3) Wind Speed (m/s)
4) Wind Direction (degrees)

Statistical Products (Statistical Tables)

This product shows region-specific statistical tables for all applicable surface variables other than precipitation. The data are parsed temporally such that:

1) All hours are considered
2) Only 00Z-11Z ("nighttime") hours are considered
3) Only 12Z-23Z ("daytime") hours are considered

The variable/stat labels are very cryptic. Here's how to interpret them:
Variables in first part of table:

1) TMP-1.5m: Temperature at 1.5 m (deg K)
2) QV: Mixing ratio (g/kg)
3) RH: Relative humidity (%)
4) WSPD-10m: Wind speed reduced by MCIP2 to 10m observational height (m/s)
5) SPD-lyr1: Layer 1 wind speed (m/s)
6) CLD: Cloud cover – original (%) (use CLD2 instead)
7) CLD2: Cloud cover – alternate (%)
8) TMP-lyr1: Layer 1 temperature (deg K) (use TMP-1.5m instead)

Labels in first part of table:

1) obsmean: Average of observations
2) modmean: Average of model predictions
3) bias: Simple bias
4) abserr: Absolute error
5) r2: Coefficient of determination
6) ia: Index of Agreement
7) rmse: Root Mean Square Error
8) nbias: Normalized bias
9) jtot: Number of valid obs/model pairs for stats

The WDIR (wind direction, degrees) metric has its own label structure:

1) obsmean: Average of observations
2) modmean: Average of model predictions
3) bias: Simple bias (Should be ignored for this discontinuous measure)
4) abserr: Absolute error
5) ubias: Simple bias for U-wind component (m/s)
6) vbias: Simple bias for V-wind component (m/s)
7) uerr: Absolute error of U-wind component (m/s)
8) verr: Absolute error of V-wind component (m/s)
9) newtot: Number of valid obs/model pairs for wind direction
10) dbias: Correct direction bias (Use instead of bias!)

Monthly Products (Spatial Statistical Plots)

This page shows basic statistical metrics (bias, absolute error) plotted on a per station basis. The idea is to graphically display these metrics so that the analyst can see the spatial pattern of model bias/error. There are two forms of these plots. The string "TOTAL" in the variable name designates the first of the forms. The resultant plot shows the metric calculated over all valid times. If the string "TOTAL" does not appear in the variable name, then a 24-hr animation appears. The first plot (hour 0) in the animation shows the metric calculated over all valid 00Z times, the second plot (hour 1) shows the metric calculated over all valid 01Z times, and so on through 23Z. This enables one to see the average diurnal/spatial variation of the metrics. Since only the hour field has meaning in these plots (and not even the hour has meaning in the "TOTAL" plots), we've arbitrarily set the Julian date for display to be January 1, 0000, and the "TOTAL" plots have an arbitrarily defined hour of 0. These are only placeholders so that we can use PAVE to visualize the results.

The naming convention for the variables that can be displayed has already partially been described. In review, variable names that have "BIAS" in them display the bias metric, while variable names that have "ERR" in them display the absolute error metric. If "TOTAL" appears in the variable name, a single plot showing the metric for all valid hours will be displayed at the arbitrarily defined time of Jan 1, 0000, 00Z. If "TOTAL" does not appear in the variable name, then an animation of the metric will appear cycling from 00Z-23Z, Jan 1, 0000. The actual variable to be plotted is listed first in the variable name string. They are:

1) CLD: Cloud cover (orig), as defined in spatial plots (%).
2) CLD2: Cloud cover (alt)
3) DIR: Wind direction (degrees)
4) Q: Water vapor mixing ratio (g/kg)
5) RH: Relative humidity (%)
6) SPD…10M: Wind speed reduced by MCIP2 to 10m obs height (m/s)
7) SPD…LYR1: Layer 1 wind speed (m/s)
8) T…1P5M: Temperature reduced by MCIP2 to 1.5m obs height (K)
9) T…LYR1: Layer 1 temperature (K)
10) UV: This is a unique variable in that only "ERR" is plotted. UV_ERR can be interpreted as the average magnitude of the error vector, defined as the square root of (U_ERR^2+V_ERR^2). This metric essentially combines wind speed error and wind direction error into one quantifiable metric.

Monthly Products (Spatial Summary Plots)

This product is designed to show daily summary information for a few of the key meteorological variables. Whenever possible the observations are overlaid onto the MM5 predicted fields. Generally speaking for each variable a 24-hr average (01Z-00Z), a "daytime" average (18Z-21Z) and a "nighttime" average (07Z-10Z) are generated. For temperature the "daytime" average is replaced by a daily maximum, and the "nighttime" average is replaced with the daily minimum. For precipitation a 24-hr accumulation ending at 00Z is created, as well as a "daytime" accumulation that we define to be 18Z-00Z. Since observations may include missing data, we require at least 3 (out of 4) valid observations per "daytime"/"nighttime" block, and 22 valid observations for the daily averages. These fields are generated for all regions. Here are the variables available for the three output averages:

1) Temperature (deg K)
2) Mixing Ratio (g/kg)
3) Precipitation (in)
4) Relative Humidity (%)
5) PBL height (m), with no obs overlay.
6) Wind Vectors with a wind speed (m/s) background
7) Cloud cover (alt)

Monthly Products (Monthly "Bakergram" Plots)

This product shows key statistical quantities summarized in a tile plot following the paradigm Kirk Baker developed for his "Mosaic" plots. This particular product has hours (00Z-23Z, top to bottom) as the y-axis and day of month (1-31, left to right) as the x-axis, as illustrated in figure 73.

We produce bias, error, and index of agreement plots for the following variables:

1) Temperature (deg K)
2) Mixing Ratio (g/kg)
3) Relative Humidity (%)
4) Cloud cover – alt (%)
5) Wind Speed (m/s)
6) Wind direction (degrees), bias and error only

Additionally we produce a plot showing the magnitude of error vector (m/s).

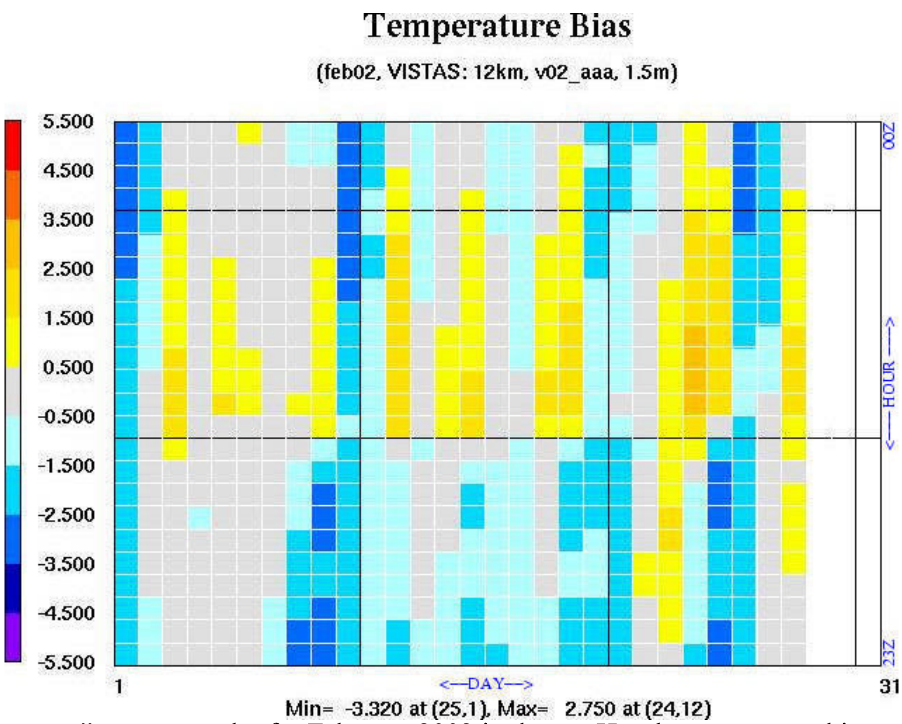

Figure 73. "Bakergram" prototype plot for February 2002 is shown. Hourly temperature biases (K) are plotted for the 12-km VISTAS region. The upper left tile represents the average bias in the selected region for 00Z, February 1, 2002. Hours increase from 00Z at the top to 23Z at the bottom, while the day of the month increases from 1 on the left to 31 on the right. Missing periods (e.g. Feb 29-31) are set to the default white background.

Monthly Products (Annual "Bakergram" Plots)

This page shows key statistical quantities summarized in a tile plot following the paradigm Kirk Baker developed for his "Mosaic" plots. This particular product has days (1-31, top to bottom) as the y-axis and month (1-12, left to right) as the x-axis, creating a calendar effect as illustrated in figure 3. (This particular example only shows the first six months of the year.) The available variables exactly match the variable list from the Monthly "Bakergram" Plot list.

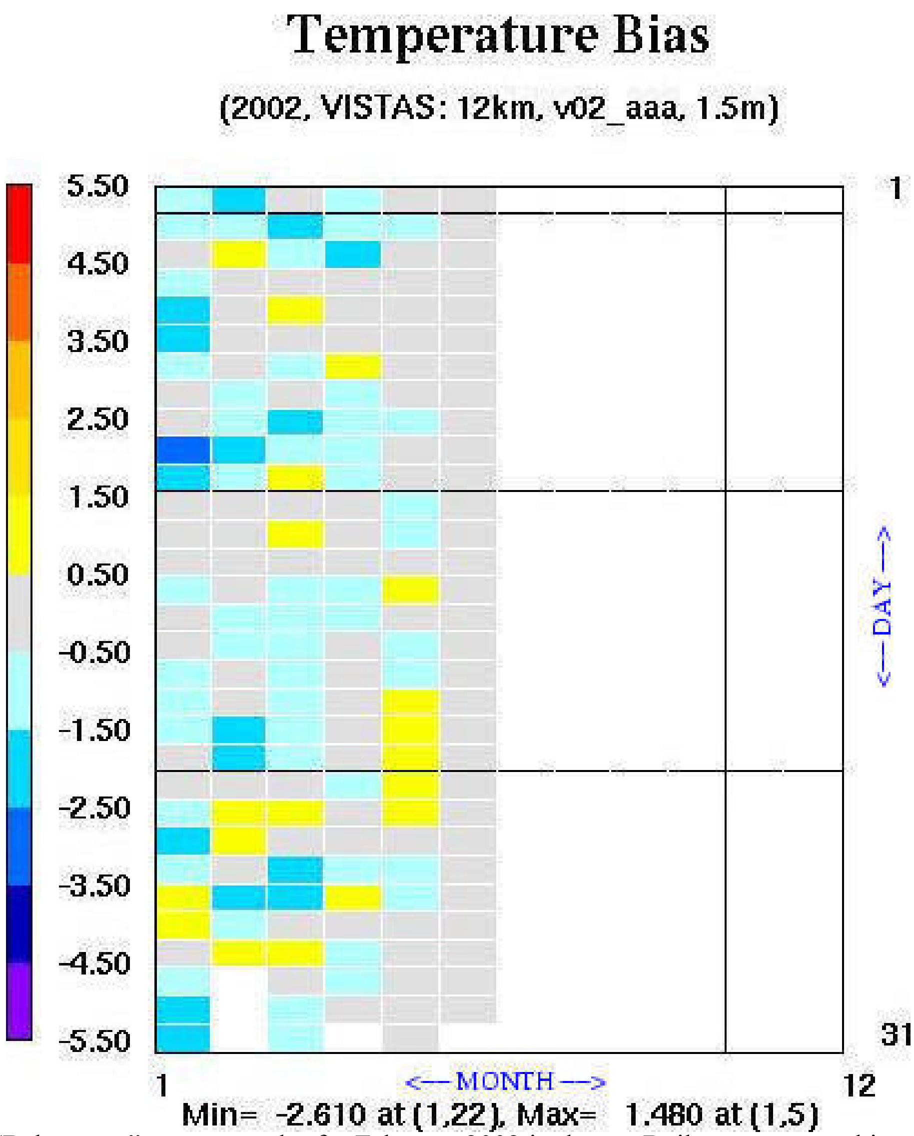

Figure 74. "Bakergram" prototype plot for February 2002 is shown. Daily temperature biases (K) are plotted for the 12-km VISTAS region. The upper left tile represents the average bias in the selected region for January 1, 2002. Days of month increase from 1 at the top to 31 at the bottom, while the month increases from 1 (January) on the left to 12 (December) on the right. Missing periods (e.g. Feb 29-31, Apr 31) are set to the default white background.

Monthly Products (Monthly Summary Statistical Tables)

This product is analogous to the 5-day segment statistical tables, except it covers a full month. These also include precipitation performance metrics when applicable.

Monthly Products (Monthly Accumulated Precipitation)

This product is analogous to the precipitation combination plots, except precipitation will be accumulated over monthly intervals.

D. Computing Resources

Except for the TERRAIN preprocessor and a few miscellaneous analysis routines, we anticipate using MCNC-GTEC's Linux cluster, which is a 64-node IBM X335's with dual 2.8Ghz Xeon processors, 4GB of memory, 40GB online storage. The actual MM5 runs will be run in MPP mode using 32 processors. Since TERRAIN did not readily work on the cluster, it was easier to run that processor on a 300 MHZ SGI machine.

Once runs are completed, we will archive the model inputs/outputs onto 100/200 GB LTO tapes. Additionally we will make triplicate copies of those files onto 250 GB FireWire/USB 2.0 external drives.

E. Project Schedule

Here are some key deliverable dates in the project:

Draft Protocol Approved:	Dec 12, 2003
Annual Modeling Begins:	Dec 15, 2003
First 6 Months MM5 Completed:	Jan 30, 2004
Website for Annual Products:	Feb 5, 2004
Revised Protocol:	Feb 11, 2004
First 6 Months MM5 Results to Air Quality Team:	Feb 19, 2004
MM5 Runs Completed:	Mar 1, 2004
MM5 Evaluation Completed:	Mar 19, 2004
Delivery of Second 6 Months to Air Quality Team:	Mar 19, 2004
Documentation of Annual Run:	Jun 30, 2004

Appendix J

Air Quality Model Performance Evaluation

(This page intentionally left blank)

Table of Contents

List of Figures

List of Tables

1. Overview

The discussion of model performance in this Appendix will focus on the comparison of observational data from the Federal Reference Monitor (FRM) and Speciated Trends Network (STN) monitoring sites and model output data from the 2002 VISTAS actual annual air quality modeling. The evaluation will primarily focus on the air quality model's performance with respect to individual components of fine particulate matter ($PM_{2.5}$), as good model performance of the component species will dictate good model performance of total or reconstituted fine particulate matter. Model performance of the total fine particulate matter will also be provided as a means to discuss the overall model performance for this Implementation Plan.

1.1 Monitoring Sites

The US EPA designated two areas as nonattainment for $PM_{2.5}$ in North Carolina. The Hickory Nonattainment area for $PM_{2.5}$ consists of Catawba County, while the Greensboro-Winston-Salem-High Point Nonattainment area (referred to as the Triad) consists of Davidson and Guilford counties. At the time of designations, Catawba County had both an FRM and STN monitor, and Davidson and Guilford counties each had an FRM monitor. The monitoring network has since been expanded to include STN monitors in Davidson and Guilford counties, as well as other additional monitoring sites around the state. The North Carolina $PM_{2.5}$ nonattainment areas and the current PM monitoring network are noted in Figure 1-1.

The model evaluation will focus on both the FRM and STN monitors across the state, due to the nature of the attainment test. Designations were based on FRM monitors, and calculations of future design values are calculated using current design value information from these sites. Since future attainment demonstrations hinge on the models representing the FRM sites well, it follow that model performance for these sites should be evaluated. STN data also needs to be evaluated as this data is used to speciate the FRM data so component based relative response factors can be calculated for each FRM monitoring site. More detailed information on the attainment test process is described in Appendix L.

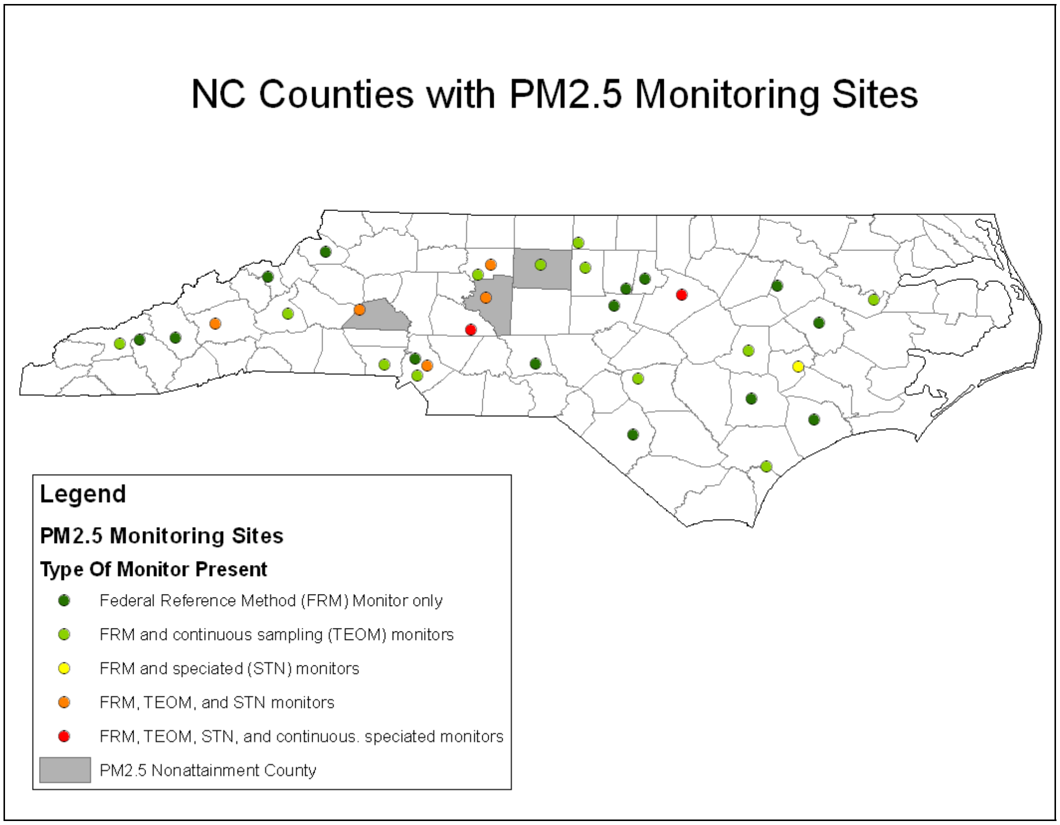

Figure 1-1: PM Nonattainment Areas and PM monitors in North Carolina.

1.2 Particulate Matter and Component Species

Particulate Matter can be liquid, solid, or can have a solid core surrounded by liquid. PM can include material produced by combustion, photochemical reactions, and can contain salt from sea spray and soil like particles. Particles are distinguished based on the method of formation. Primary particles are particles directly emitted into the atmosphere and retain the same chemical composition as when they were released. Secondary particles are those formed through chemical reactions involving atmospheric oxygen (O_2), water vapor (H_2O), hydroxyl radical (OH), nitrate (NO_3), sulfur dioxide (SO_2), oxides of nitrogen (NO_x), and organic gases from natural and anthropogenic sources. Fine particulate matter can therefore be composed of varying amount of different species, including:

- Sulfates
- Nitrates (usually found in the form of ammonium nitrate)
- Ammonium
- Hydrogen ion
- Particle bound water
- Elemental carbon
- Organic compounds
  - Primary organic species (from cooking and combustion)
  - Secondary organic compounds
- Crustal material (includes calcium, aluminum, silicon, magnesium, and iron)

- Sea salt (generally only found at coastal monitoring sites)
- Transitional metals
- Potassium (generally from wood burning or cooking)

For the purposes of model performance associated with this Implementation Plan, we will examine the species of particulate matter that are collected by the STN monitoring network. The components measured at STN include nitrate, sulfate, ammonia, and organic and elemental carbon. From these components we can also reconstruct a total $PM_{2.5}$ mass, which can be compared to a model total reconstructed fine mass. For this model performance evaluation, we will also examine the total $PM_{2.5}$ mass with respect to the total mass from the FRM monitoring sites.

2. Model Performance Statistics

To quantify model performance, several statistical measures were calculated and evaluated for all the STN and FRM monitors within the VISTAS 12km domain and individually for each STN and FRM monitor associated with North Carolina's $PM_{2.5}$ nonattainment areas. The statistical measures selected were based on the recommendations outlined in section 18.4.1 of the USEPA's Guidance On The Use Of Models And Other Analyses for Demonstrating Attainment of Air Quality Goals for Ozone, $PM_{2.5}$, and Regional Haze ("*Attainment Guidance*").

In 2004 VISTAS established model performance goals and criteria for components of fine particle mass (Table 2.1) based on previous model performance for ozone and fine particles. EPA modeling guidance for fine particulate matter at the time noted that PM models might not be able to achieve the same level of performance as ozone models. VISTAS' evaluation considered several statistical performance measures and displays.

Table 2-1 Model performance goals and criteria for components of fine particle mass.

Fractional Bias	**Fractional Error**	**Comment**
$\leq$15%	$\leq$35%	Goal for PM model performance based on ozone model performance, considered excellent performance
$\leq$30%	$\leq$50%	Goal for PM model performance, considered good performance
$\leq$60%	$\leq$75%	Criteria for PM model performance, considered average performance. Exceeding this level of performance indicates fundamental concerns with the modeling system and triggers diagnostic evaluation.

The statistical measures were calculated for all of the component species of particulate matter responsible for light extinction, and for total light extinction. For convenience, these statistical measures or metrics, along with a variety of additional statistical measures, are summarized in Table 2-2.

Table 2-2 Statistical Metric Calculations

Statistical Measure	Shorthand Notation	Mathematical Expression	Notes
Accuracy of Paired Peak	A_p	$\frac{P - O_{peak}}{O_{peak}}$	
Coefficient of Determination	R^2	$\frac{\left[\sum_{i=1}^{N}\left(P_i - \overline{P}\right)\left(O_i - \overline{O}\right)\right]^2}{\sum_{i=1}^{N}(P_i - \overline{P})^2 \sum_{i=1}^{N}(O_i - \overline{O})^2}$	P_i= prediction at time and location i; O_i = observation at time and location i; $\overline{P}$ = arithmetic average of P_i, i = 1, 2, . . ., N; $\overline{O}$ = arithmetic average of O_i, i = 1, 2, . . ., N;
Normalized Mean Error	NME	$\frac{\sum_{i=1}^{N}\left\|P_i - O_i\right\|}{\sum_{i=1}^{N}O_i}$	Reported as %
Root Mean Square Error	RMSE	$\left[\frac{1}{N}\sum_{i=1}^{N}\left(P_i - O_i\right)^2\right]^{\frac{1}{2}}$	Reported as %
Mean Fractional Error	MFE	$\frac{2}{N}\sum_{i=1}^{N}\left\|\frac{P_i - O_i}{P_i + O_i}\right\|$	Reported as %
Mean Absolute Gross Error	MAGE	$\frac{1}{N}\sum_{i=1}^{N}\left\|P_i - O_i\right\|$	
Mean Normalized Gross Error	MNGE	$\frac{1}{N}\sum_{i=1}^{N}\frac{\left\|P_i - O_i\right\|}{O_i}$	Reported as %
Mean Biased	MB	$\frac{1}{N}\sum_{i=1}^{N}\left(P_i - O_i\right)$	Reported as concentration
Mean Normalized Bias	MNB	$\frac{1}{N}\sum_{i=1}^{N}\frac{\left(P_i - O_i\right)}{O_i}$	Reported as %
Mean Fractionalized Bias (Fractional Bias)	MFB	$\frac{2}{N}\sum_{i=1}^{N}\left(\frac{P_i - O_i}{P_i + O_i}\right)$	Reported as %
Normalized Mean Bias	NMB	$\frac{\sum_{i=1}^{N}\left(P_i - O_i\right)}{\sum_{i=1}^{N}O_i}$	Reported as %
Bias Factor	BF	$\frac{1}{N}\sum_{i=1}^{N}\left(\frac{P_i}{O_i}\right)$	Reported as BF:1 or 1:BF or in fractional notation (BF/1 or 1/BF)

2.1 Statistical Tables

The statistical metrics were calculated for the Hickory (Catawba County) and Hattie Avenue (Forsyth County) STN monitors to demonstrate model performance on for the components of $PM_{2.5}$ in and near the $PM_{2.5}$ nonattainment areas. Model performance statistics for the STN sites were calculated on a component and total $PM_{2.5}$ basis for the entire base year.

Model performance statistics have also been calculated for collectively for the FRM monitors within the VISTAS 12km domain, as well as individually for the 3 FRM monitors in the nonattainment areas (Hickory, Lexington, and Mendenhall) to demonstrate the model's ability to replicate total $PM_{2.5}$ mass at these sites. Summaries of the statistical tables are presented separately for the STN monitoring sites (Section 2.1.1) and FRM monitoring sites (Section 2.1.2).

2.1.1 Model Performance Statistics for STN Sites

Both the Hickory (Table 2-3) and Hattie Avenue (Table 2-4) STN sites show similar statistical trends for the components of $PM_{2.5}$. The mean fractional bias values presented in the tables suggest that all the components, except ammonia, are under predicted at each of the sites. This leads to an overall under-prediction of total $PM_{2.5}$ at both sites for the year. The mean fractional bias for ammonia indicates only a very slight over prediction at both sites; however the mean fractional error values suggest this number is the result of balance between over and under prediction across the year. Normalized bias and error produces more encouraging model performance statistics, as bias and error values decrease. We also see nitrates shift from being under predicted to being over predicted. Overall, model performance statistics, while not perfect, are reasonable for the components of $PM_{2.5}$.

2.1.2 Model Performance Statistics for the FRM Sites

The tables for the FRM model performance statistics are broken out by month, which show that there is a trend for total $PM_{2.5}$ to start off as slightly over predicted, then shift to slightly under predicted in the spring. Negative bias values peak in the summer months, before a trend back toward positive bias values by October. This trend is seen in both the mean fractional bias and the normalized mean fractional bias in the collective statistics for the all the FRM sites in the VISTAS domain, as well as the 3 FRM sites in the North Carolina $PM_{2.5}$ nonattainment areas. The model performance statistics tables can be found in Table 2-5 through Table 2-8 starting on page 44.

2.2 Statistical Plots

An additional way to evaluate model performance statistics is to visualize performance via "soccer plots" and "bugle plots". The soccer plot is so named because the dotted lines resemble a soccer goal. The soccer plot is useful as both bias and error are shown on a single plot. As bias and error approach zero, the points are plotted closer to or within the "goal", represented here by the dashed boxes.

The "bugle plot", named for the shape formed by the criteria and goal lines. The bugle plots are shaped as such because the goal and criteria lines are adjusted based on the average concentration of the observed species. As the average concentration becomes smaller, the criteria and goal lines become larger to adjust for the model's poor ability to predict at low concentrations.

The analysis of "bugle plots" demonstrated that greater emphasis should be placed on performance of those components with the greatest contribution to $PM_{2.5}$ mass (e.g. sulfate and organic carbon) and that greater bias and error could be accepted for components with smaller contributions to total $PM_{2.5}$ mass (e.g. elemental carbon, nitrate, and soil). The "soccer plots" and "bugle plots" have been included as model performance evaluation displays in EPA's modeling guidance for Ozone, $PM_{2.5}$, and Regional Haze. (2006).

The soccer and bugle plots for the North Carolina STN and FRM monitors follow. Plots have been developed for the average monthly concentrations of $PM_{2.5}$ and its component species at the STN sites for the all the sites within the VISTAS 12km, for all North Carolina STN sites, and individually for the Hickory and Hattie Avenue STN sites (Figures 2-1 through 2-16). FRM based soccer and bugle plots have been constructed for the monthly average total $PM_{2.5}$ for the all the VISTAS FRM sites collectively, for all North Carolina FRM sites collectively, and individually for the 3 FRM sites within the nonattainment areas (Figures 2-17 through 2-32).

From the STN plots plot one can see the general tendency for the model to have some difficulty in predicting nitrates, as the monthly average values tend to fall outside the criteria goals for performance in the soccer plots. Because nitrates are generally found in low concentration across the southeast, the bugle plots are more encouraging with nitrates largely falling within criteria is not goals levels of model performance. There is some variation of individual model performance at the individual STN sites within North Carolina (e.g. elemental carbon performance at Hickory), however model performance is still generally with in acceptable or criteria levels. This is further supported by the FRM soccer and scatter plots, which generally show total $PM_{2.5}$ model performance largely falls within the "goal" modeling performance range. A more detailed summary of model performance for each site level is presented prior to the presented soccer and bugle plots in the following sections

2.2.1 STN Statistical Plots

2.2.1.1 All VISTAS STN Monitoring Sites

The soccer plots for monthly average component performance for all the VISTAS sites shows generally good model performance for most species of $PM_{2.5}$ and total $PM_{2.5}$. The exception is the prediction of nitrate values, which most values fall outside the criteria goal (Figure 2-1).

There are a few months that fall on the criteria level goal, which is better seen in the zoomed view presented in Figure 2-2. However, when the very low concentration of nitrates is taken into consideration, as presented in the bugle plots (Figures 2-3 and 2-4), nitrate performance largely falls within the criteria and goal model performance lines. One can still note a general tendency for under prediction in nitrates, and other species in Figure 2-3, which leads to a slight under prediction in total reconstructed $PM_{2.5}$.

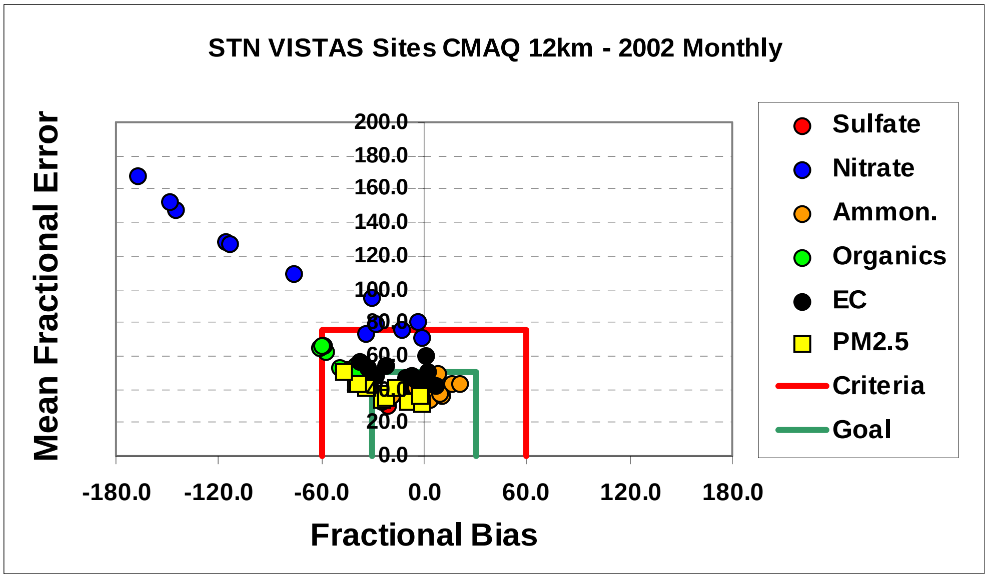

Figure 2-1: Soccer plot depicting both the mean fractional error and fractional bias for component concentration for all VISTAS STN monitoring sites. Each point represents a monthly value as compared to the model performance criteria (red box) and modeling performance goals (green box).

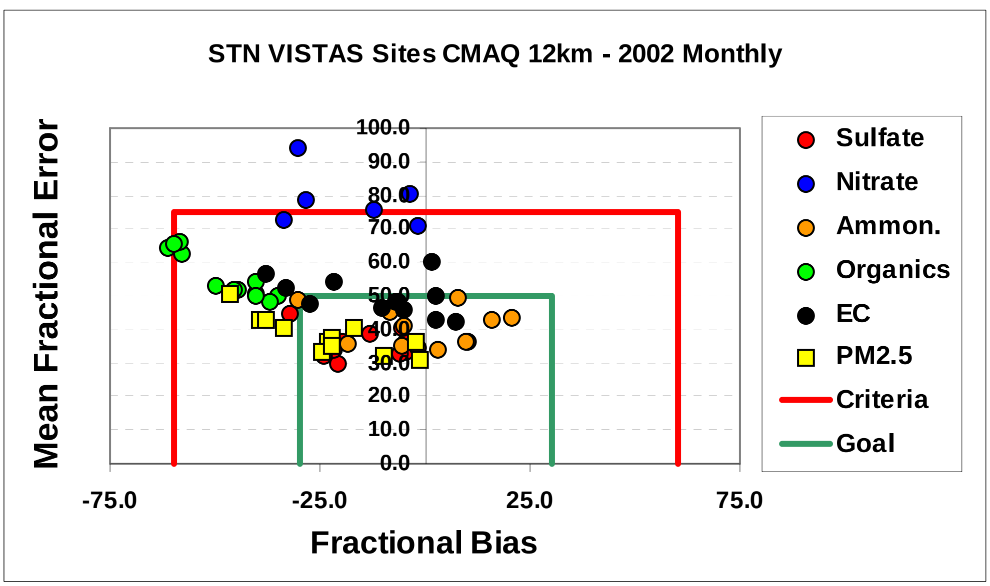

Figure 2-2: A zoomed view of the soccer plot depicting both the mean fractional error and fractional bias for all VISTAS STN monitoring sites. Each point represents a monthly value as compared to the model performance criteria (red box) and modeling performance goals (green box).

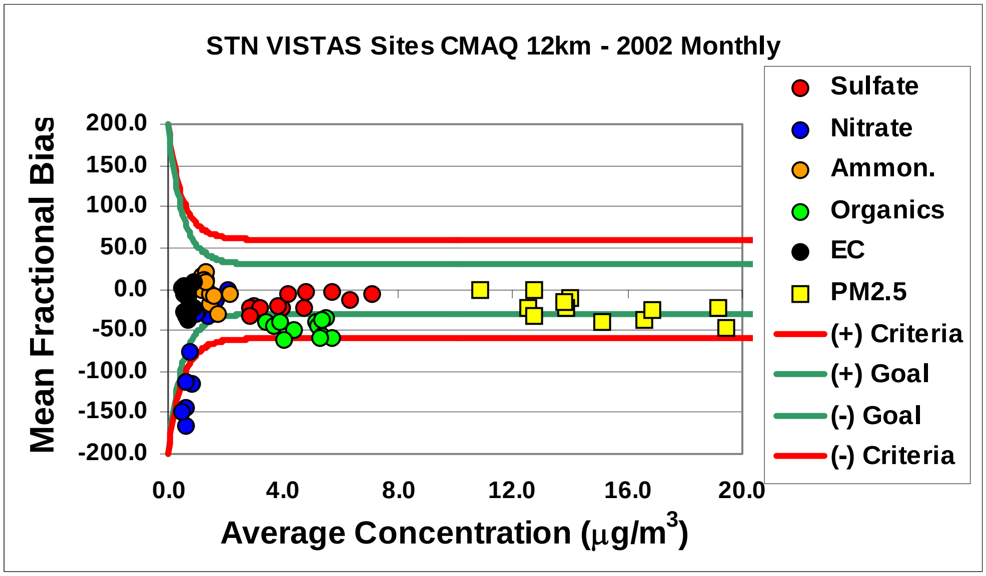

Figure 2-3: Bugle plot of the mean fraction bias for particulate matter and its component concentrations for all VISTAS STN monitoring sites. Each point represents a monthly mean fraction bias value as compared to the model performance criteria (red lines) and modeling performance goals (green lines).

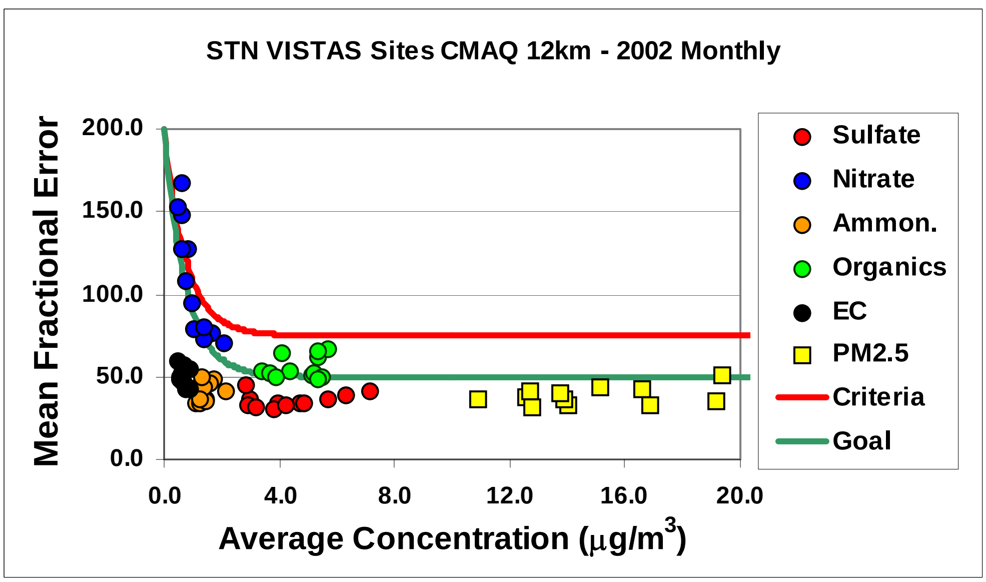

Figure 2-4: Bugle plot of mean fraction error for particulate matter and its component species for all VISTAS STN monitoring sites. Each point represents a monthly mean fraction bias value as compared to the model performance criteria (red lines) and modeling performance goals (green lines).

2.2.1.2 All North Carolina STN Monitoring Sites

The North Carolina STN sites correlate well to what was seen collectively across the VISTAS STN sites, as nitrate prediction under performs as seen in the soccer plots (Figure 2-5). However, wee see again that when performance is weighted by concentration, as in the bugle plots, nitrate performance again falls within criteria modeling performance goals. A slight deviation from the

VISTAS level figures is a slight under prediction in organic carbon values. Four months fall just outside criteria level model performance goals in the soccer plots, and continue to just fall outside criteria goals for mean fractional bias when concentration is considered (Figure 2-7). It is not surprising that model performance does not improve for organic carbon when concentration is taken into consideration, as organic carbon is generally a larger portion of total $PM_{2.5}$ mass in North Carolina. Otherwise, the model performs well in for STN sites in North Carolina.

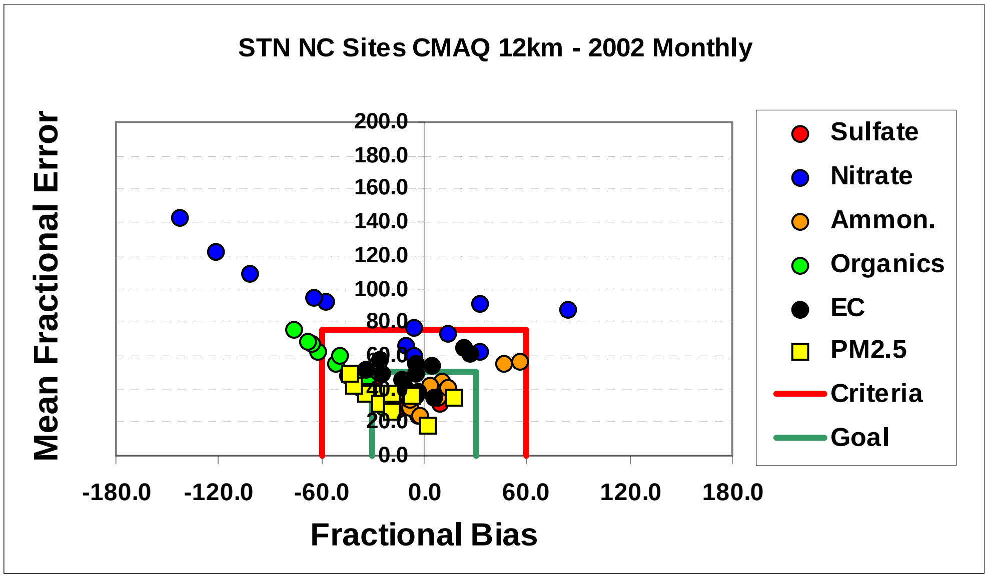

Figure 2-5: Soccer plot depicting both the mean fractional error and fractional bias for component concentration for all North Carolina STN monitoring sites. Each point represents a monthly value as compared to the model performance criteria (red box) and modeling performance goals (green box).

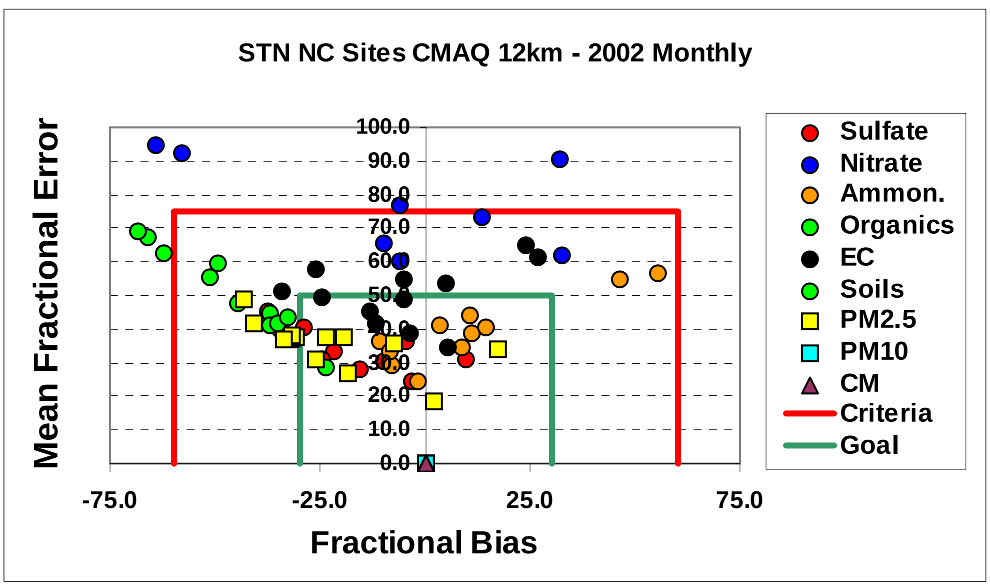

Figure 2-6: A zoomed view of the soccer plot depicting both the mean fractional error and fractional bias for all North Carolina STN monitoring sites. Each point represents a monthly value as compared to the model performance criteria (red box) and modeling performance goals (green box).

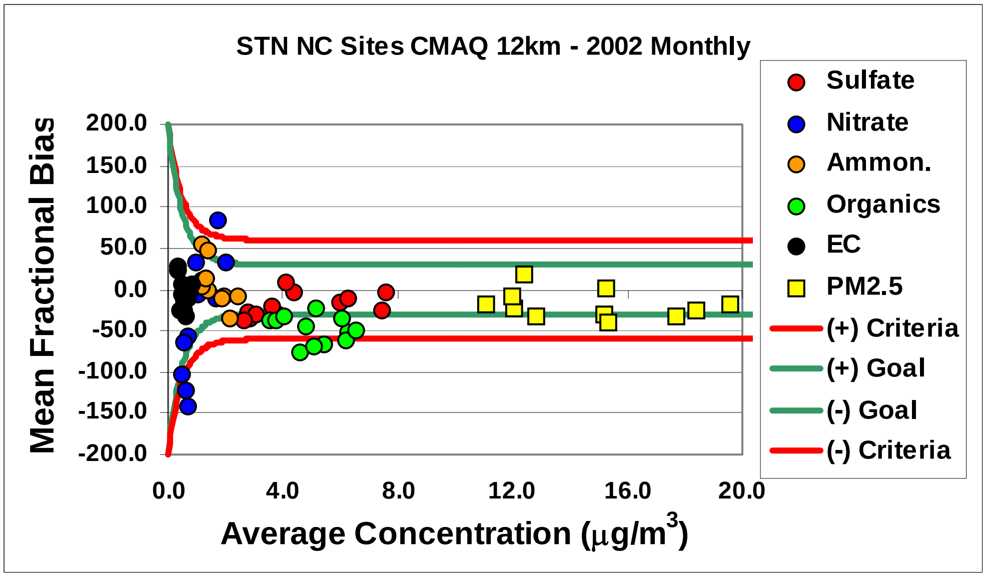

Figure 2-7: Bugle plot of the mean fraction bias for particulate matter and its component concentrations for all North Carolina STN monitoring sites. Each point represents a monthly mean fraction bias value as compared to the model performance criteria (red lines) and modeling performance goals (green lines).

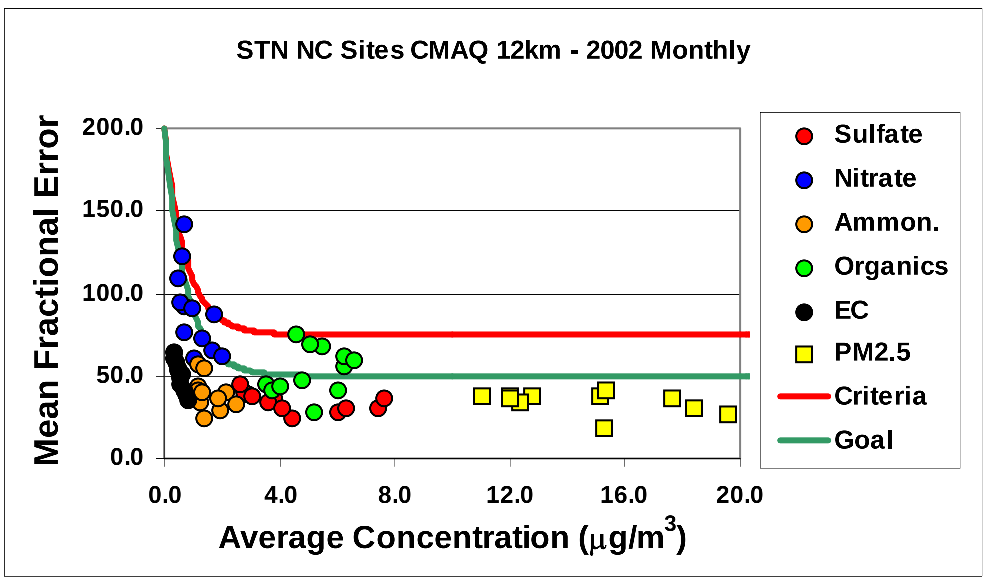

Figure 2-8: Bugle plot of mean fraction error for particulate matter and its component species for all North Carolina STN monitoring sites. Each point represents a monthly mean fraction bias value as compared to the model performance criteria (red lines) and modeling performance goals (green lines).

2.2.1.3 Hickory STN Monitoring Site (37-035-004)

The soccer plots of monthly concentrations for the Hickory STN site again show that values for, nitrate generally fall outside of criteria performance thresholds. For Hickory, we also see some month for elemental carbon fall outside of criteria performance thresholds, as well as a couple of months of organic carbon values. Other pollutants generally fall within criteria thresholds, with a portion of months within goal thresholds. When concentration is factored into performance criteria, nitrate performance improves with respect to mean fractional bias and error. We do see organic carbon fall outside of criteria goals for mean fractional bias, just as with the North Carolina total STN plots.

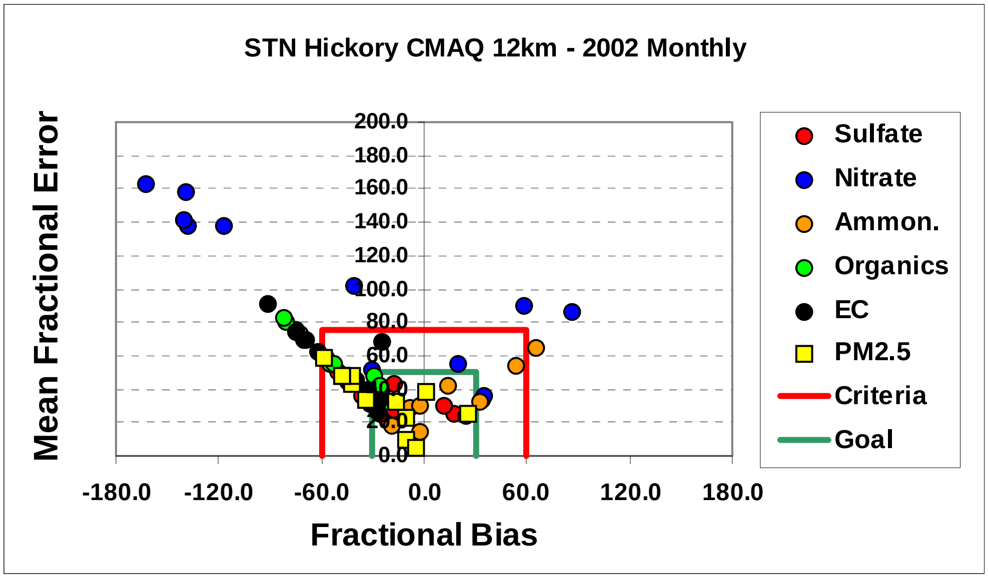

Figure 2-9: Soccer plot depicting both the mean fractional error and fractional bias for component concentration for the Hickory (37-035-0004) STN monitoring site. Each point represents a monthly value as compared to the model performance criteria (red box) and modeling performance goals (green box).

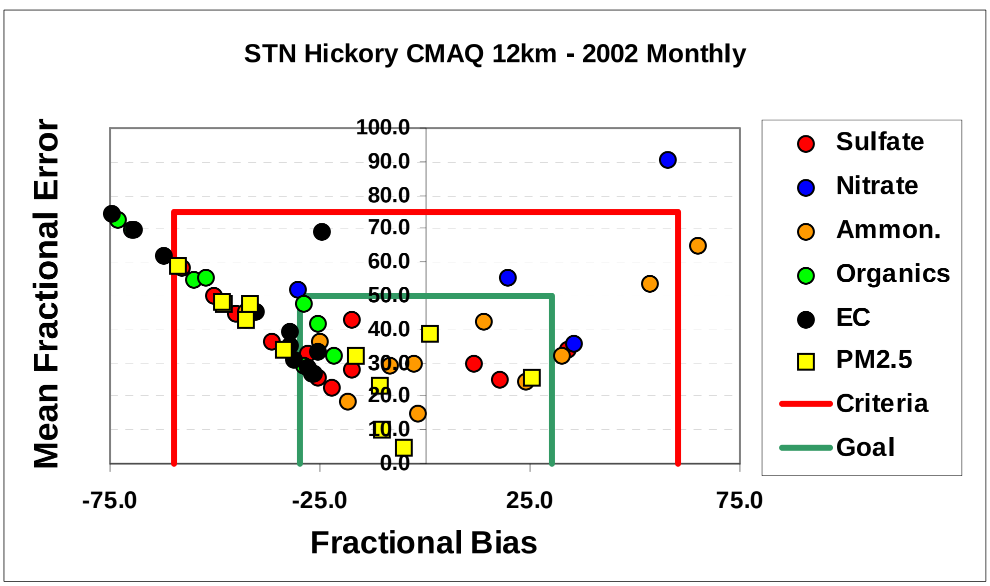

Figure 2-10: A zoomed view of the soccer plot depicting both the mean fractional error and fractional bias for component concentration for the Hickory (37-035-0004) STN monitoring site. Each point represents a monthly value as compared to the model performance criteria (red box) and modeling performance goals (green box).

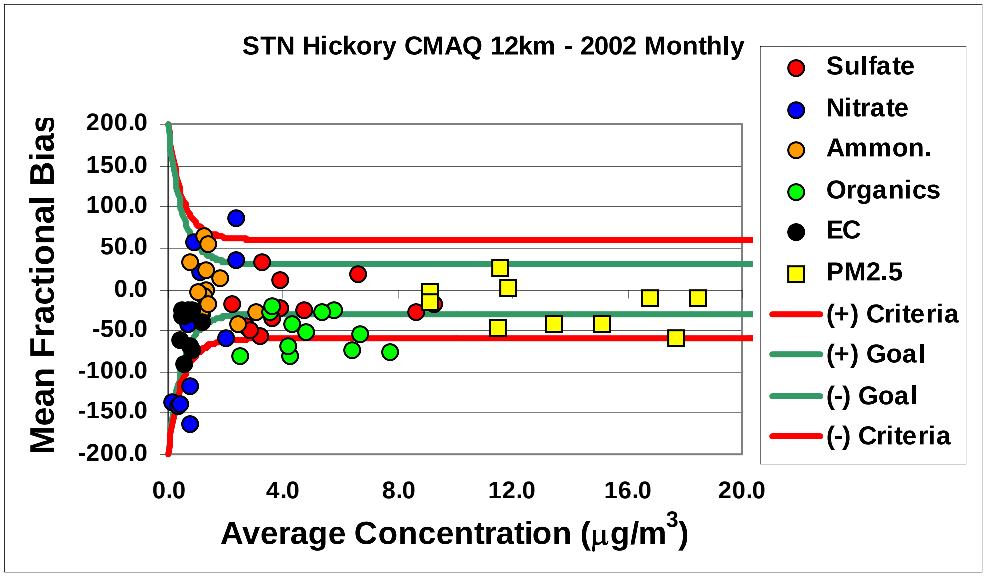

Figure 2-11: Bugle plot of the mean fraction bias for particulate matter and its component species concentrations for the Hickory (37-035-0004) STN monitoring site. Each point represents a monthly mean fraction bias value as compared to the model performance criteria (red lines) and modeling performance goals (green lines).

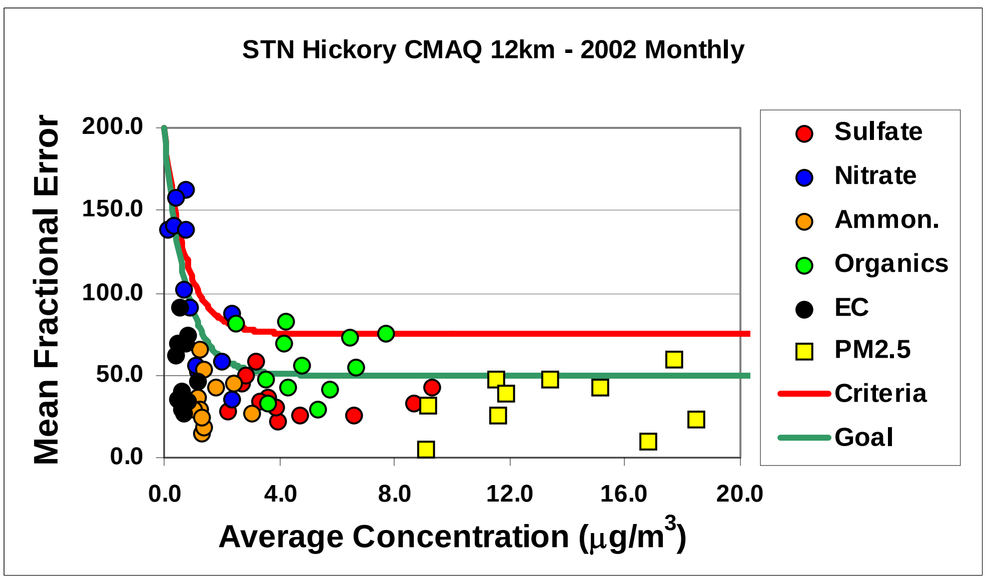

Figure 2-12: Bugle plot of mean fraction error for particulate matter and its component species for the Hickory (37-035-0004) STN monitoring site. Each point represents a monthly mean fraction bias value as compared to the model performance criteria (red lines) and modeling performance goals (green lines).

2.2.1.4 Hattie Avenue STN Monitoring Site (37-07-000)

Monthly average component concentration performance is similar to the Hickory STN site. Nitrate generally falls outside of suggested criteria model performance goals. The main difference is seen with organic and elemental carbon performance. More monthly values of organic carbon fall outside of criteria levels at Hattie Avenue than at Hickory, with more monthly values of elemental carbon falling within criteria values. When concentration is taken into consideration, all elemental carbon and nitrate values fall with in criteria goals (Figure 2-15 and 2-16). Under prediction of organic carbon values still persist, but this is in line with the overall model performance seen across North Carolina, and overall $PM_{2.5}$ performance is within criteria level, if not within the goal level thresholds.

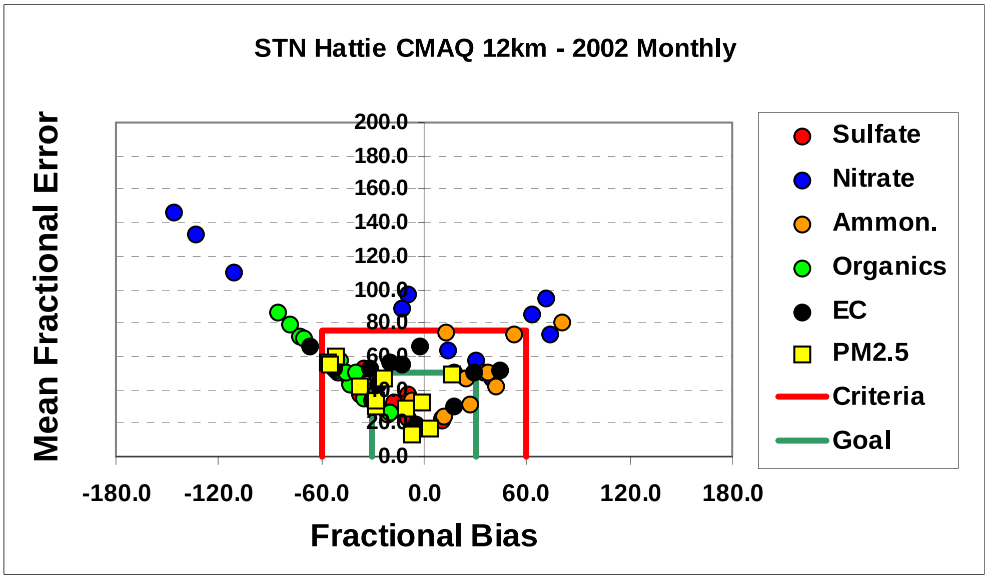

Figure 2-13: Soccer plot depicting both the mean fractional error and fractional bias for component concentration for the Hattie Avenue (37-037-0022) STN monitoring site. Each point represents a monthly value as compared to the model performance criteria (red box) and modeling performance goals (green box).

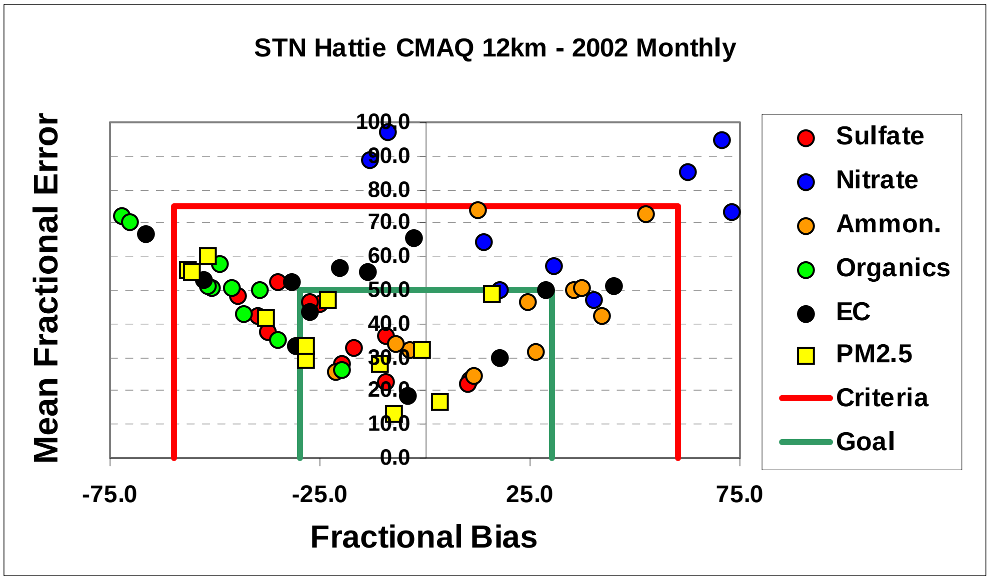

Figure 2-14: A zoomed view of the soccer plot depicting both the mean fractional error and fractional bias for component concentration for the Hattie Avenue (37-037-0022) STN monitoring site. Each point represents a monthly value as compared to the model performance criteria (red box) and modeling performance goals (green box).

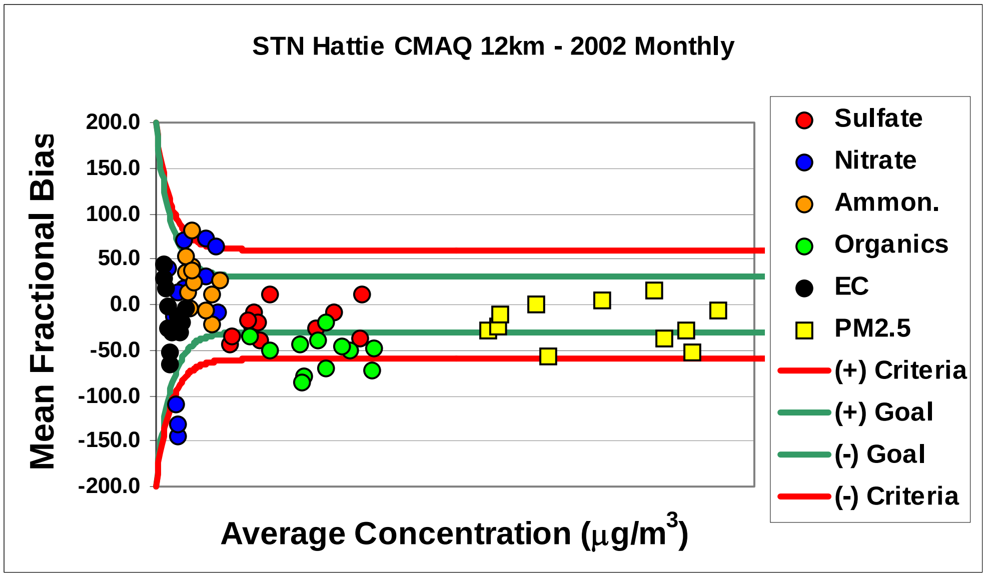

Figure 2-15: Bugle plot of the mean fraction bias for particulate matter and its component species concentrations for the Hattie Avenue (37-037-0022) STN monitoring site. Each point represents a monthly mean fraction bias value as compared to the model performance criteria (red lines) and modeling performance goals (green lines).

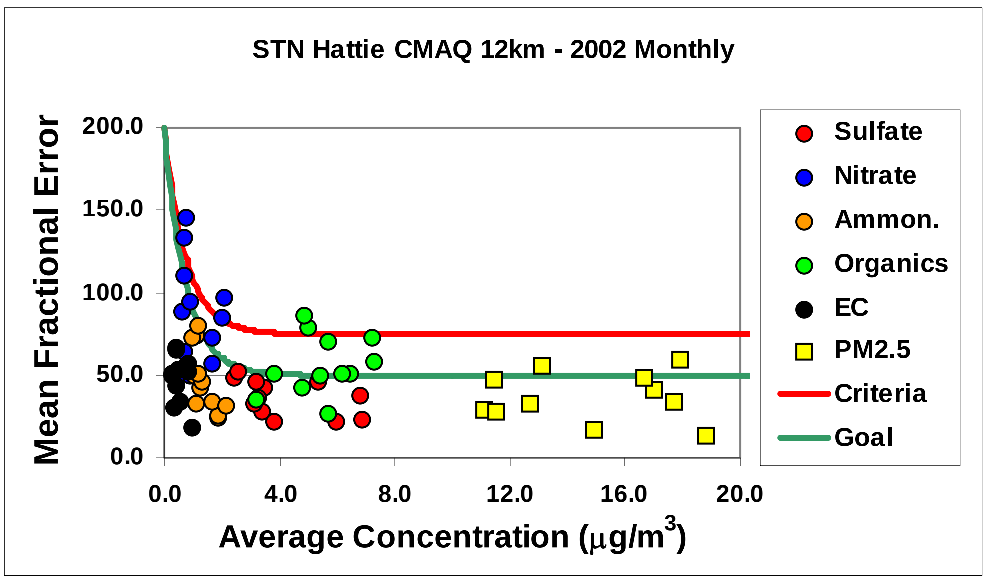

Figure 2-16: Bugle plot of mean fraction error for particulate matter and its component species for the Hattie Avenue (37-037-0022) STN monitoring site. Each point represents a monthly mean fraction bias value as compared to the model performance criteria (red lines) and modeling performance goals (green lines).

2.2.2 FRM Monitoring Sites

2.2.2.1 All VISTAS FRM Monitoring Sites

Monthly total $PM_{2.5}$ concentration performance at All the VISTAS FRM monitors largely falls within goal level thresholds, with only two months falling just outside goal level performance.

Figure 2-19 suggests a negative bias in $PM_{2.5}$ prediction for most of the year. However, Figure 2-20 shows mean fractional error values remain within goal levels across the year.

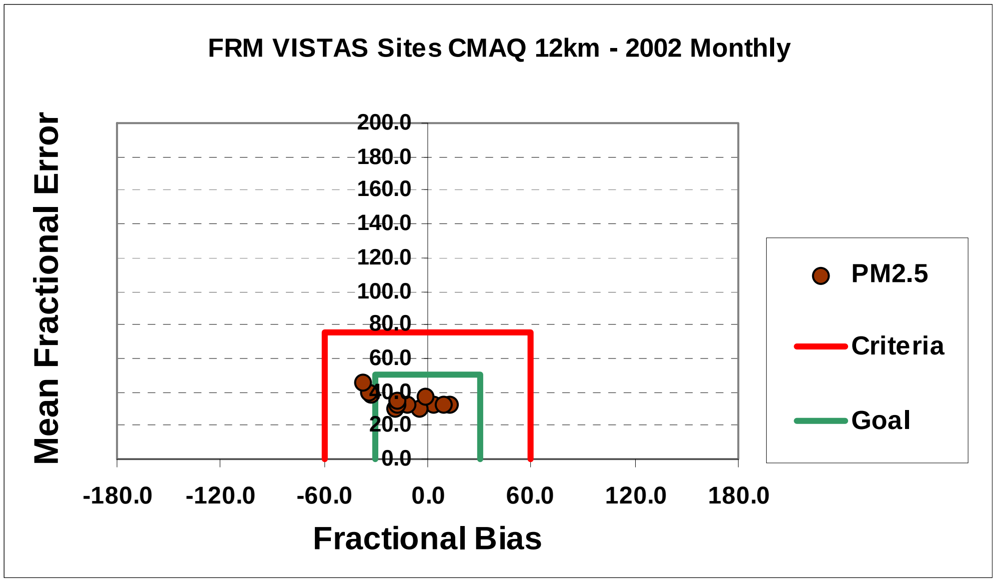

Figure 2-17: Soccer plot depicting both the mean fractional error and fractional bias for component concentration for all the VISTAS FRM Monitoring sites. Each point represents a monthly value as compared to the model performance criteria (red box) and modeling performance goals (green box).

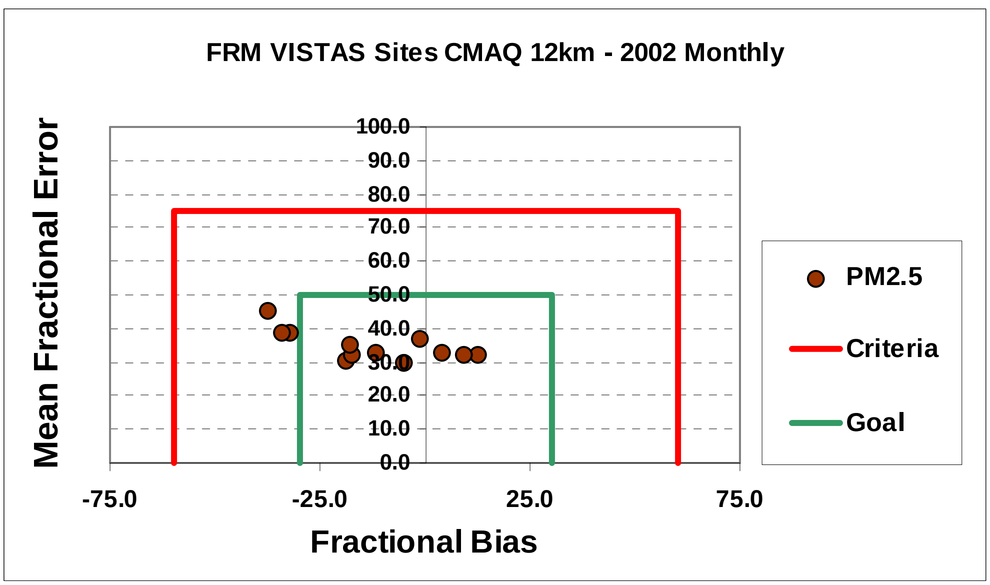

Figure 2-18: A zoomed view of the soccer plot depicting both the mean fractional error and fractional bias for component concentration for all the VISTAS FRM Monitoring sites. Each point represents a monthly value as compared to the model performance criteria (red box) and modeling performance goals (green box).

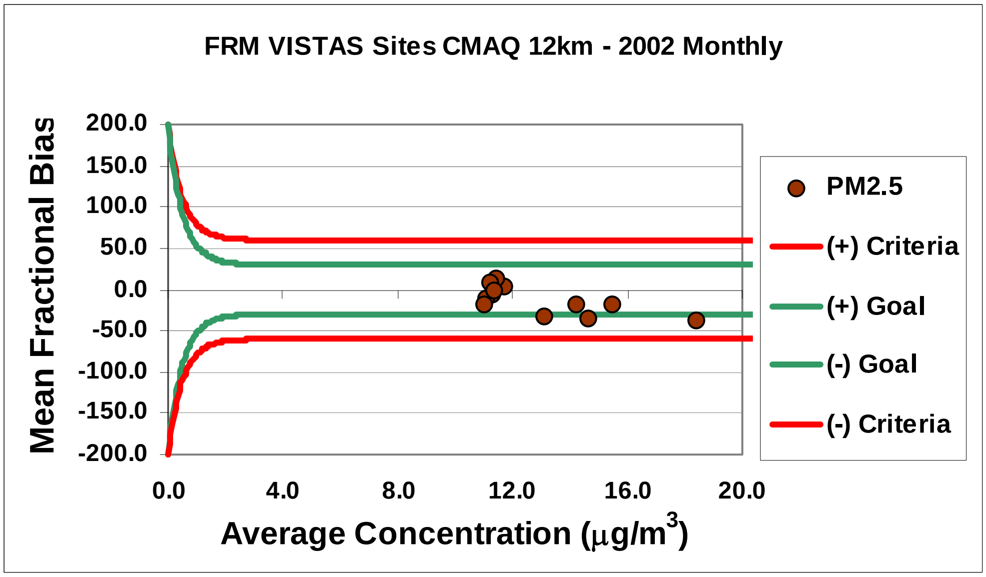

Figure 2-19: Bugle plot of the mean fraction bias for particulate matter and its component species concentrations for all the VISTAS FRM Monitoring sites. Each point represents a monthly mean fraction bias value as compared to the model performance criteria (red lines) and modeling performance goals (green lines).

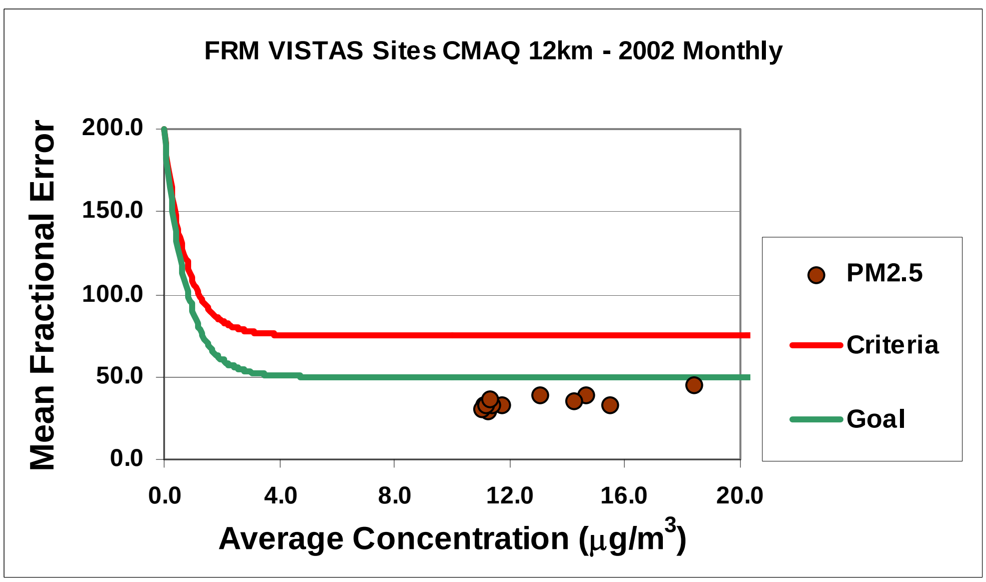

Figure 2-20: Bugle plot of mean fraction error for particulate matter and its component species for all the VISTAS FRM Monitoring sites. Each point represents a monthly mean fraction bias value as compared to the model performance criteria (red lines) and modeling performance goals (green lines).

2.2.2.2 All North Carolina FRM Monitoring Sites

Model performance for North Carolina FRM sites is very similar to that for the VISTAS sites collectively. Most months fall within the goal threshold, with only two month falling just outside due to a larger negative fractional bias. The under prediction, or large negative bias is reiterated in the mean fractional bias bugle plot (Figure 2-22). Again, mean fractional error remains well within goal model performance levels.

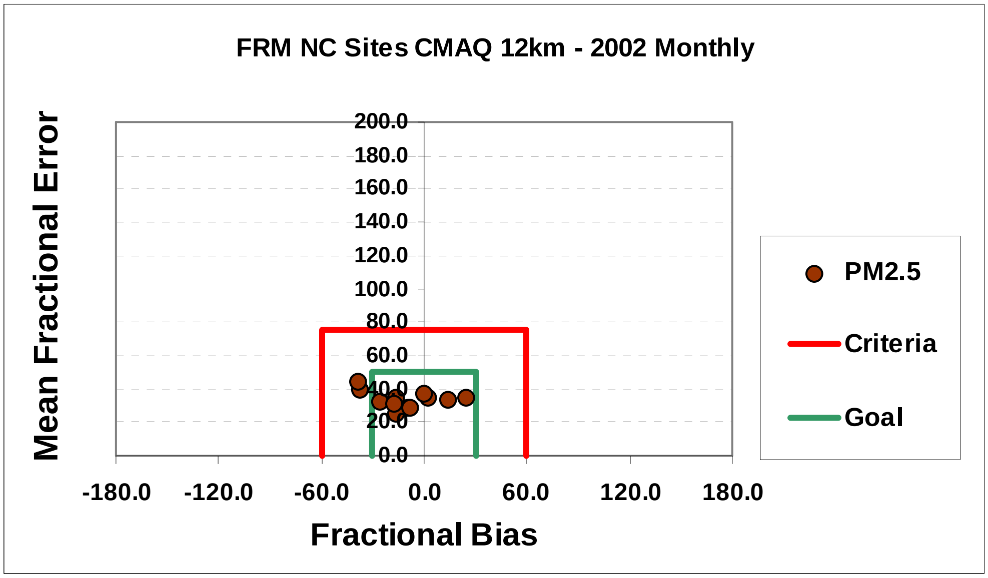

Figure 2-21: Soccer plot depicting both error and bias for the light extinction due to particulate matter and its component species for all the North Carolina FRM Monitoring sites. Each point represents a monthly mean fraction bias value as compared to the model performance criteria (red box) and modeling performance goals (green box).

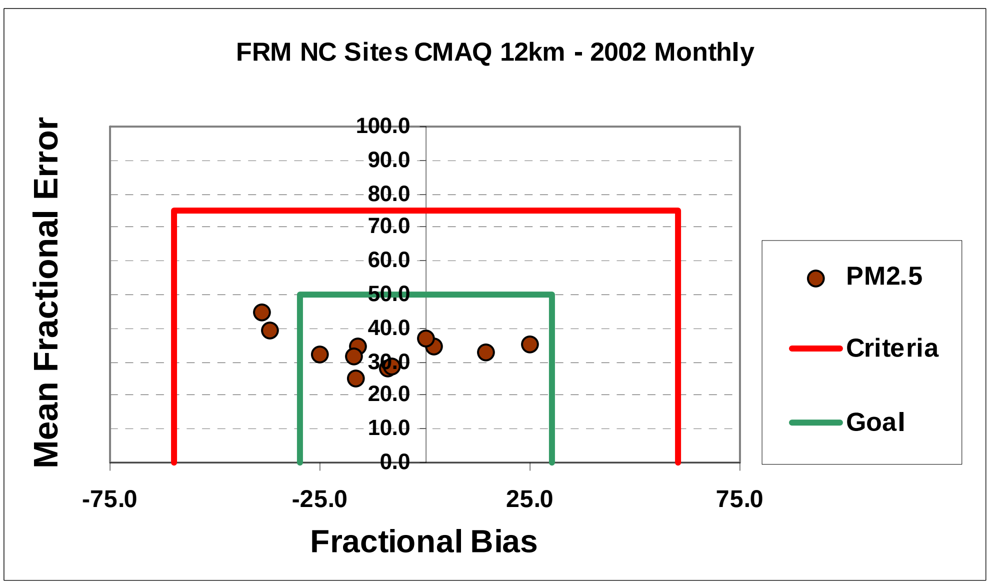

Figure 2-22: A zoomed view of the soccer plot depicting both the mean fractional error and fractional bias for component concentration for all the North Carolina FRM Monitoring sites. Each point represents a monthly value as compared to the model performance criteria (red box) and modeling performance goals (green box).

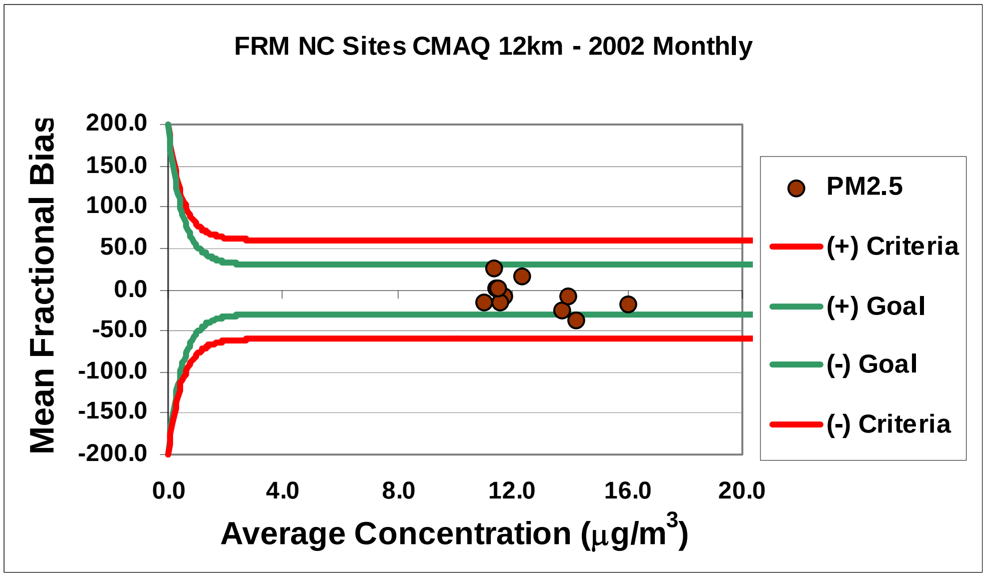

Figure 2-23: Bugle plot depicting the mean fractional bias for the light extinction due to particulate matter and its component species for all the North Carolina FRM Monitoring sites. Each point represents a monthly mean fraction bias value as compared to the model performance criteria (red lines) and modeling performance goals (green lines).

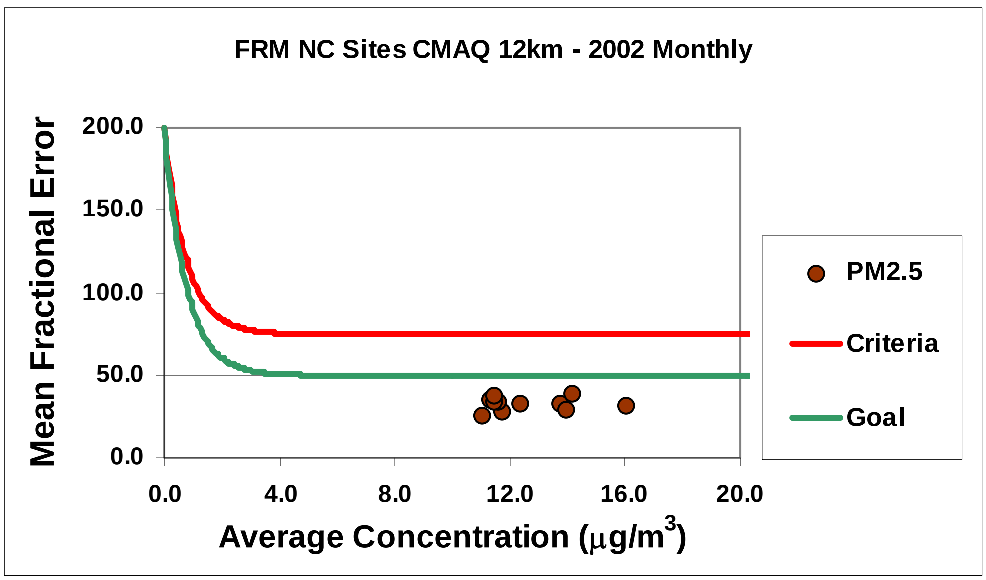

Figure 2-24: Bugle plot depicting the mean fractional error for the light extinction due to particulate matter and its component species for all the North Carolina FRM Monitoring sites. Each point represents a monthly mean fraction bias value as compared to the model performance criteria (red lines) and modeling performance goals (green lines).

2.2.2.3 Hickory FRM Monitoring Site (37-035-004)

Overall model performance at the Hickory FRM site follows model performance seen on average at all North Carolina sites. However, we see a slightly more pronounce negative bias trend than in the bugle plot (Figure 2-25) than seen across all North Carolina sites. Figure 2-26 shows a month with a higher mean fractional error level than seen previously, though it remained within goal performance levels.

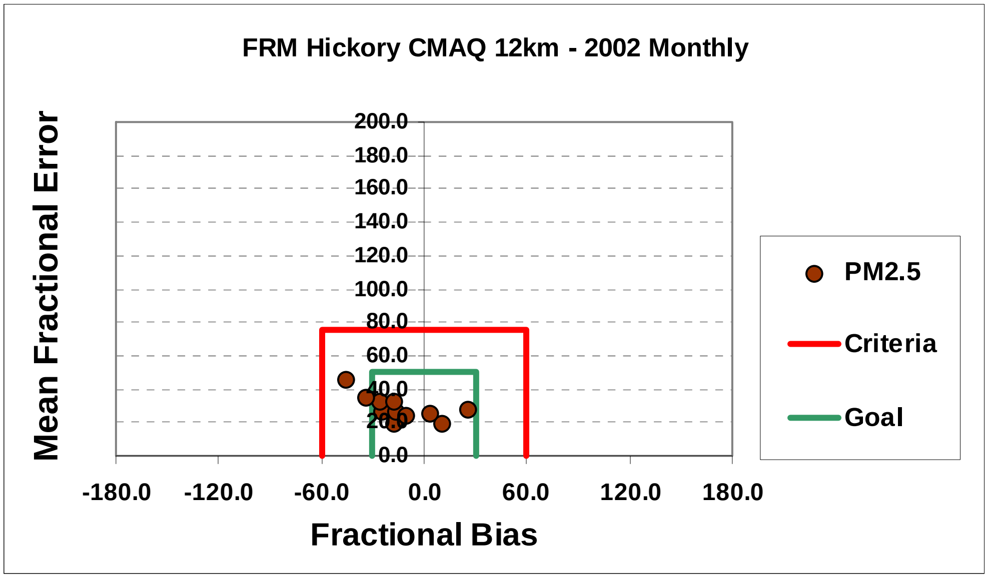

Figure 2-25: Soccer plot depicting both error and bias for the light extinction due to particulate matter and its component species for the Hickory FRM monitoring site (37-035-0004). Each point represents a monthly mean fraction bias value as compared to the model performance criteria (red box) and modeling performance goals (green box).

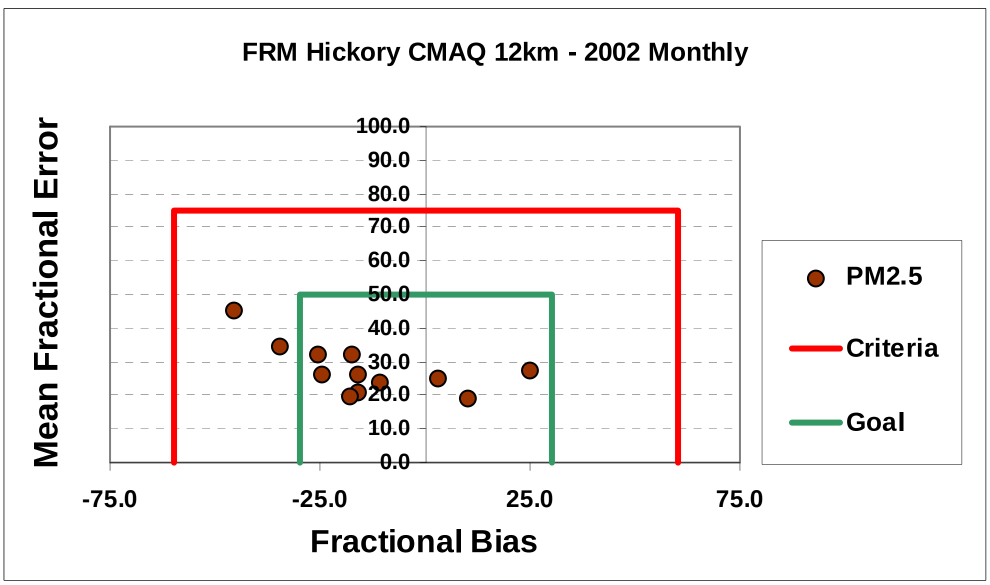

Figure 2-26: A zoomed view of the soccer plot depicting both the mean fractional error and fractional bias for component concentration for Hickory FRM monitoring site (37-035-0004). . Each point represents a monthly value as compared to the model performance criteria (red box) and modeling performance goals (green box).

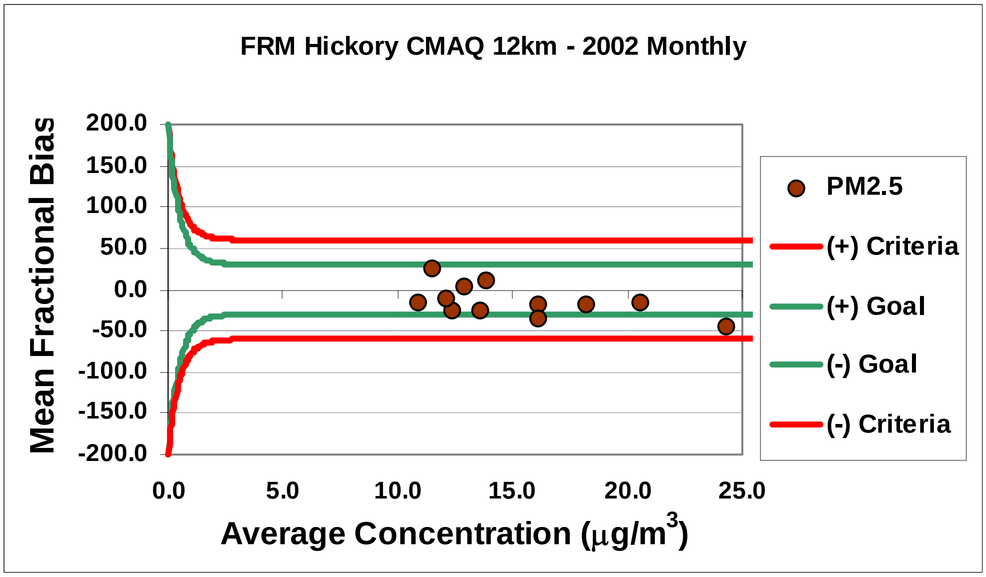

Figure 2-27: Bugle plot depicting the mean fractional bias for the light extinction due to particulate matter and its component species for the Hickory FRM monitoring site (37-035-0004). . Each point represents a monthly mean fraction bias value as compared to the model performance criteria (red lines) and modeling performance goals (green lines).

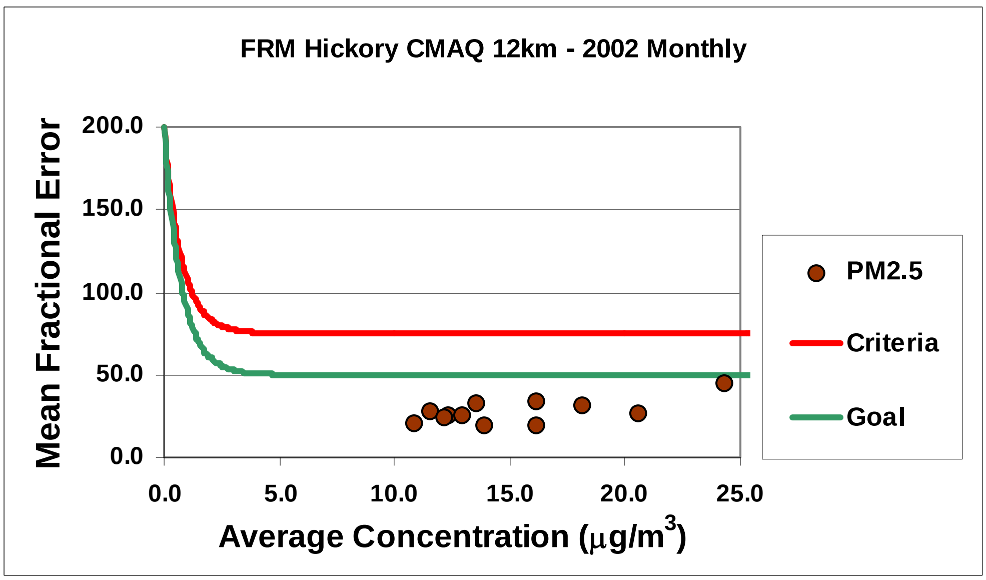

Figure 2-28: Bugle plot depicting the mean fraction error for the light extinction due to particulate matter and its component species for the Hickory FRM monitoring site (37-035-0004). . Each point represents a monthly mean fraction bias value as compared to the model performance criteria (red lines) and modeling performance goals (green lines).

2.2.2.4 Lexington FRM Monitoring Site (37-057-0002)

FRM model performance at Lexington is similar to Hickory. We again see a slightly more pronounce negative bias trend than in the bugle plot (Figure 2-28) than seen across all North Carolina sites. Figure 2-29 shows that a few months showed a higher mean fractional error level than seen with even the Hickory FRM site. Figure 2-29 also shows a month (March) slipping just outside goal performance levels.

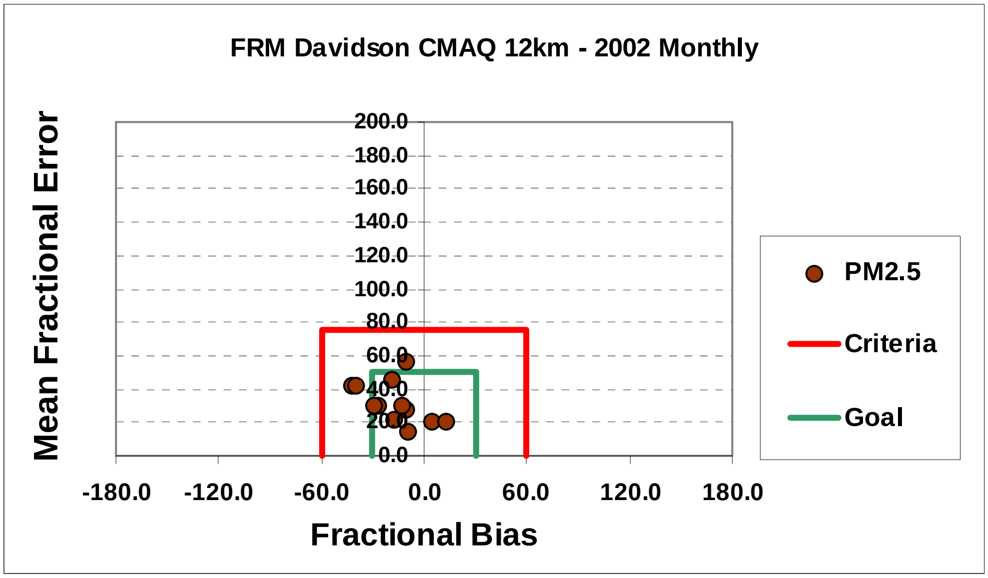

Figure 2-29: Soccer plot depicting both error and bias for the light extinction due to particulate matter and its component species for the Lexington FRM Monitoring site (37-057-0002). Each point represents a monthly mean fraction bias value as compared to the model performance criteria (red box) and modeling performance goals (green box).

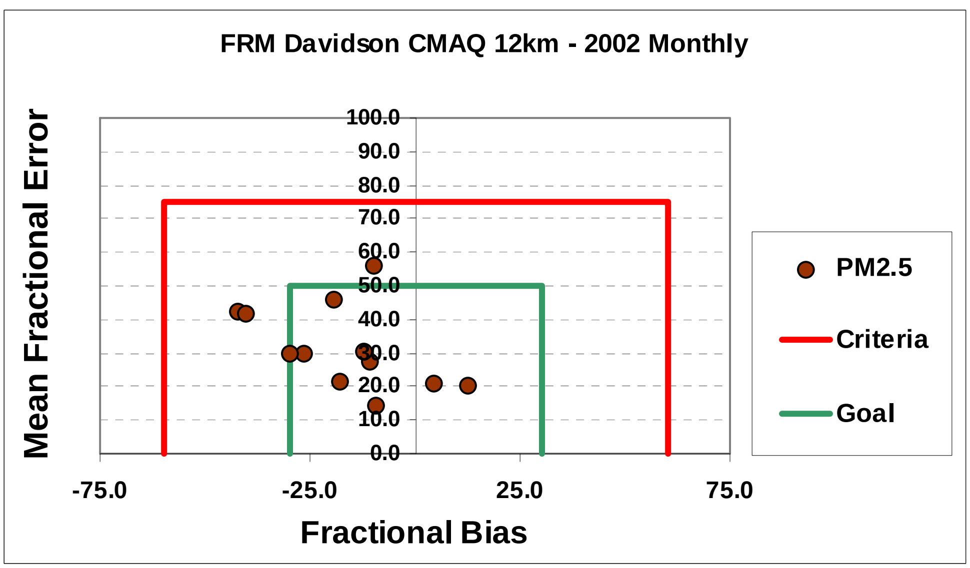

Figure 2-30: A zoomed view of the soccer plot depicting both the mean fractional error and fractional bias for component concentration for the Lexington FRM Monitoring site (37-057-0002). . Each point represents a monthly value as compared to the model performance criteria (red box) and modeling performance goals (green box).

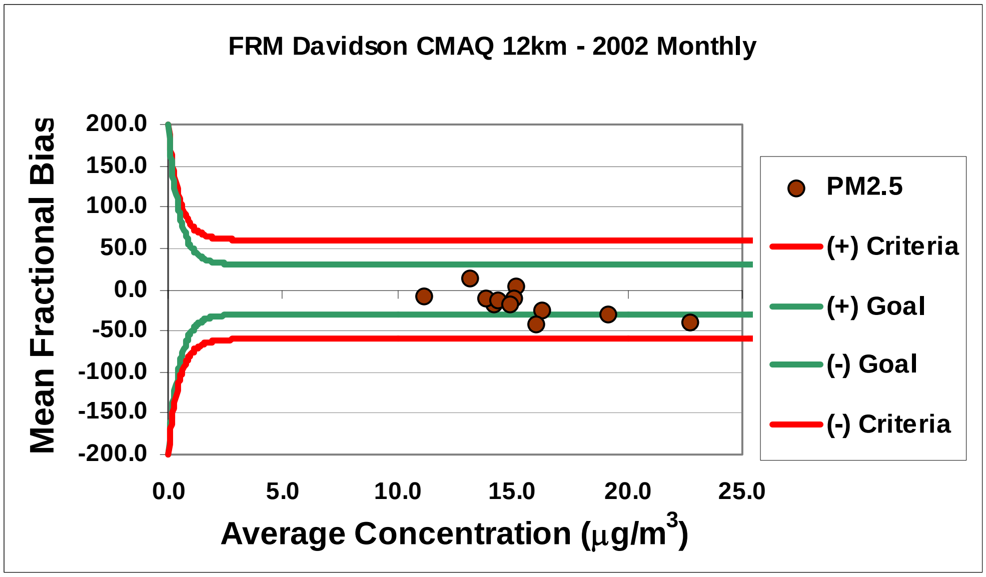

Figure 2-31: Bugle plot depicting the mean fractional bias for the light extinction due to particulate matter and its component species for the Lexington FRM Monitoring site (37-057-0002). Each point represents a monthly mean fraction bias value as compared to the model performance criteria (red lines) and modeling performance goals (green lines).

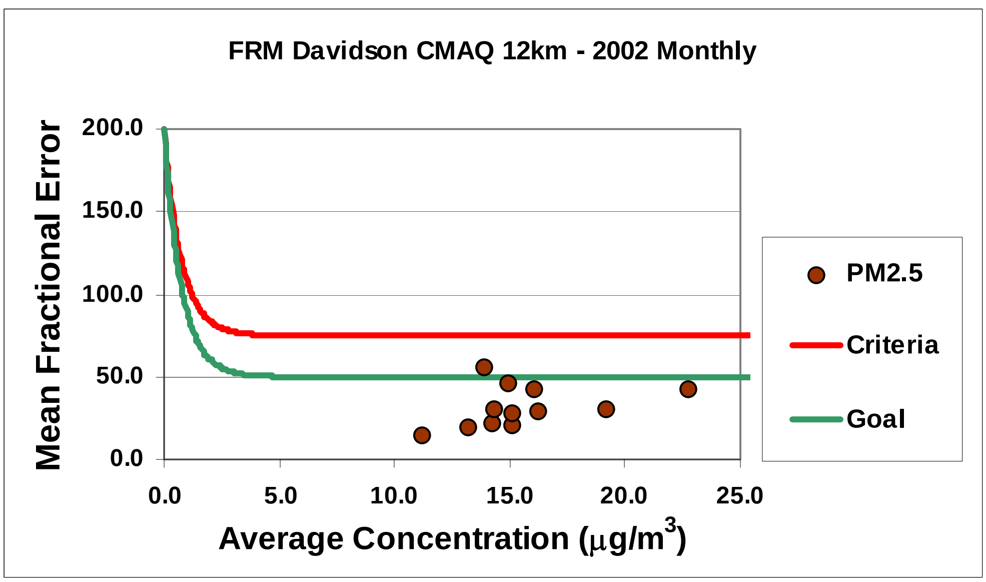

Figure 2-32: Bugle plot depicting the mean fraction error for the light extinction due to particulate matter and its component species for the Lexington FRM Monitoring site (37-057-0002). Each point represents a monthly mean fraction bias value as compared to the model performance criteria (red lines) and modeling performance goals (green lines).

2.2.2.5 Mendenhall FRM Monitoring Site (37-081-0013)

Model performance at the Mendenhall FRM site again is similar to Hickory, more so than Lexington. We again see a slightly more pronounce negative bias trend than in the bugle plot (Figure 2-31) than seen across all North Carolina sites. Figure 2-32 shows that a few months showed a higher mean fractional error level than seen with even the Hickory FRM site, but still fall within goal performance levels.

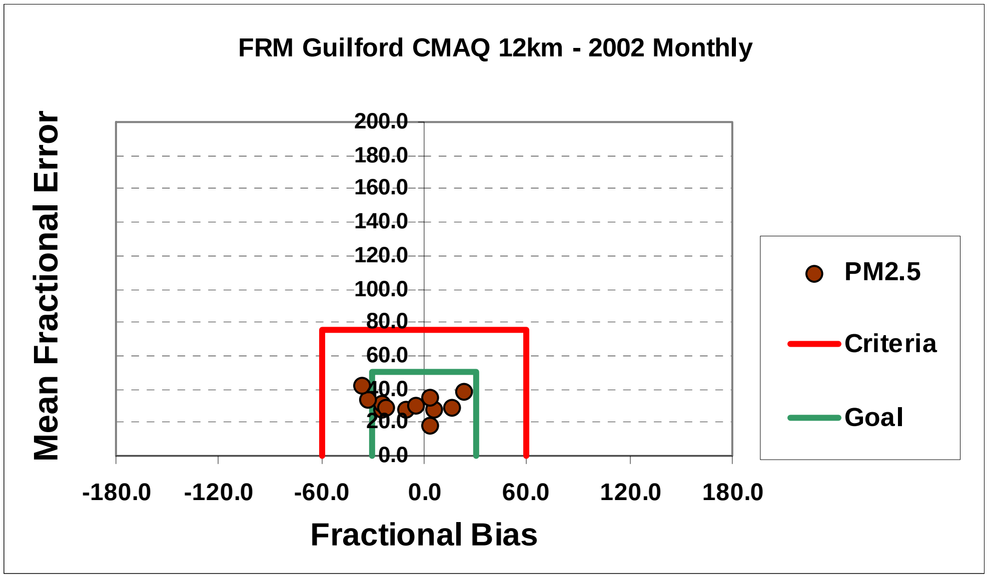

Figure 2-33: Soccer plot depicting both error and bias for the light extinction due to particulate matter and its component species for the Mendenhall FRM Monitoring site (37-081-0013). Each point represents a monthly mean fraction bias value as compared to the model performance criteria (red box) and modeling performance goals (green box).

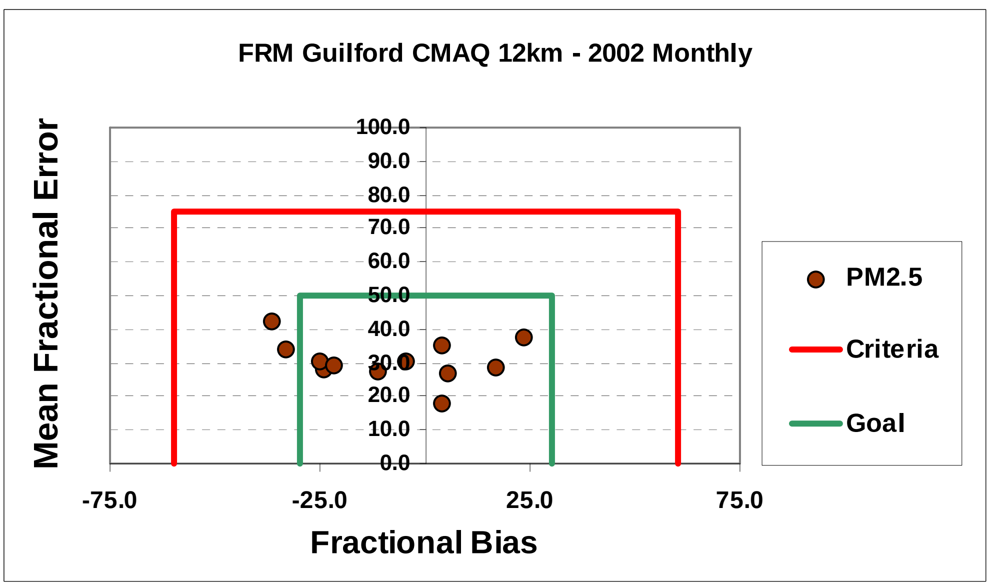

Figure 2-34: A zoomed view of the soccer plot depicting both the mean fractional error and fractional bias for component concentration for the Mendenhall FRM Monitoring site (37-081-0013). Each point represents a monthly value as compared to the model performance criteria (red box) and modeling performance goals (green box).

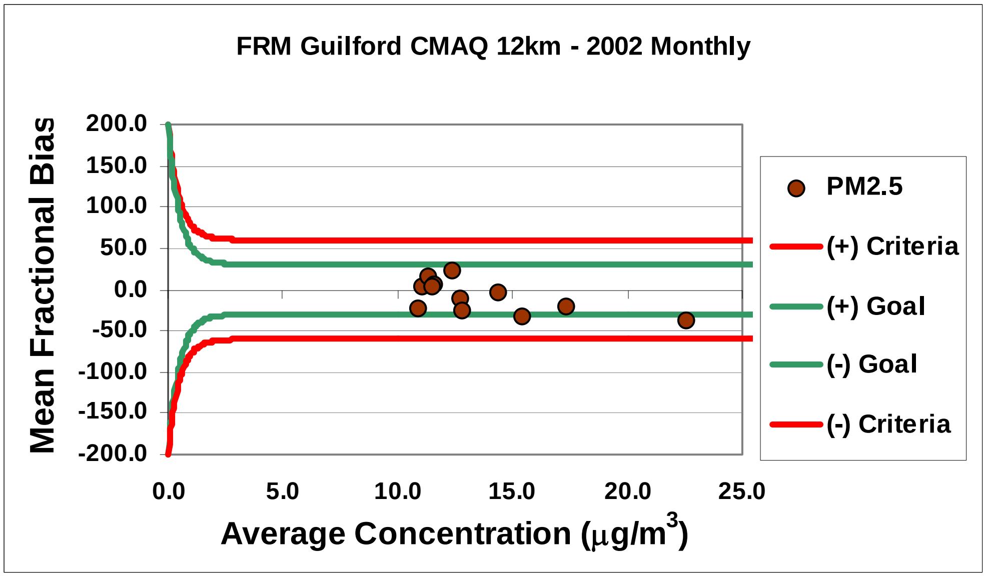

Figure 2-35: Bugle plot depicting the mean fractional bias for the light extinction due to particulate matter and its component species for the Mendenhall FRM Monitoring site (37-081-0013). Each point represents a monthly mean fraction bias value as compared to the model performance criteria (red lines) and modeling performance goals (green lines).

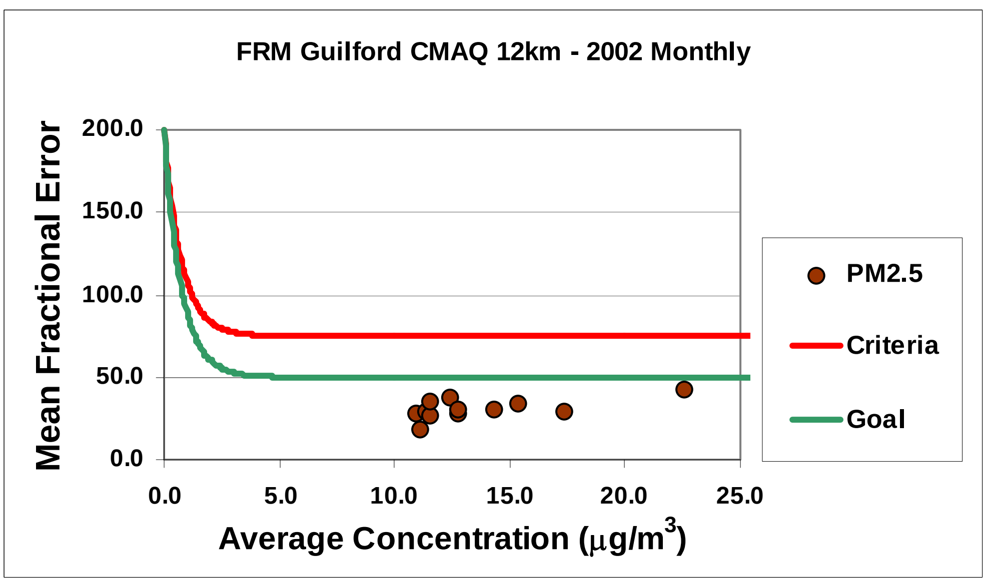

Figure 2-36: Bugle plot depicting the mean fraction error for the light extinction due to particulate matter and its component species for the Mendenhall FRM Monitoring site (37-081-0013). Each point represents a monthly mean fraction bias value as compared to the model performance criteria (red lines) and modeling performance goals (green lines).

3. Spatial Plots

The 12km domain spatial plots of model-simulated daily concentration of the constituents of particle pollution most responsible for light extinction for 2002, with the actual observed concentrations overlaid are presented in this section. These plots are presented for the entire 12km domain.

A subset of days from 2002 is presented in this appendix, though all days from 2002 are used in developing the relative reduction factor (RRF) and subsequently the future design value (DVF). For model performance evaluation, the USEPA's Attainment Guidance suggests looking at days with a daily average $PM_{2.5}$ concentration greater than 65 micrograms per meter cubed (μg/m^3). However, neither the Hickory nor the Triad $PM_{2.5}$ nonattainment area has any observed values greater than or equal to 65 μg/m^3. This lead the North Carolina Division of Air Quality chose to use a cut off of 30 μg/m^3 at any of the monitoring sites in either nonattainment area, as an initial method to select days for examination in the model performance evaluation and in the results section.

To ensure at least four days from each quarter were presented, daily $PM_{2.5}$ values form each quarter were ranked, and the four days with the highest average daily values in each quarter were also chosen. This selection process identified 28 days for presentation in this appendix, and examination in the model results section (Appendix K). The selected days are presented in Table 3-1 below.

There are two pages of overlays for each identified date. The first page for each date contains the daily average spatial plots for sulfate (SO4), nitrate (NO3), ammonium (NH4), and organic carbon (OC) overlaid with STN data. The second page in the series contains two plots: one with STN elemental carbon (EC) observations overlaid on modeled EC levels, and the other with FRM data overlaid on daily average total $PM_{2.5}$. Note that because of the varying polling frequencies at the monitors, the number of observation available for plots between the days varies.

A table immediately precedes the plots, which details the actual observed daily average total $PM_{2.5}$ values for the STN and FRM sites within the North Carolina $PM_{2.5}$ nonattainment areas. The color scale for all the plots moves from lower concentrations in shade of blue to warmer colors for higher concentrations.

Overall, the spatial plots correspond to results seen in the statistical metrics and plots. Nitrate has a tendency to be slightly under predicted across the domain for the year. The modeled nitrates tend to be more representative on higher concentration days. However, the model also tends to spread areas of high nitrate concentrations further than the observations suggest, especially in the first quarter. The model has some instances of under prediction of organic and elemental carbon from day to day. However, the general spatial pattern is generally well represented through out the year.

Sulfates were generally well represented, especially on high concentrations days. There was some under prediction of peaks, especially isolated peaks. Ammonium was actually fair well represented in the model. Peaks were generally captured fairly well, and the model identified a peak in eastern North Carolina associated with livestock activities, despite limited observations.

The spatial patter of total $PM_{2.5}$ compared to the FRM mass is actually well represented across the year. August 3rd stands out, as the model captured the gradient of $PM_{2.5}$ concentration across North Carolina particularly well. However, we do see some performance issues along the Great lakes area, which are likely due to under prediction of nitrates and occasionally sulfates in that area.

Table 3-1: Days selected for model evaluation and the observed value at each of the monitoring sites in the Hickory and Triad PM Nonattainment areas. Gray cells indicate no monitoring data was available for that day either due to the sampling frequency or the site being off line

4. Scatter Plots

Monthly scatter plots of the model-simulated mass of the components of $PM_{2.5}$ versus the observed mass of each of the components of $PM_{2.5}$ are presented in this section. As with previous model performance statistics and plots, scatter plots were produced for all the STN sites in the VISTAS 12km domain (38 monitors), for all the STN monitors in North Carolina (8 monitors), and individually for the Hickory and Hattie Avenue STN monitors. These scatter plots are presented in Section 4.1, by species, by month.

Section 4.2 has the monthly scatter plots of the model-simulated $PM_{2.5}$ mass versus the observed $PM_{2.5}$ mass at FRM monitors. Scatter plots have been produced for all the FRM sites in the VISATAS domain (226 monitors), for all the FRM monitors within North Carolina (36 monitors), and individually for the 3 FRM monitors in the $PM_{2.5}$ nonattainment areas (Hickory, Lexington, and Mendenhall).

The green line on the scatter plots represents the 1:1 line, with points falling on the line suggesting accurate model prediction and points falling above (below) indicating over (under) prediction by the model. The equation for the best fit line, the correlation coefficient, fractional bias, and fraction gross error for the data presented in the scatter plot appear in the top of the graph area for reference. The scatter plots contain information on both the 12km domain (blue x's) and the 36km domain (red +'s) modeling results. Though both are presented in this appendix, the model performance evaluation focuses on the 12km results, as the attainment test calculations are based on the 12km modeling.

The sulfate spatial plots (Figures 4-1 through 4-12) show a good spread across the 1:1 line for the VISTAS sites collectively, though a slight negative bias remains. The negative bias does decrease during the summer months through fall (June through October). The negative bias is more pronounced when looking at the North Carolina STN sites collectively. However, North Carolina STN sites do show a positive bias for the month of October. Looking and the Hickory and Hattie Avenue sites separately, the negative bias trend is seen across the year, with each site has a couple months of positive bias during the period of June to October. Additionally, Hattie Avenue has a slightly less biased than the Hickory site for sulfates.
Nitrate performance (Figure 4-13 through 4-24) is similar to other statistics presented previously. For the VISTAS sites on the whole, we see good scatter across the 1:1 line, with a slight negative bias, especially during the April to September timeframe. Overall VISTAS performance does become better in November and December, though there is still a negative bias. Model performance for the North Carolina STN sites as a whole, and for both the Hickory and Hattie Avenue sites individually, differ from the VISTAS level performance in that nitrates are actually over predicted for January and the winter months (October through December). In addition, the North Carolina sites on the whole and Hattie Avenue show better that VISTAS model performance for the February to April timeframe.

Ammonium performance (Figures 4-25 though 4-36) was more of a mixed bag across sites. The modeled tended to over predict in the spring and winter and under predict in summer and fall. Data was generally spread across the 1:1 line, with many values on either side of the line. With a balance of over prediction and under prediction for most months, bias values are low, with high error values.

Organic Carbon is consistently under predicted across all level of the STN sites. The scatter plots show a majority of points falling below the 1:1 line consistently for all months (Figure 4-37 through 4-48). The magnitude of the under prediction is fairly consistent between VISTAS STN sites, North Carolina STN sites and the individual STN sites in the nonattainment areas, suggesting the under prediction is a model wide shortcoming.

As with Ammonium, elemental carbon values were well spread across the 1:1 line resulting in low bias vales for much of the year (Figure 4-49 through 4-60). The general trend across sites was to start the year slightly over predicting for January, and then trend toward slightly under predicting through the spring. Values returned to over predicting for July and August before settling back to a slight under prediction trend. Hickory did deviate from the pattern set at all VISTAS and North Carolina STN sites and the Hattie Avenue site, by consistently under predicting across the entire year. As with sulfate, model performance at Hattie Avenue appeared slightly less biased than at the Hickory STN site.

Overall the negative bias seen in the scatter plots for the components of $PM_{2.5}$ lead to a general negative bias in the reconstructed $PM_{2.5}$ mass for the STN sites (Figures 4-61 through 4-72). The negative bias is not as pronounced in January and the October through December timeframe, probably in part due to the over prediction of nitrates seen during the same period. A similar trend is seen in the FRM total $PM_{2.5}$ mass scatter plots (Figure 4-73 though 4-96), though the under prediction is not as pronounced as with the STN sites.

4.1 Monthly STN Scatter Plots

4.1.1 Sulfates

4.1.1.1 January

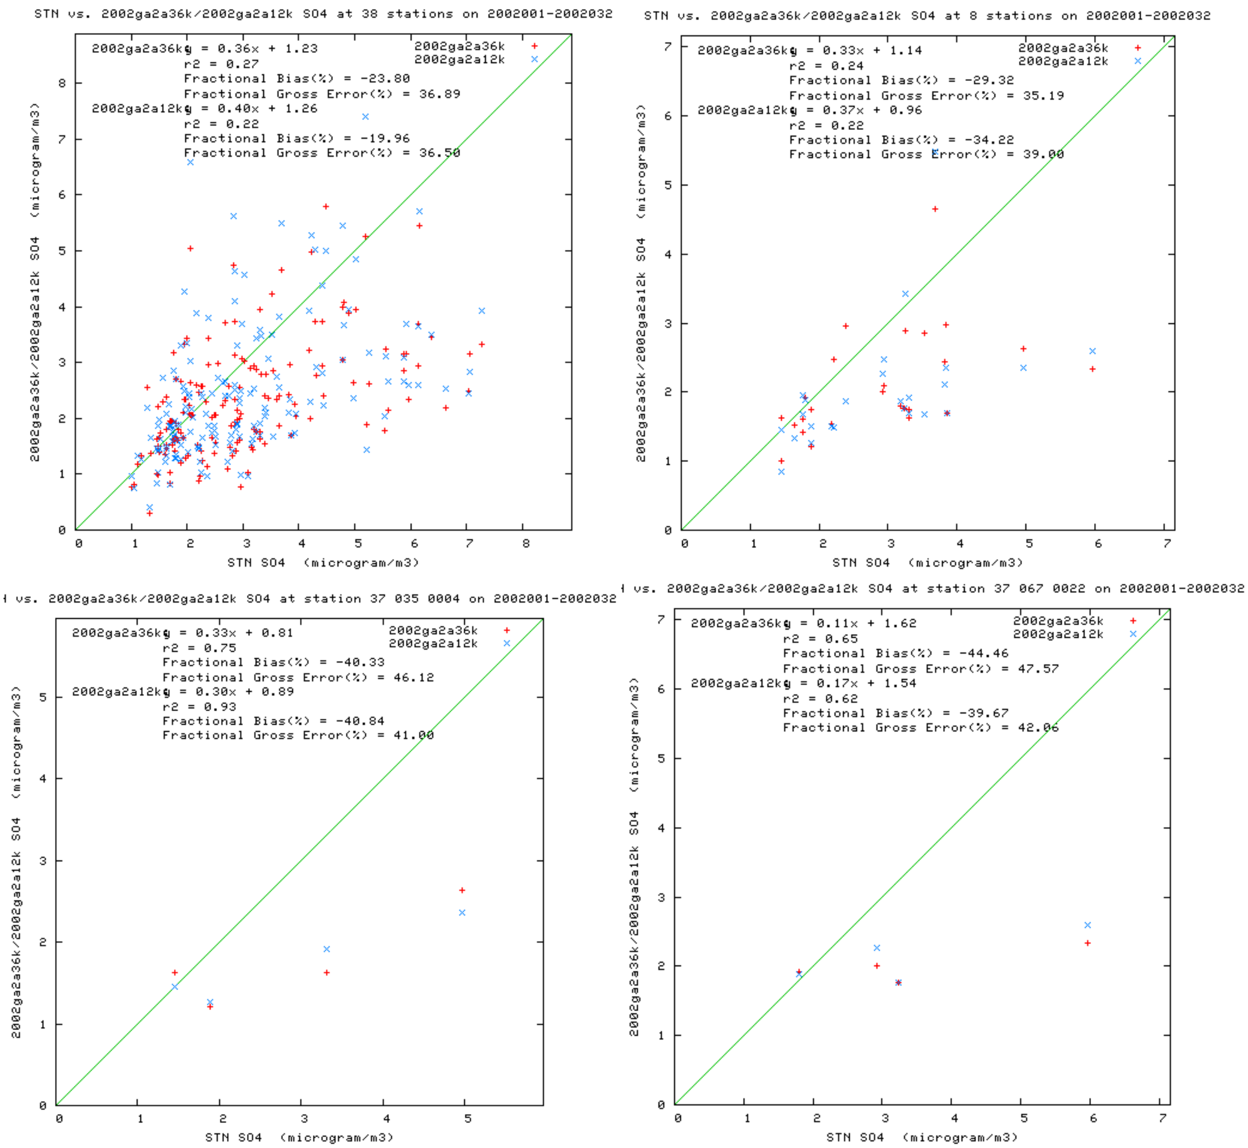

Figure 4-1: Scatter Plot of Observed Sulfate from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of January.

4.1.1.2 February

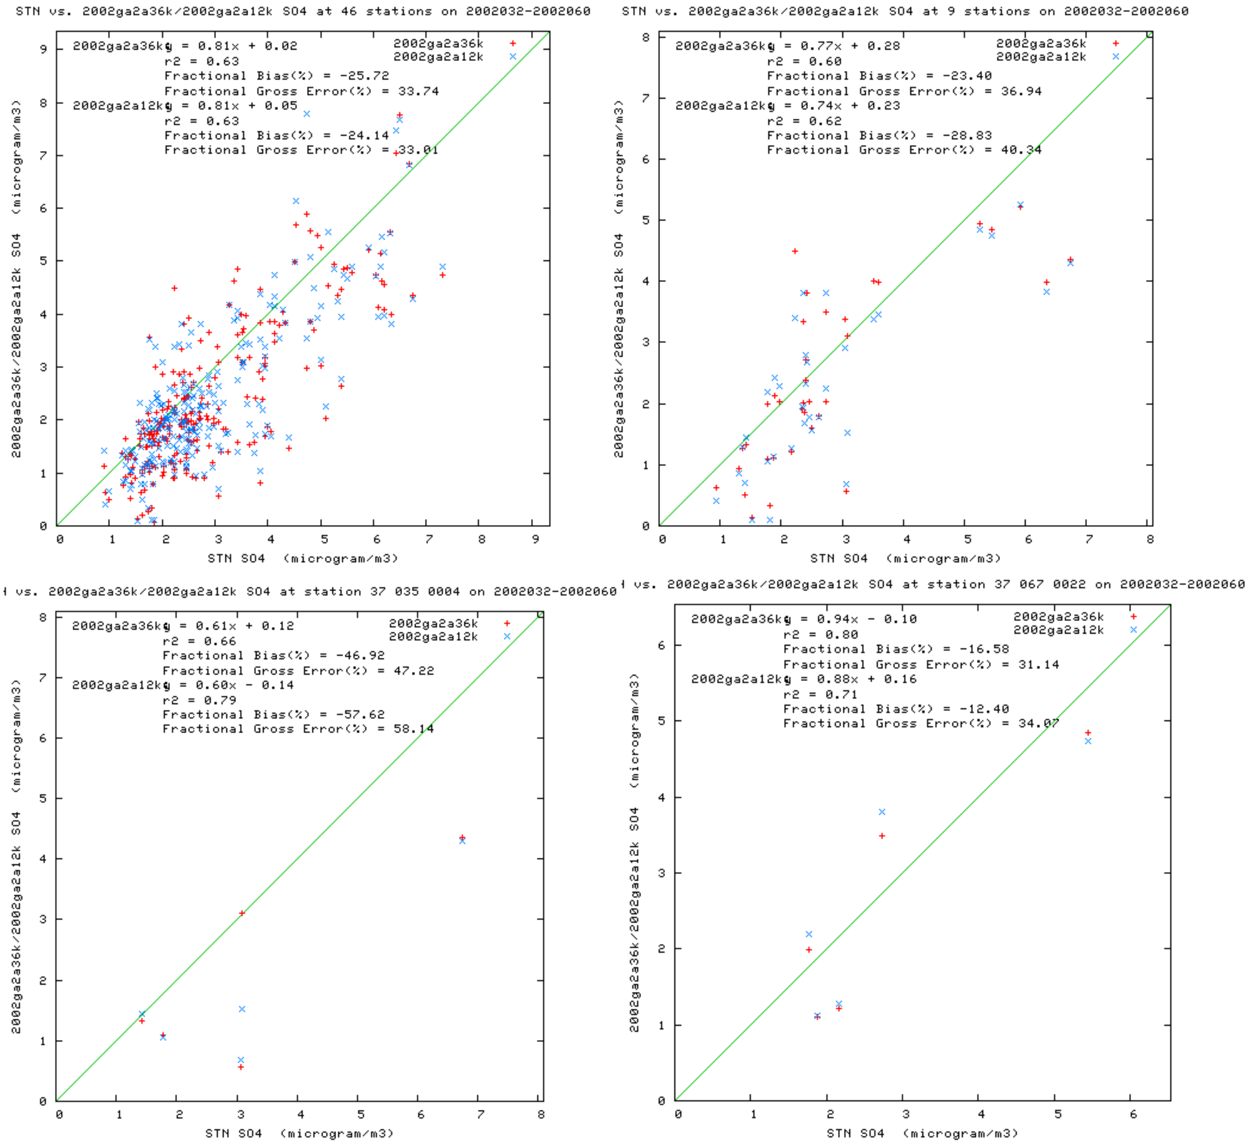

Figure 4-2: Scatter Plot of Observed Sulfate from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of February.

4.1.1.3 March

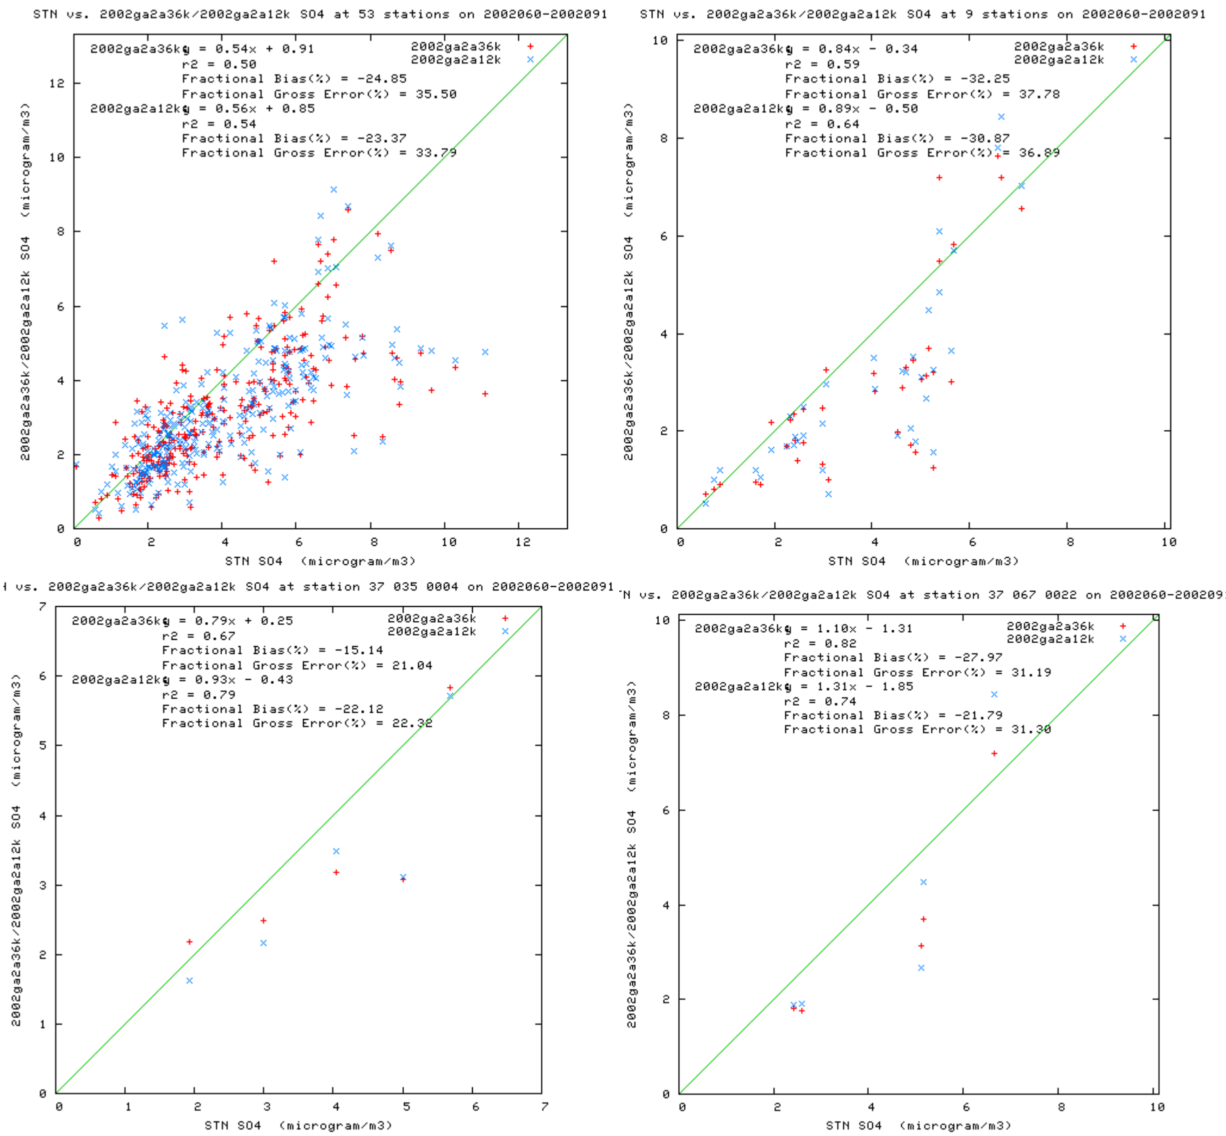

Figure 4-3: Scatter Plot of Observed Sulfate from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of March.

4.1.1.4 April

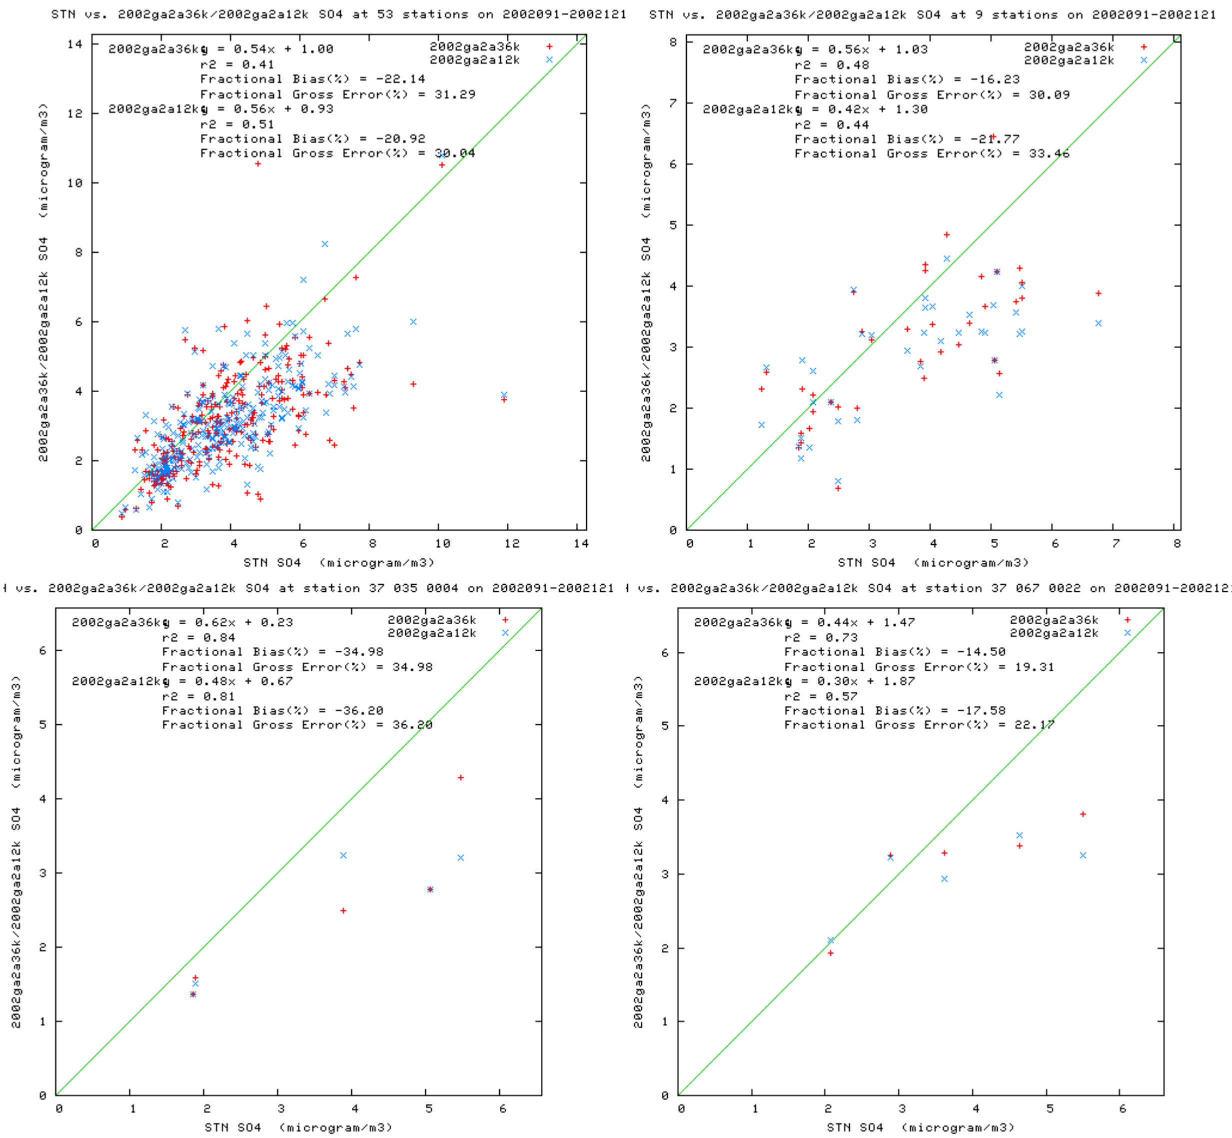

Figure 4-4: Scatter Plot of Observed Sulfate from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of April.

4.1.1.5 May

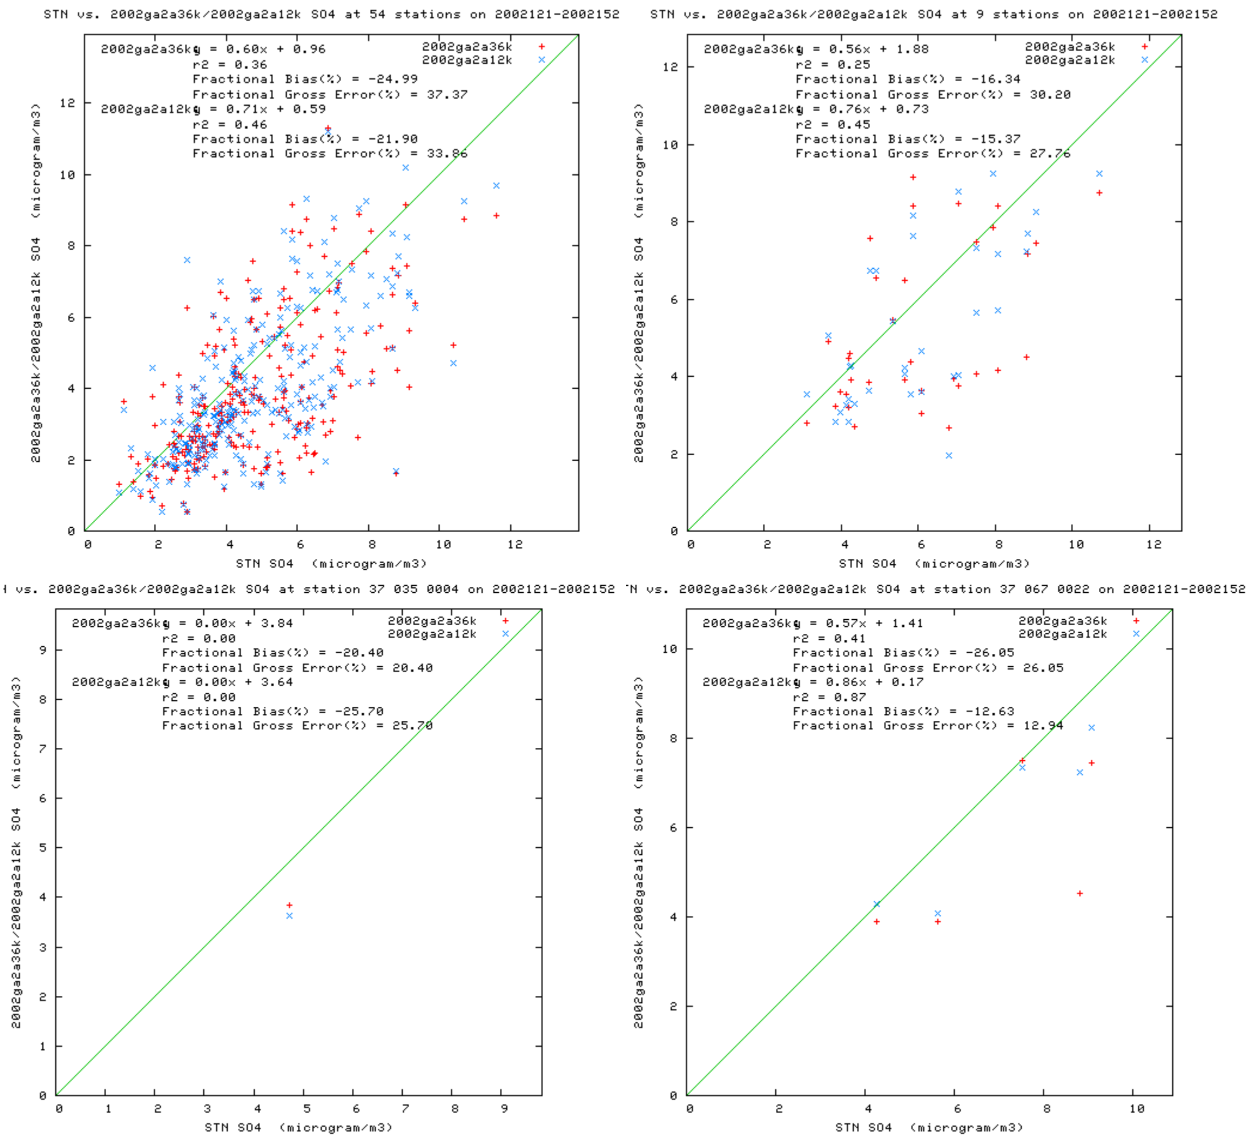

Figure 4-5: Scatter Plot of Observed Sulfate from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of May.

4.1.1.6 June

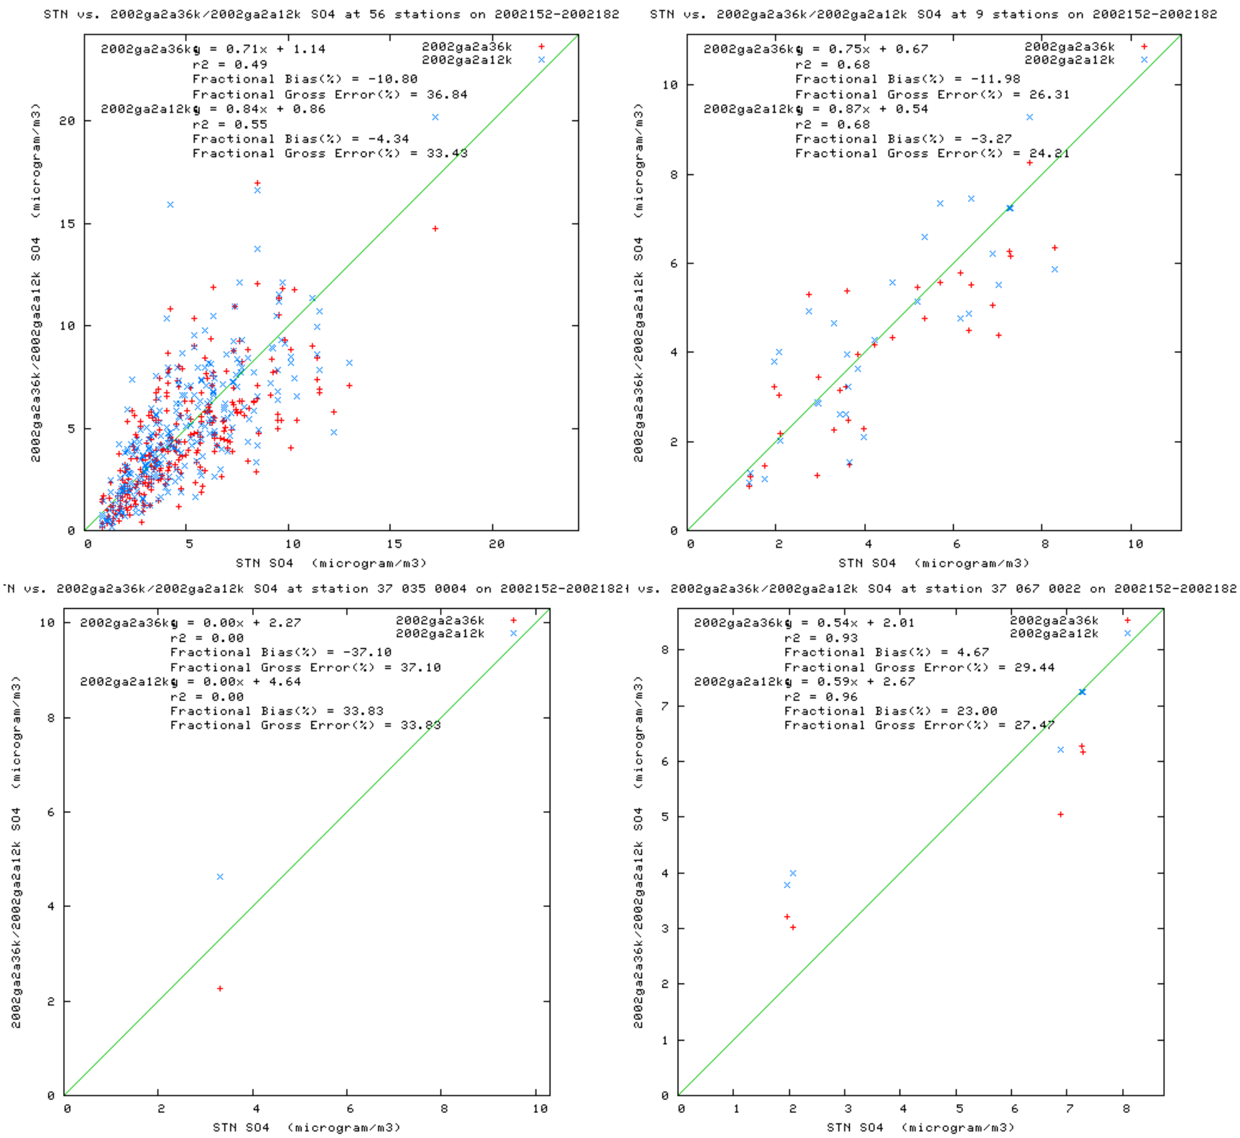

Figure 4-6: Scatter Plot of Observed Sulfate from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of June.

4.1.1.7 July

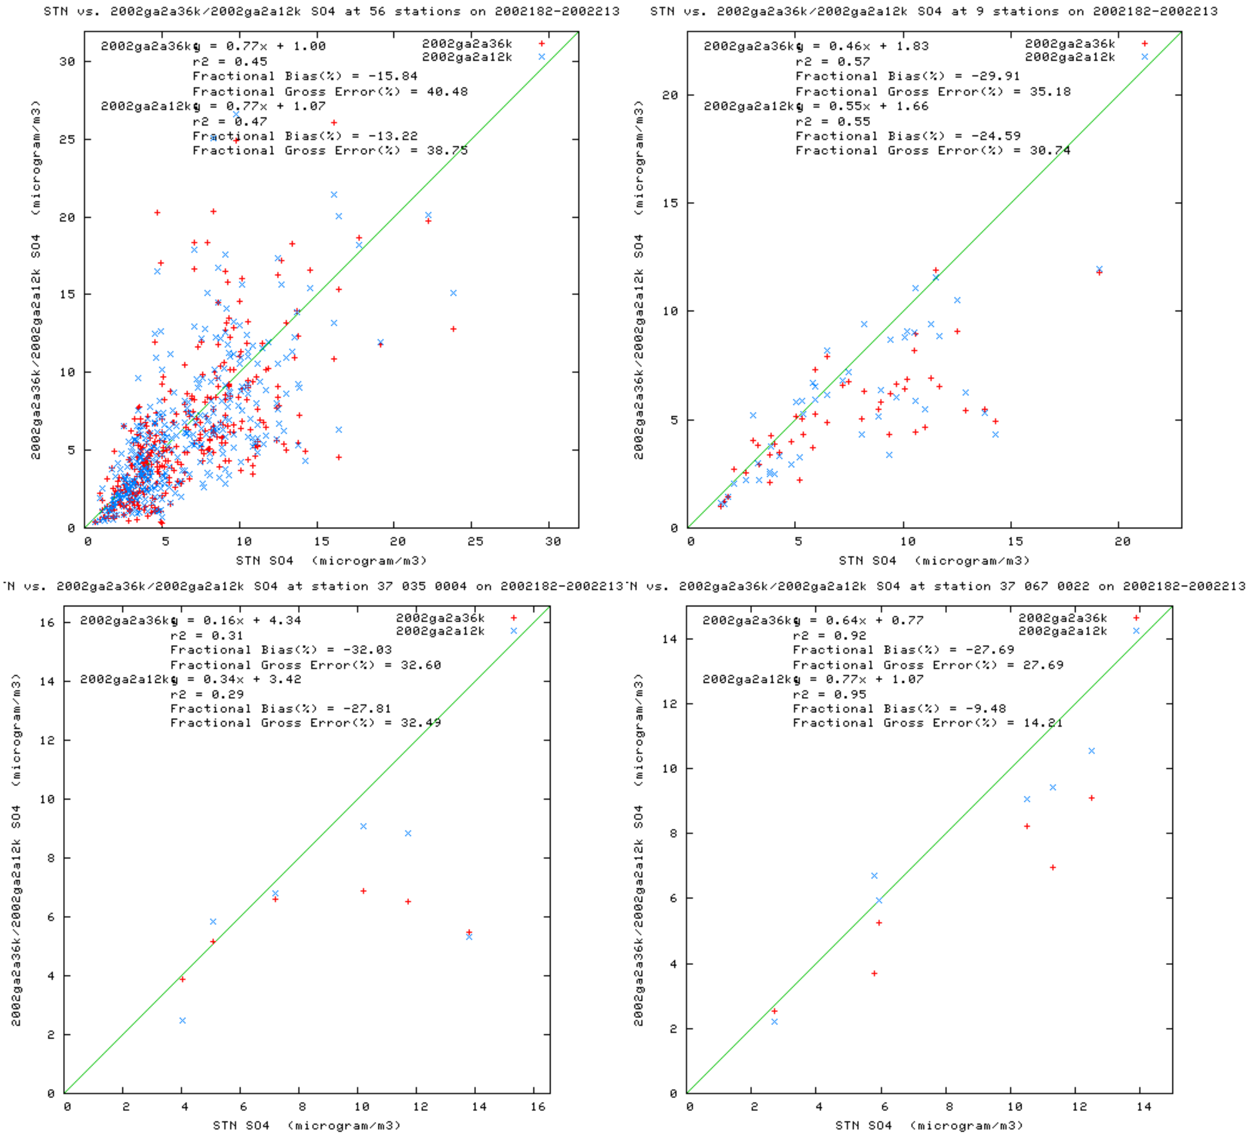

Figure 4-7: Scatter Plot of Observed Sulfate from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of July.

4.1.1.8 August

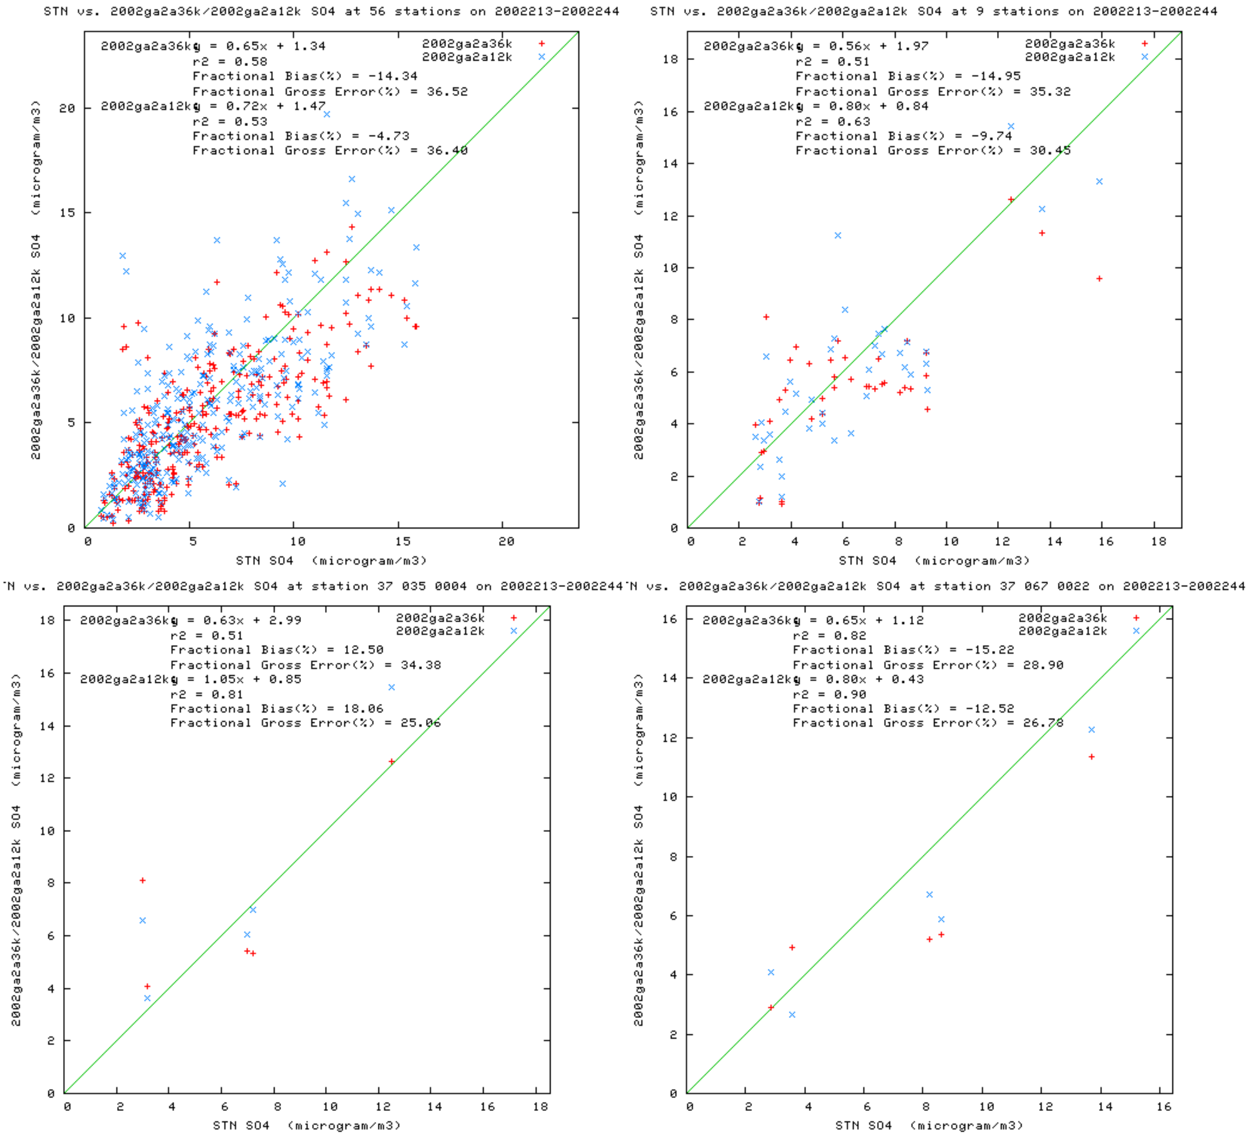

Figure 4-8: Scatter Plot of Observed Sulfate from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of August.

4.1.1.9 September

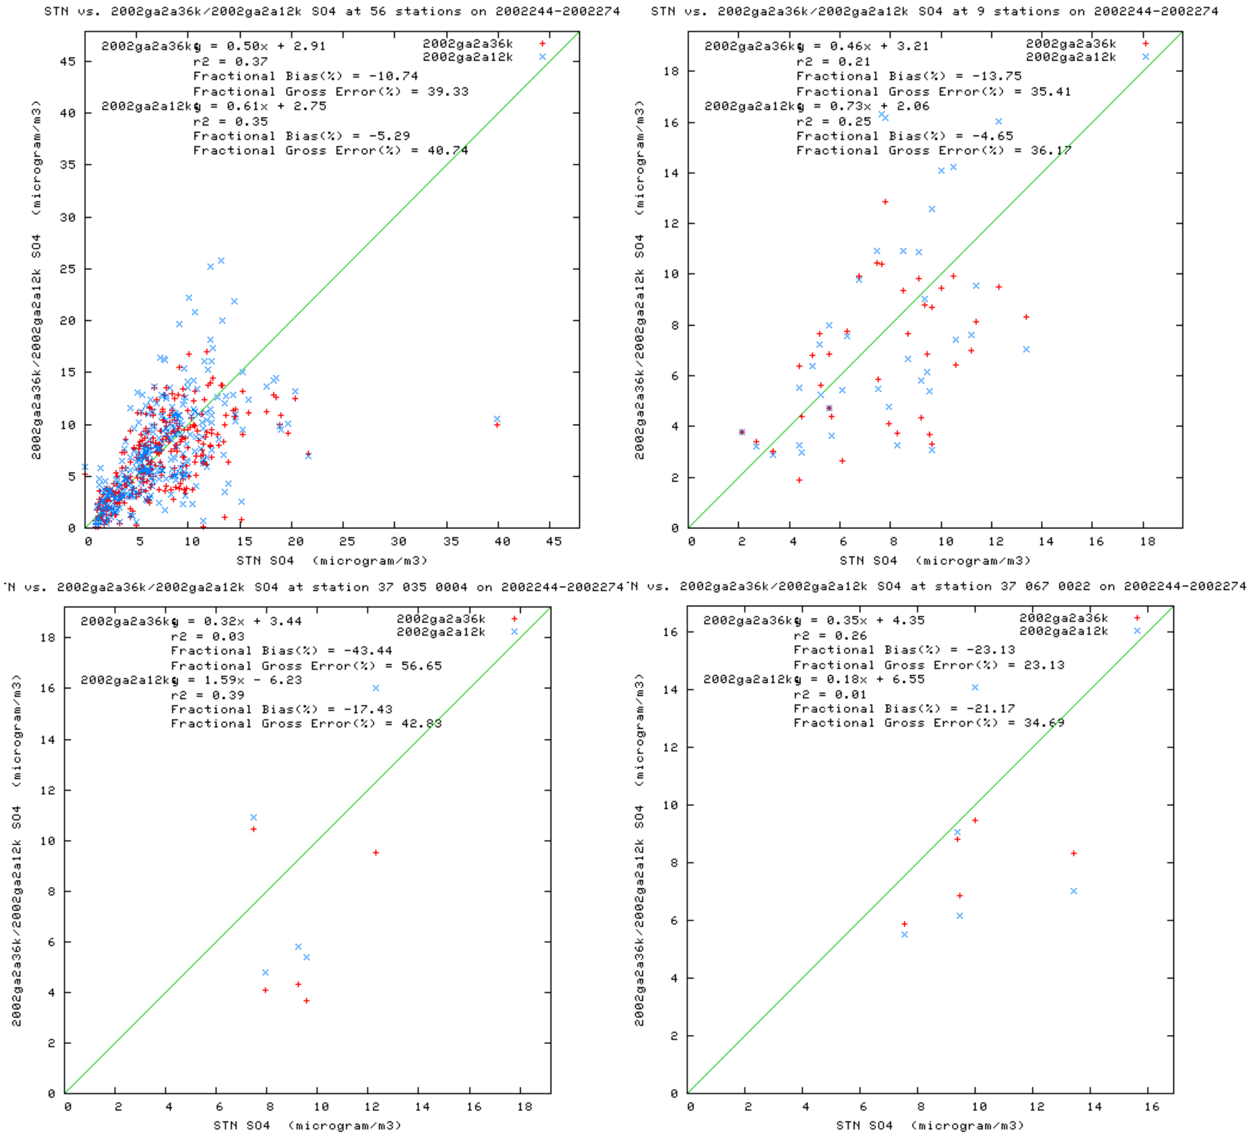

Figure 4-9: Scatter Plot of Observed Sulfate from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of September.

4.1.1.10 October

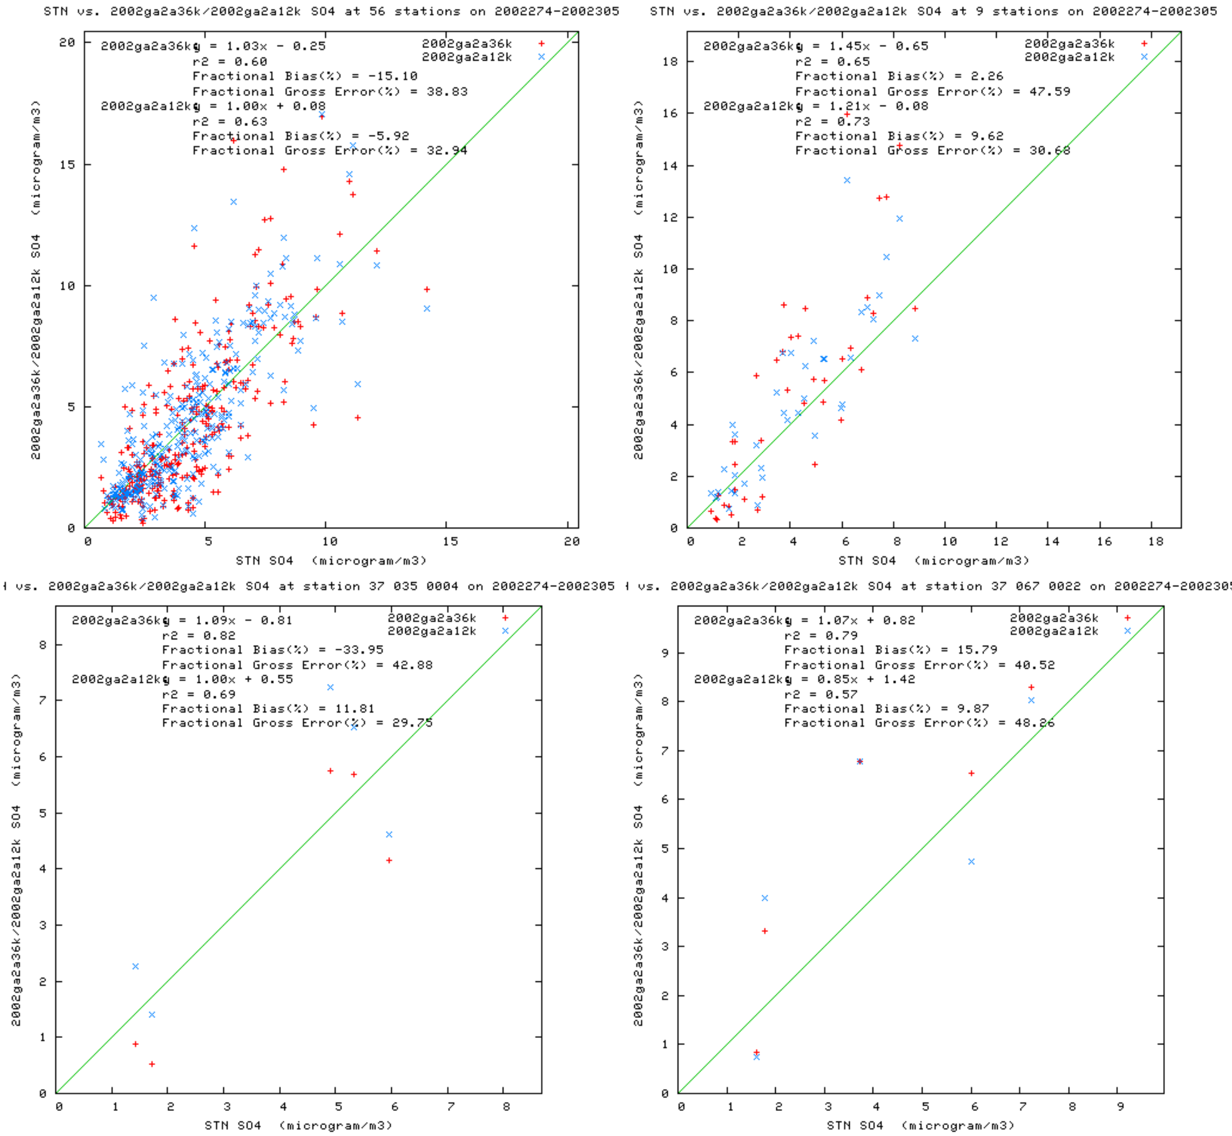

Figure 4-10: Scatter Plot of Observed Sulfate from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of October.

4.1.1.11 November

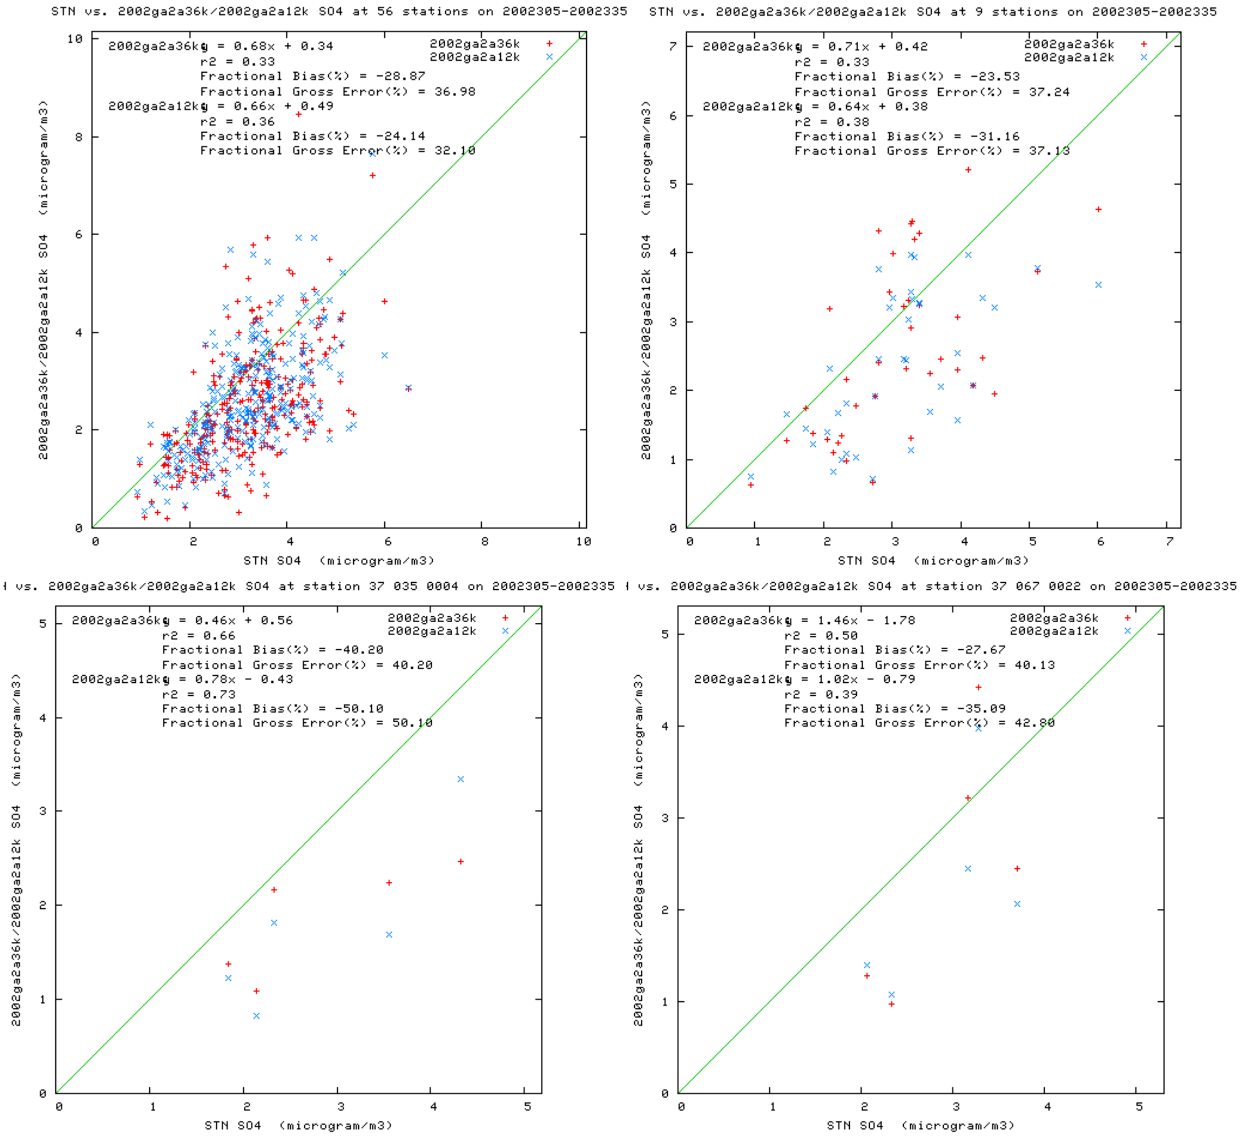

Figure 4-11: Scatter Plot of Observed Sulfate from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of November.

4.1.1.12 December

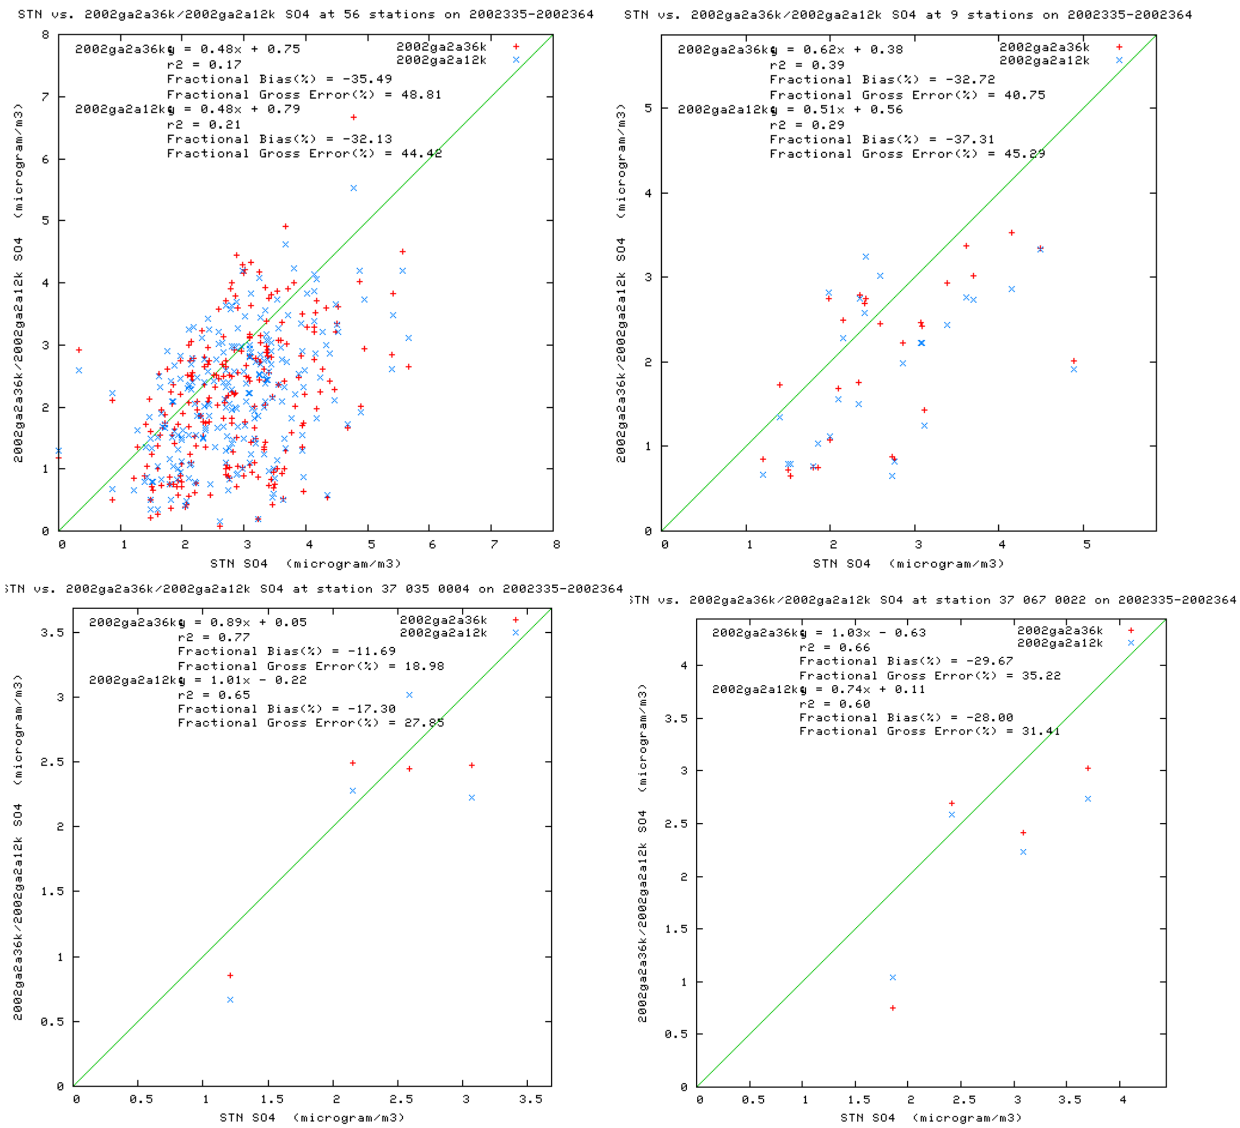

Figure 4-12: Scatter Plot of Observed Sulfate from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of December.

4.1.2 Nitrates

4.1.2.1 January

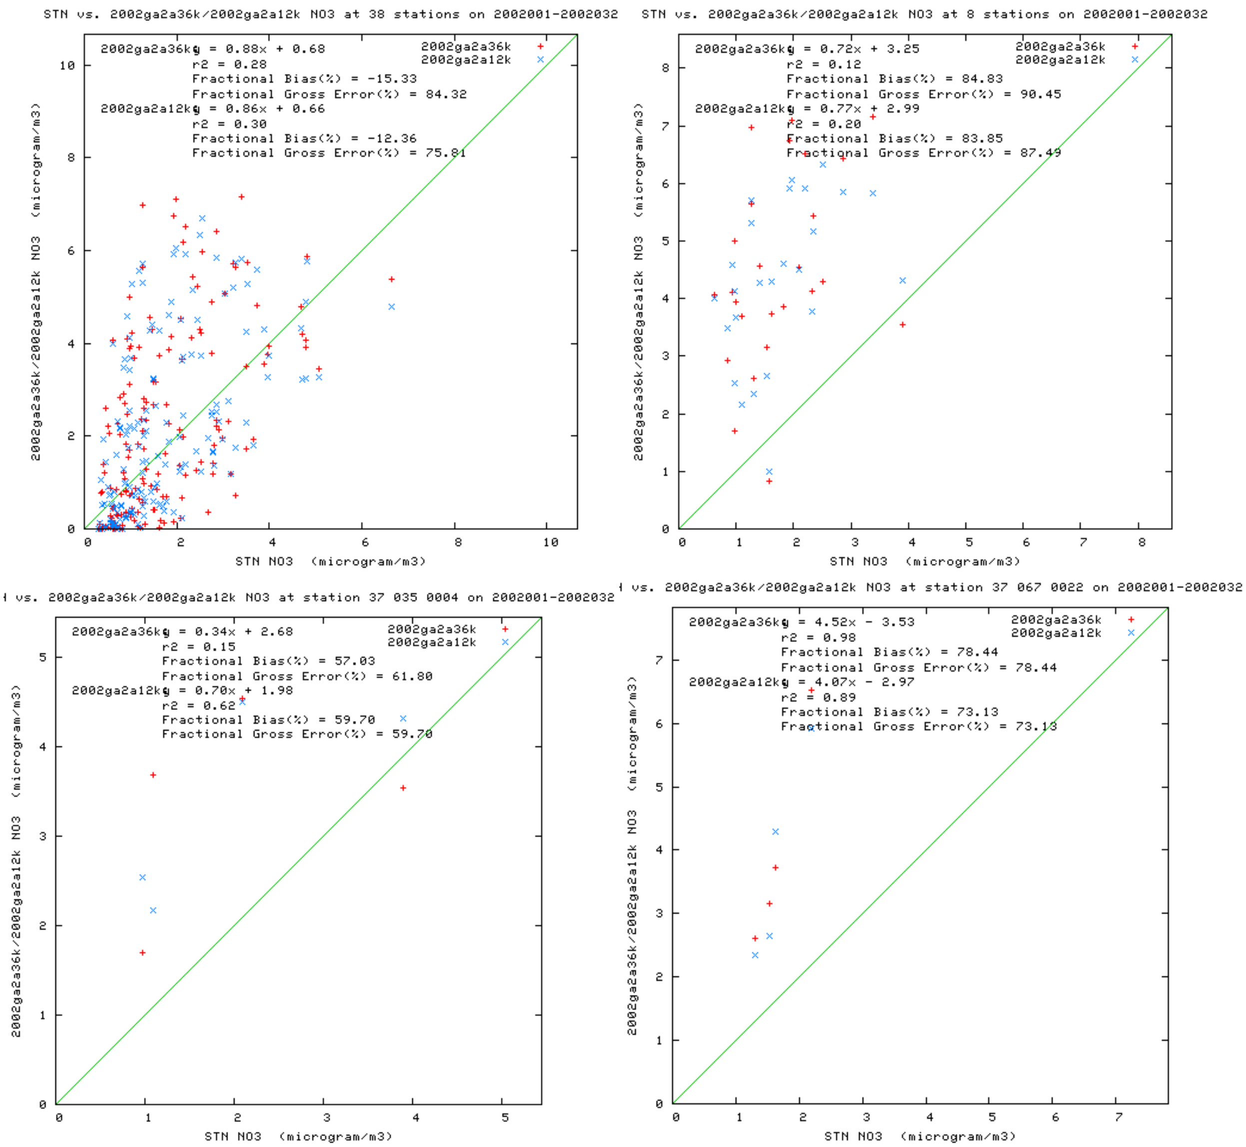

Figure 4-13: Scatter Plot of Observed Nitrates from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of January.

4.1.2.2 February

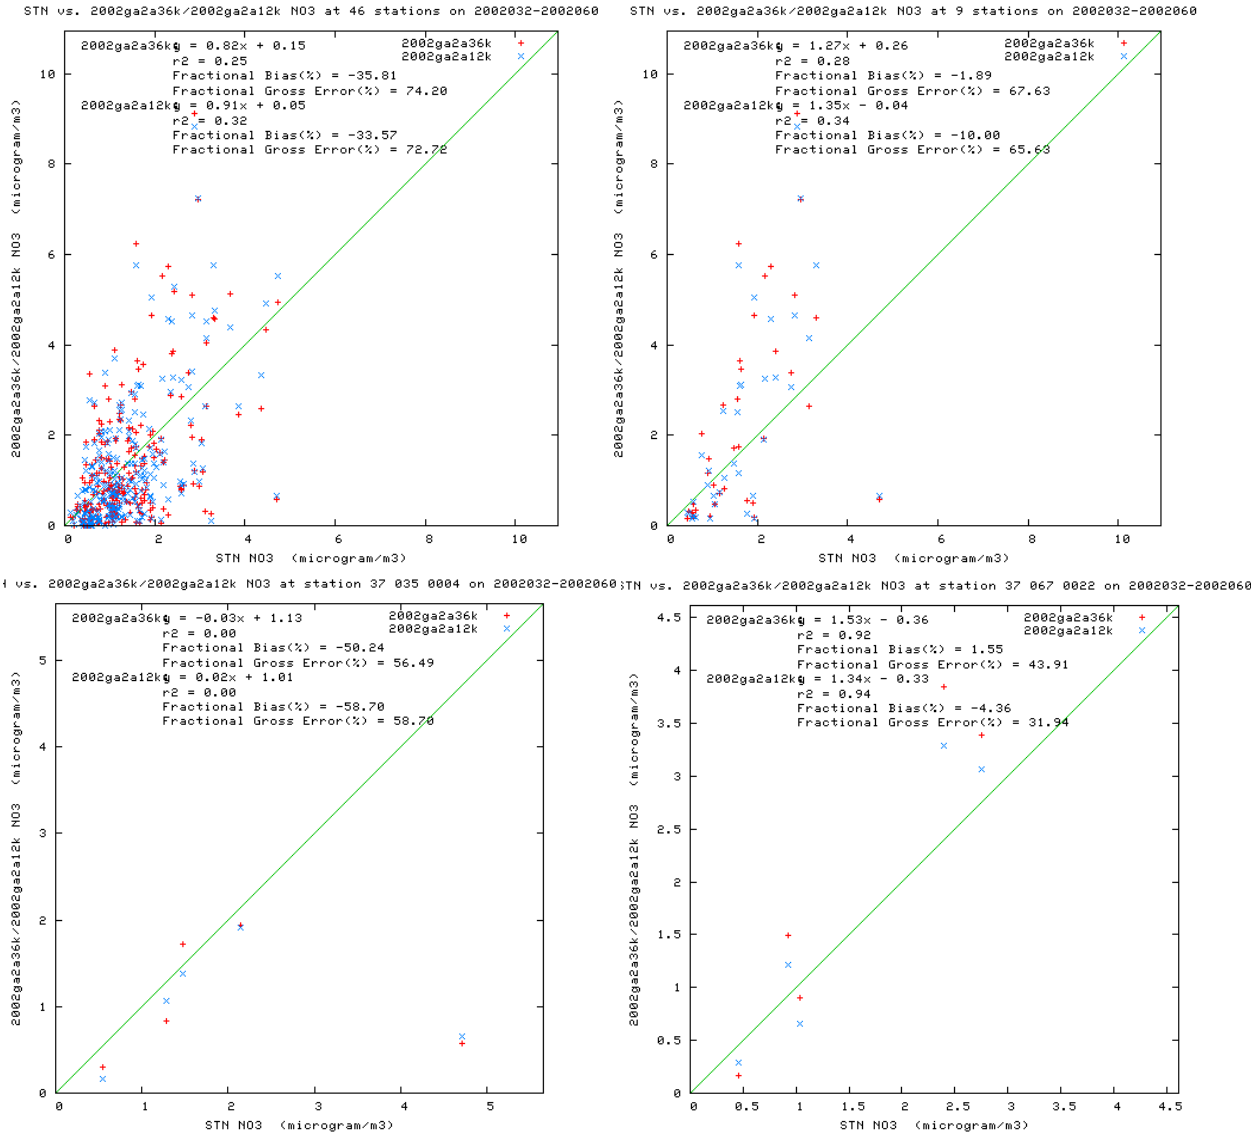

Figure 4-14: Scatter Plot of Observed Nitrates from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of February.

4.1.2.3 March

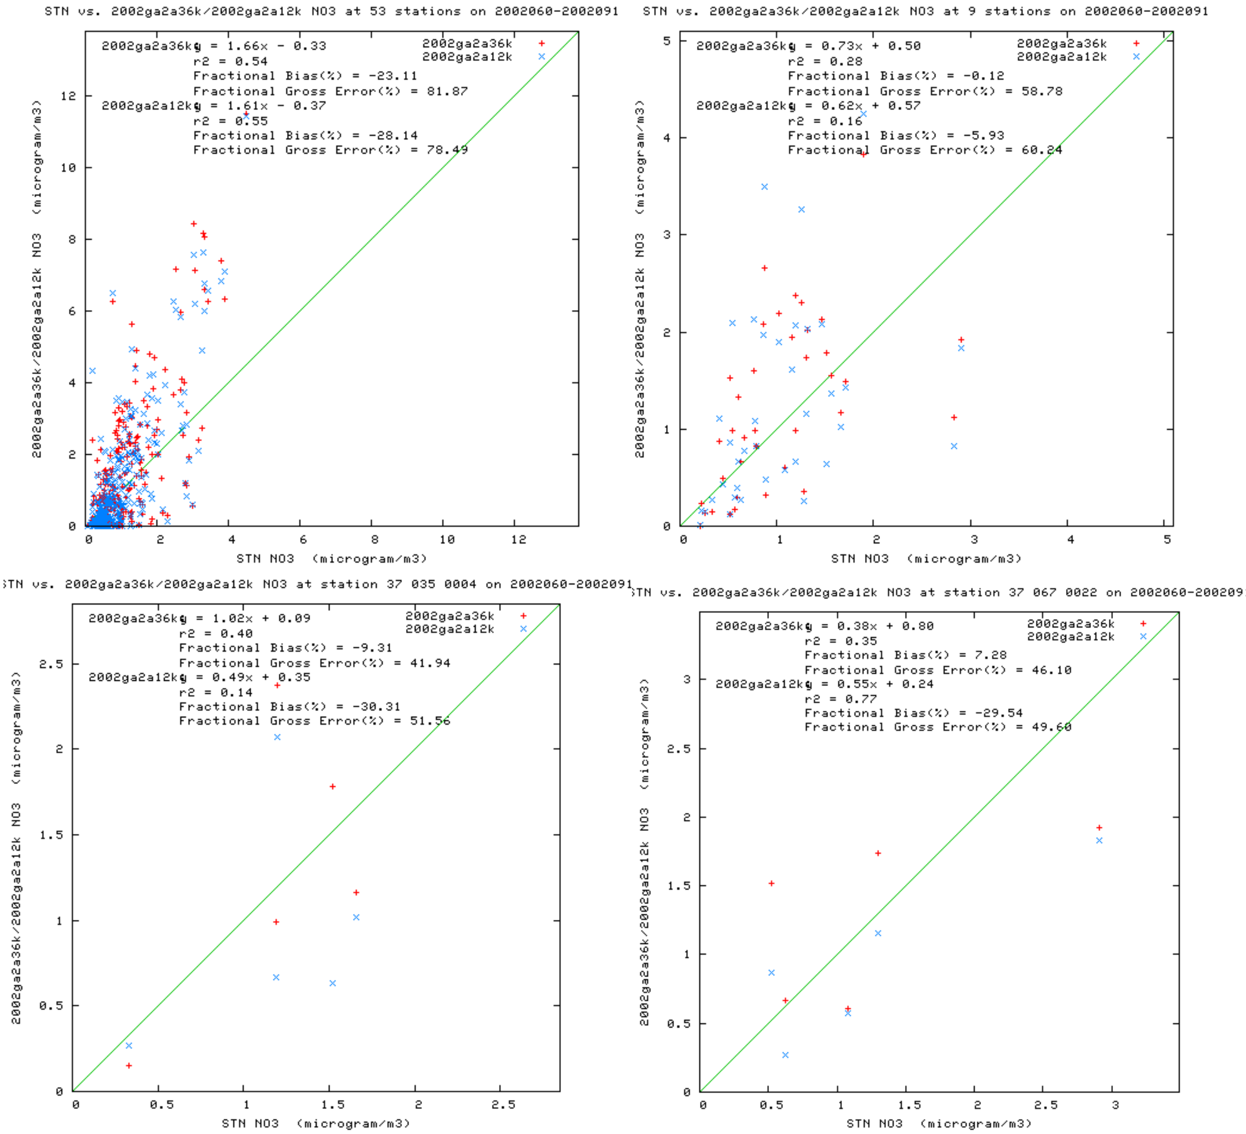

Figure 4-15: Scatter Plot of Observed Nitrates from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of March.

4.1.2.4 April

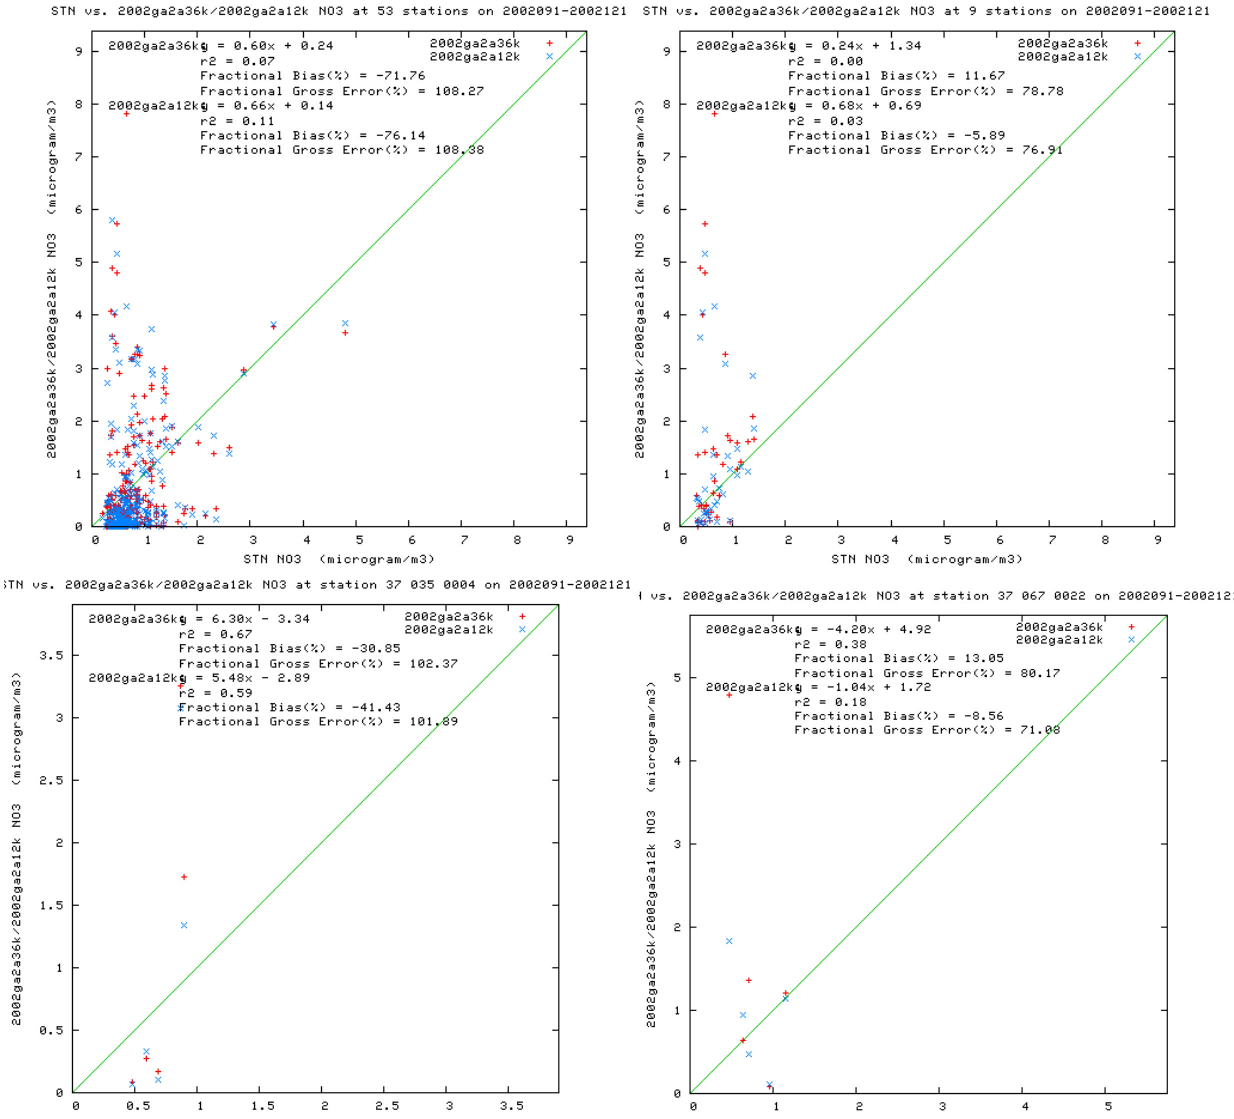

Figure 4-16: Scatter Plot of Observed Nitrates from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of April.

4.1.2.5 May

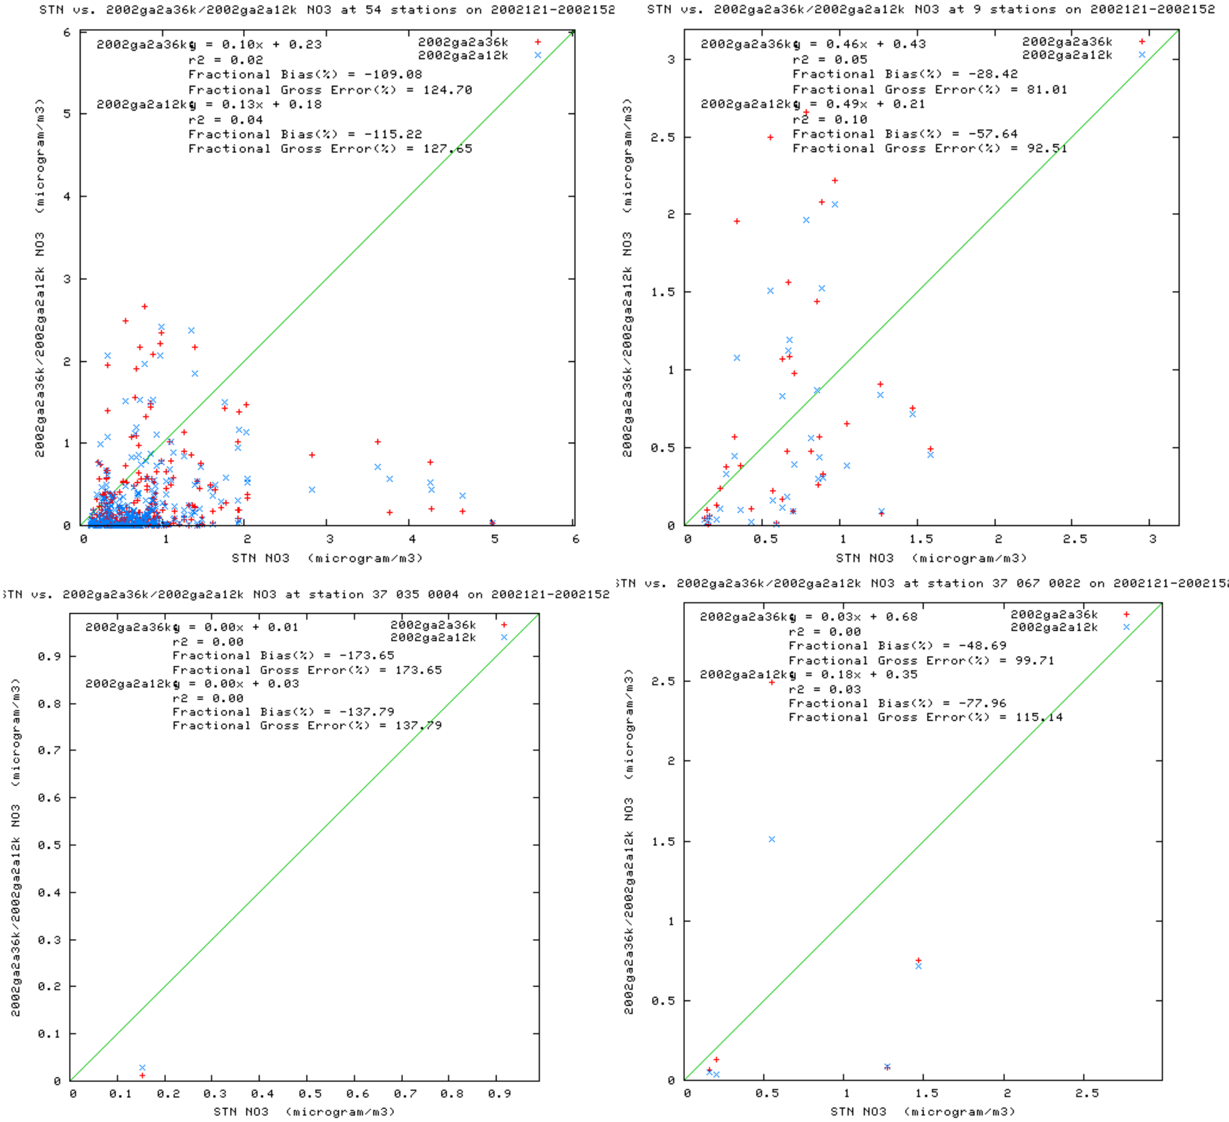

Figure 4-17: Scatter Plot of Observed Nitrates from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of May.

4.1.2.6 June

4.1.3.3 March

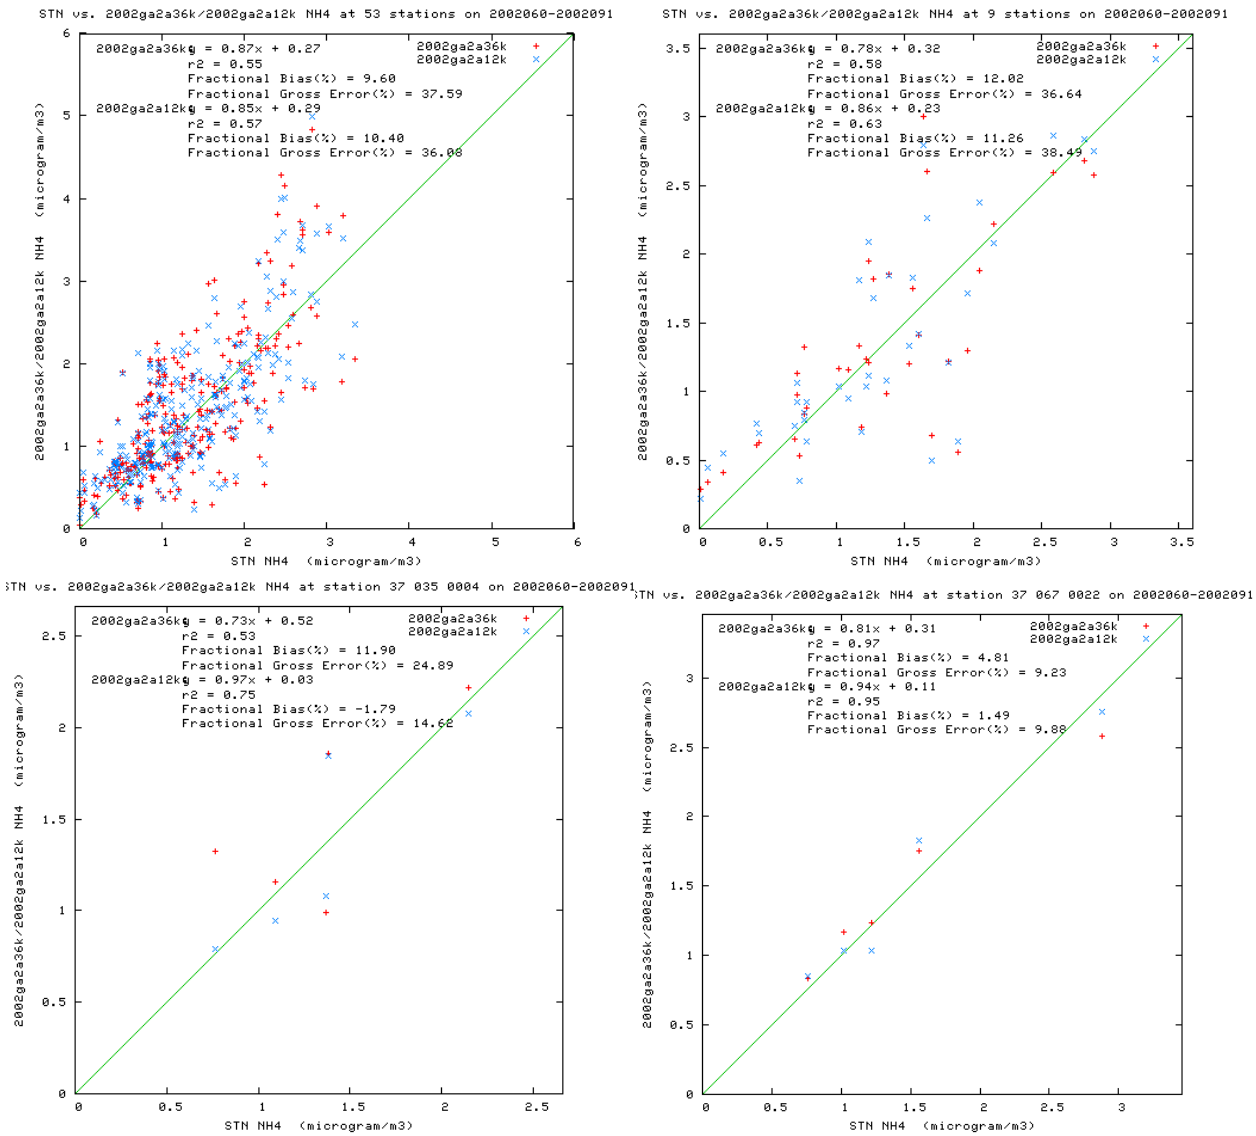

Figure 4-27: Scatter Plot of Observed Ammonium from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of March.

4.1.3.4 April

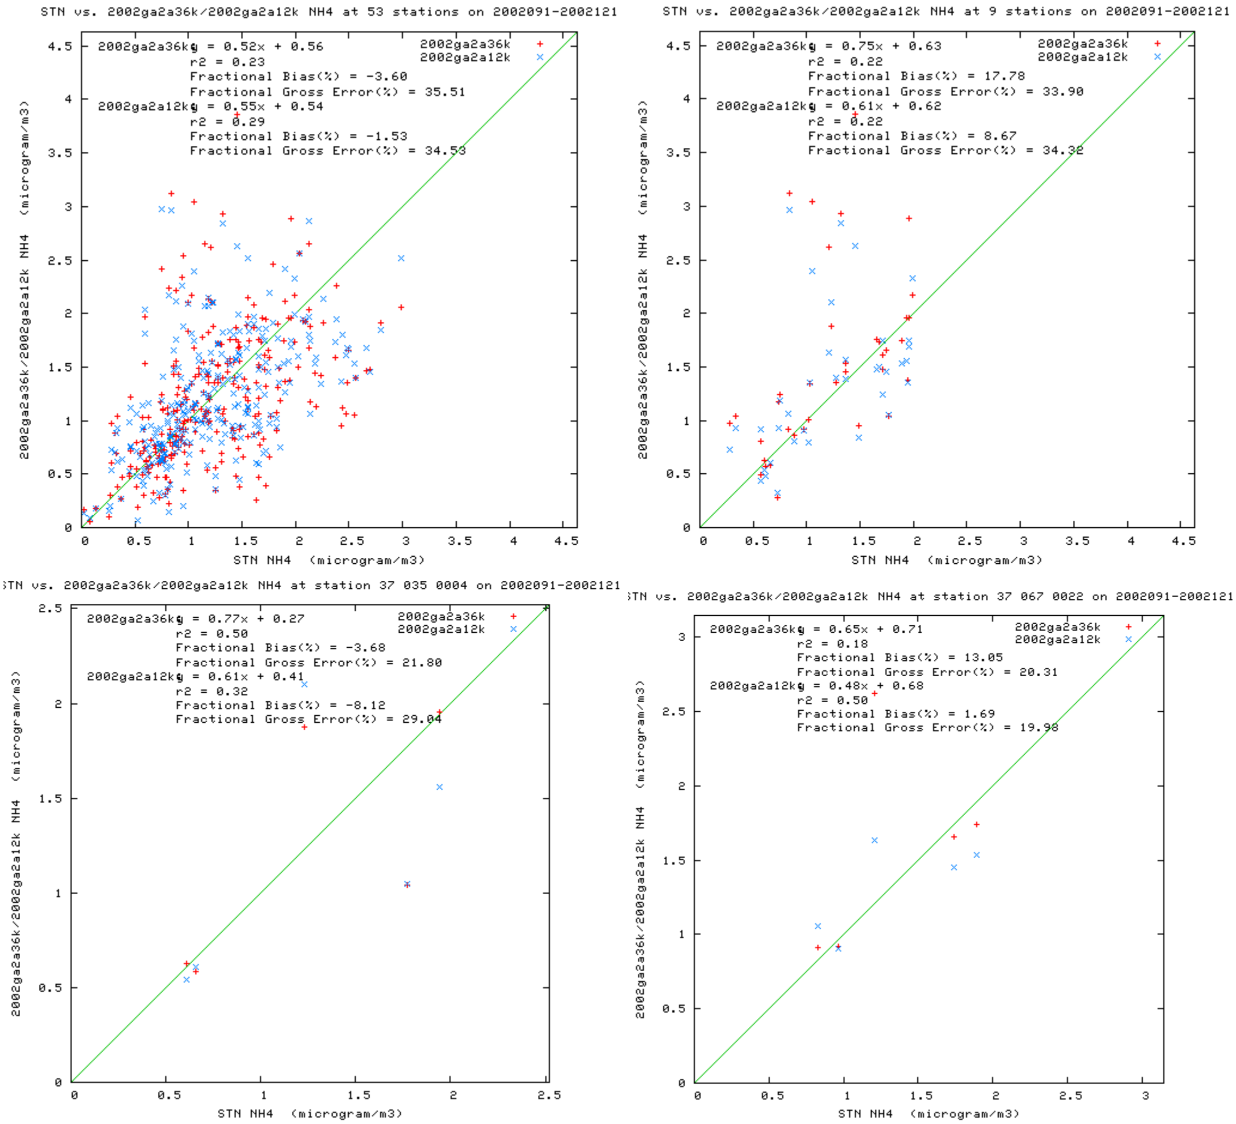

Figure 4-28: Scatter Plot of Observed Ammonium from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of April.

4.1.3.5 May

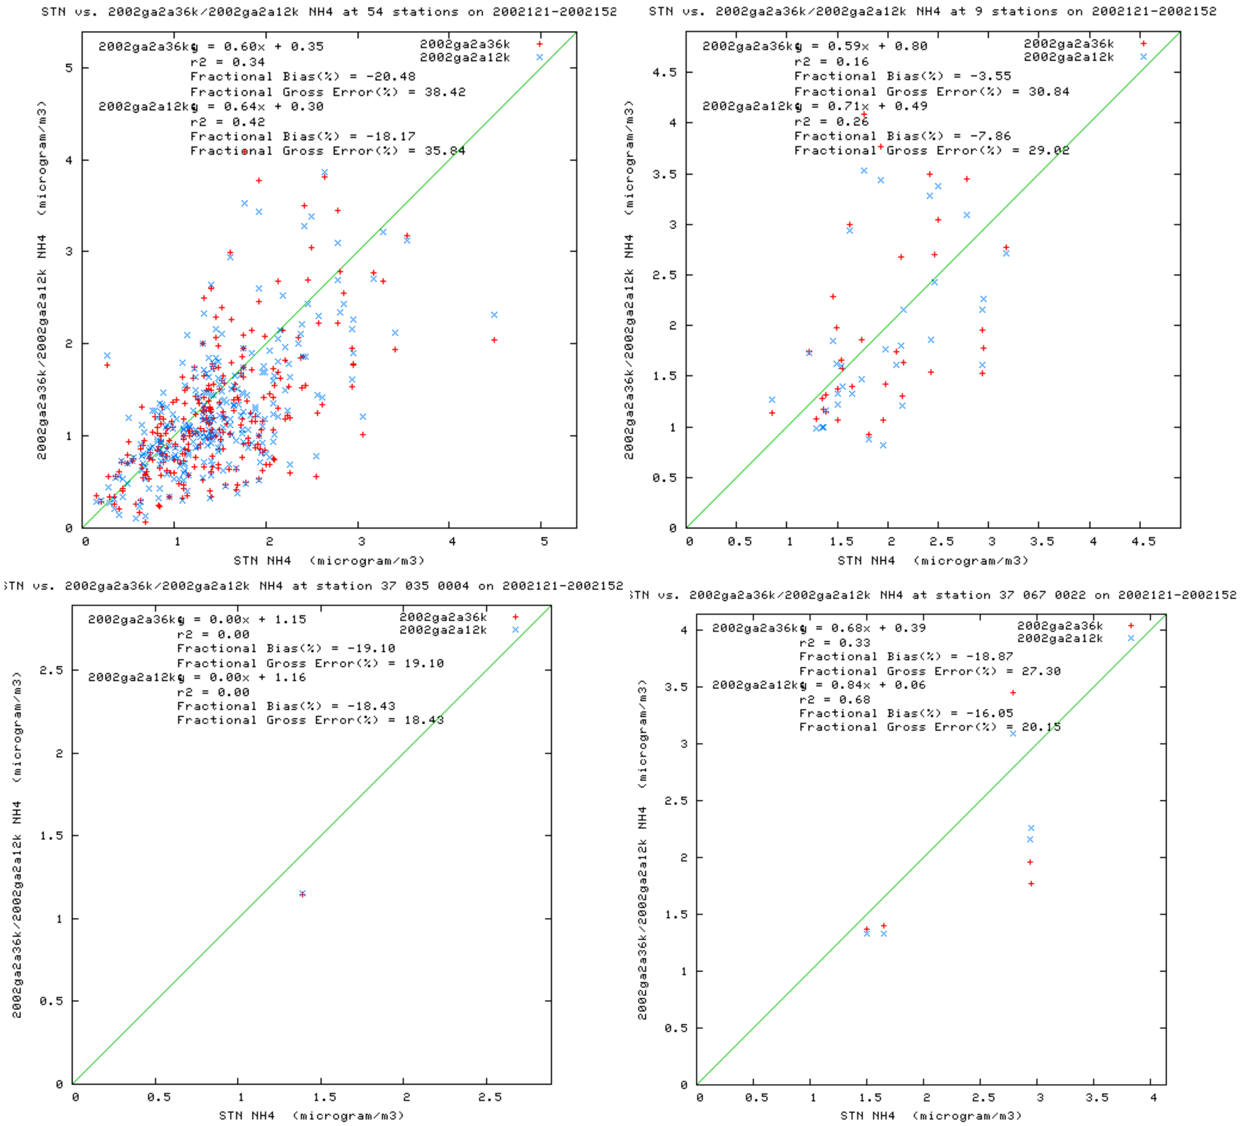

Figure 4-29: Scatter Plot of Observed Ammonium from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of May.

4.1.3.6 June

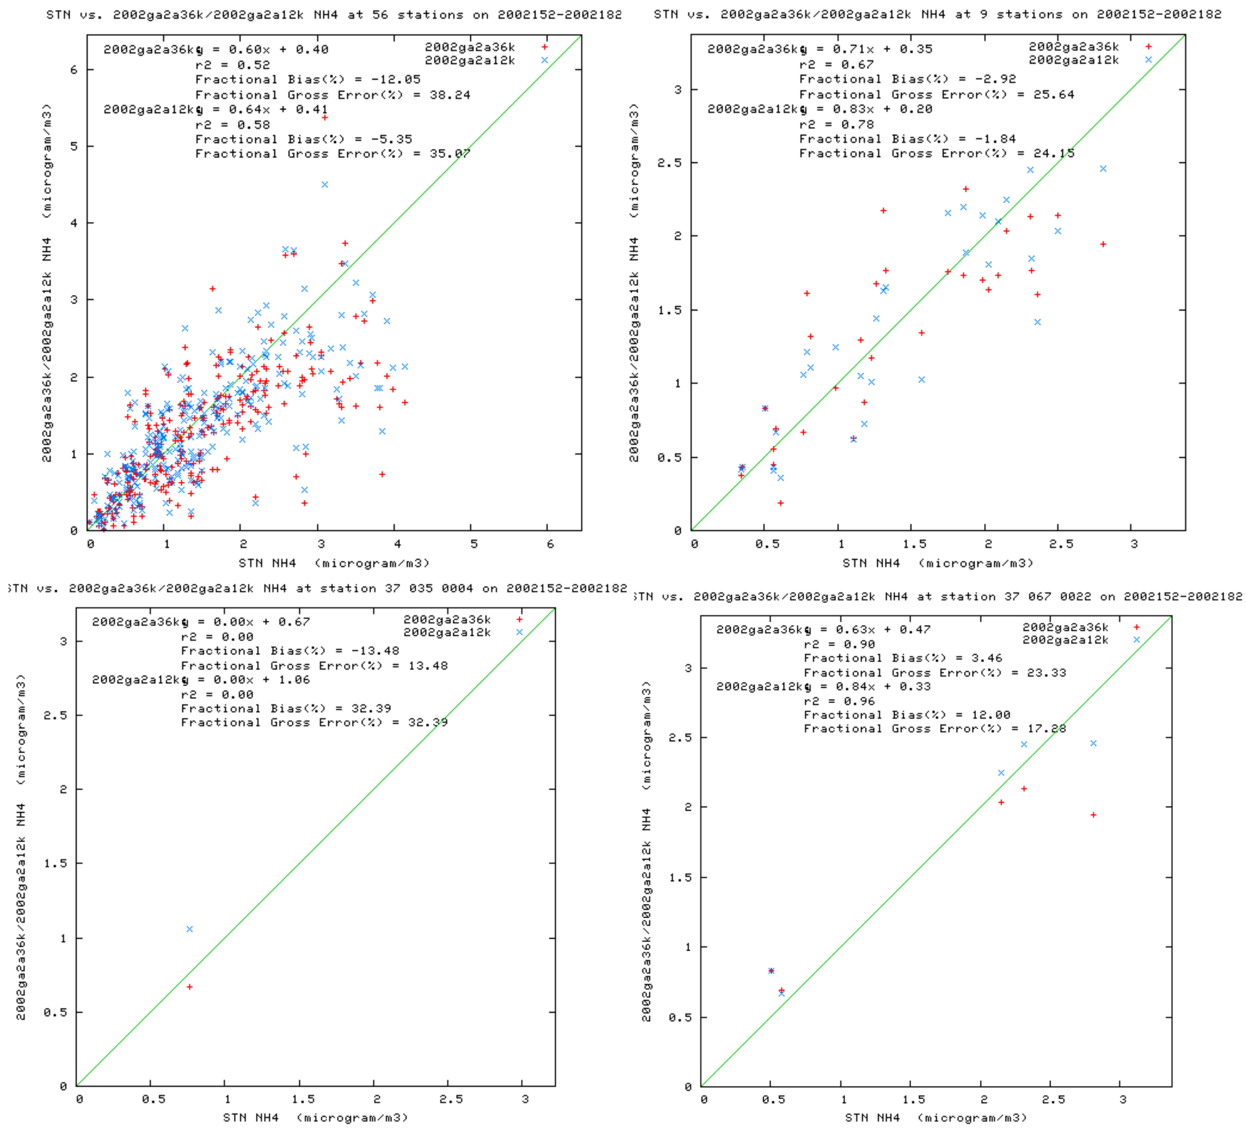

Figure 4-30: Scatter Plot of Observed Ammonium from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of June.

4.1.3.7 July

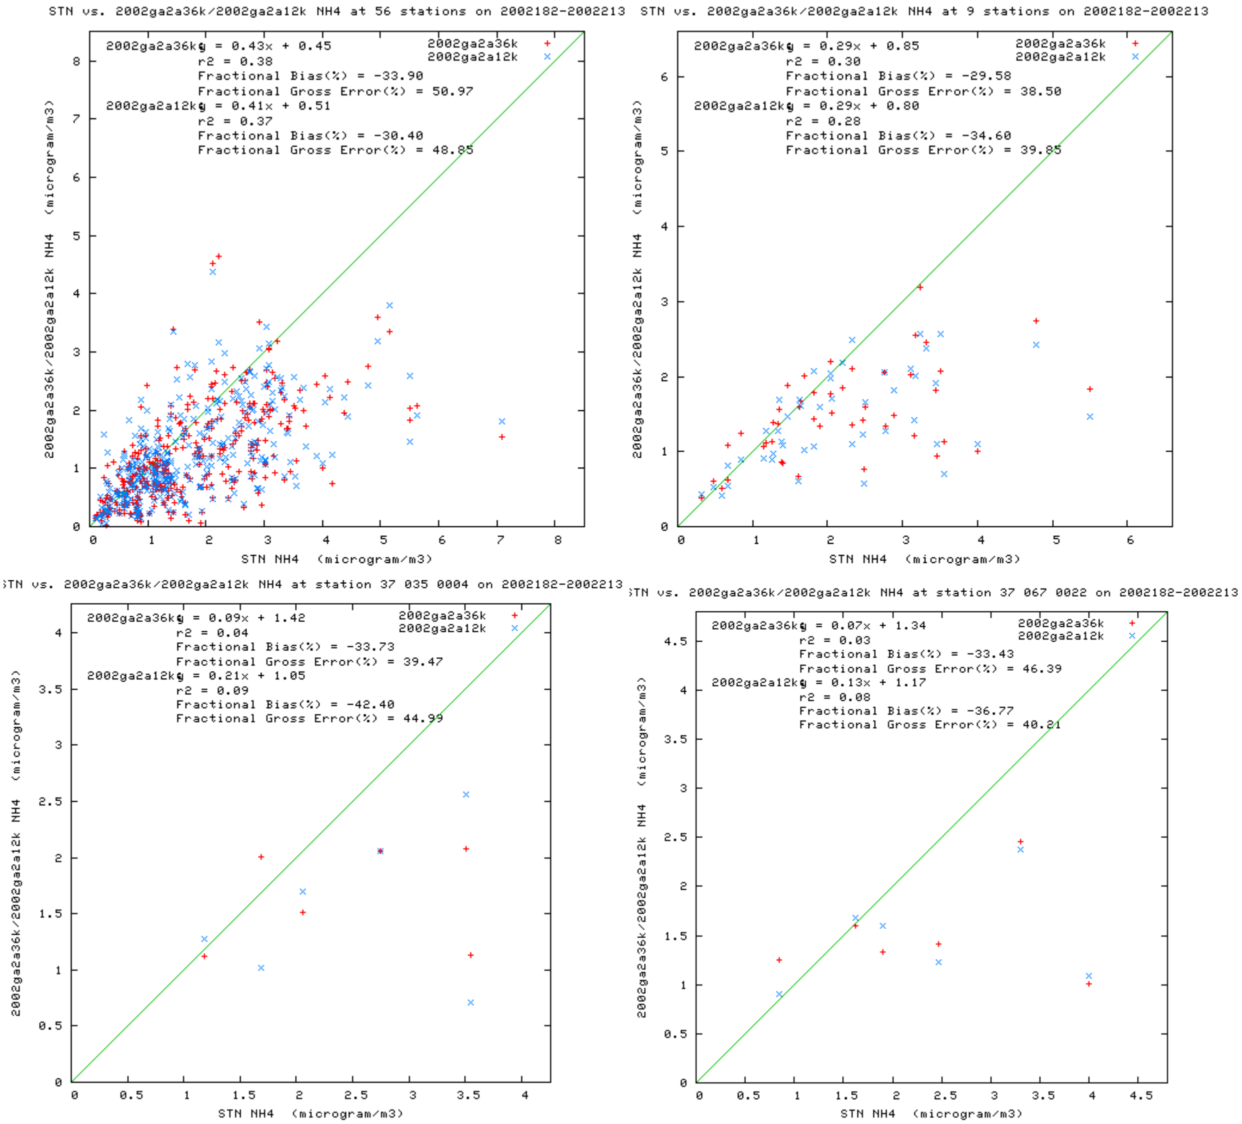

Figure 4-31: Scatter Plot of Observed Ammonium from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of July.

4.1.3.8 August

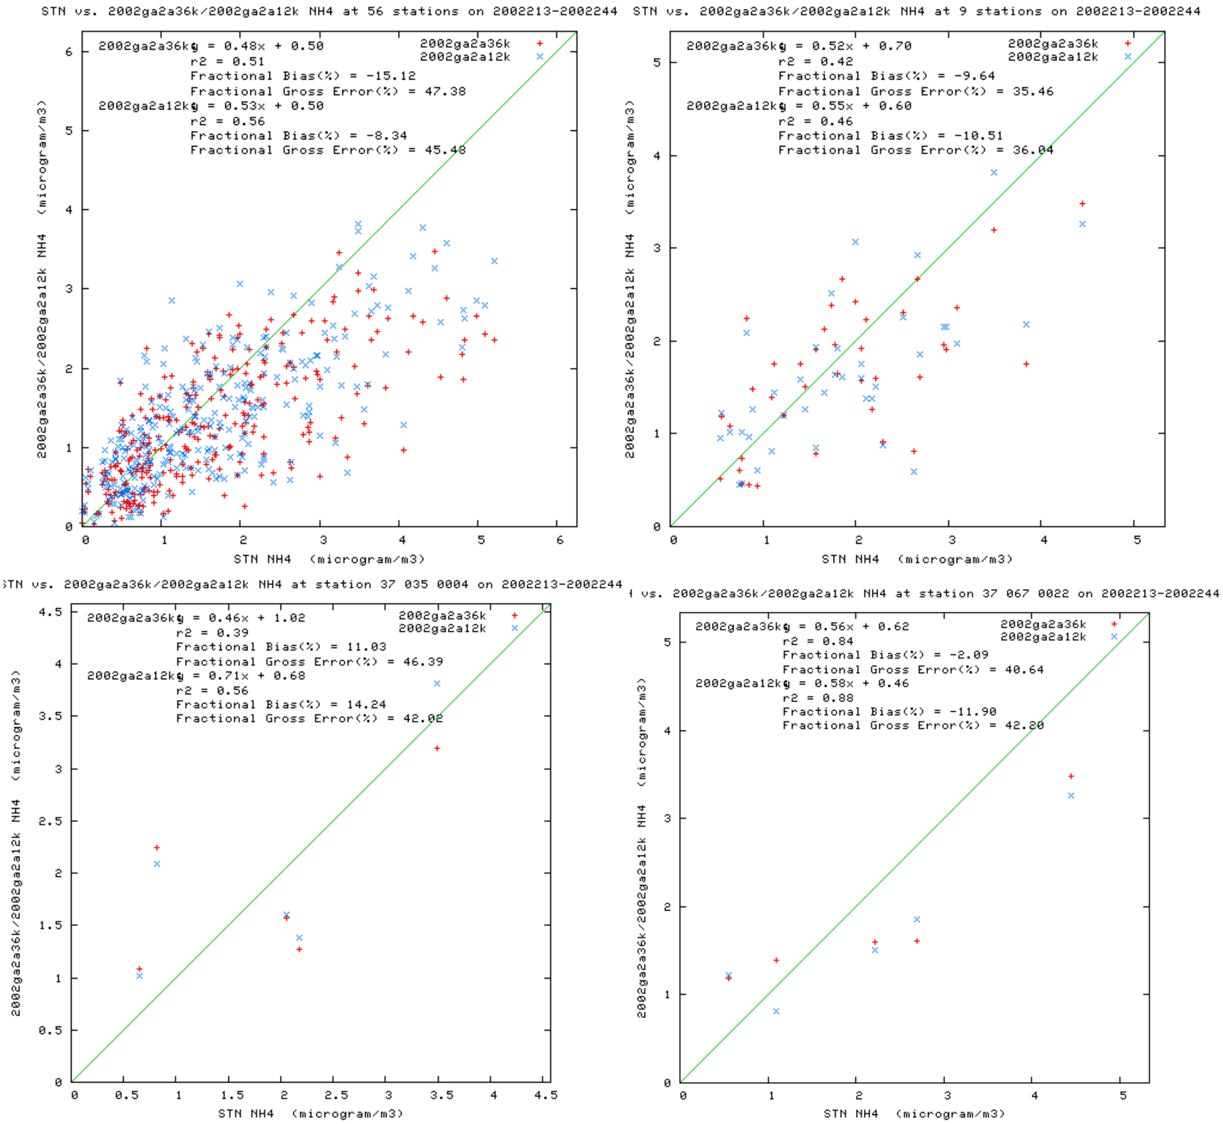

Figure 4-32: Scatter Plot of Observed Ammonium from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of August.

4.1.3.9 September

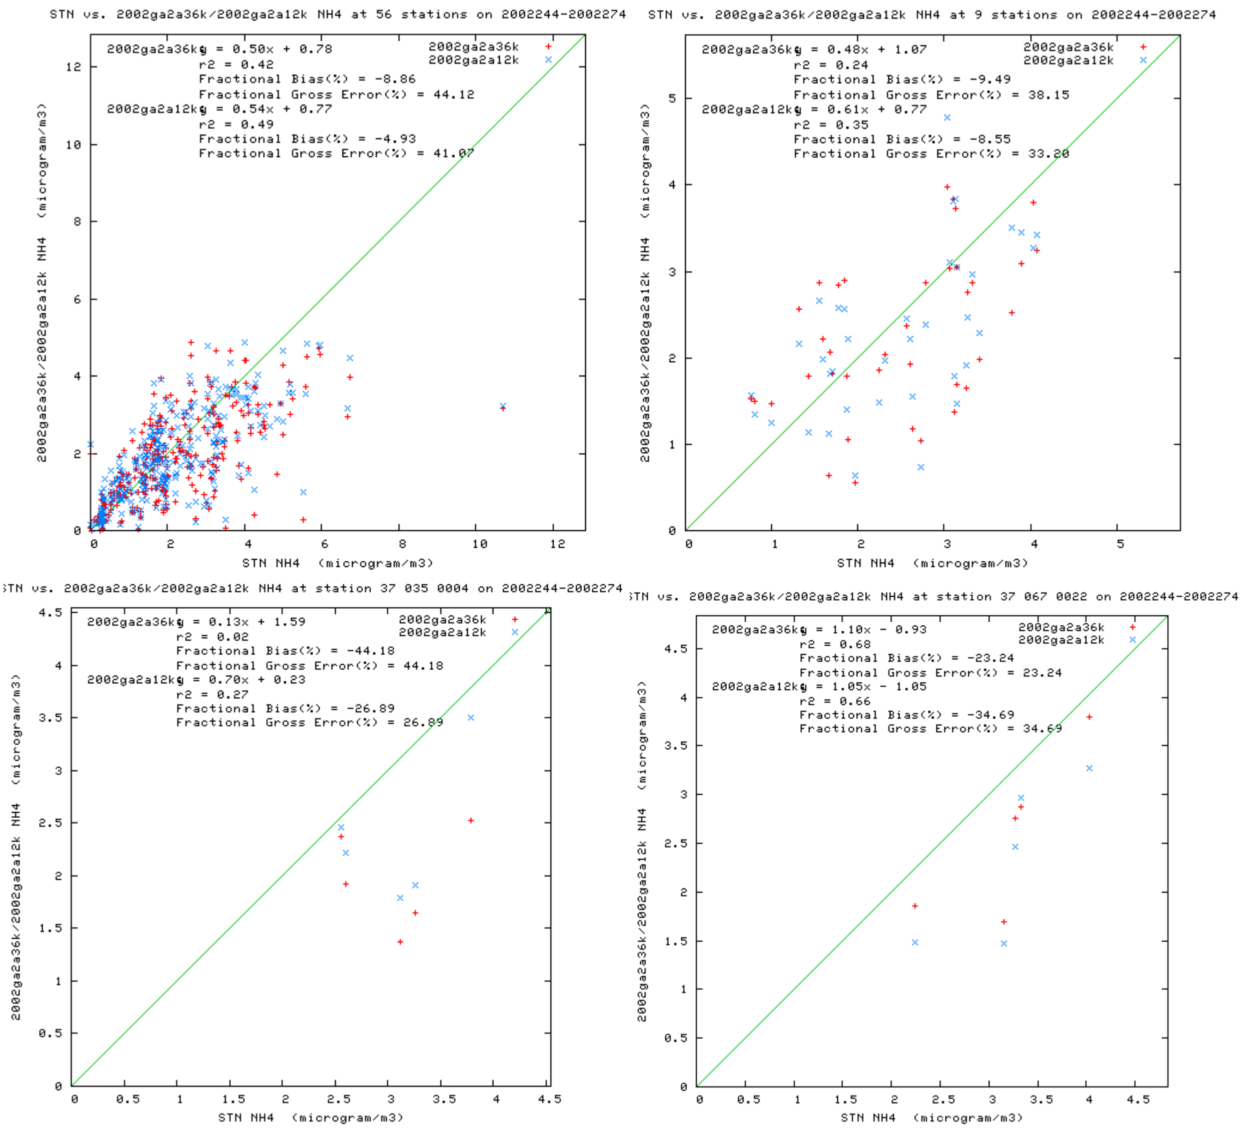

Figure 4-33: Scatter Plot of Observed Ammonium from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of September.

4.1.3.10 October

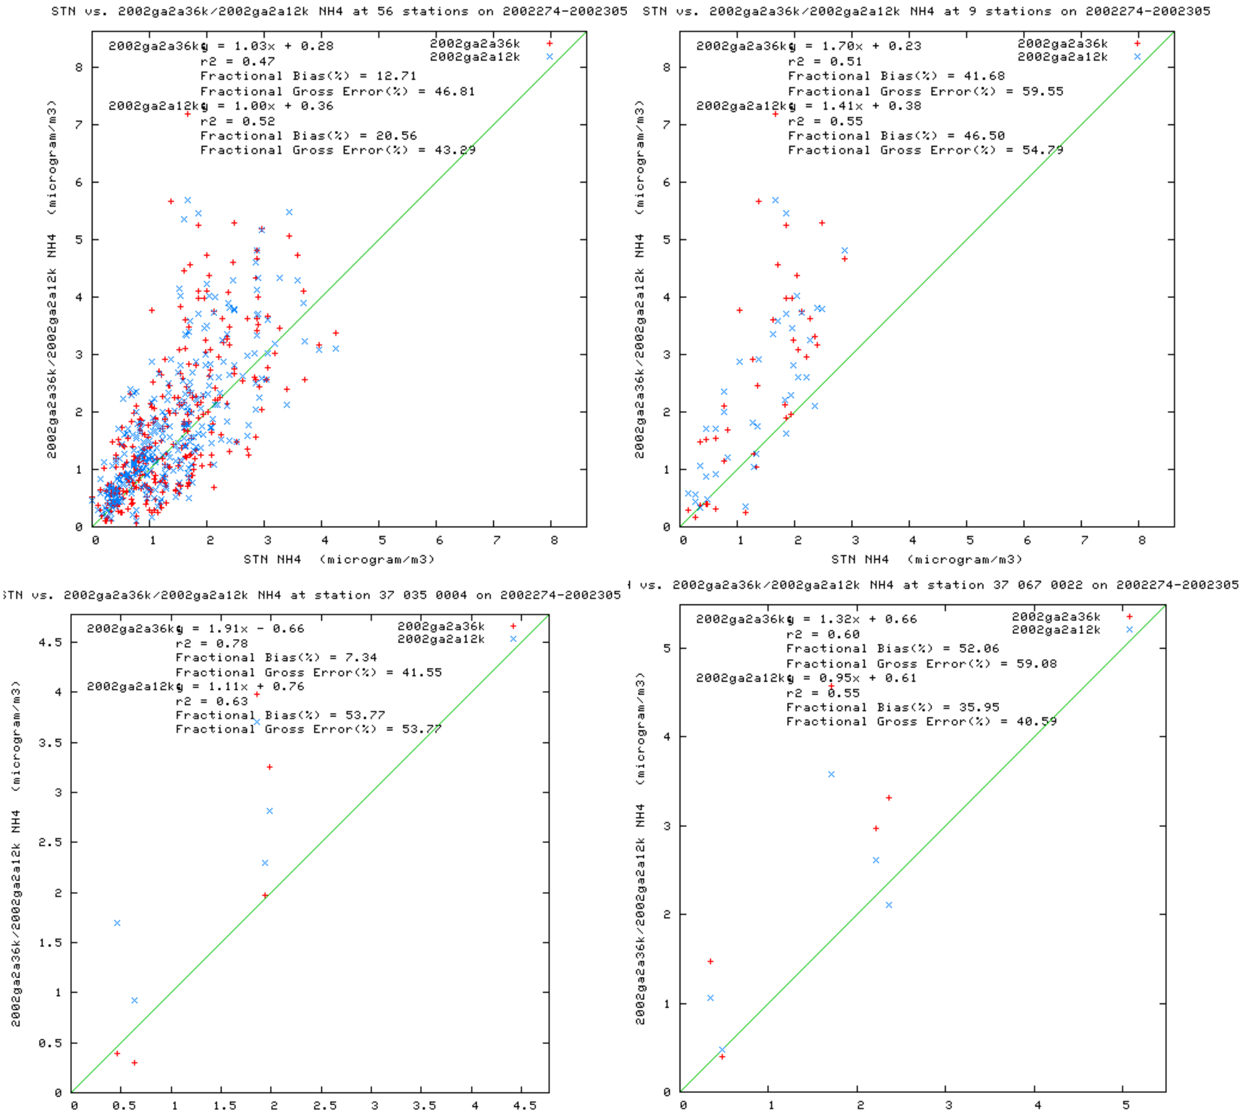

Figure 4-34: Scatter Plot of Observed Ammonium from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of October.

4.1.3.11 November

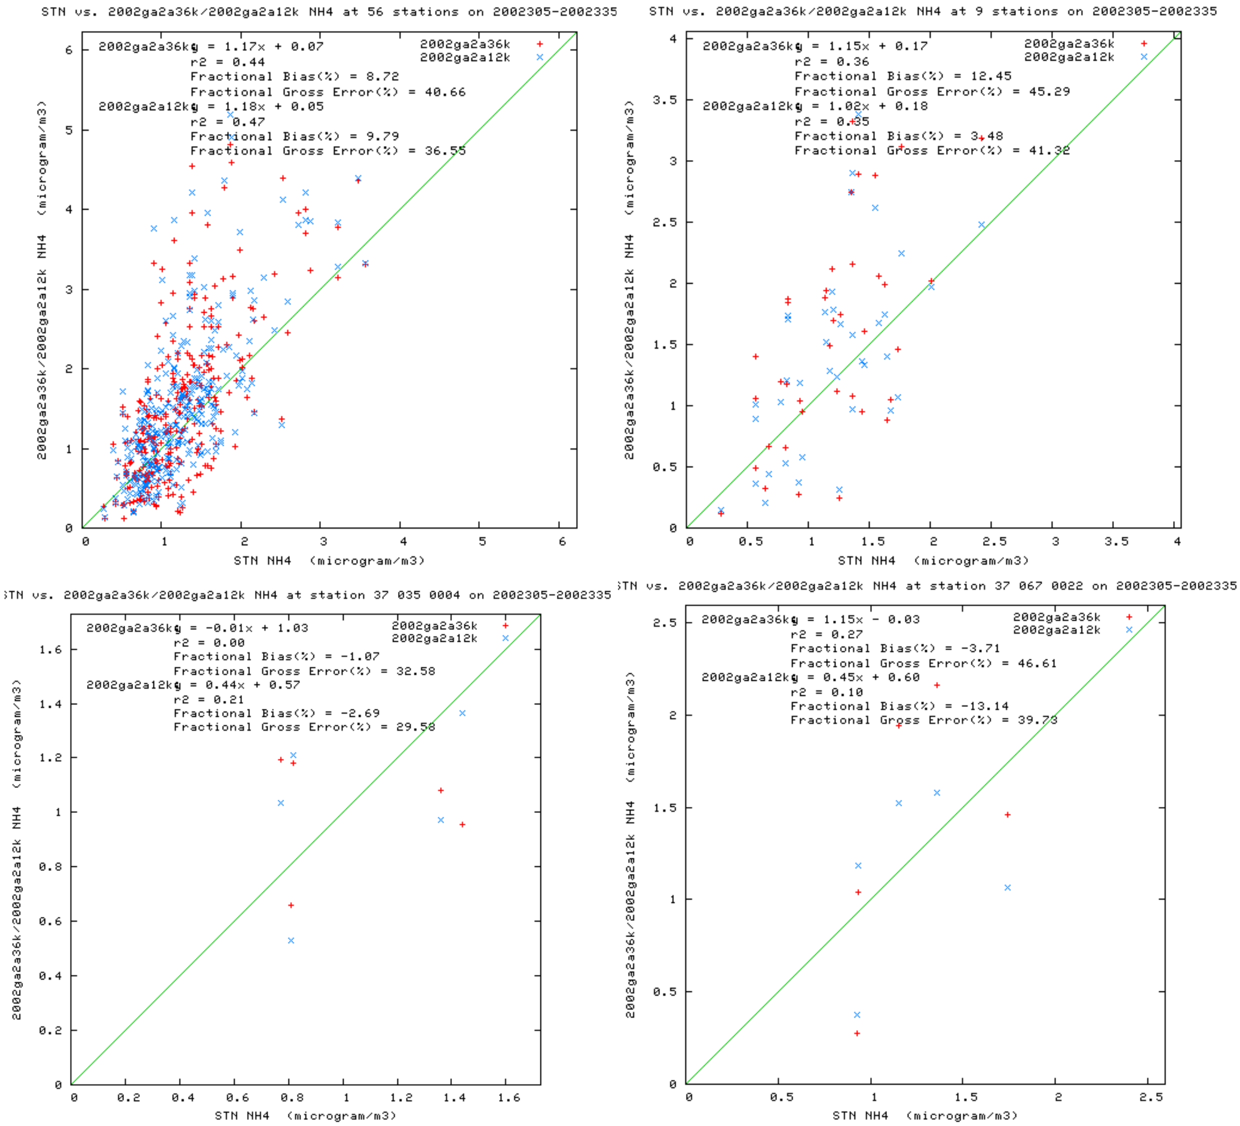

Figure 4-35: Scatter Plot of Observed Ammonium from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of November.

4.1.3.12 December

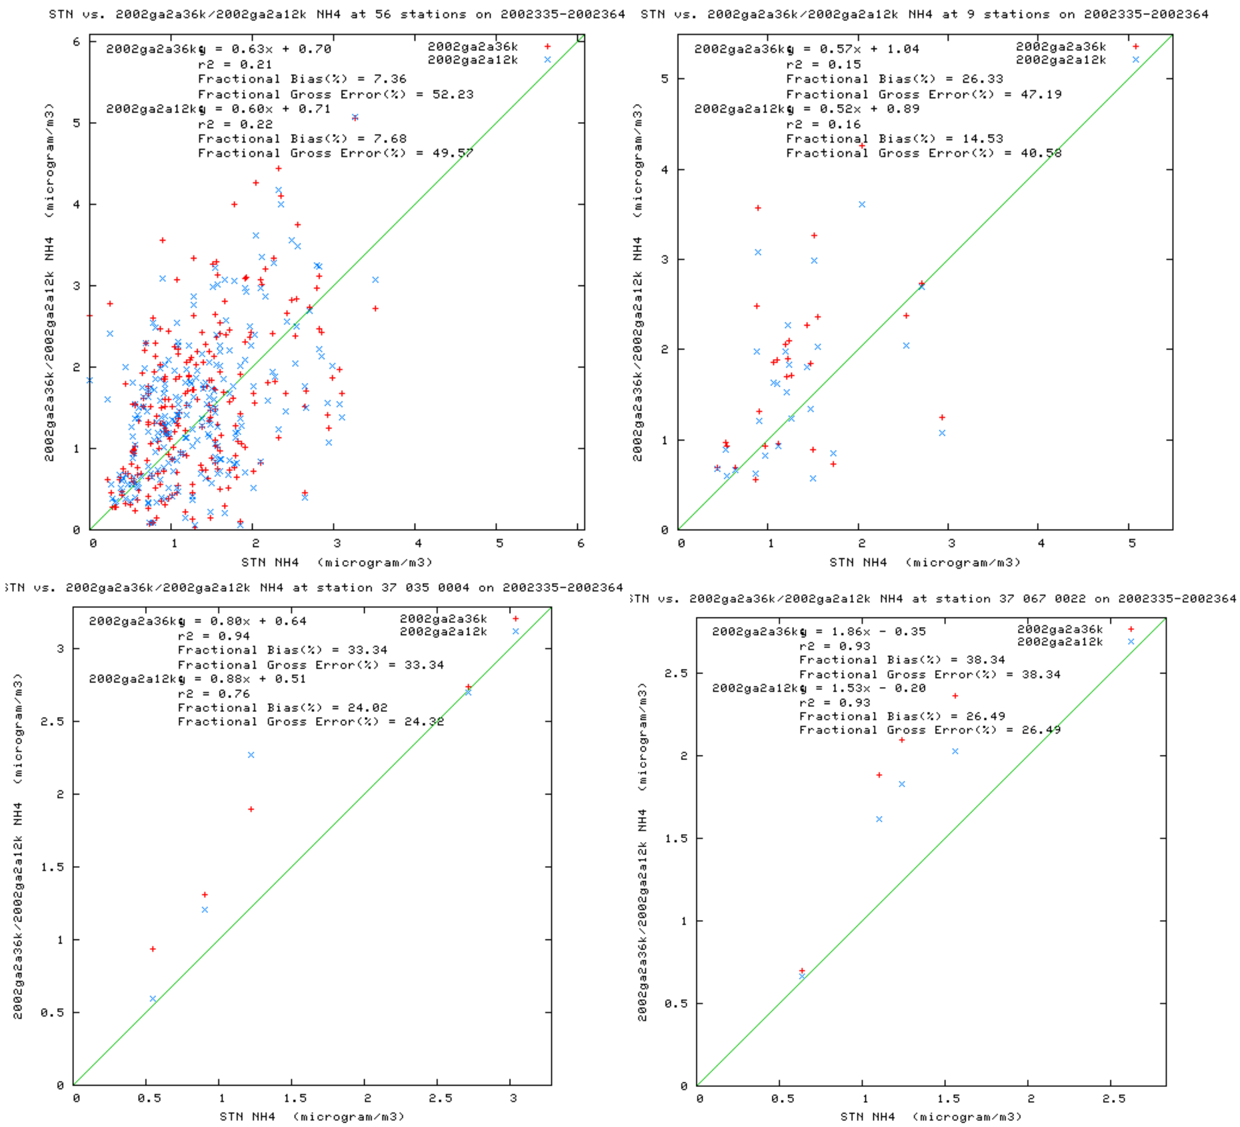

Figure 4-36: Scatter Plot of Observed Ammonium from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of December.

4.1.4 Organic Carbon

4.1.4.1 January

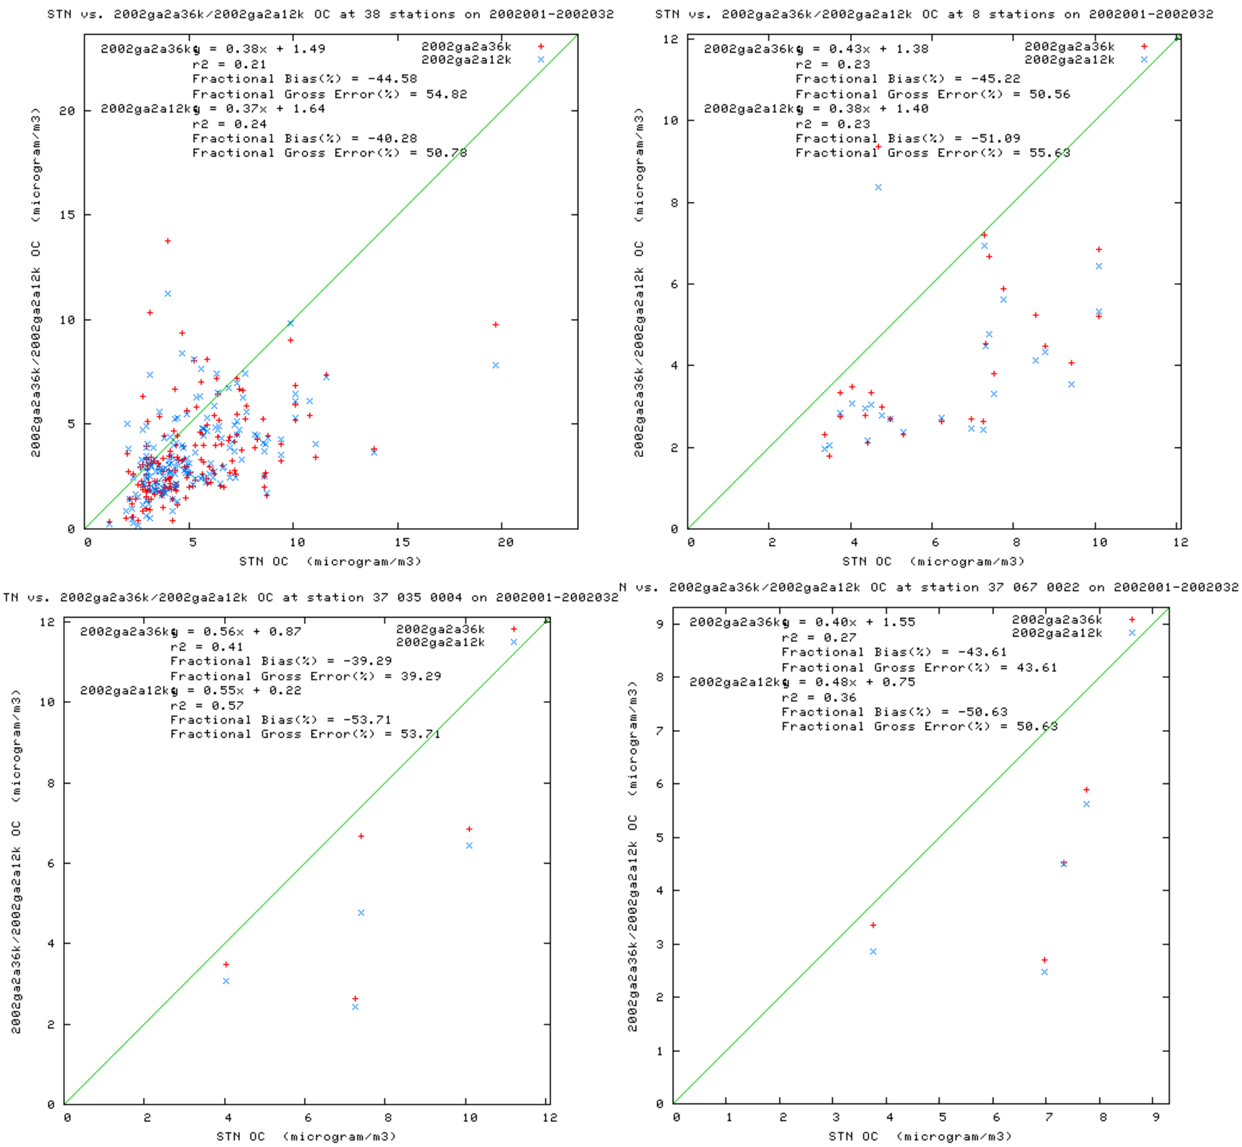

Figure 4-37: Scatter Plot of Observed Organic Carbon from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of January.

4.1.4.2 February

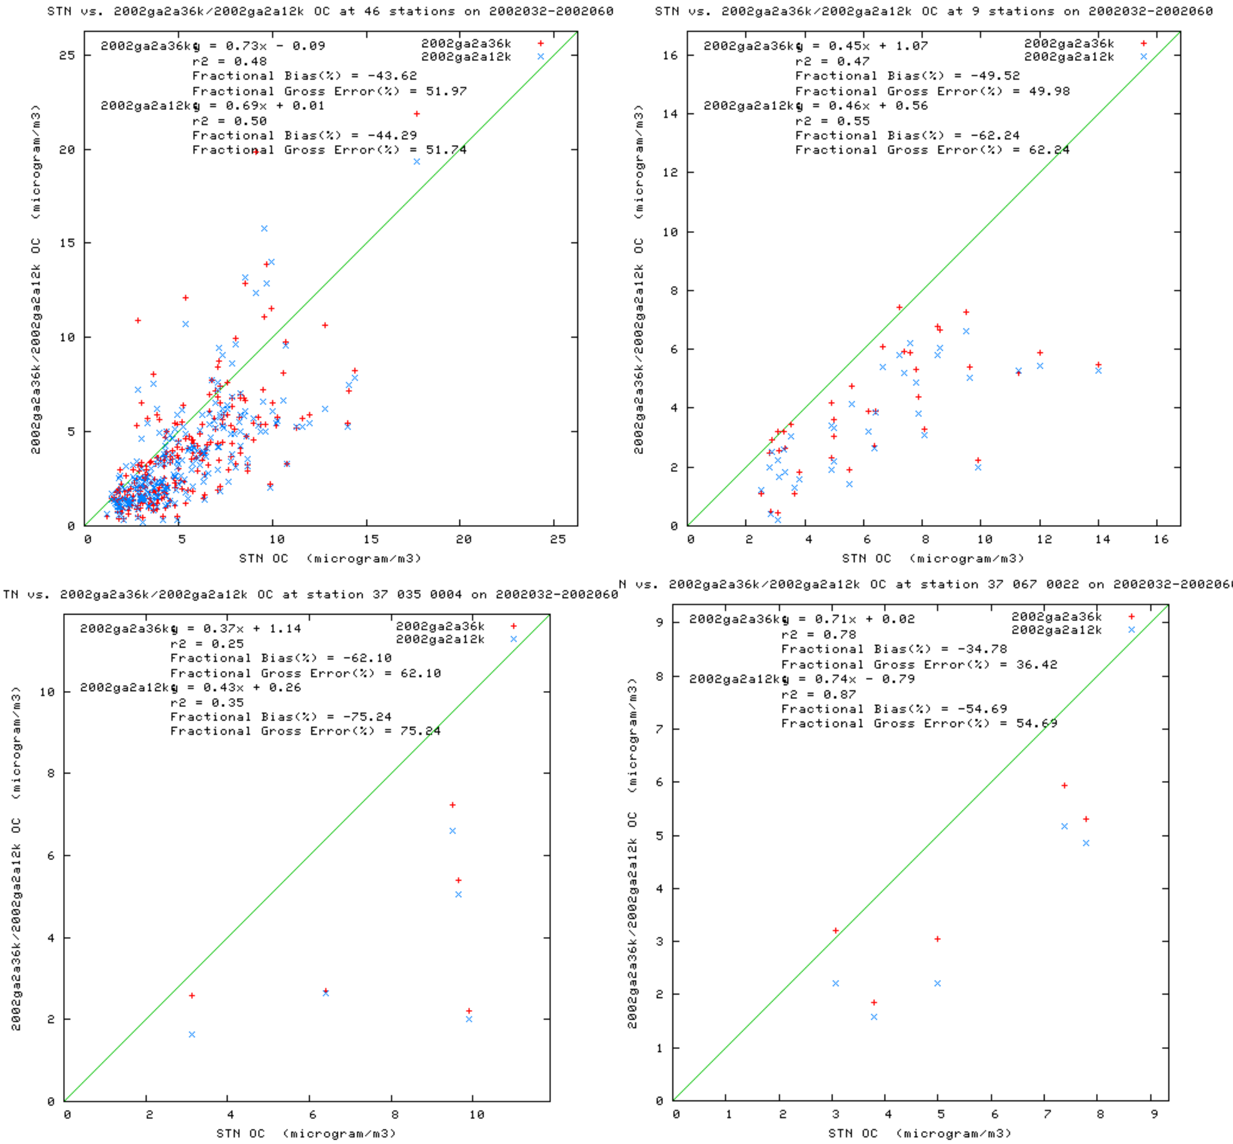

Figure 4-38: Scatter Plot of Observed Organic Carbon from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of February.

4.1.4.3 March

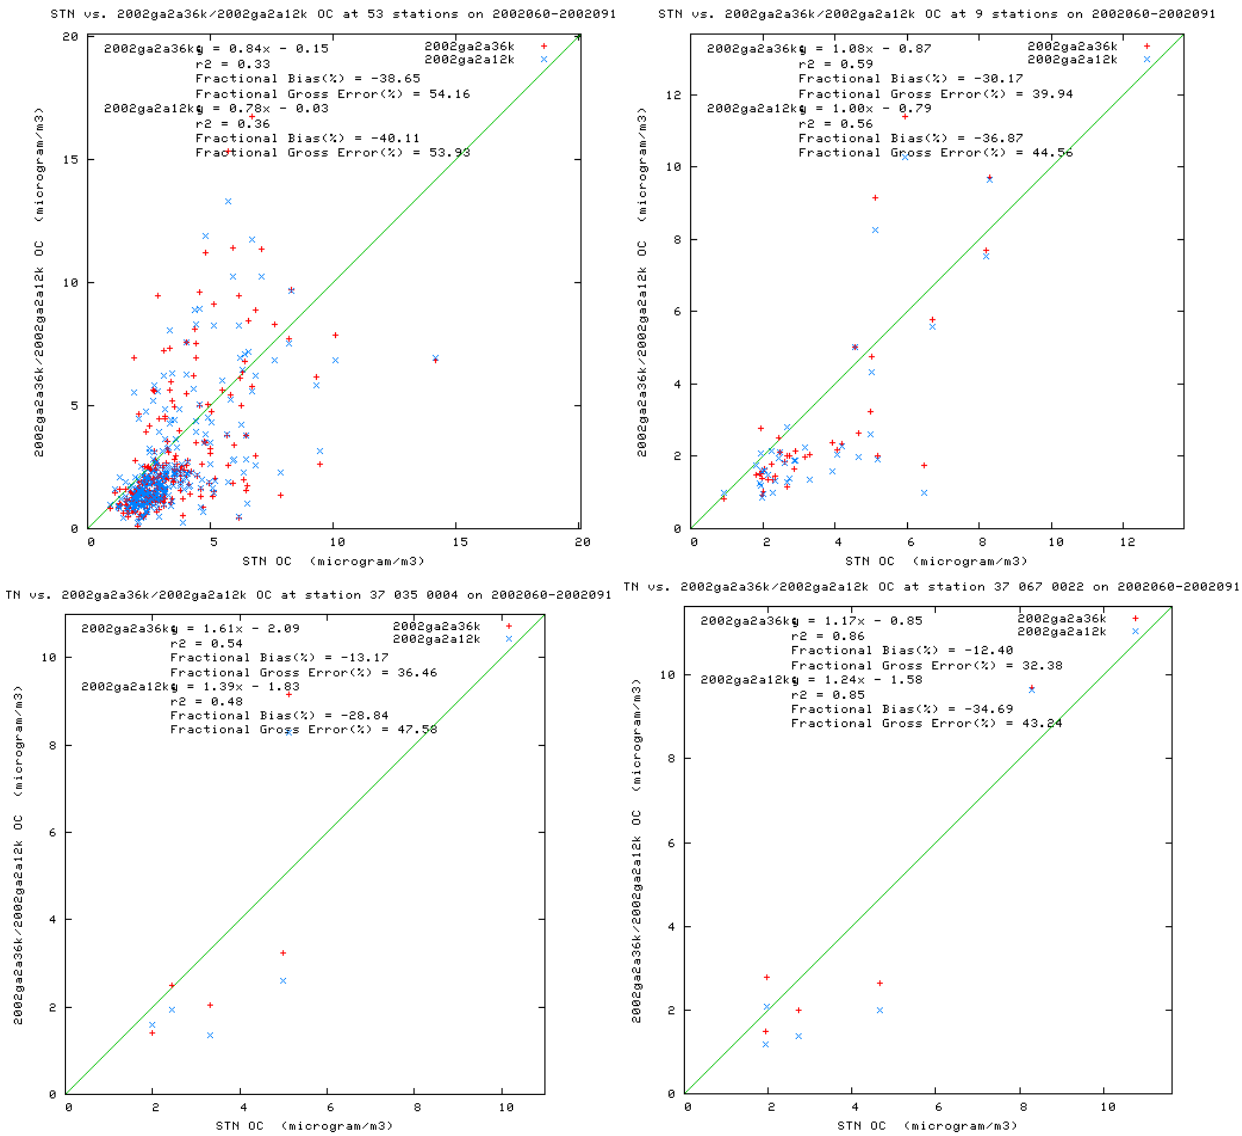

Figure 4-39: Scatter Plot of Observed Organic Carbon from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of March.

4.1.4.4 April

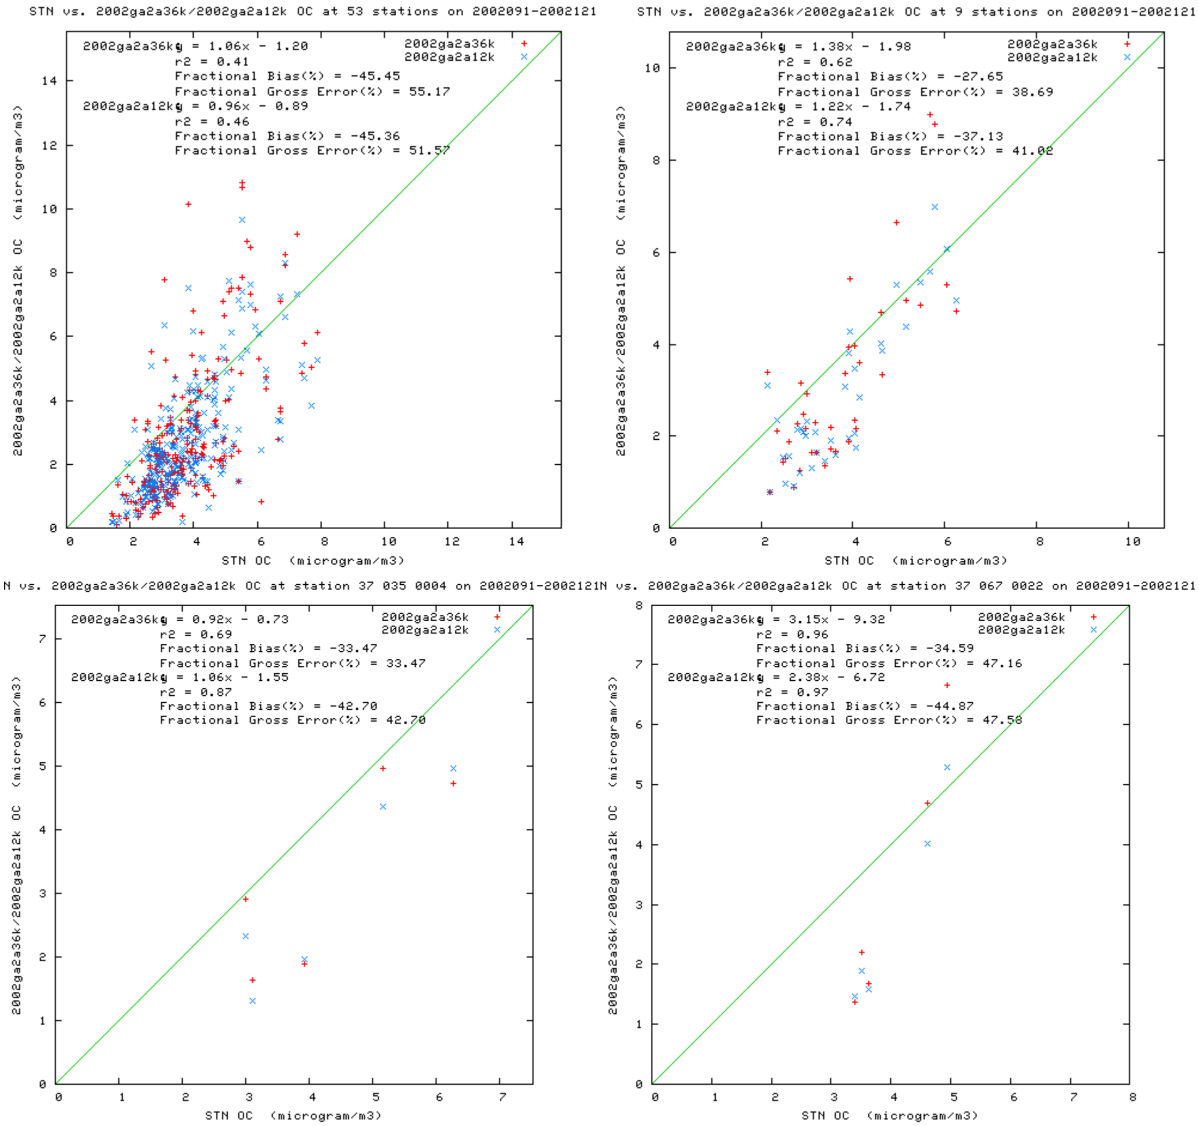

Figure 4-40: Scatter Plot of Observed Organic Carbon from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of April.

4.1.4.5 May

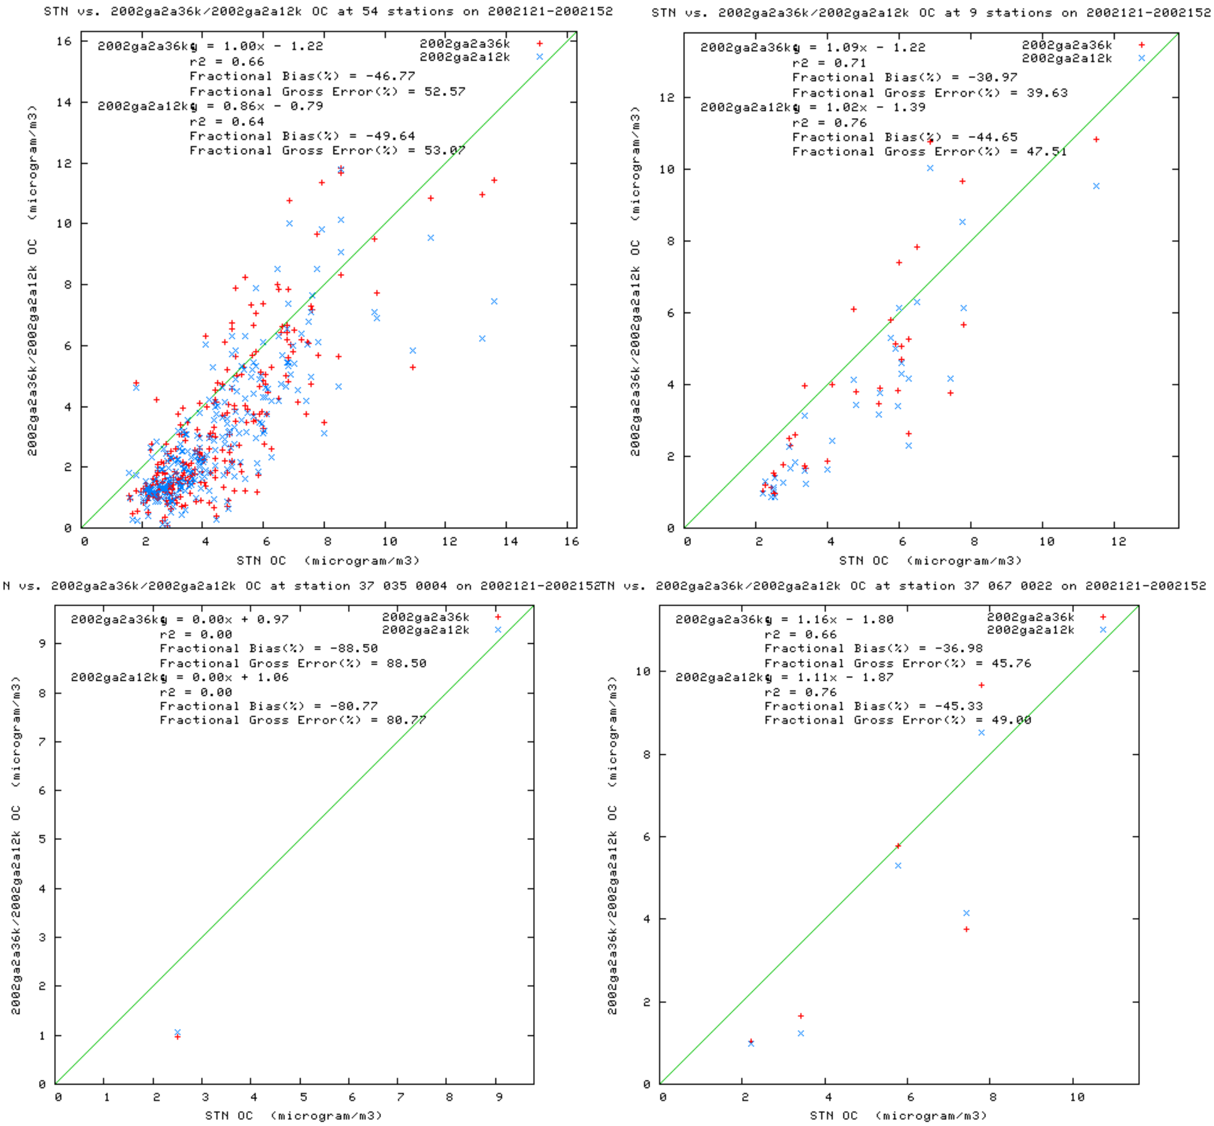

Figure 4-41: Scatter Plot of Observed Organic Carbon from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of May.

4.1.4.6 June

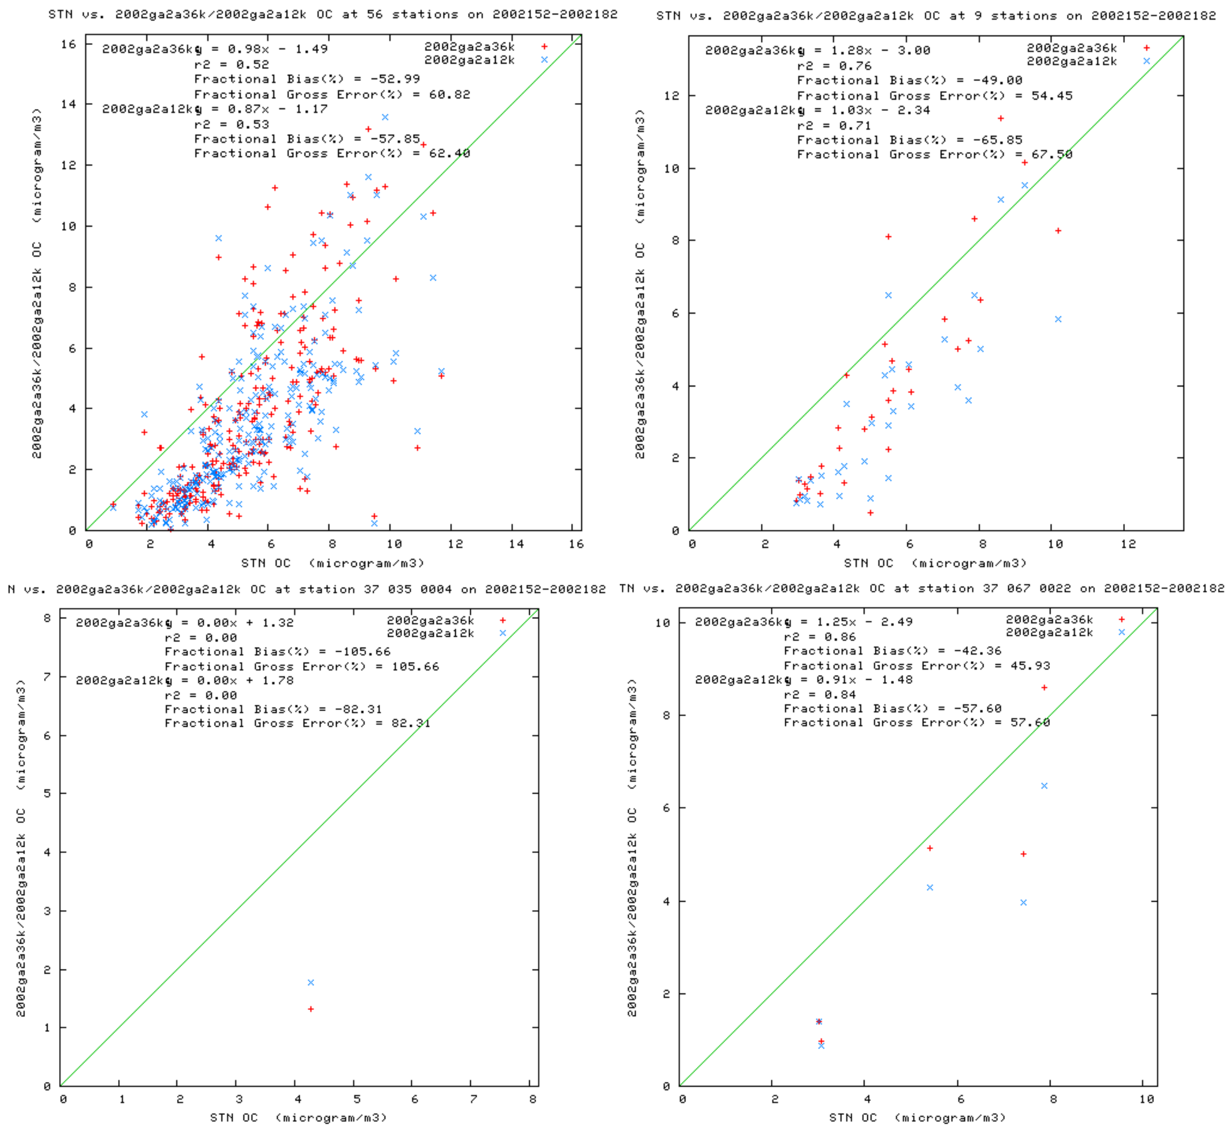

Figure 4-42: Scatter Plot of Observed Organic Carbon from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of June.

4.1.4.7 July

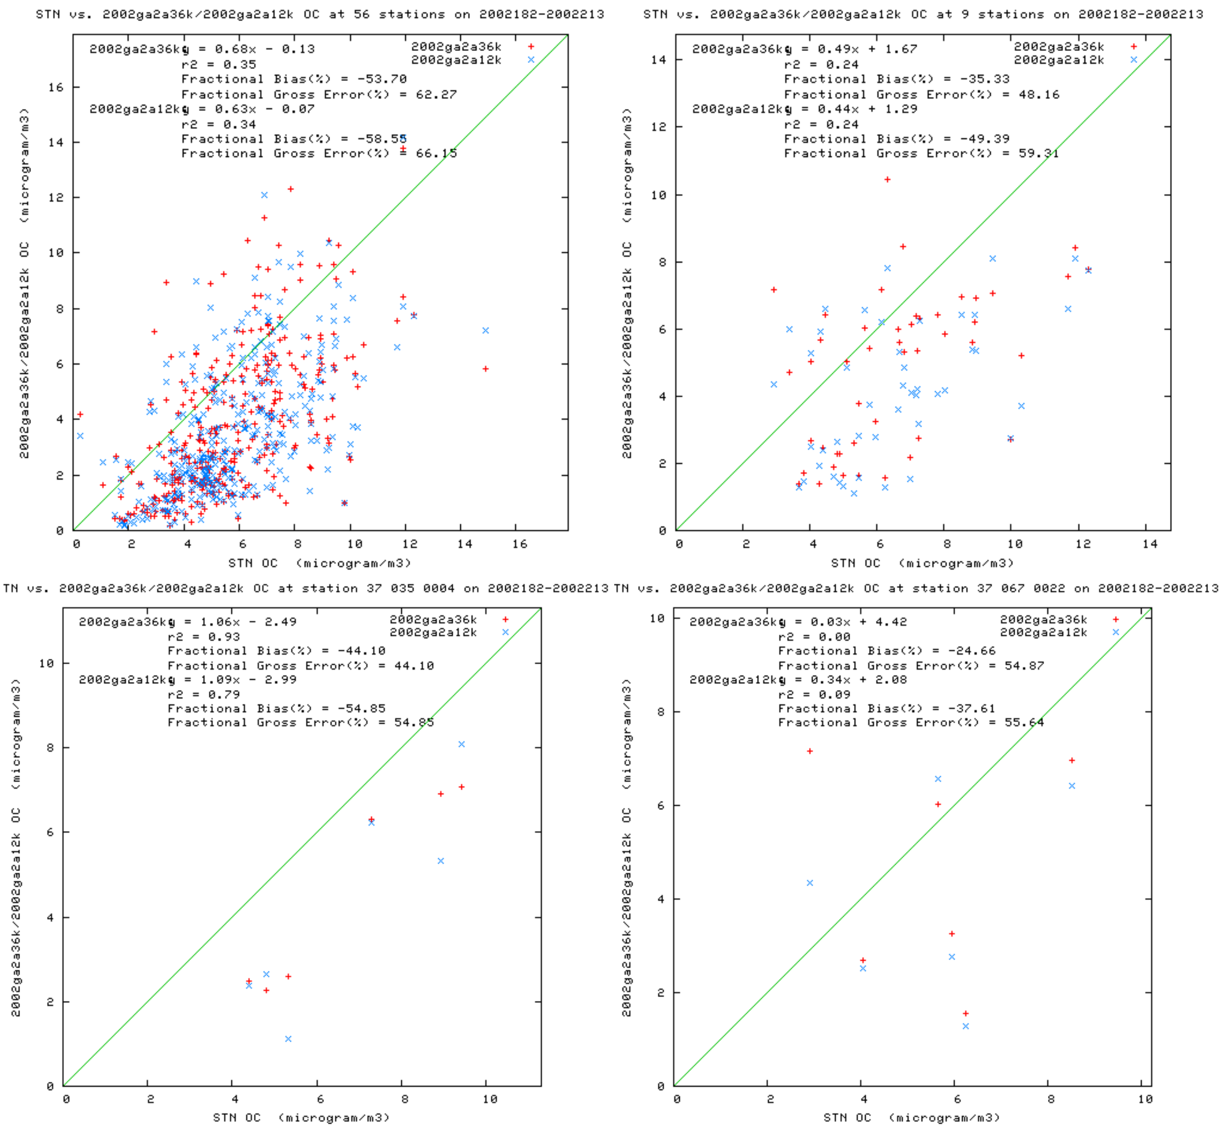

Figure 4-43: Scatter Plot of Observed Organic Carbon from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of July.

4.1.4.8 August

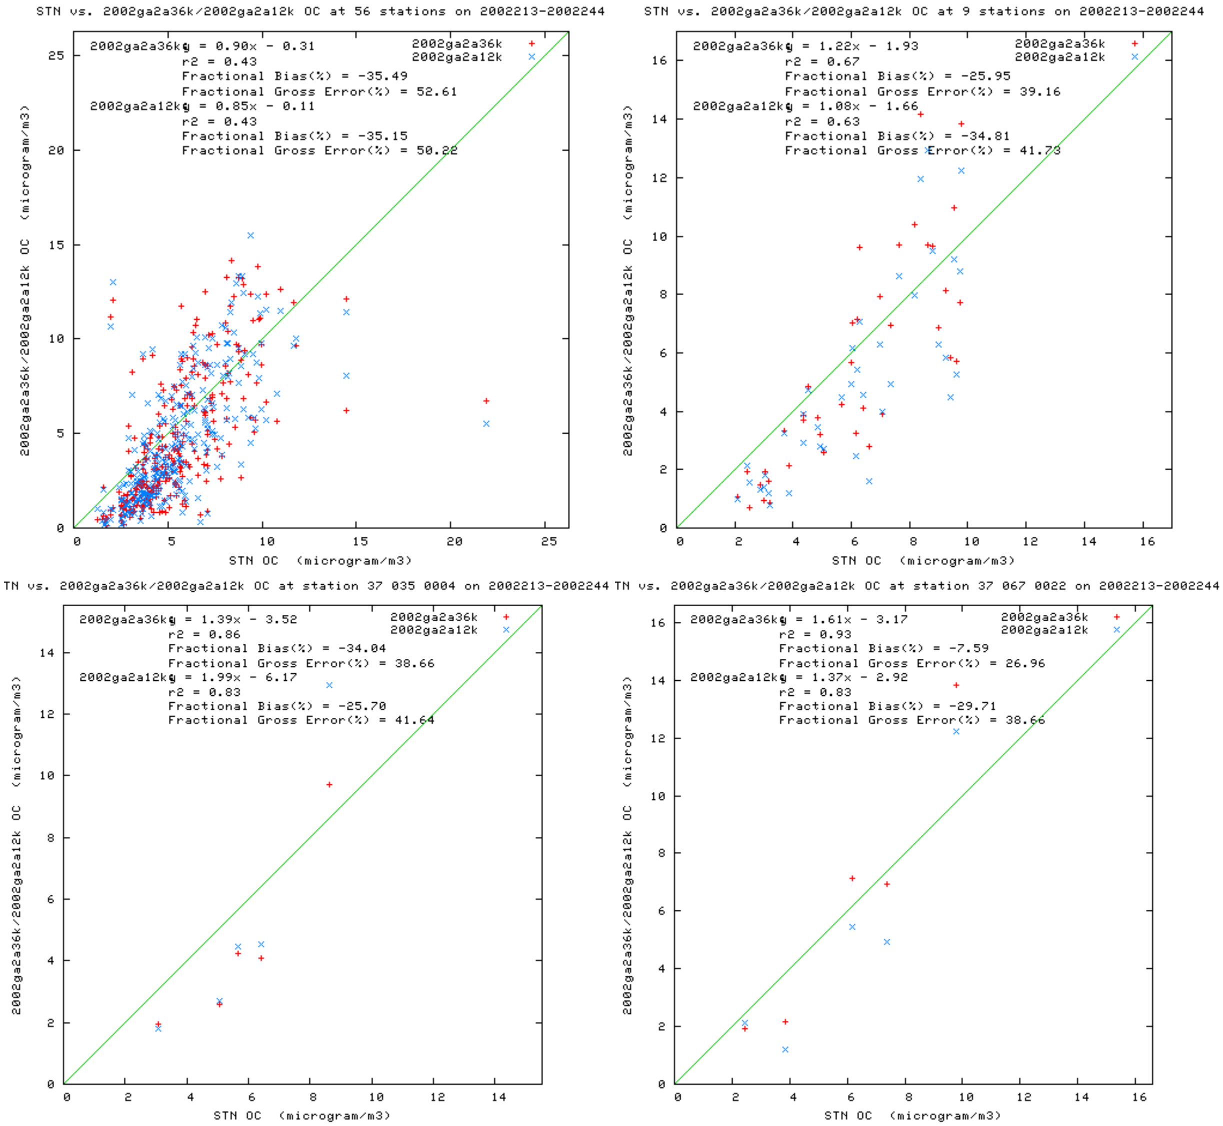

Figure 4-44: Scatter Plot of Observed Organic Carbon from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of August.

4.1.4.9 September

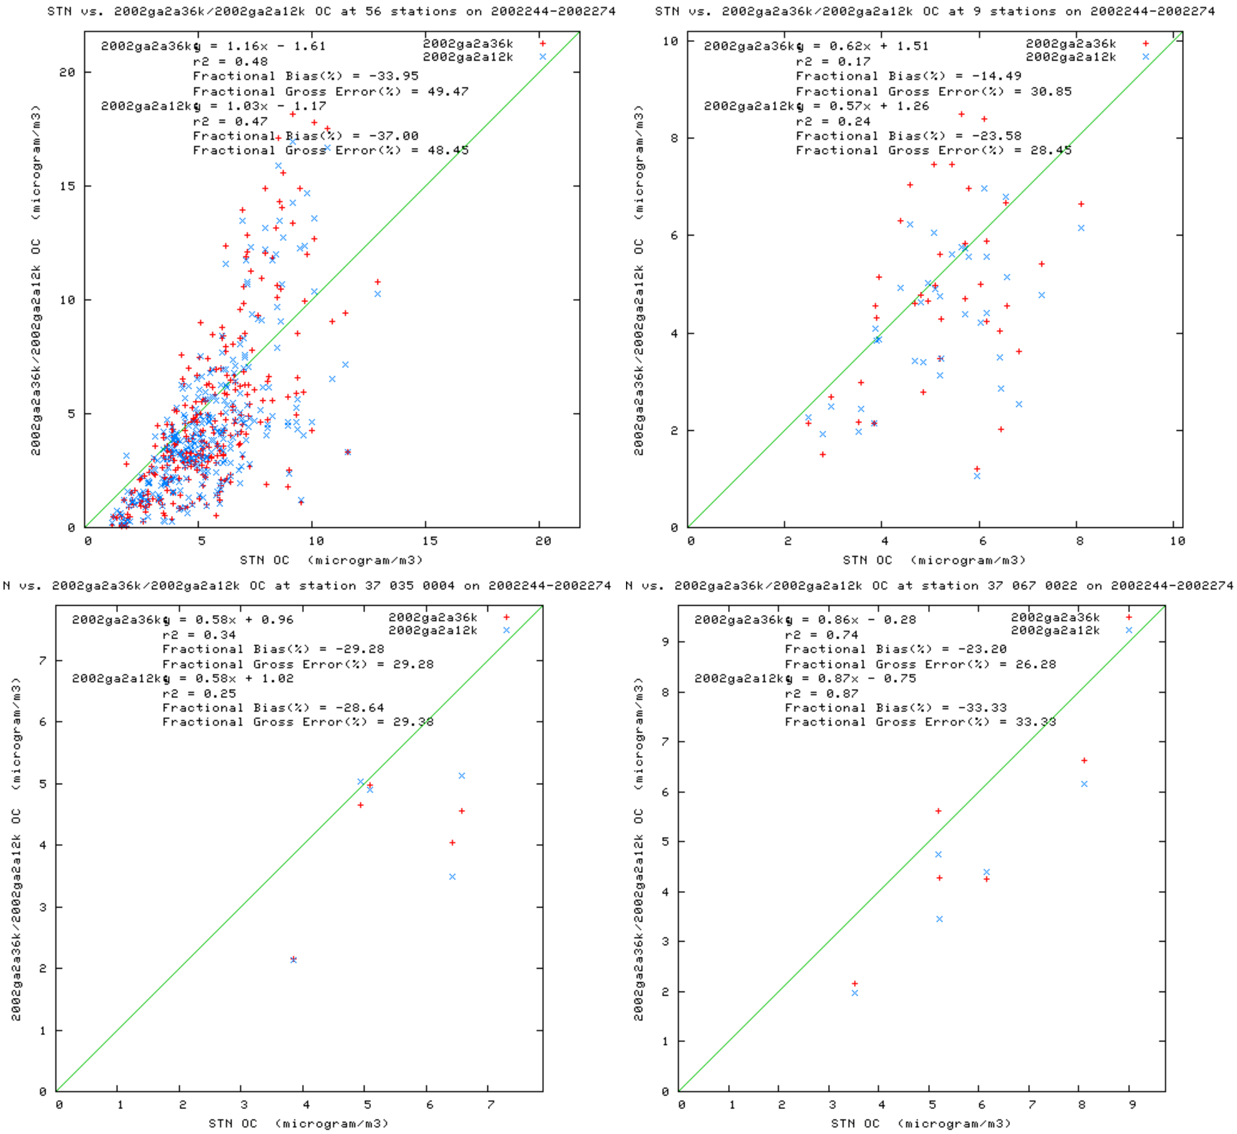

Figure 4-45: Scatter Plot of Observed Organic Carbon from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of September.

4.1.4.10 October

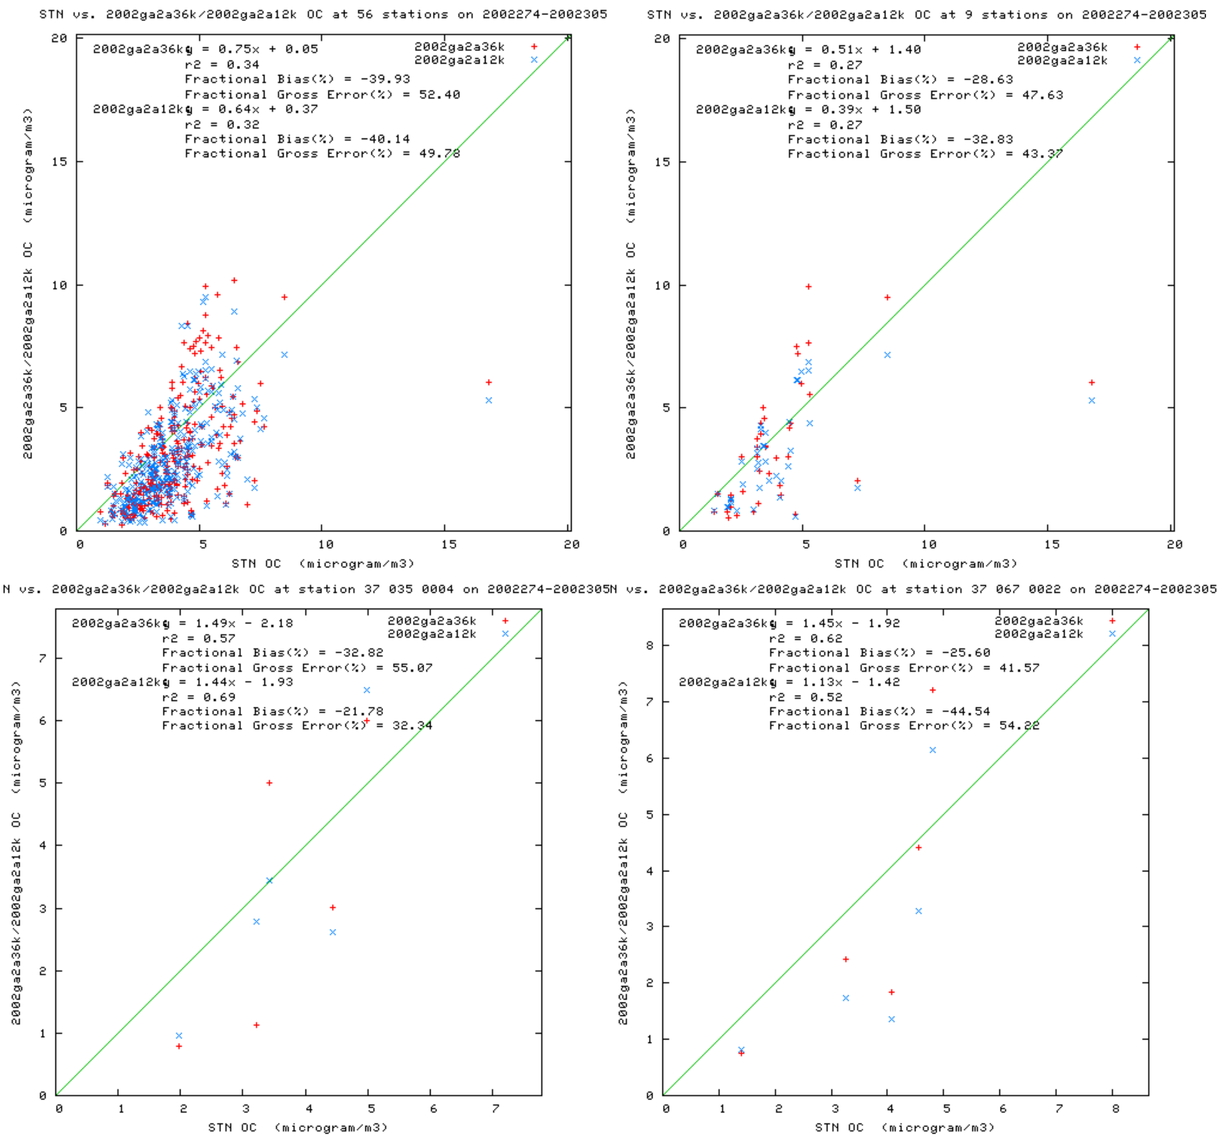

Figure 4-46: Scatter Plot of Observed Organic Carbon from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of October.

4.1.4.11 November

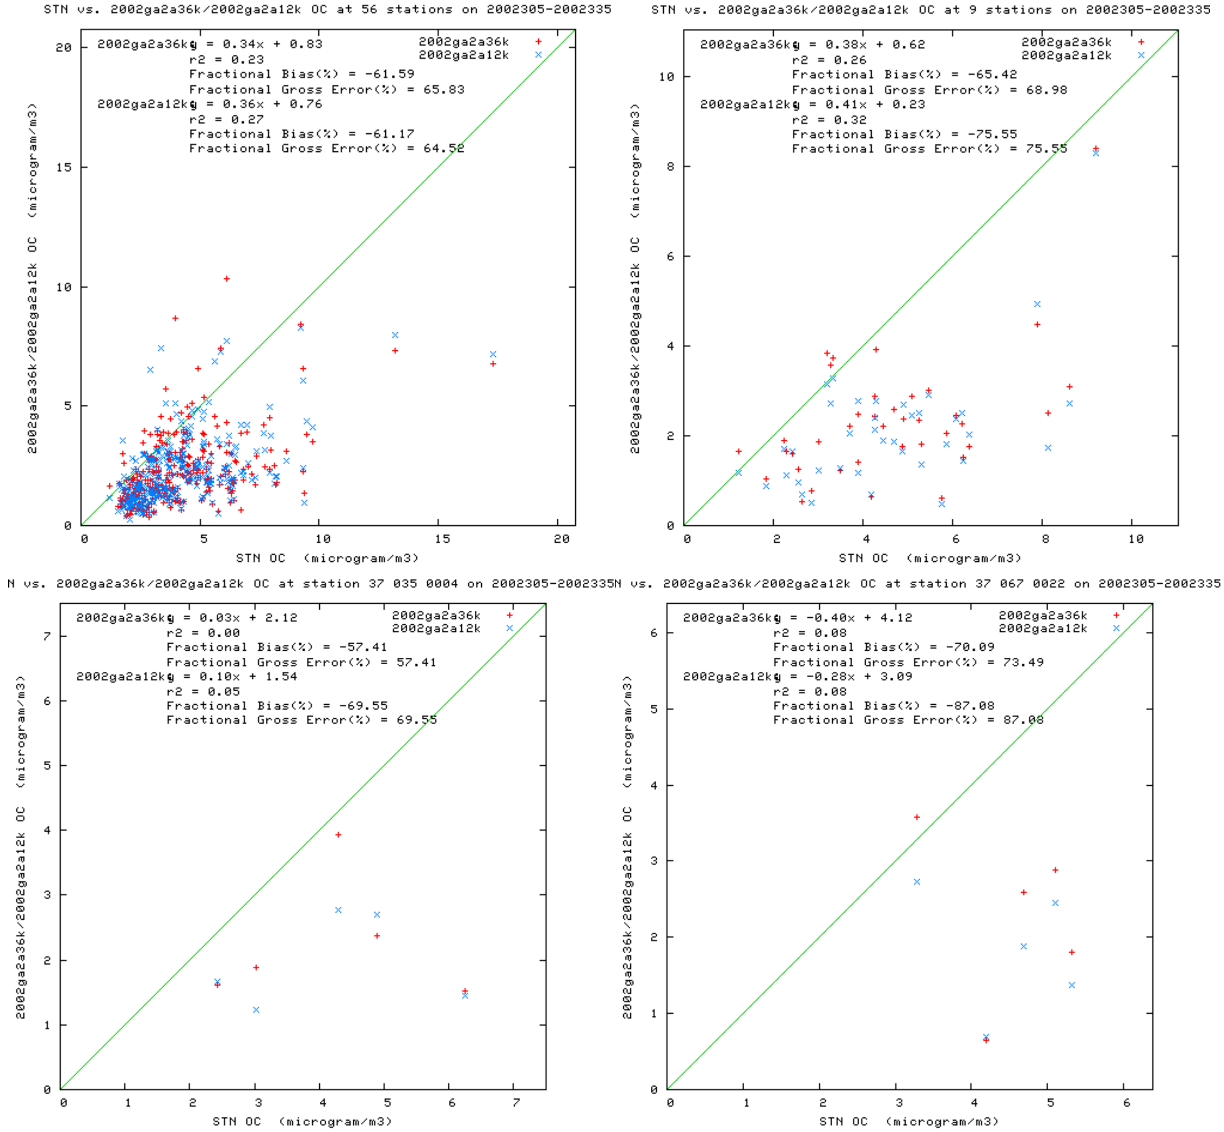

Figure 4-47: Scatter Plot of Observed Organic Carbon from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of November.

4.1.4.12 December

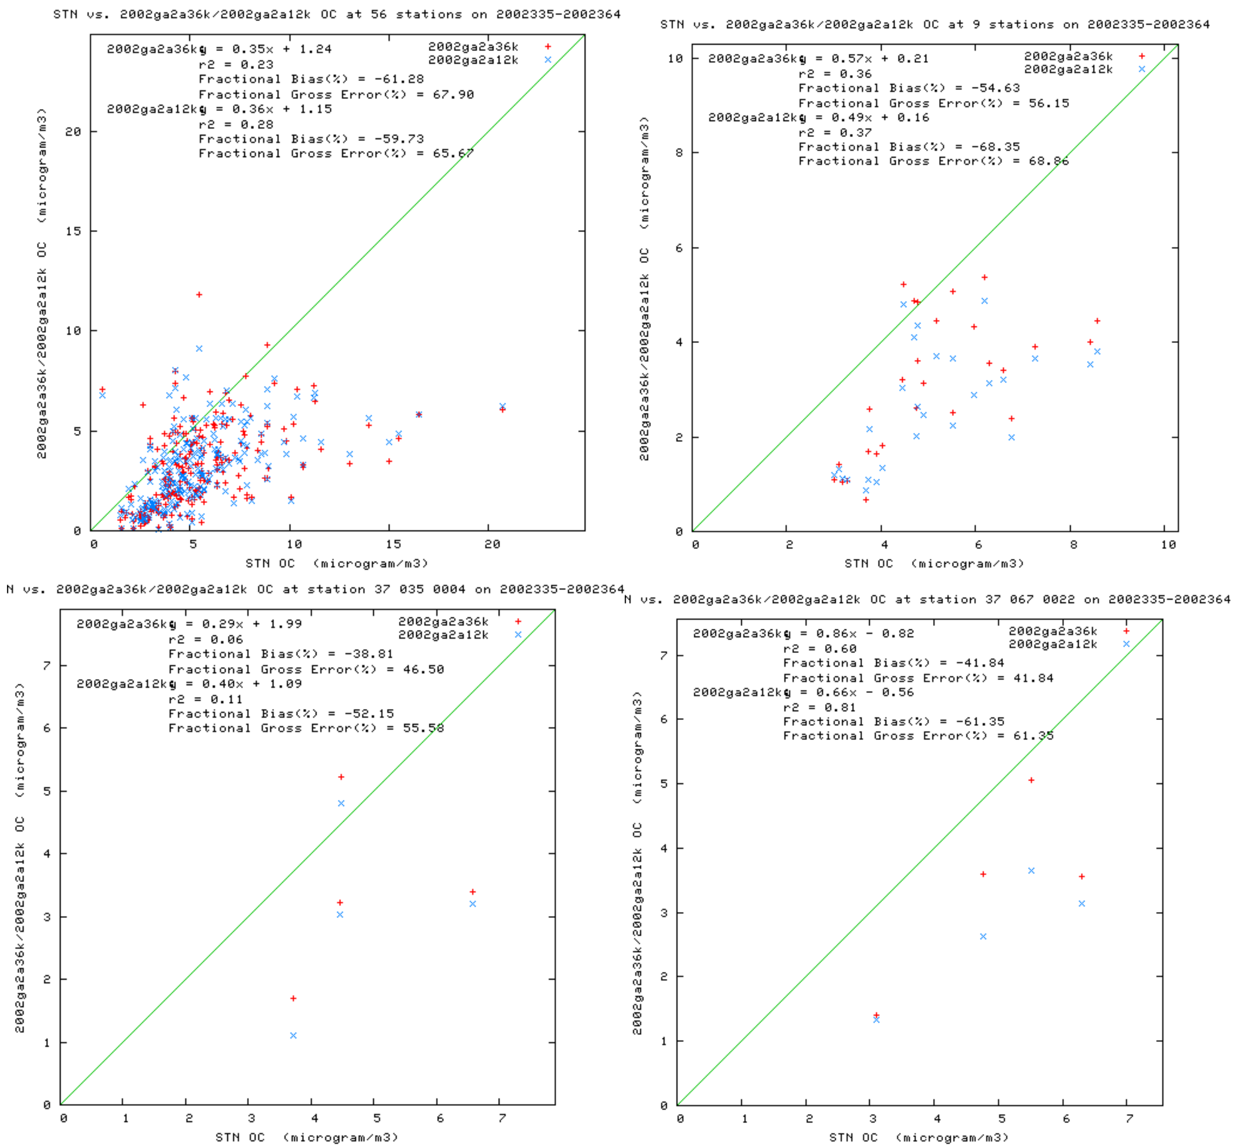

Figure 4-48: Scatter Plot of Observed Organic Carbon from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of December.

4.1.5 Elemental Carbon

4.1.5.1 January

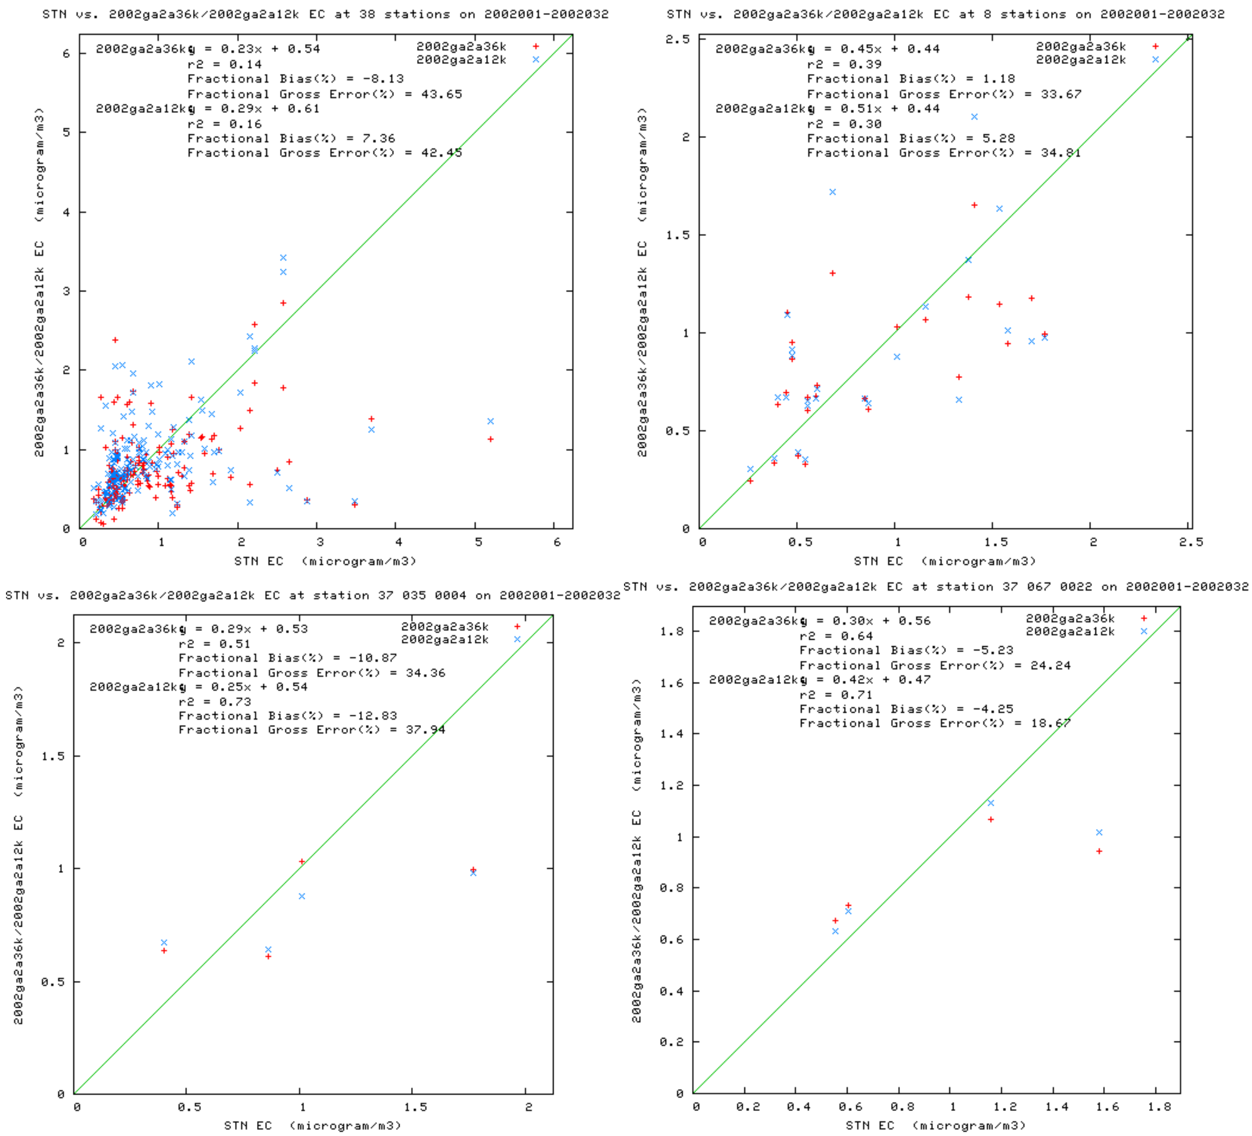

Figure 4-49: Scatter Plot of Observed Elemental Carbon from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of January.

4.1.5.2 February

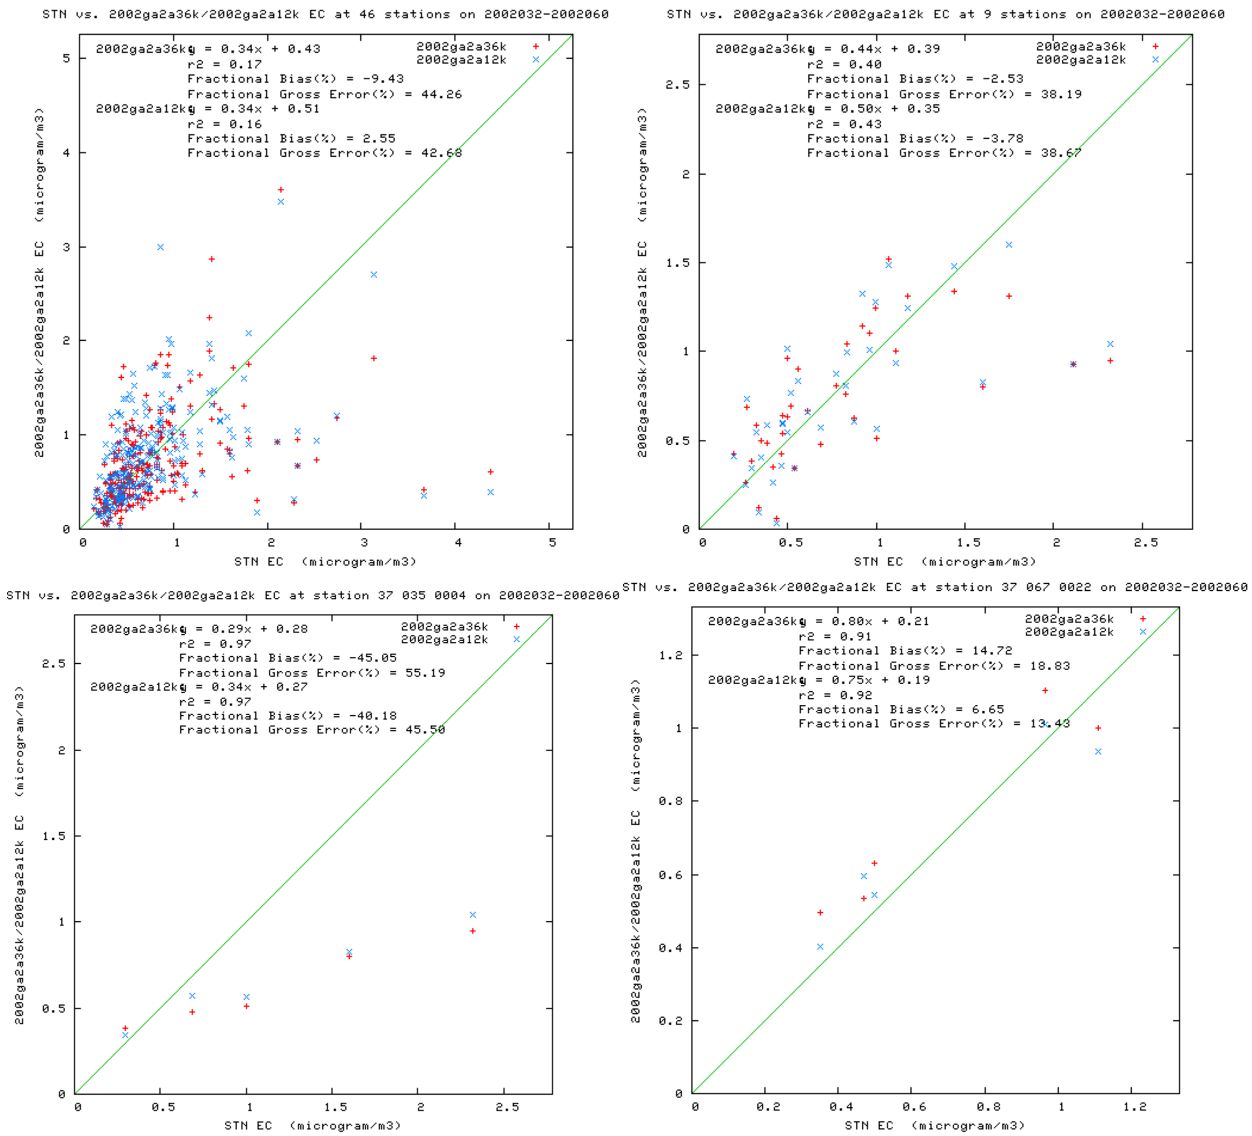

Figure 4-50: Scatter Plot of Observed Elemental Carbon from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of February.

4.1.5.3 March

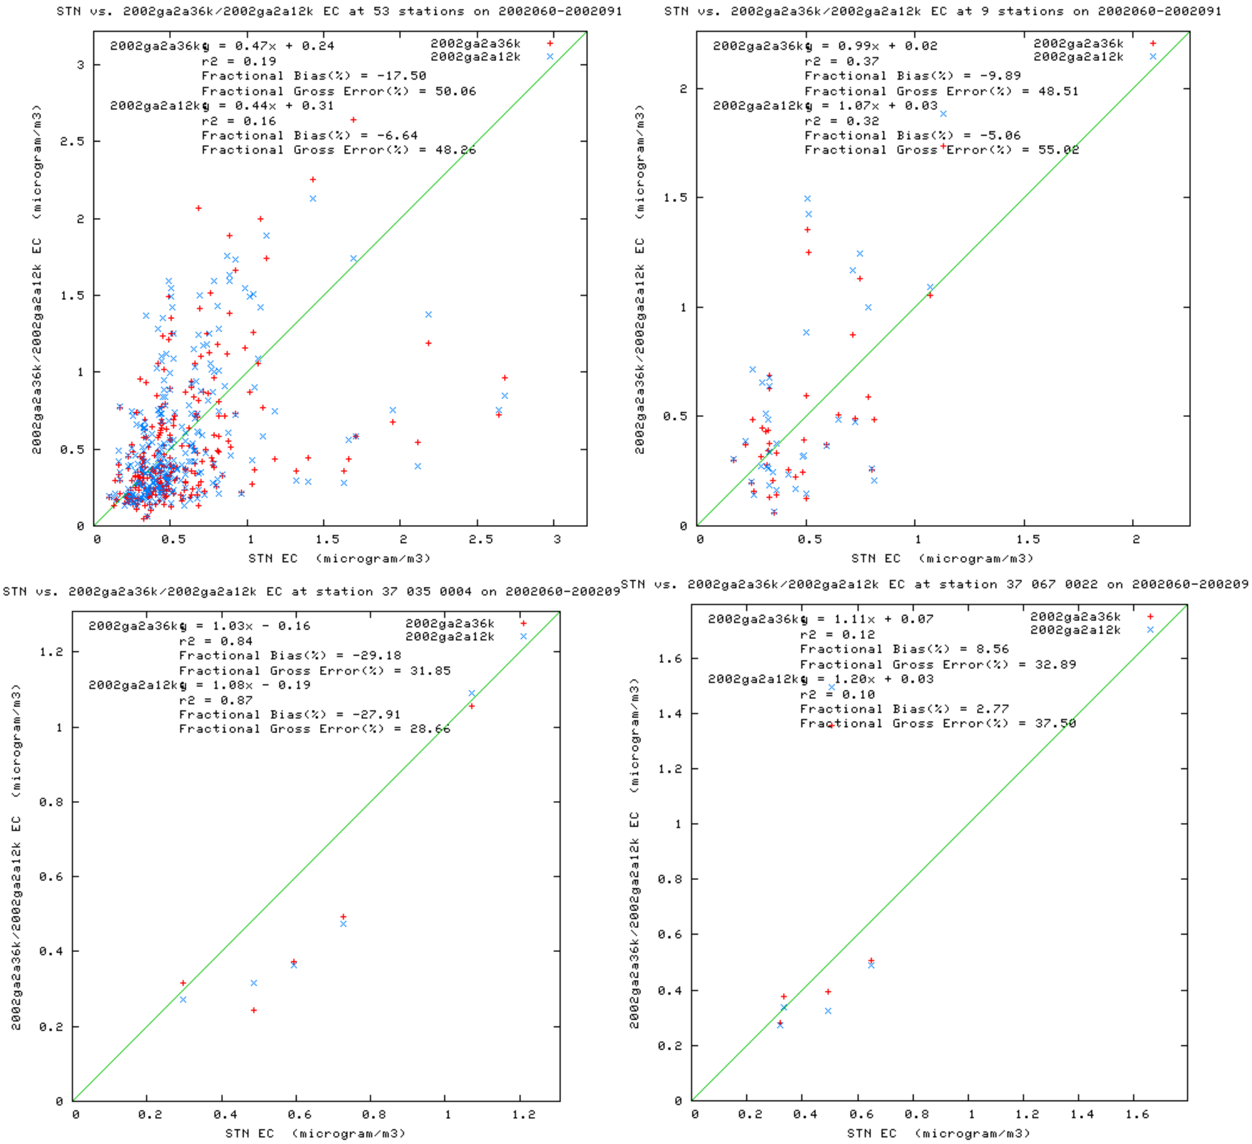

Figure 4-51: Scatter Plot of Observed Elemental Carbon from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of March.

4.1.5.4 April

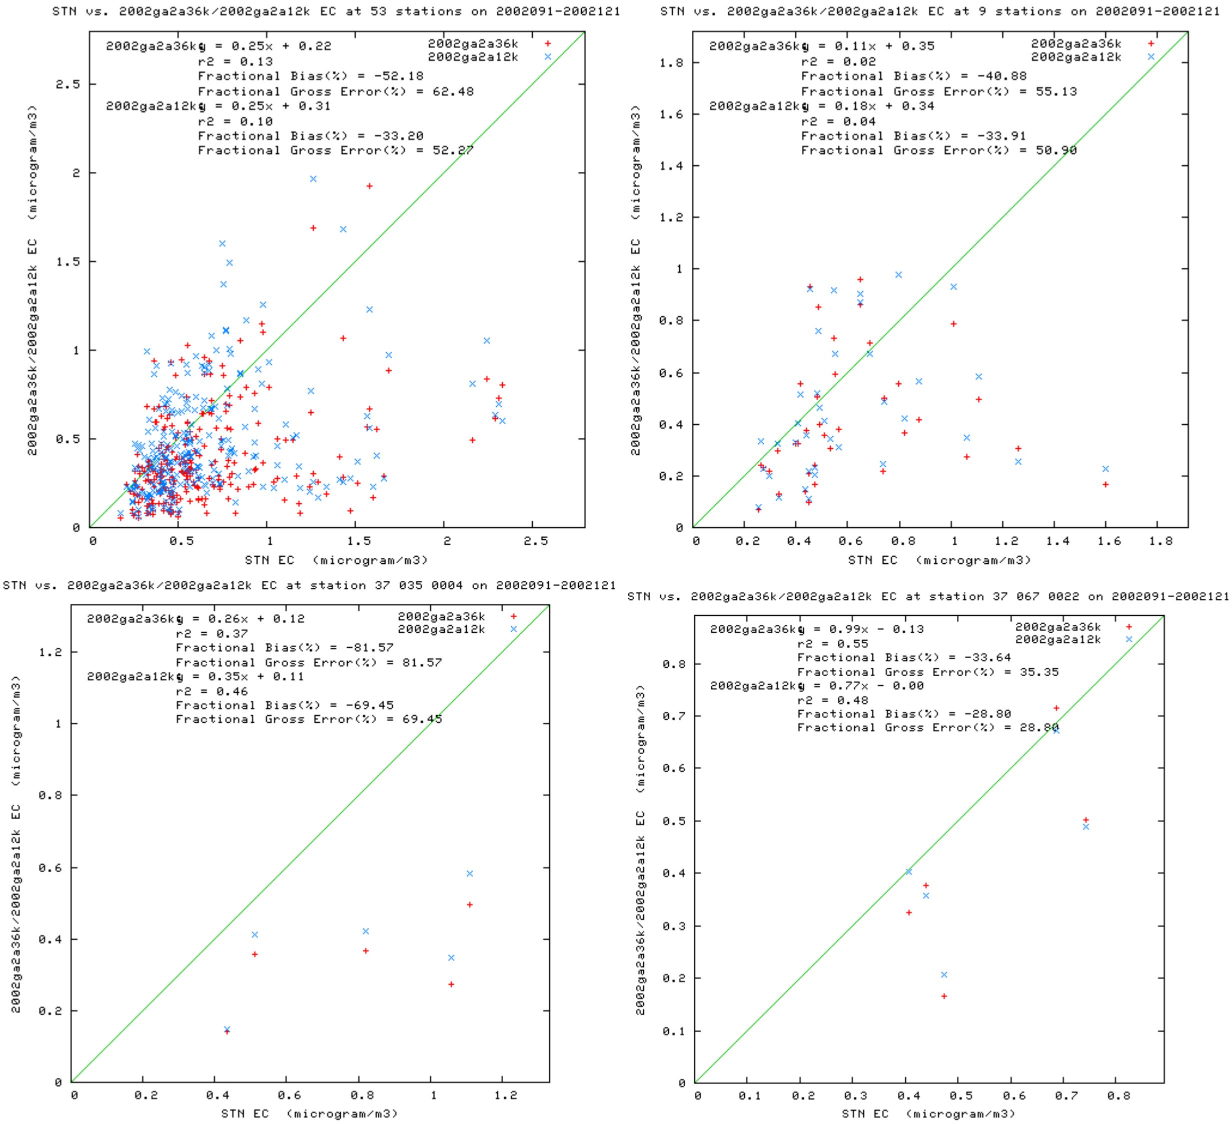

Figure 4-52: Scatter Plot of Observed Elemental Carbon from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of April.

4.1.5.5 May

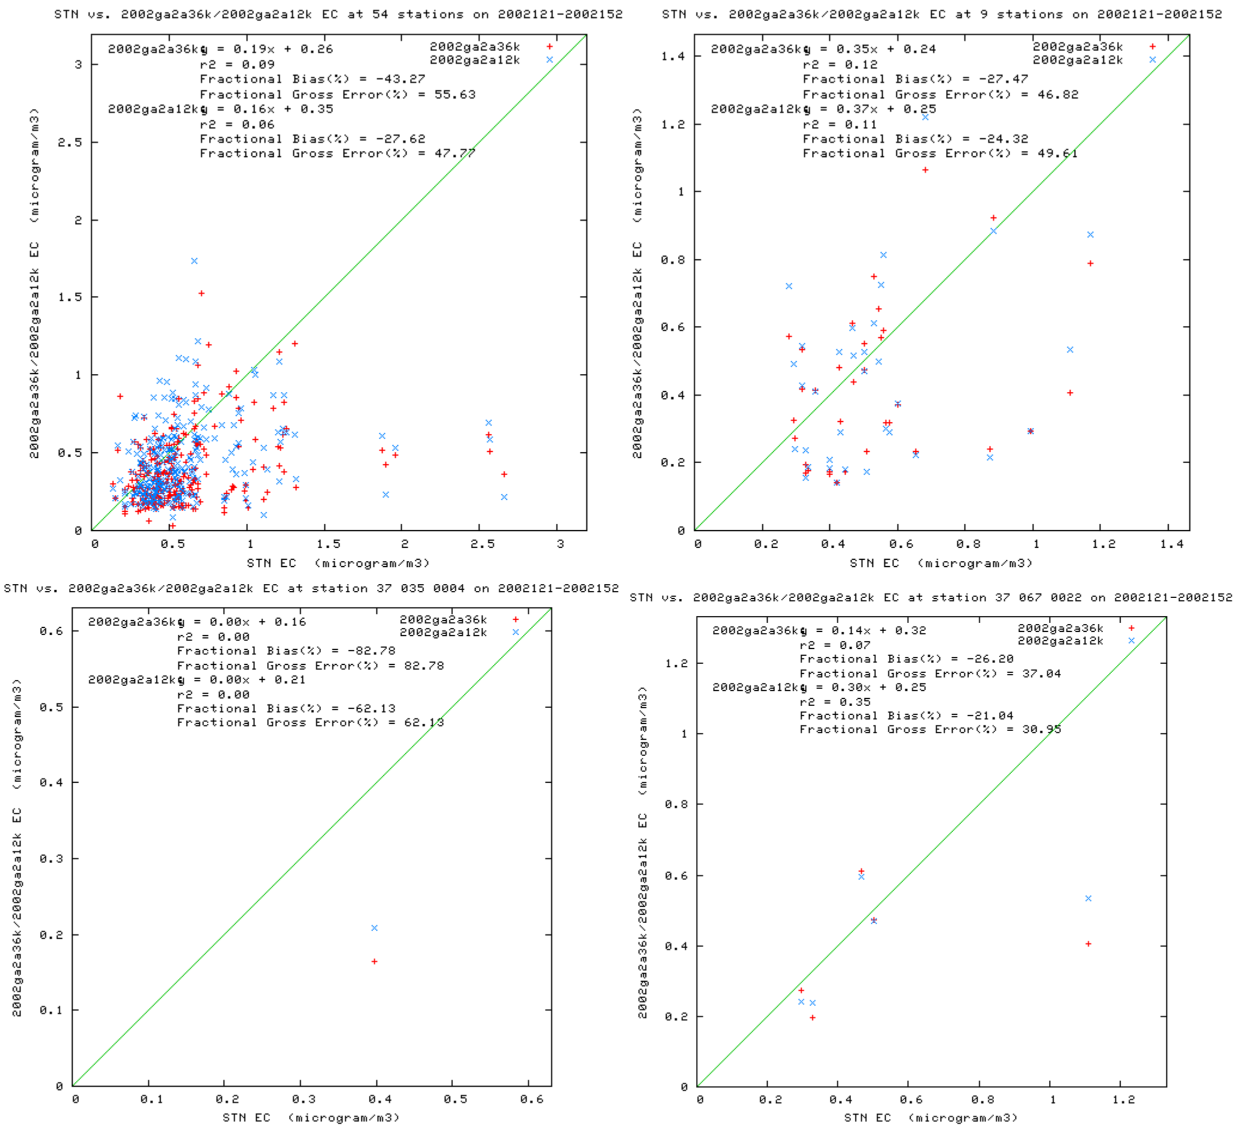

Figure 4-53: Scatter Plot of Observed Elemental Carbon from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of May.

4.1.5.6 June

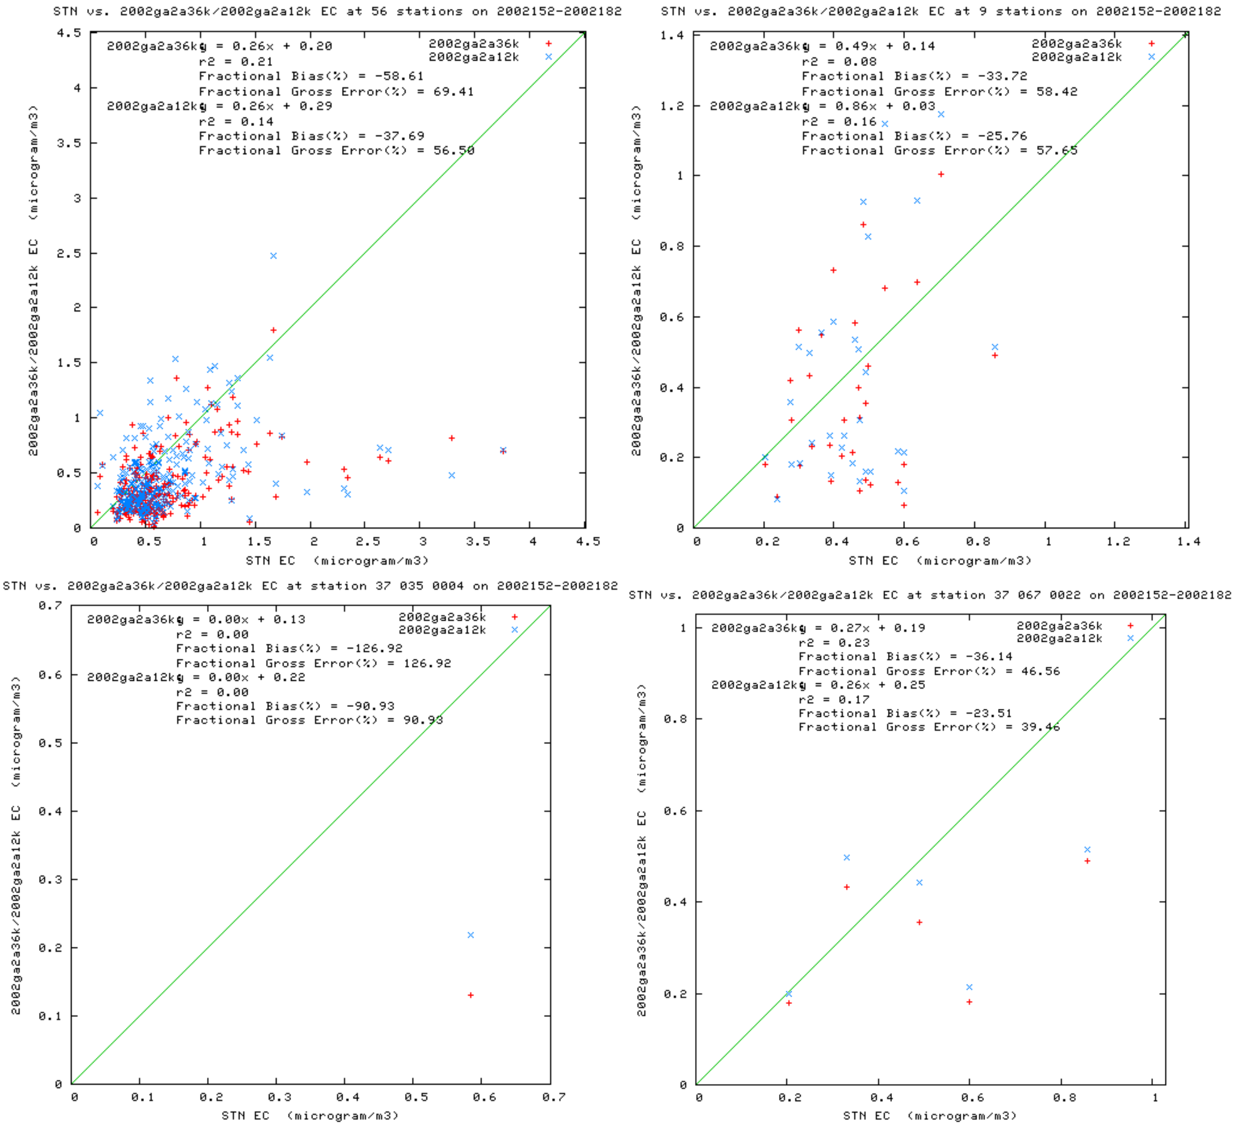

Figure 4-54: Scatter Plot of Observed Elemental Carbon from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of June.

4.1.5.7 July

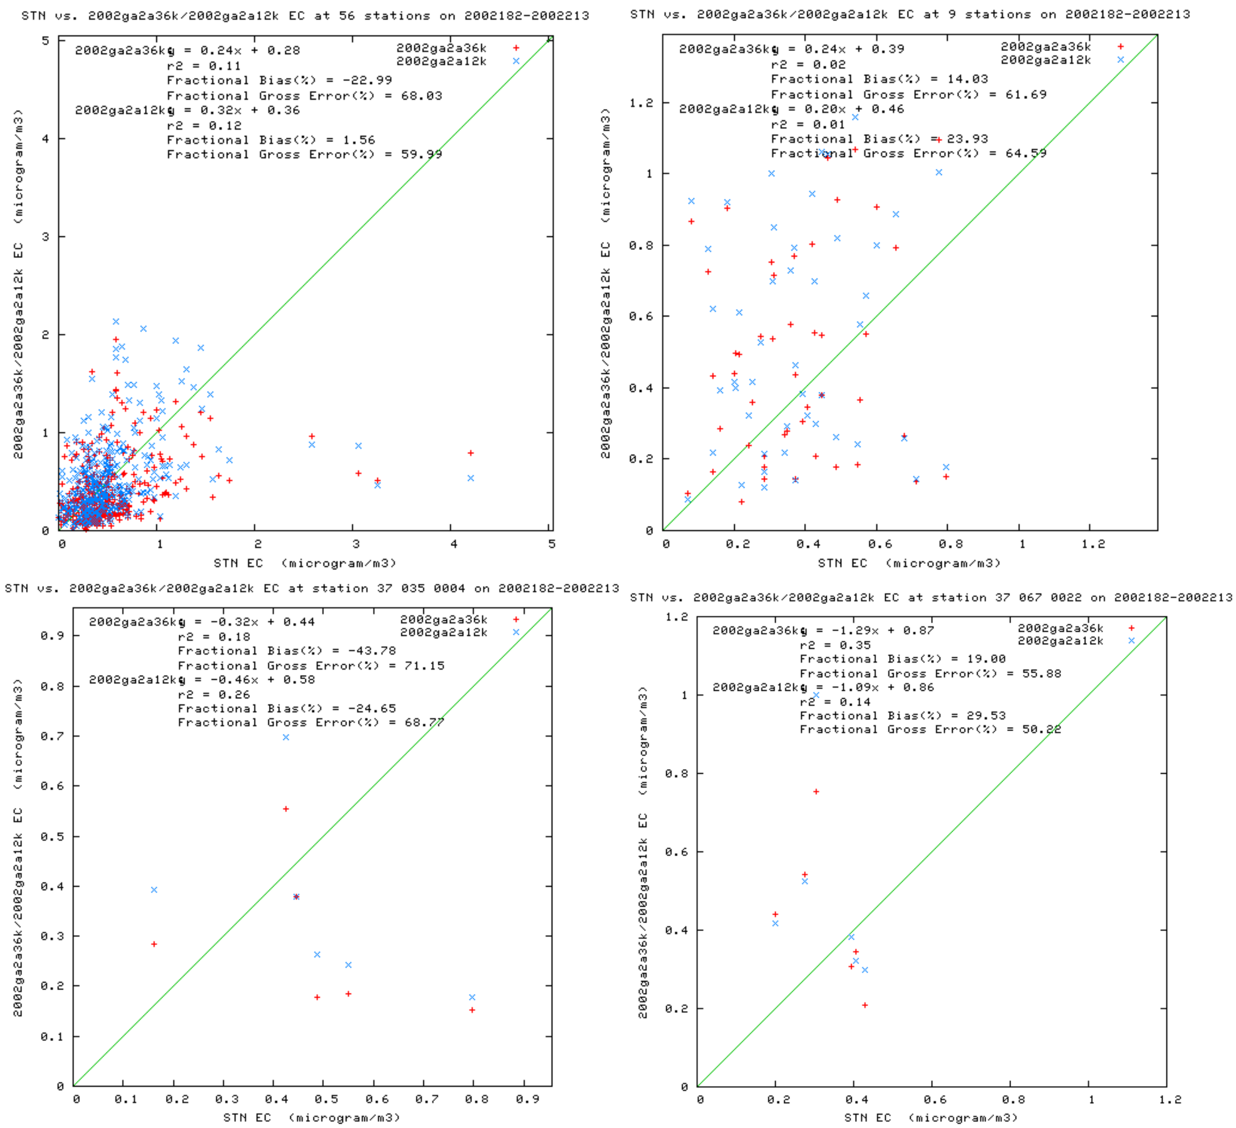

Figure 4-55: Scatter Plot of Observed Elemental Carbon from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) the month of July.

4.1.5.8 August

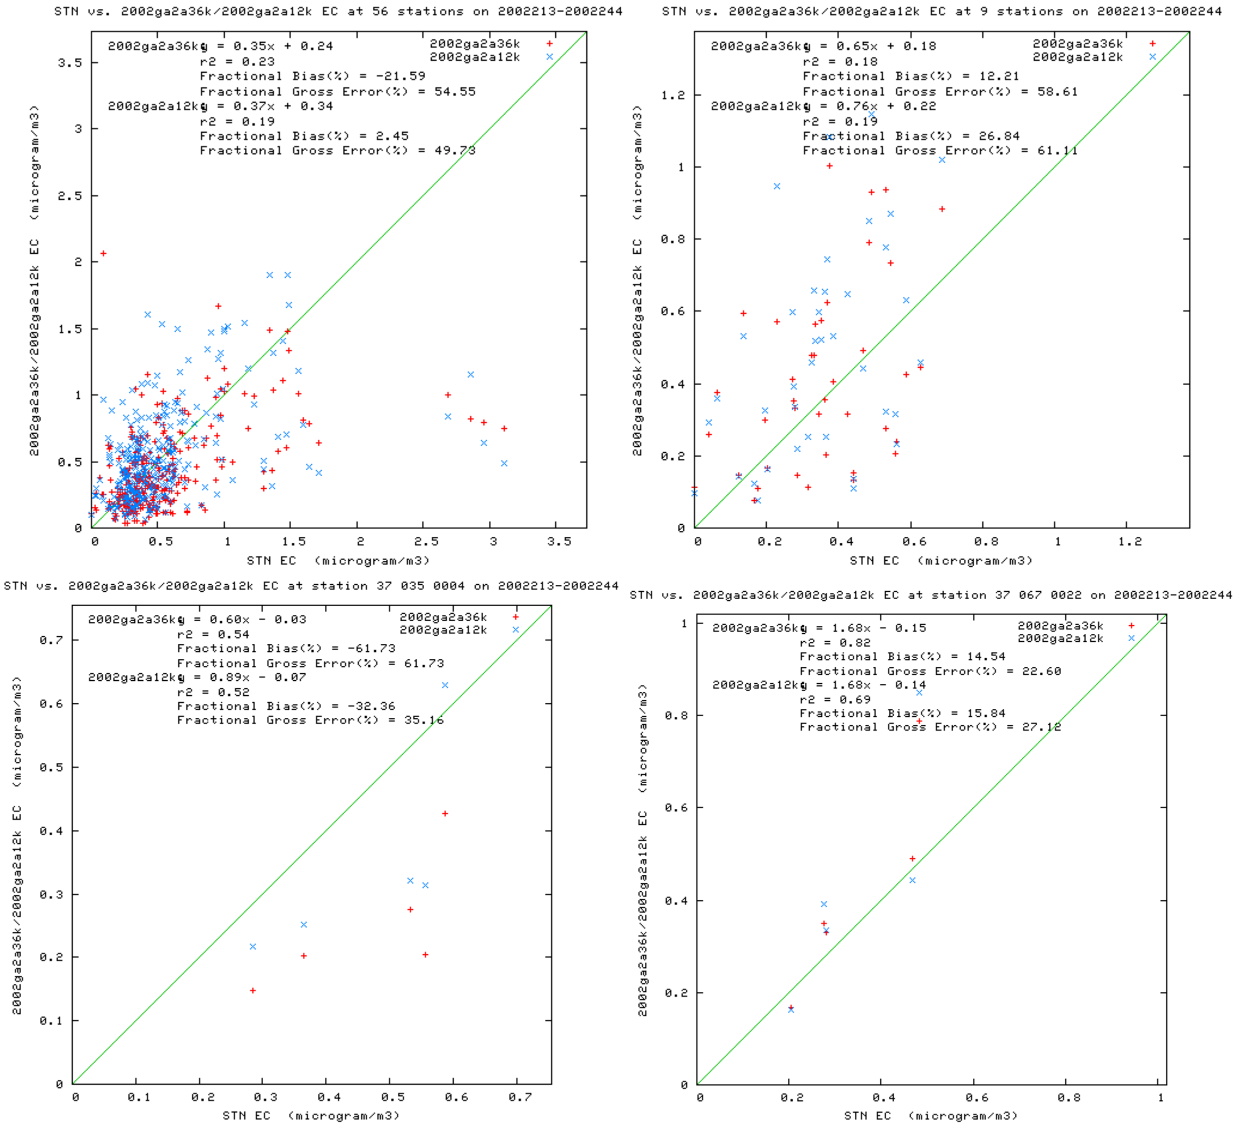

Figure 4-56: Scatter Plot of Observed Elemental Carbon from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) for the month of August.

4.1.5.9 September

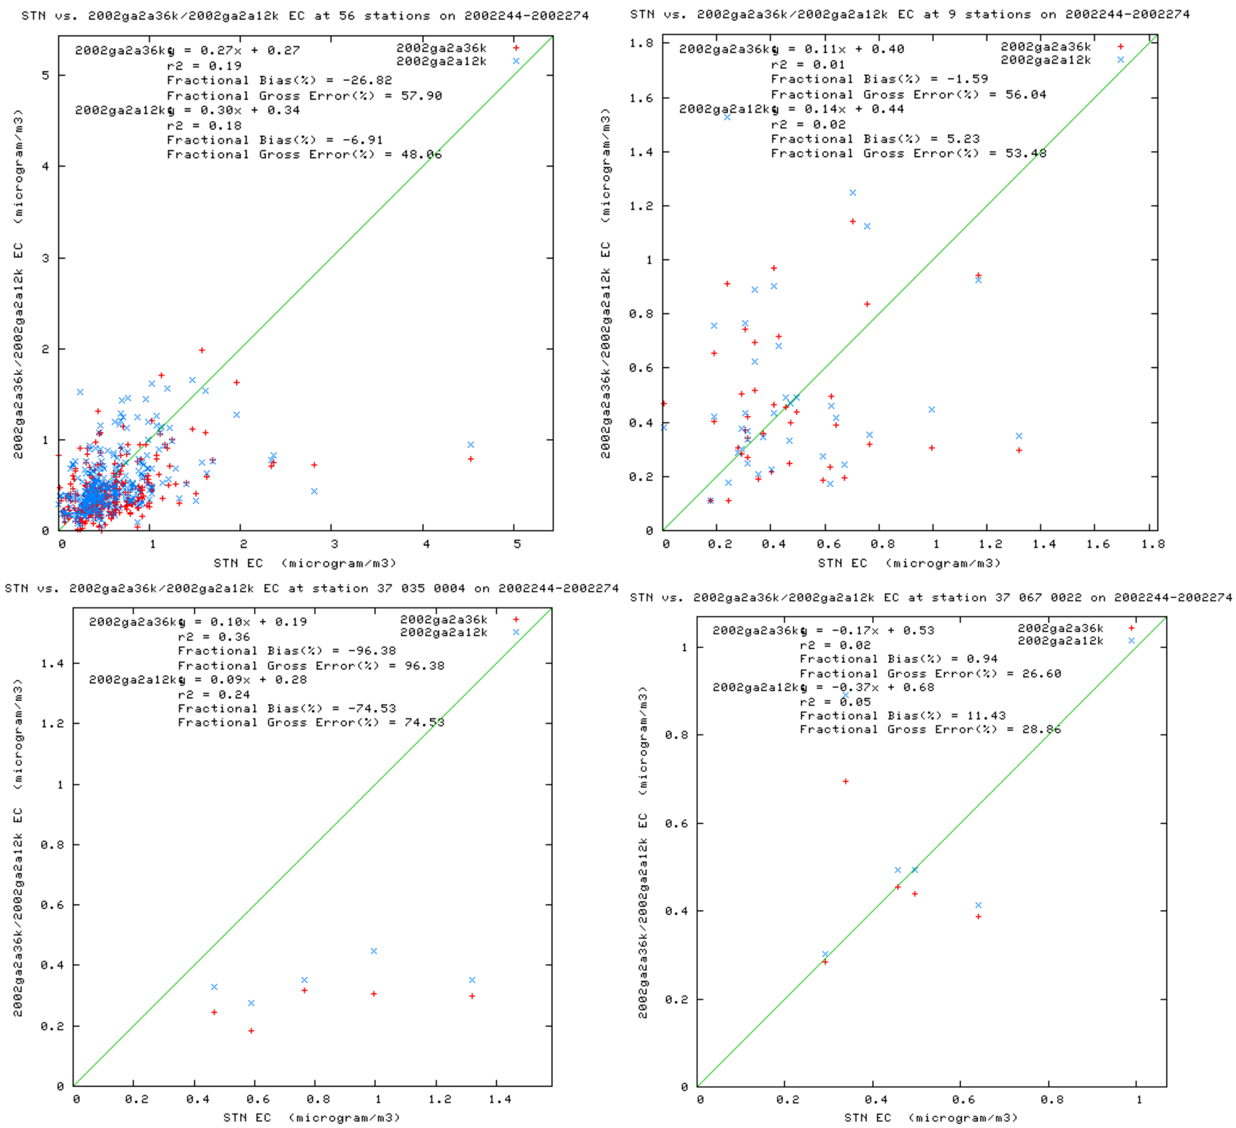

Figure 4-57: Scatter Plot of Observed Elemental Carbon from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) for the month of September.

4.1.5.10 October

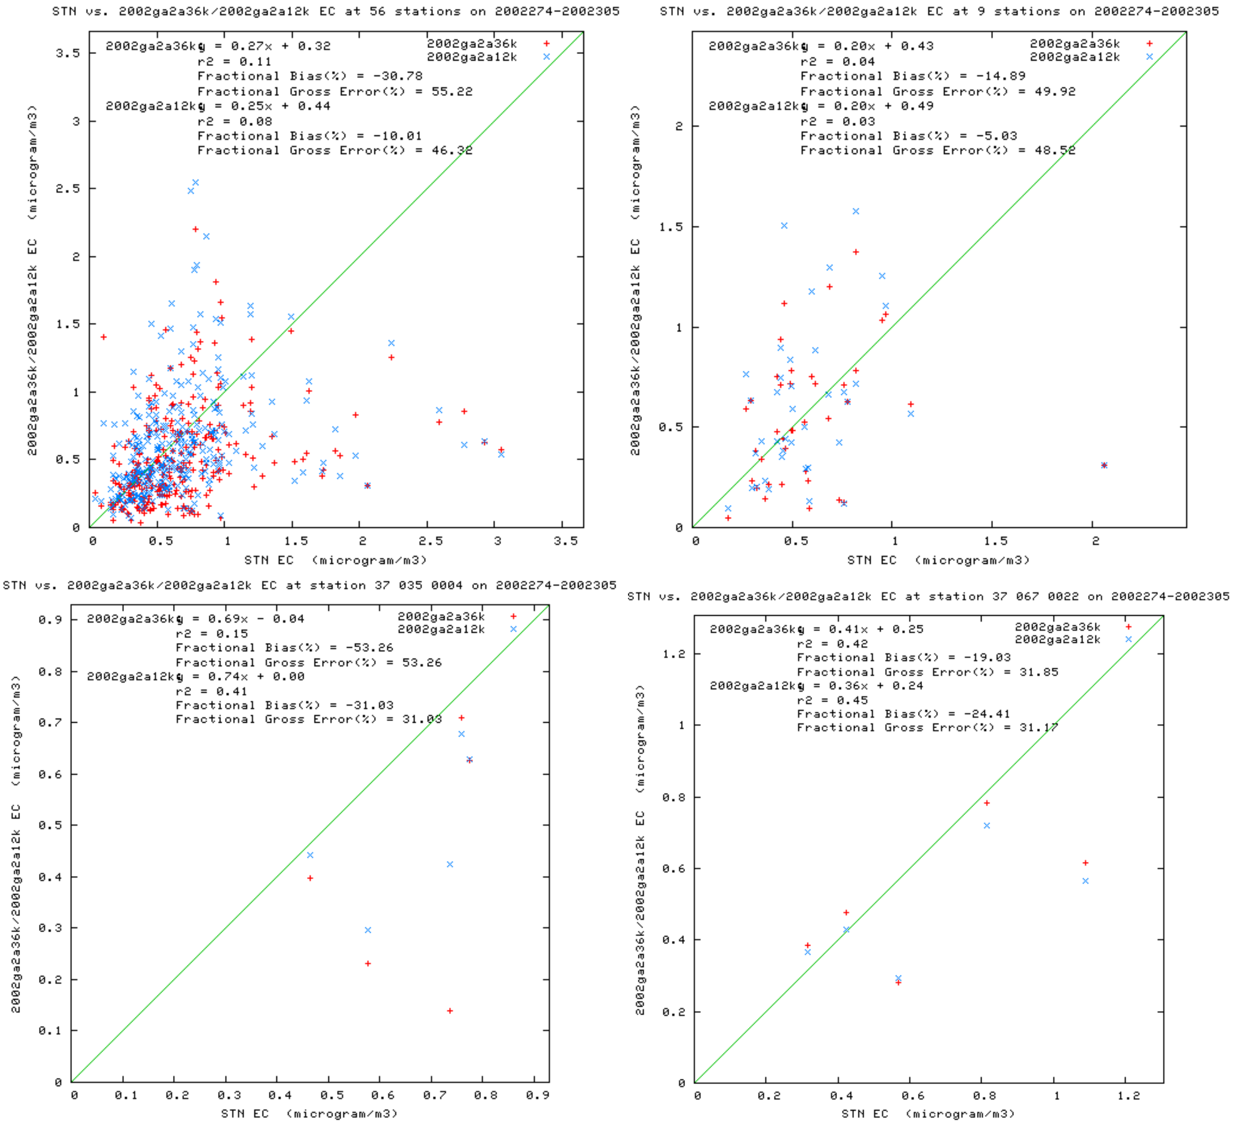

Figure 4-58: Scatter Plot of Observed Elemental Carbon from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) for the month of October.

4.1.5.11 November

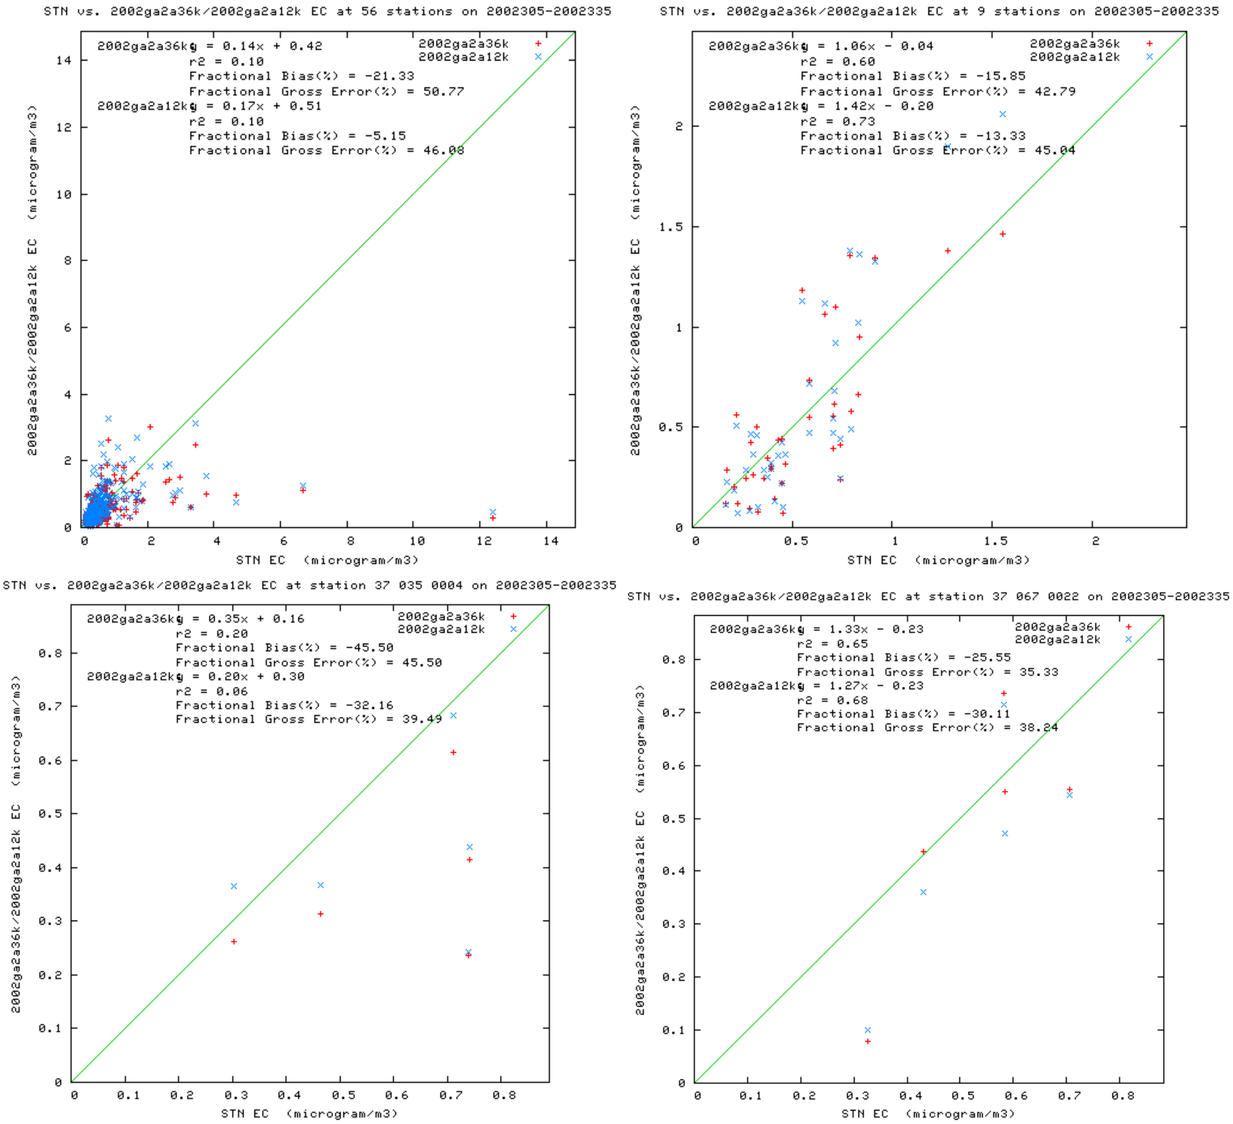

Figure 4-59: Scatter Plot of Observed Elemental Carbon from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) for the month of November.

4.1.5.12 December

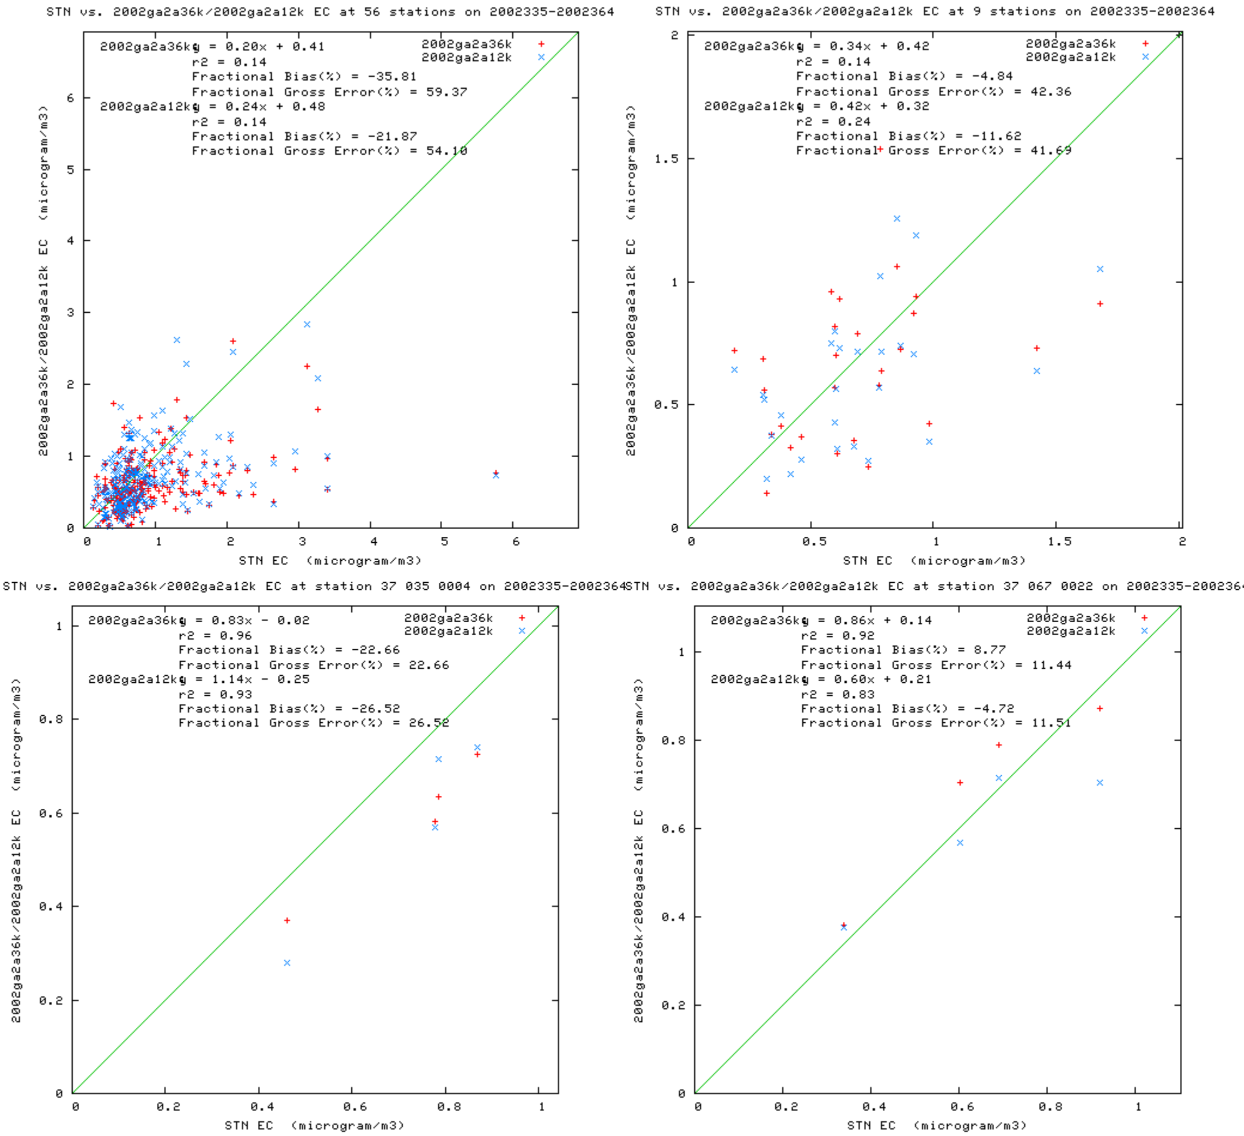

Figure 4-60: Scatter Plot of Observed Elemental Carbon from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) for the month of December.

4.1.6 Total $PM_{2.5}$

4.1.6.1 January

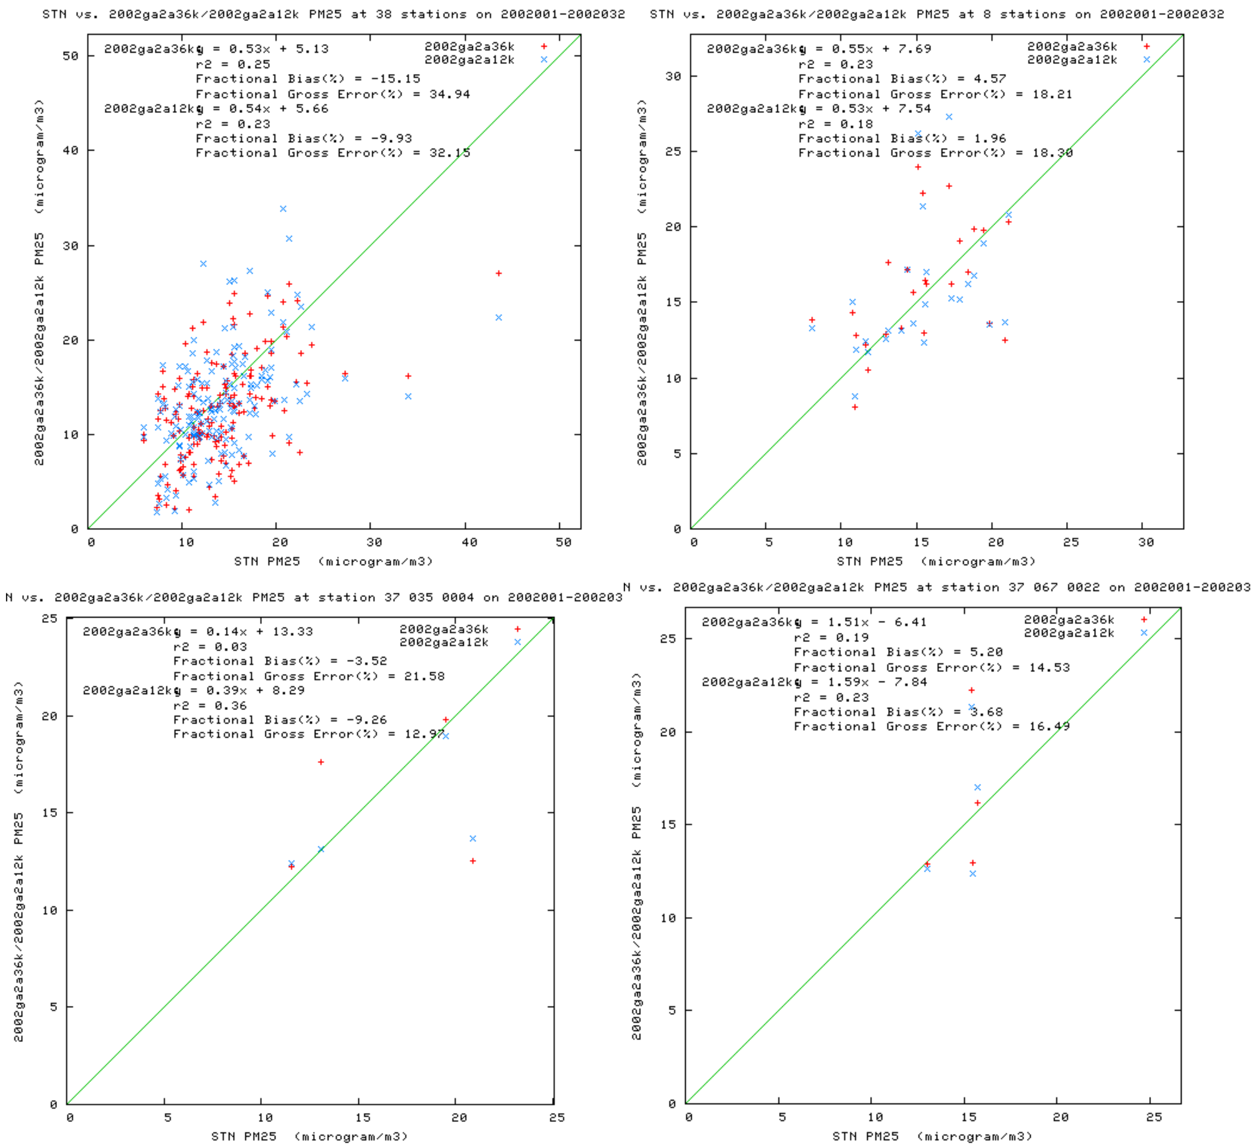

Figure 4-61: Scatter Plot of Reconstructed $PM_{2.5}$ from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) for the month of January.

4.1.6.2 February

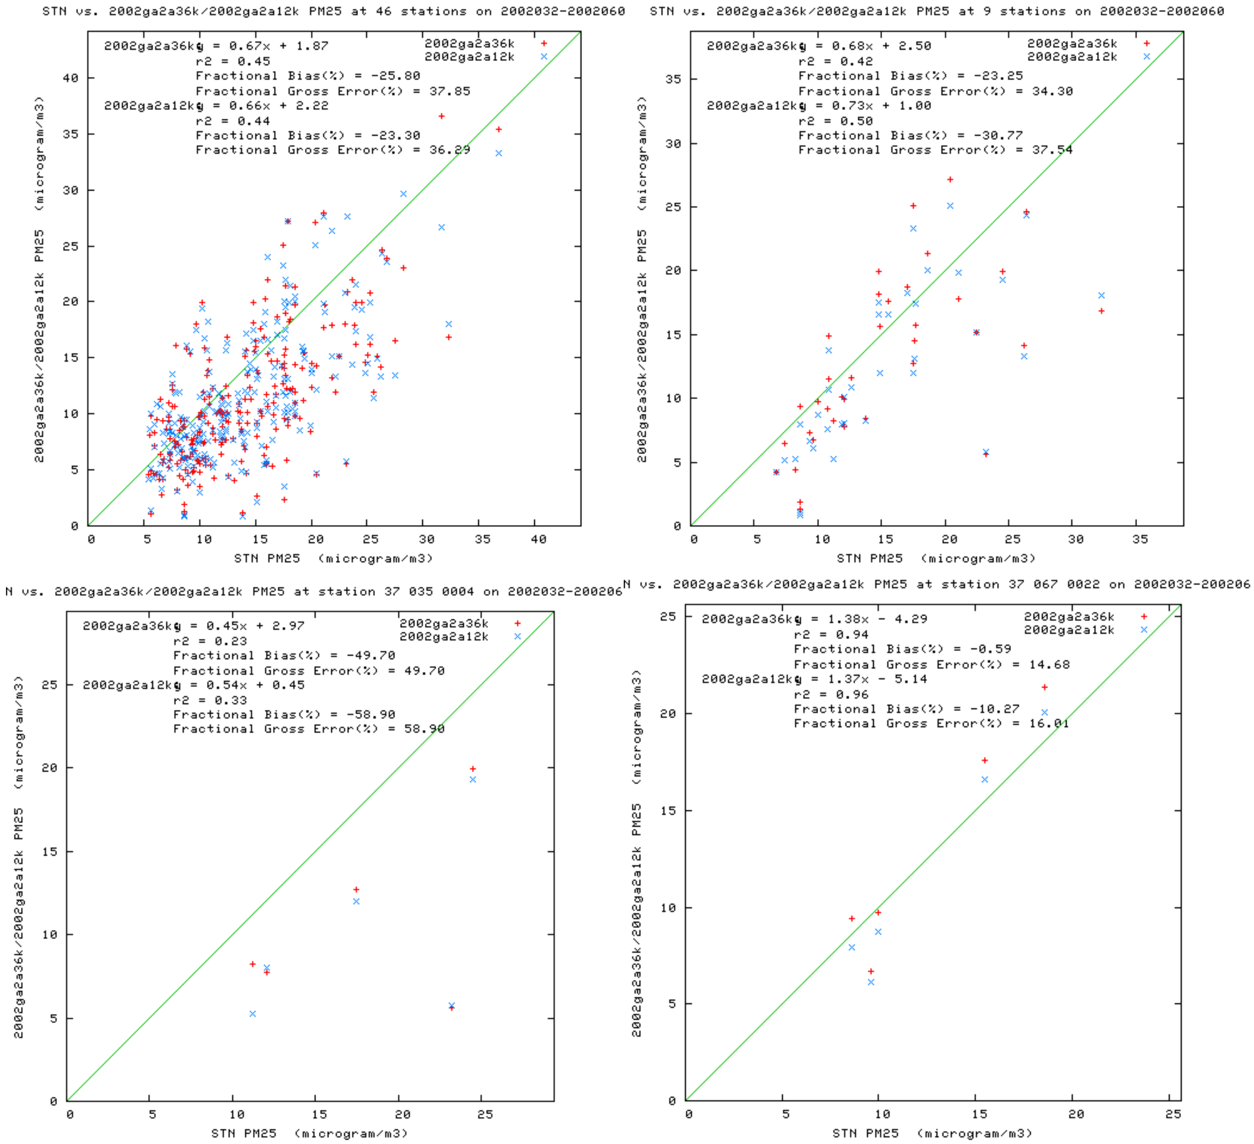

Figure 4-62: Scatter Plot of Reconstructed $PM_{2.5}$ from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) for the month of February.

4.1.6.3 March

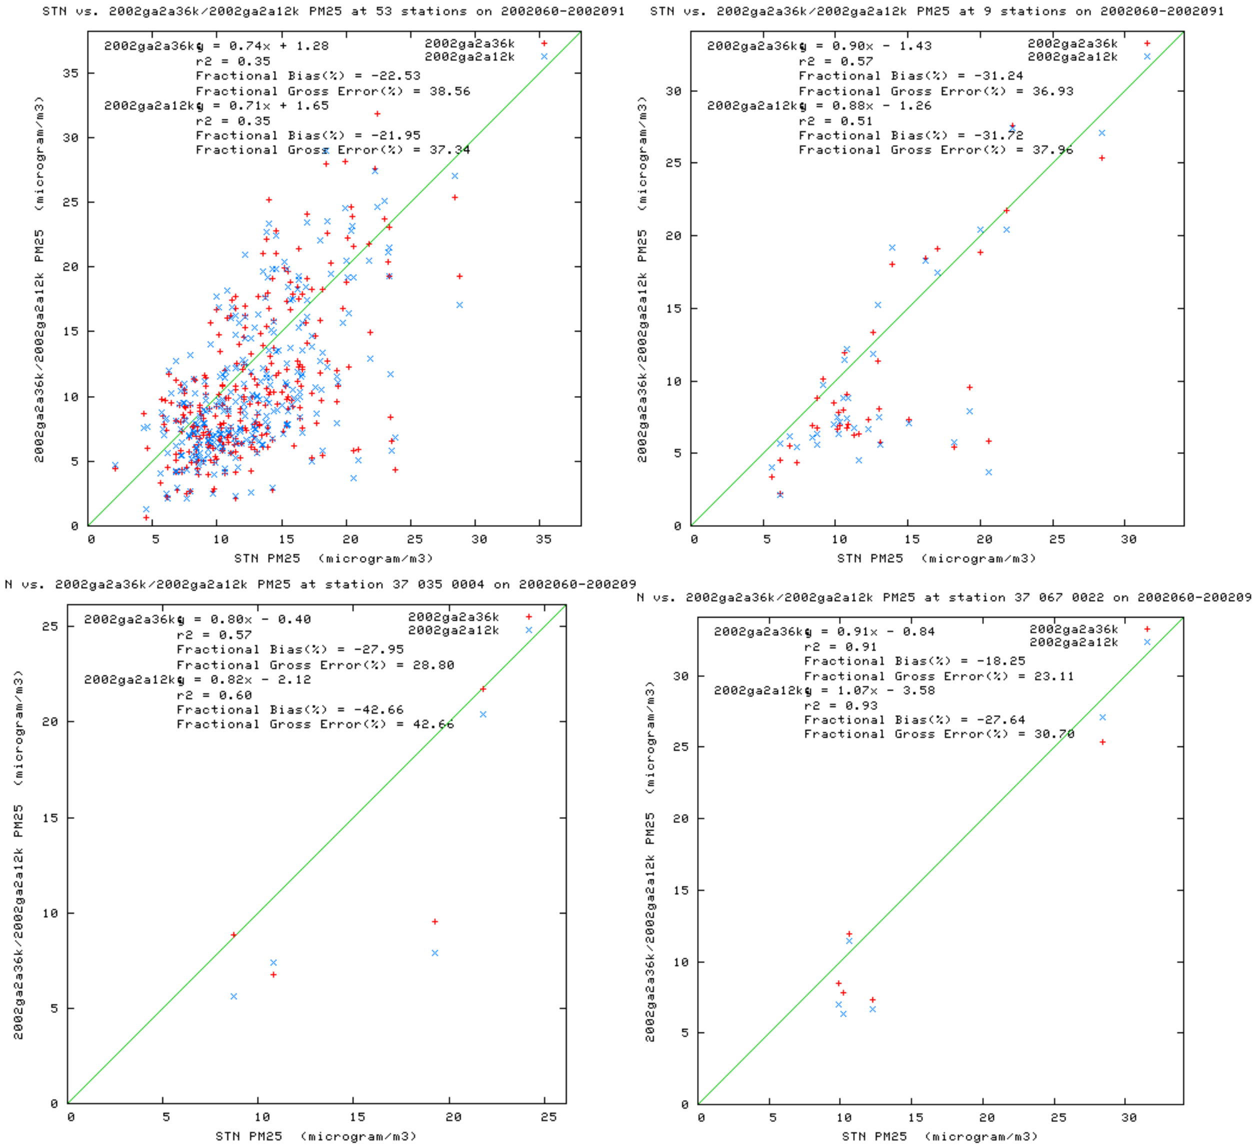

Figure 4-63: Scatter Plot of Reconstructed $PM_{2.5}$ from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) for the month of March.

4.1.6.4 April

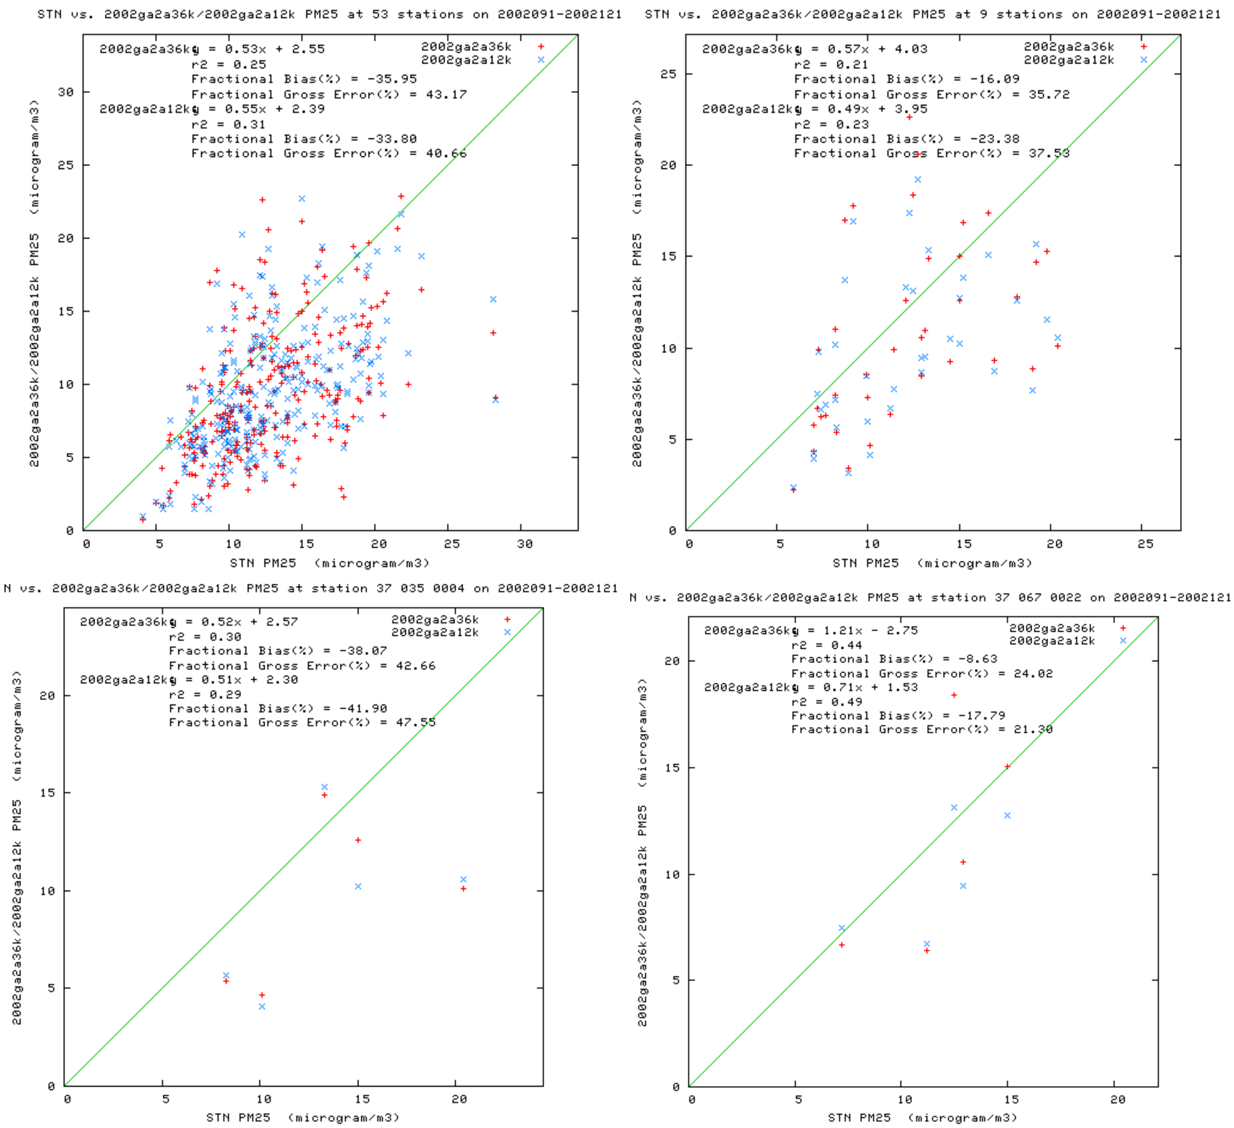

Figure 4-64: Scatter Plot of Reconstructed $PM_{2.5}$ from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) for the month of April.

4.1.6.5 May

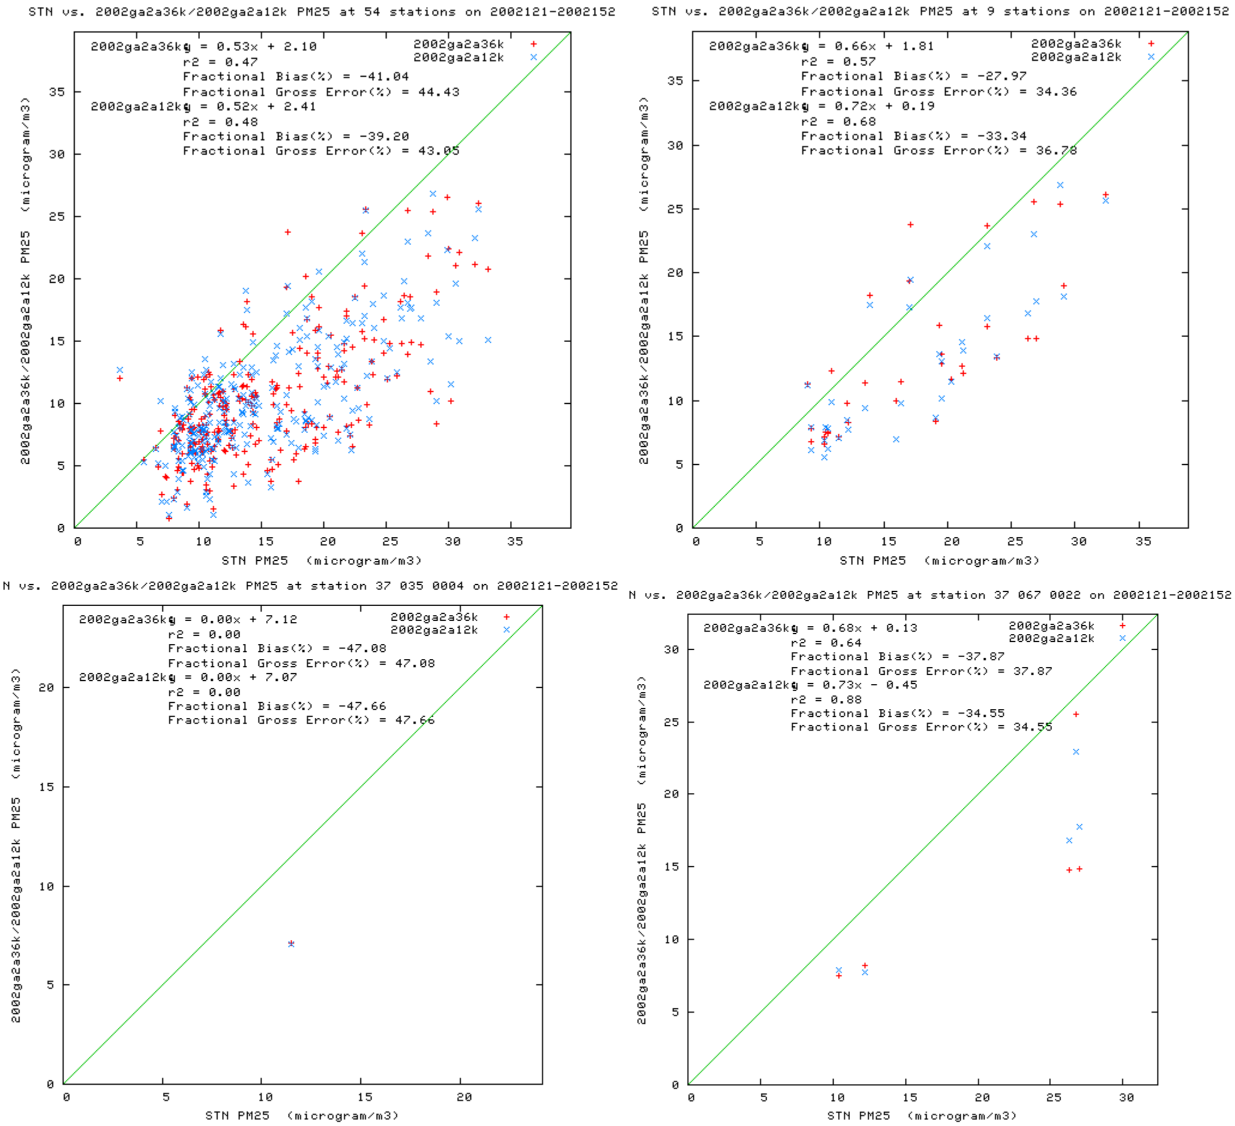

Figure 4-65: Scatter Plot of Reconstructed $PM_{2.5}$ from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) for the month of May.

4.1.6.6 June

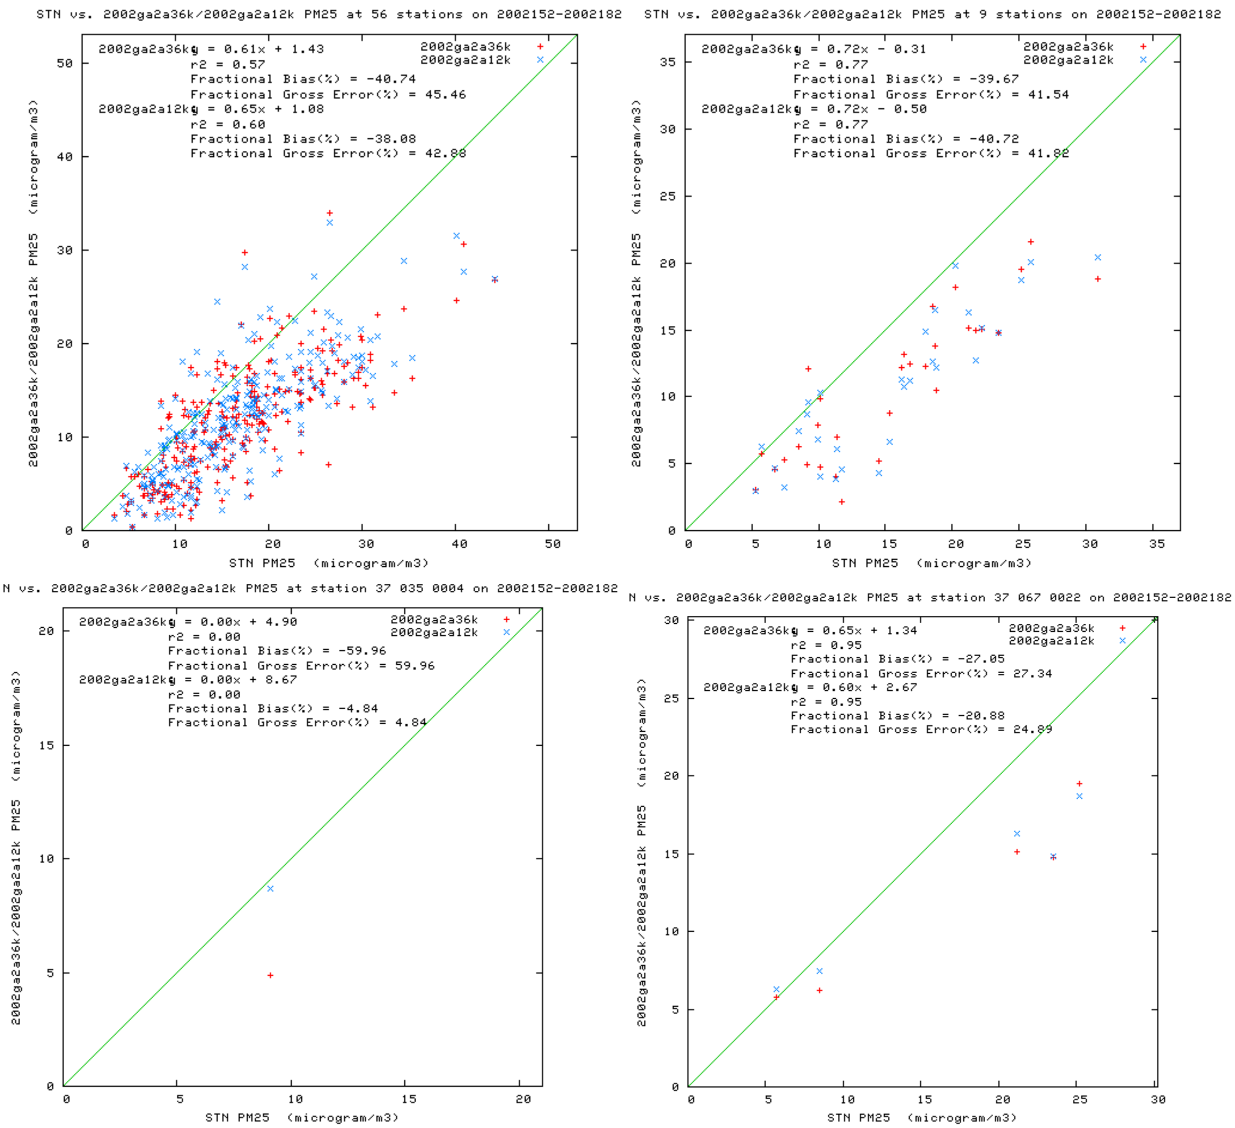

Figure 4-66: Scatter Plot of Reconstructed $PM_{2.5}$ from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) for the month of June.

4.1.6.7 July

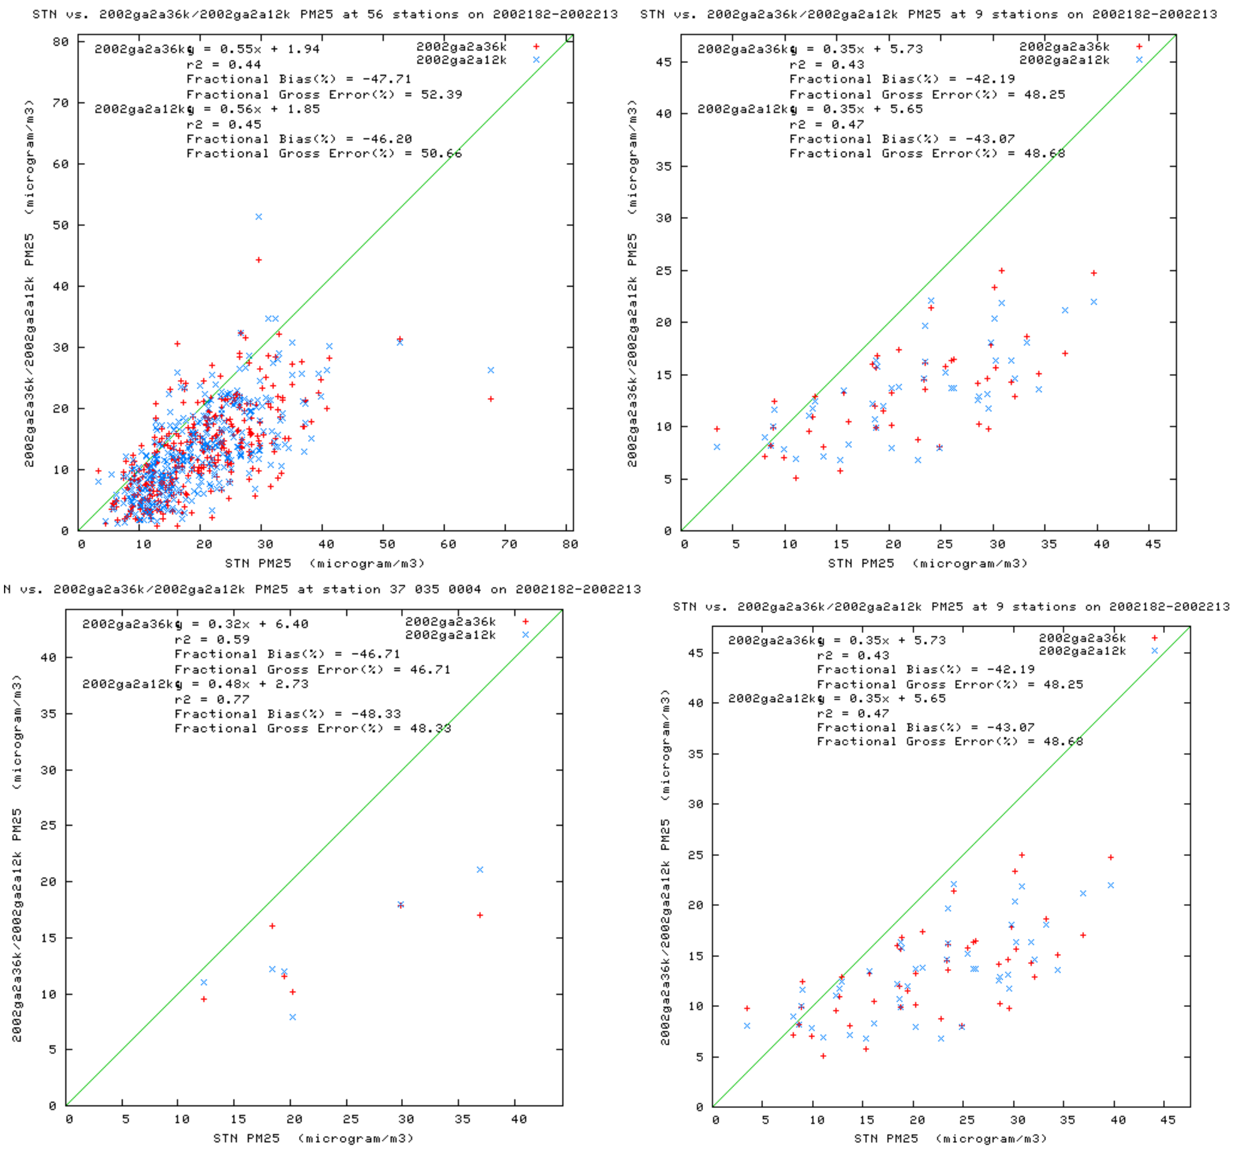

Figure 4-67: Scatter Plot of Reconstructed $PM_{2.5}$ from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) for the month of July.

4.1.6.8 August

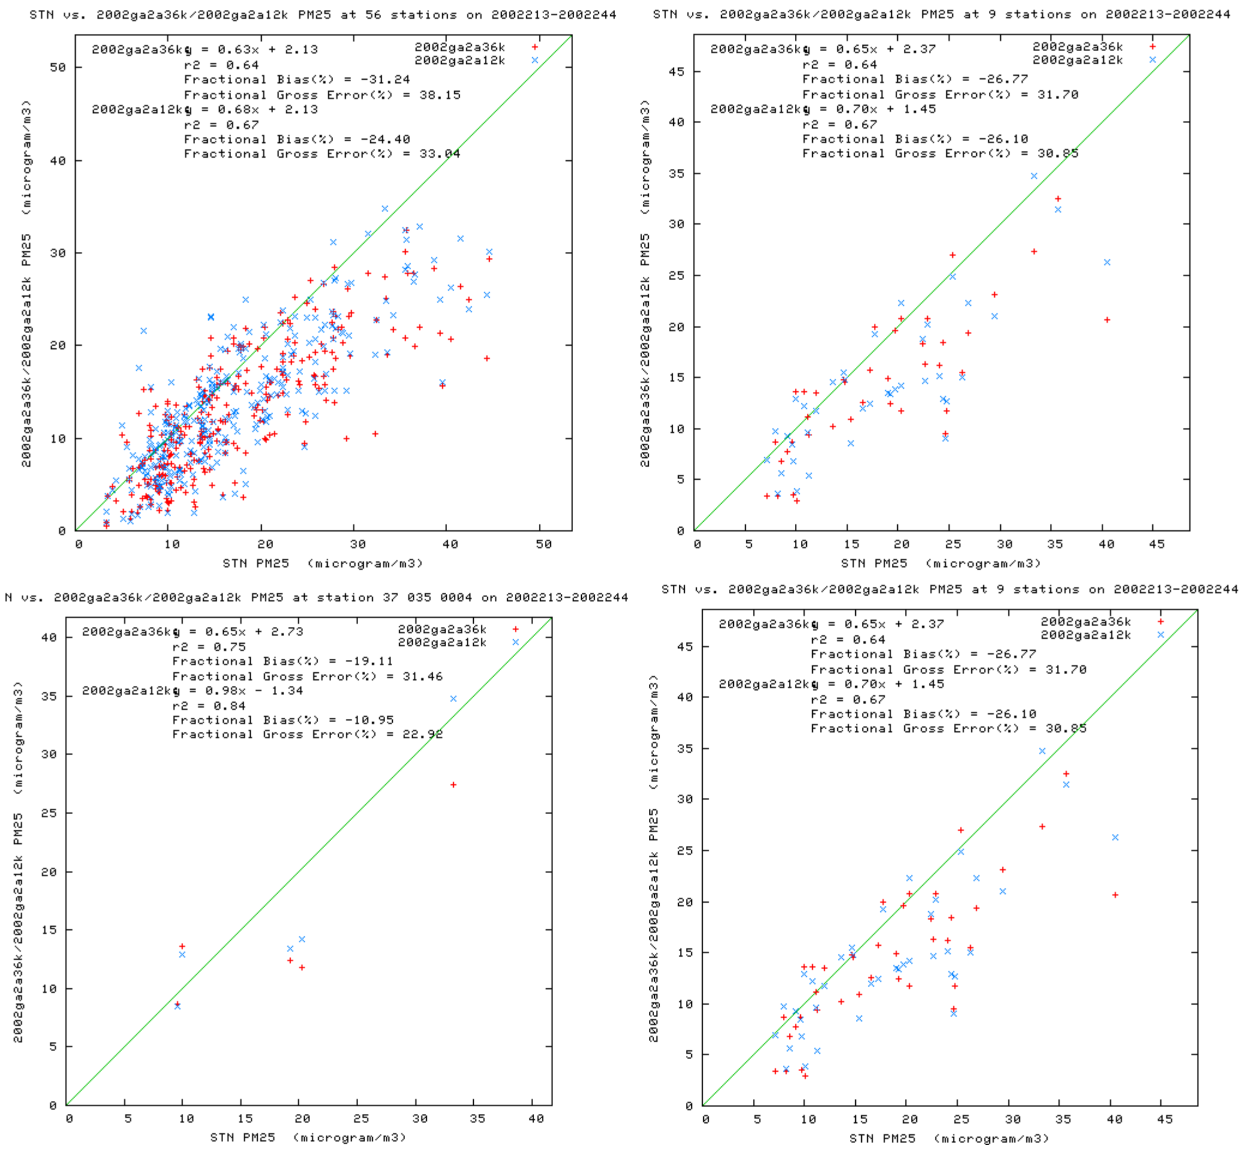

Figure 4-68: Scatter Plot of Reconstructed $PM_{2.5}$ from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) for the month of August.

4.1.6.9 September

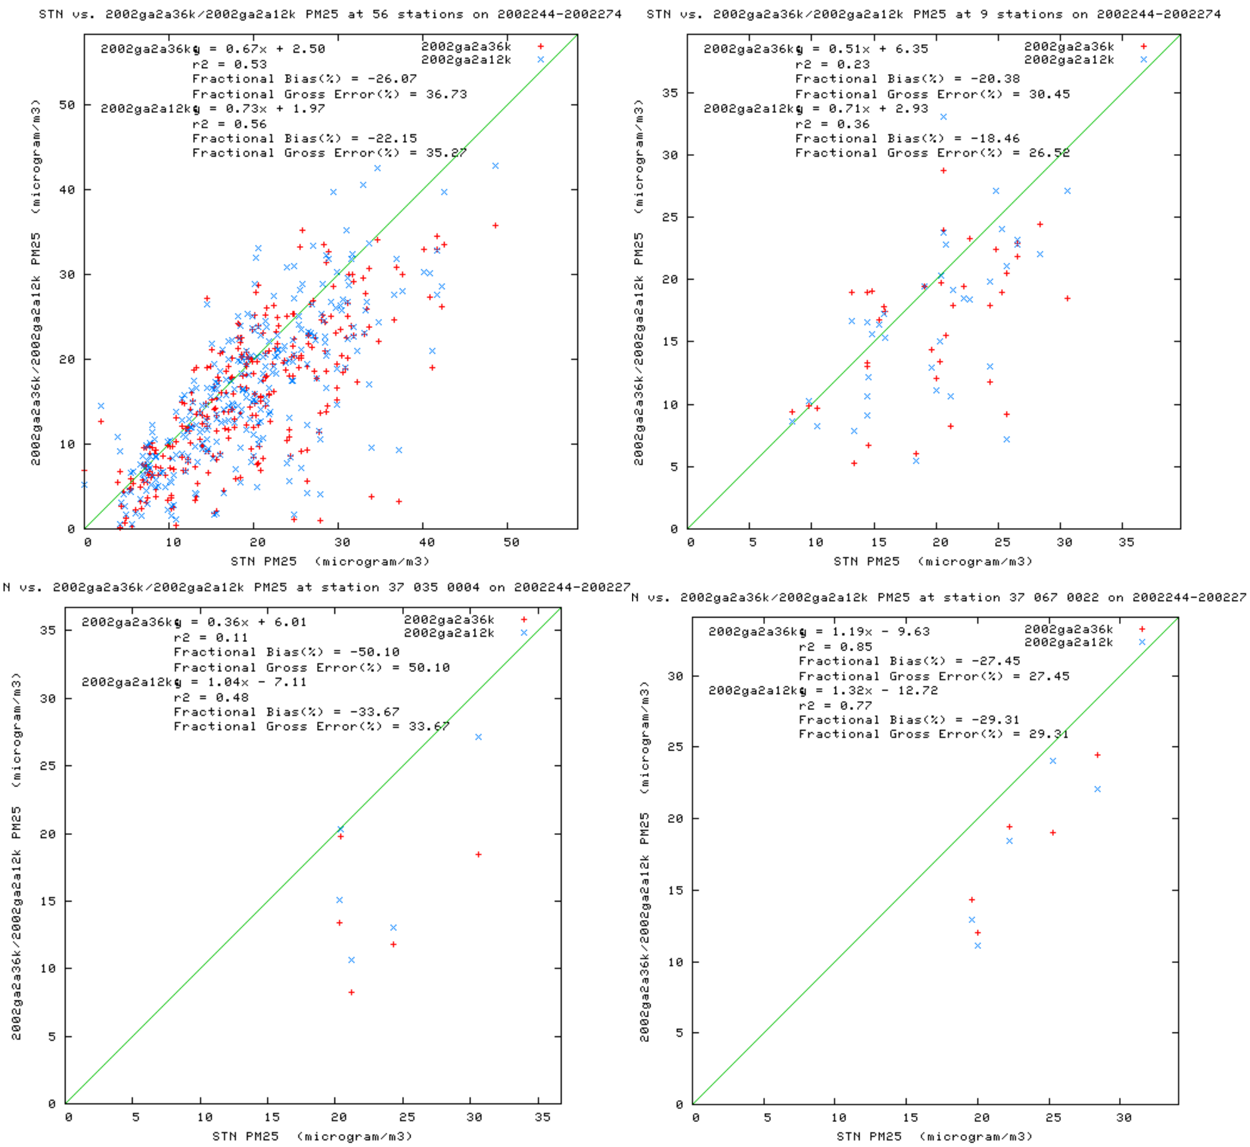

Figure 4-69: Scatter Plot of Reconstructed $PM_{2.5}$ from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) for the month of September.

4.1.6.10 October

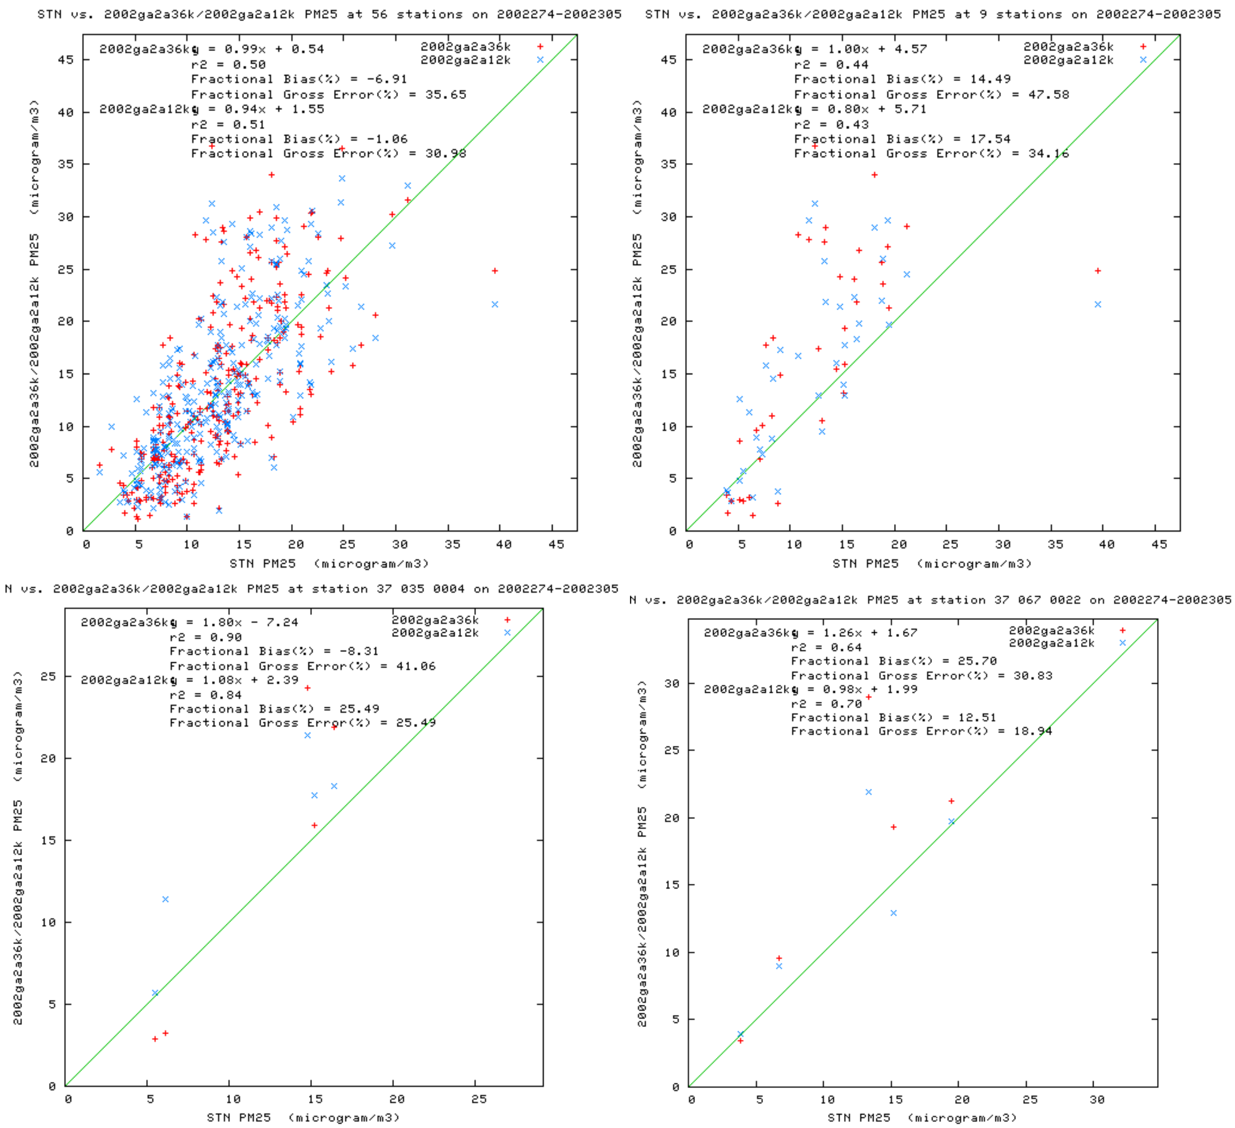

Figure 4-70: Scatter Plot of Reconstructed $PM_{2.5}$ from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) for the month of October.

4.1.6.11 November

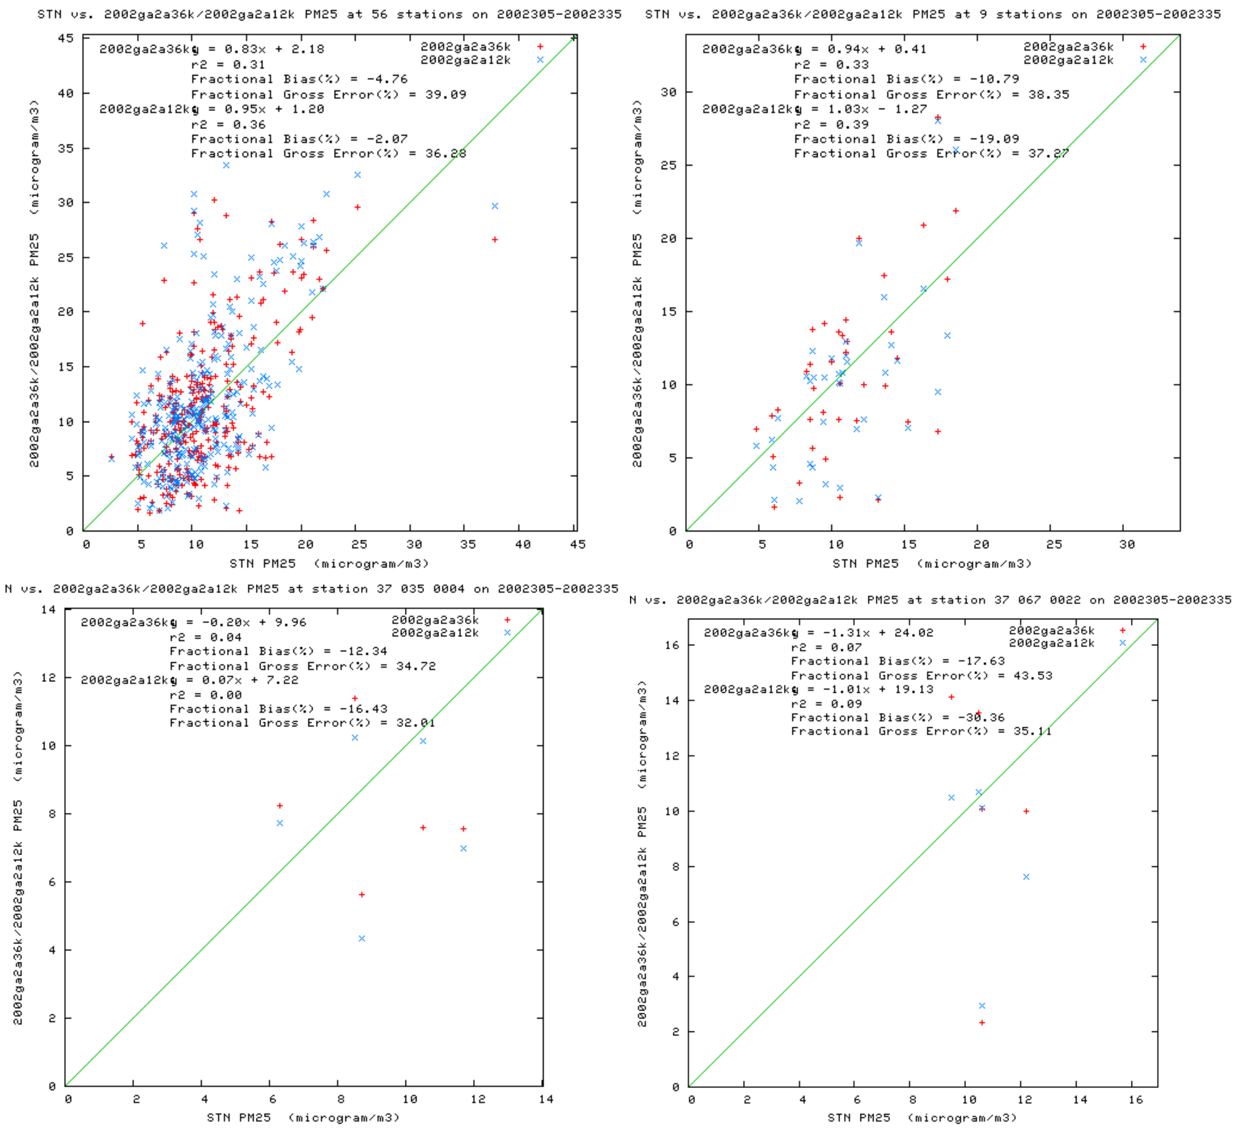

Figure 4-71: Scatter Plot of Reconstructed $PM_{2.5}$ from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) for the month of November.

4.1.6.12 December

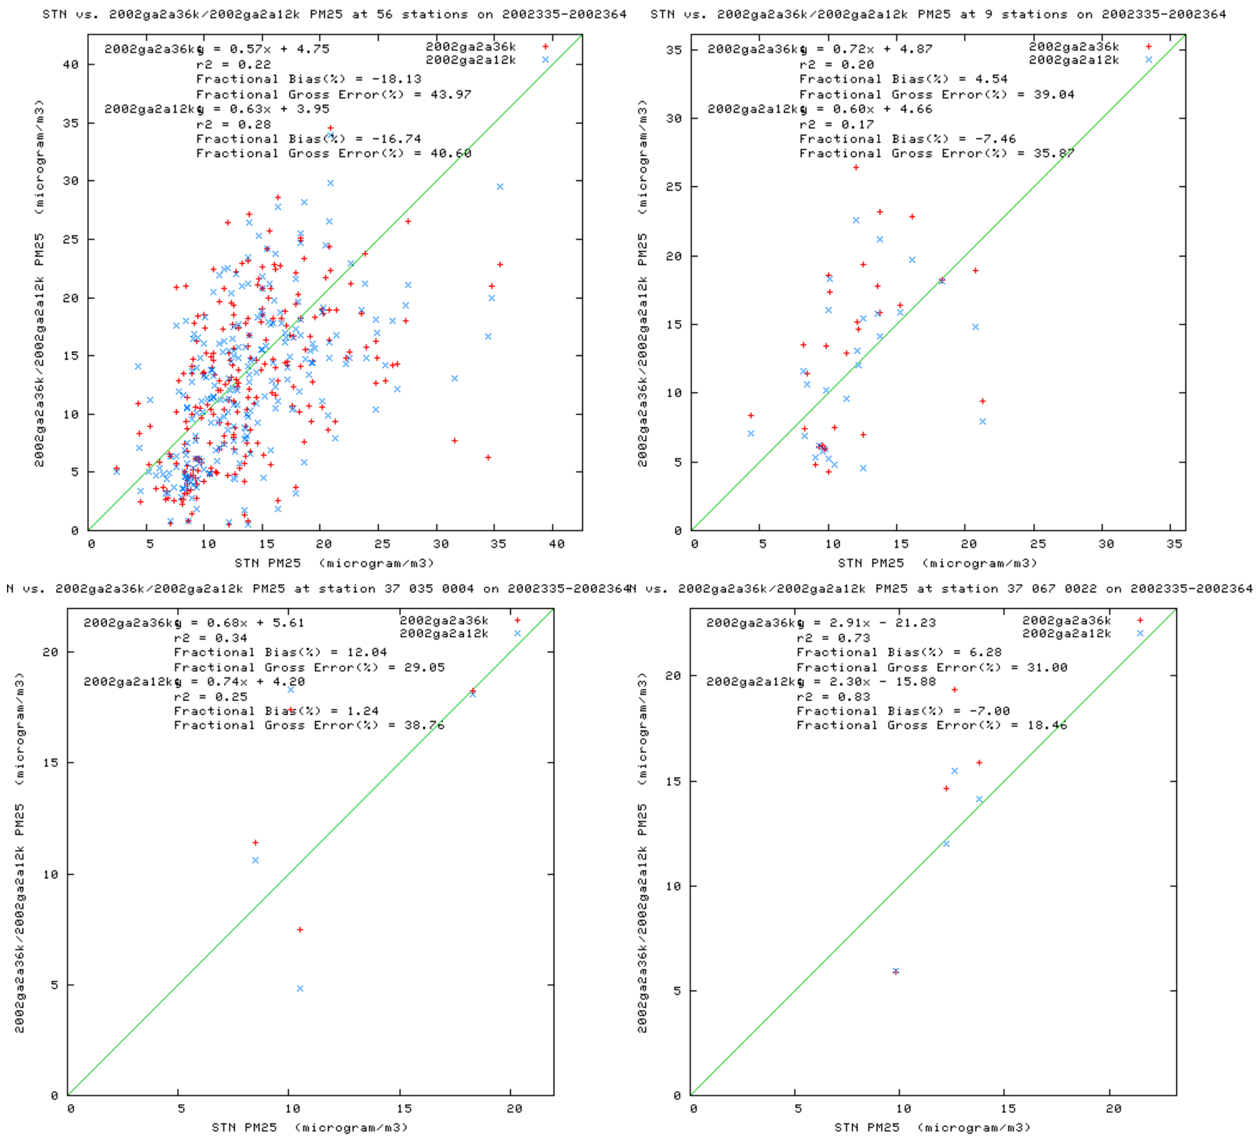

Figure 4-72: Scatter Plot of Reconstructed $PM_{2.5}$ from the STN network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS STN sites collectively (top left), all North Carolina STN sites collectively (top right), the Hickory STN site (37-035-0004)(bottom left), and the Hattie Avenue STN site (37-067-0022) (bottom right) for the month of December.

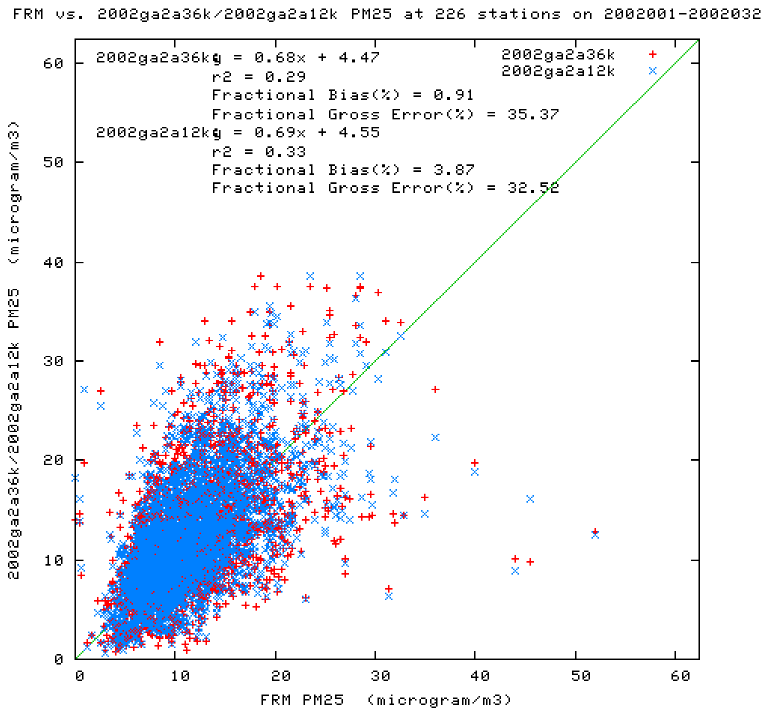
4.2 FRM Scatter plots

4.2.1 January



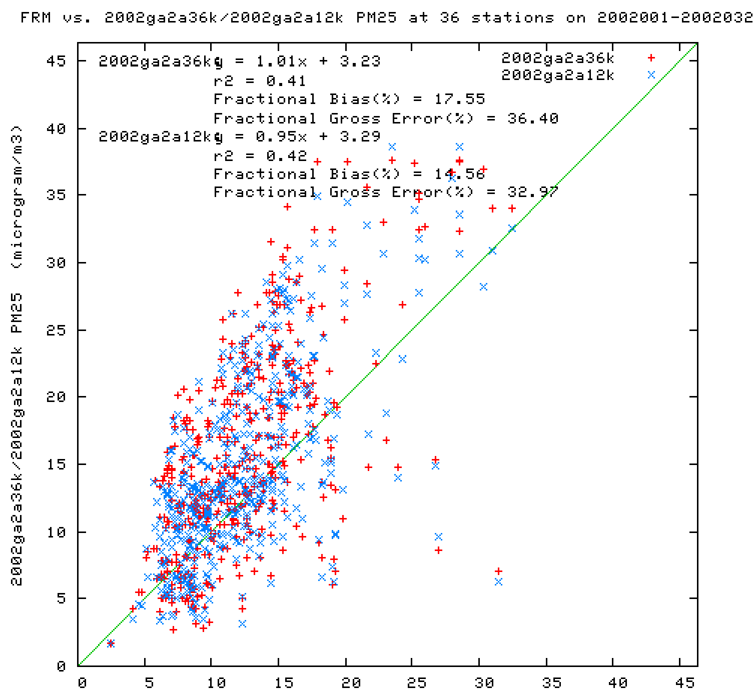


Figure 4-73: Scatter Plot of $PM_{2.5}$ from the FRM network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS FRM sites collectively (top), all North Carolina FRM sites collectively (bottom) for the month of January.

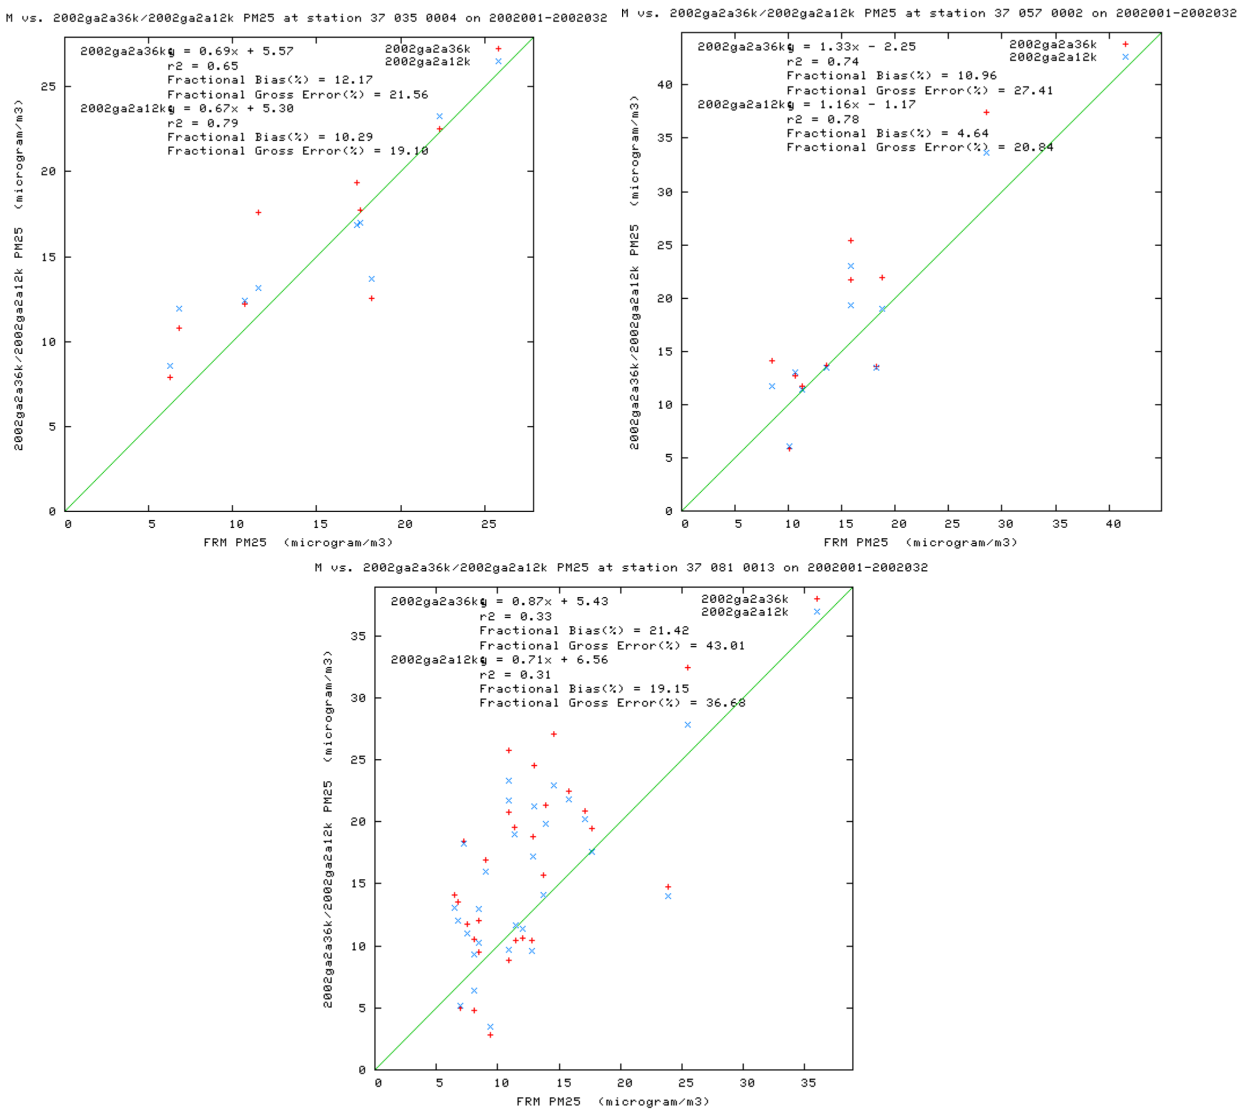

Figure 4-74: Scatter Plot of Observed $PM_{2.5}$ from the FRM network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for the Hickory FRM site (37-035-0004)(top left), the Lexington FRM site (37-057-0002) (top right), and the Mendenhall FRM site (37-081-0013) for the month of January.

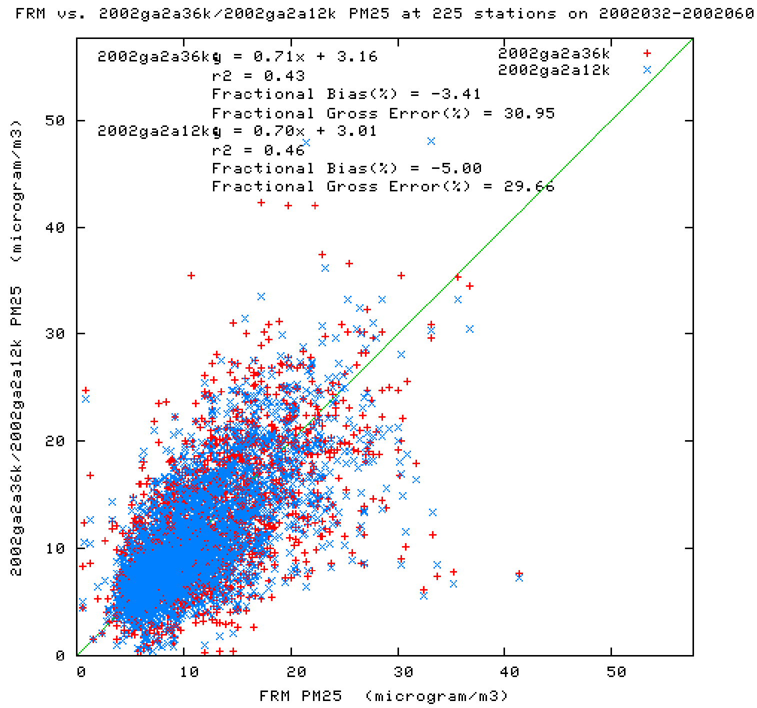
4.2.2 February



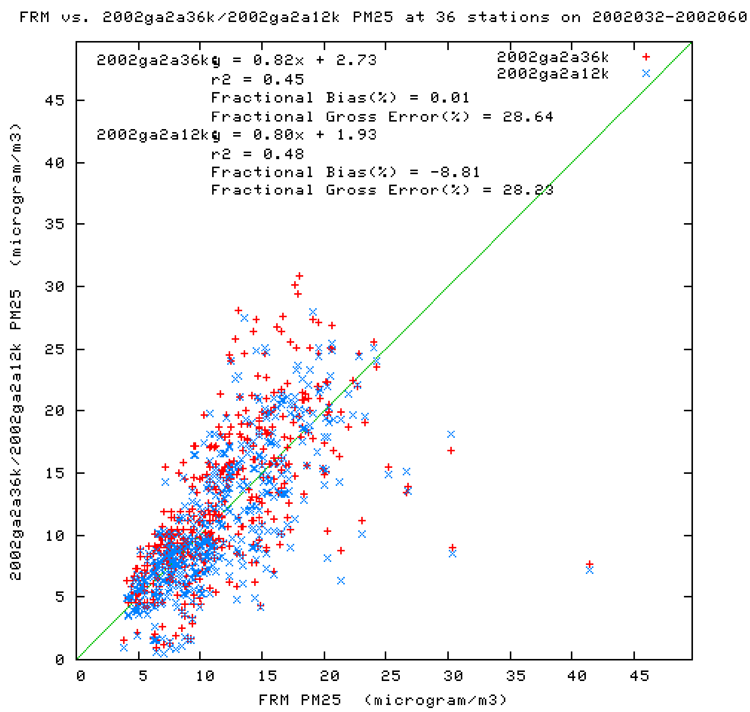


Figure 4-75: Scatter Plot of $PM_{2.5}$ from the FRM network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS FRM sites collectively (top), all North Carolina FRM sites collectively (bottom) for the month of February.

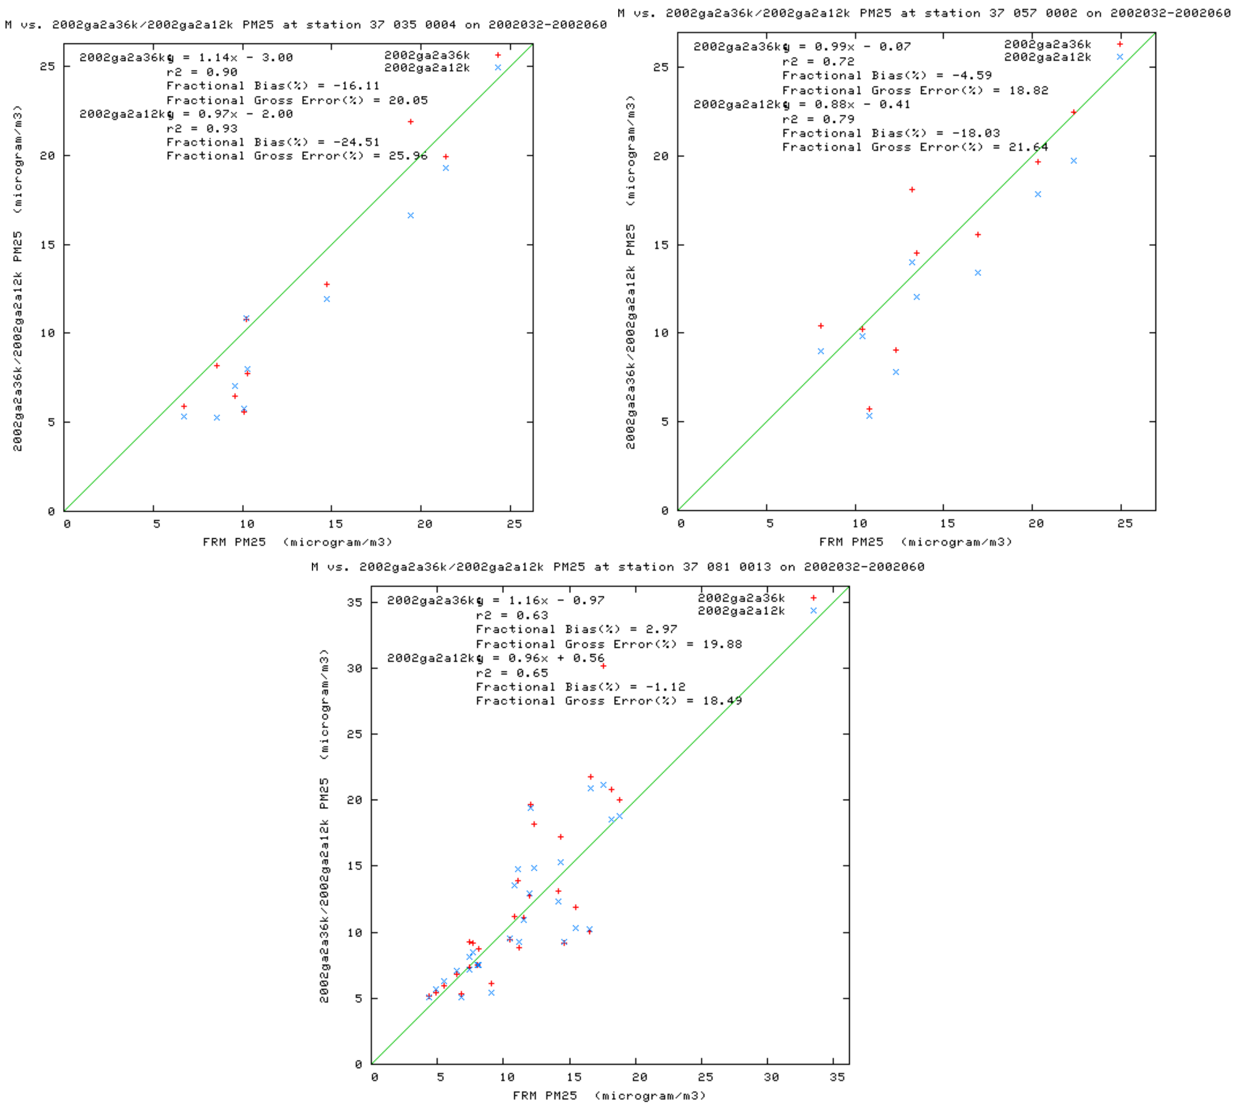

Figure 4-76: Scatter Plot of Observed $PM_{2.5}$ from the FRM network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for the Hickory FRM site (37-035-0004)(top left), the Lexington FRM site (37-057-0002) (top right), and the Mendenhall FRM site (37-081-0013) for the month of February.

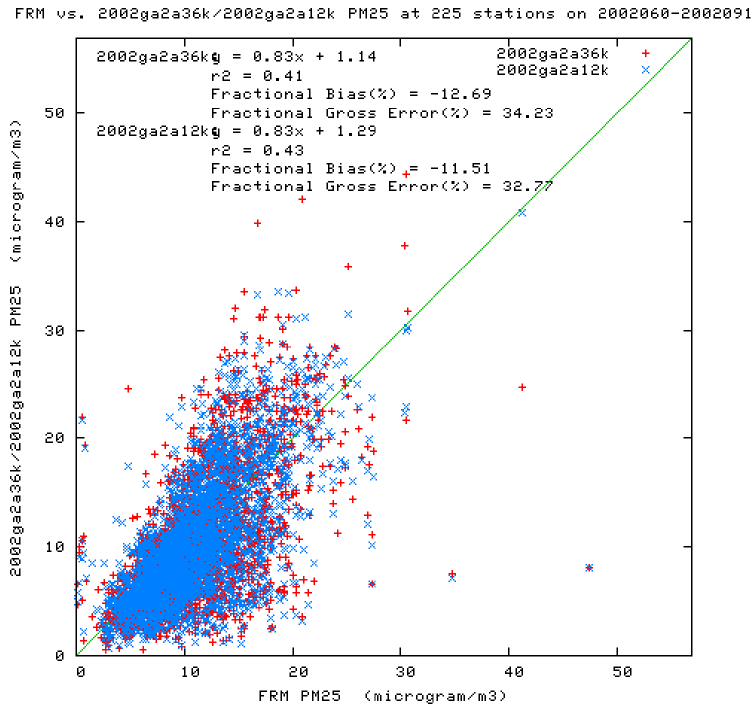
4.2.3 March



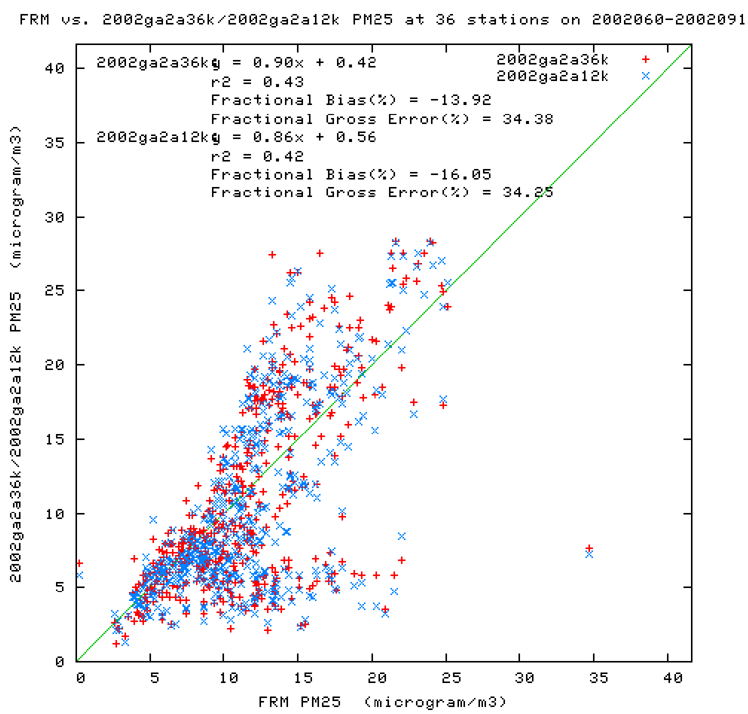


Figure 4-77: Scatter Plot of $PM_{2.5}$ from the FRM network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS FRM sites collectively (top), all North Carolina FRM sites collectively (bottom) for the month of March.

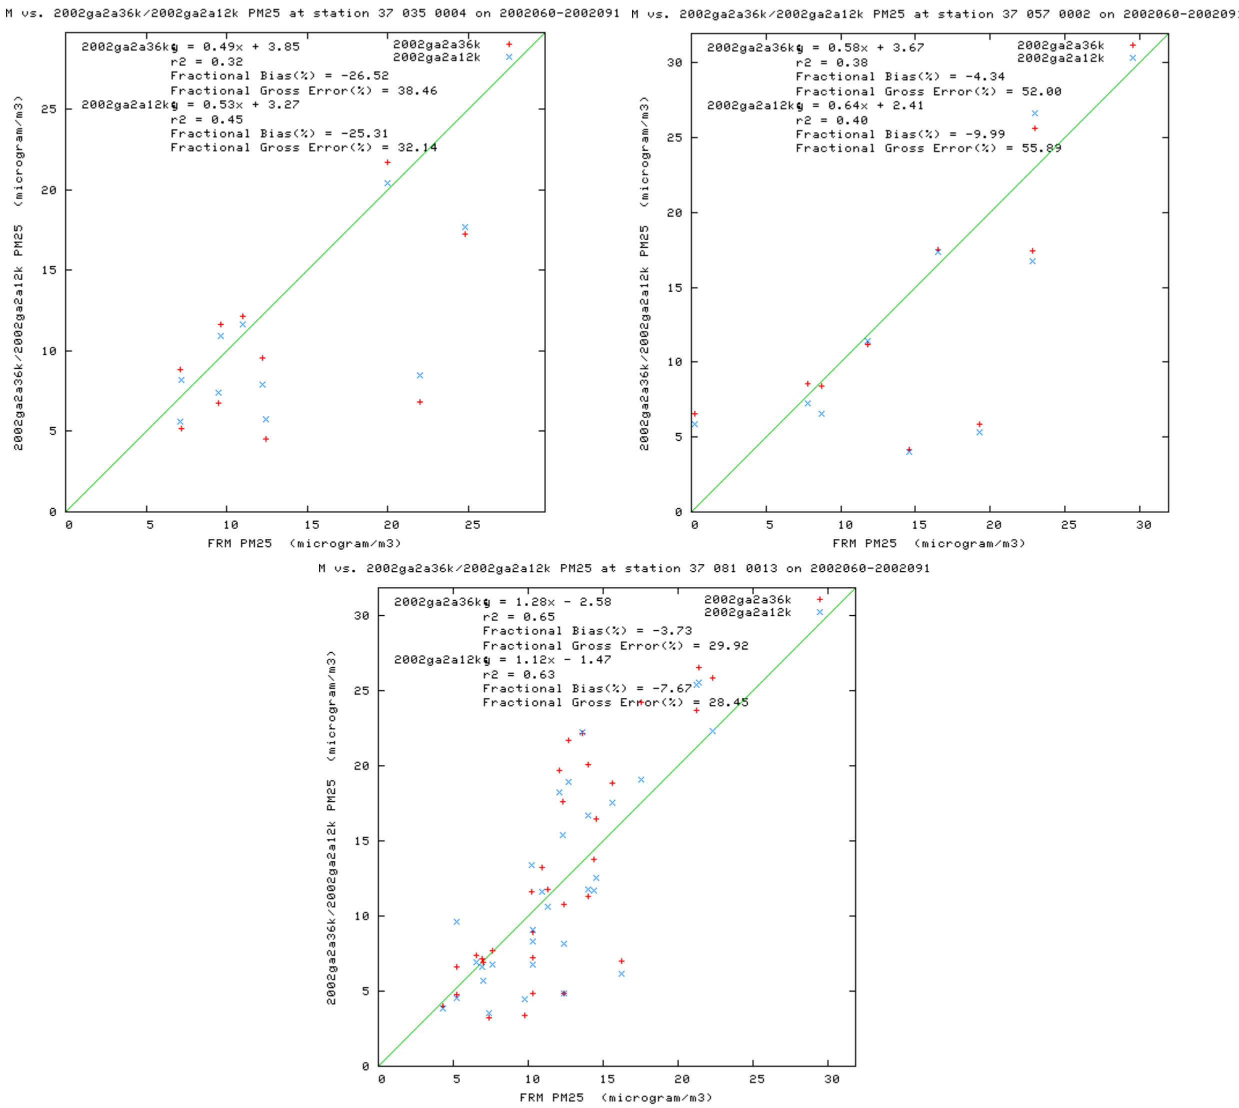

Figure 4-78: Scatter Plot of Observed $PM_{2.5}$ from the FRM network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for the Hickory FRM site (37-035-0004)(top left), the Lexington FRM site (37-057-0002) (top right), and the Mendenhall FRM site (37-081-0013) for the month of March.

4.2.4 April

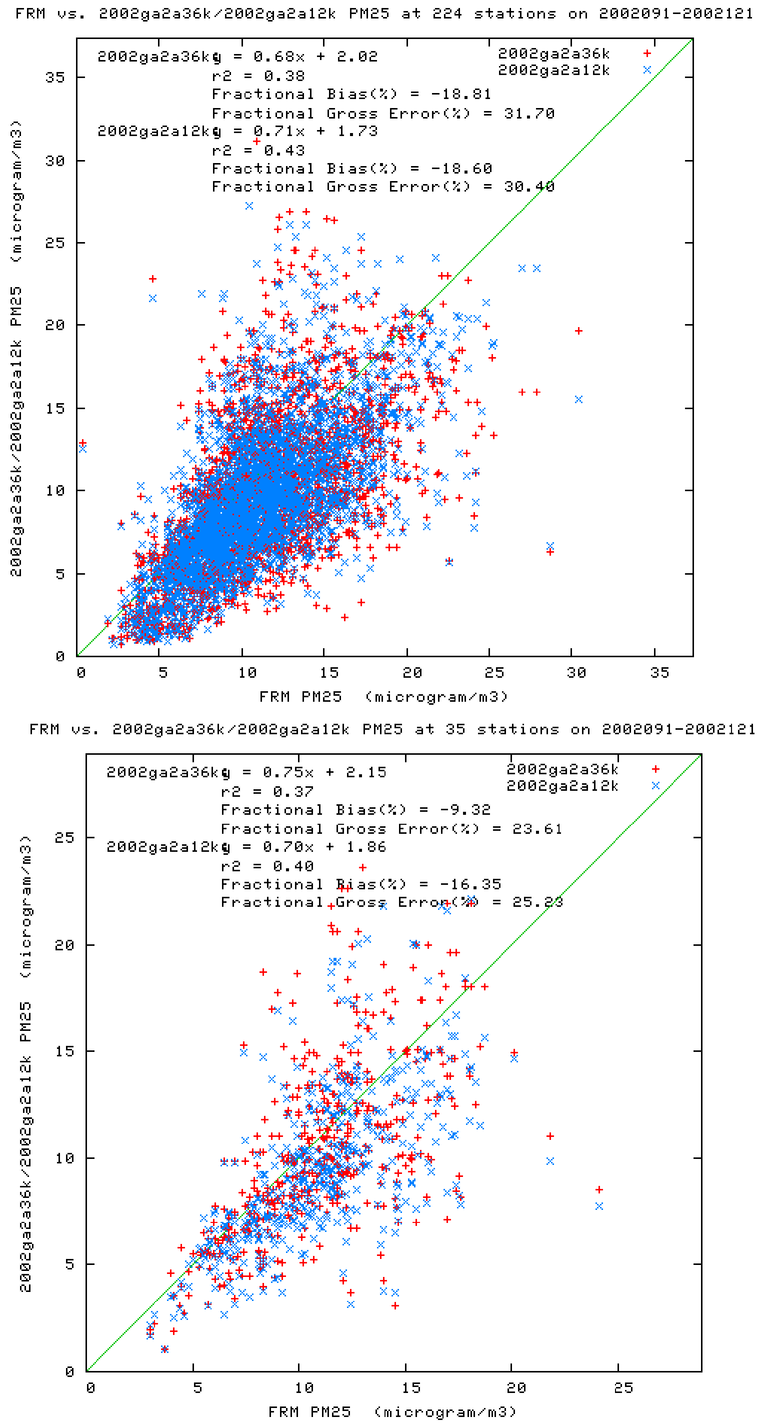

Figure 4-79: Scatter Plot of $PM_{2.5}$ from the FRM network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS FRM sites collectively (top), all North Carolina FRM sites collectively (bottom) for the month of April.

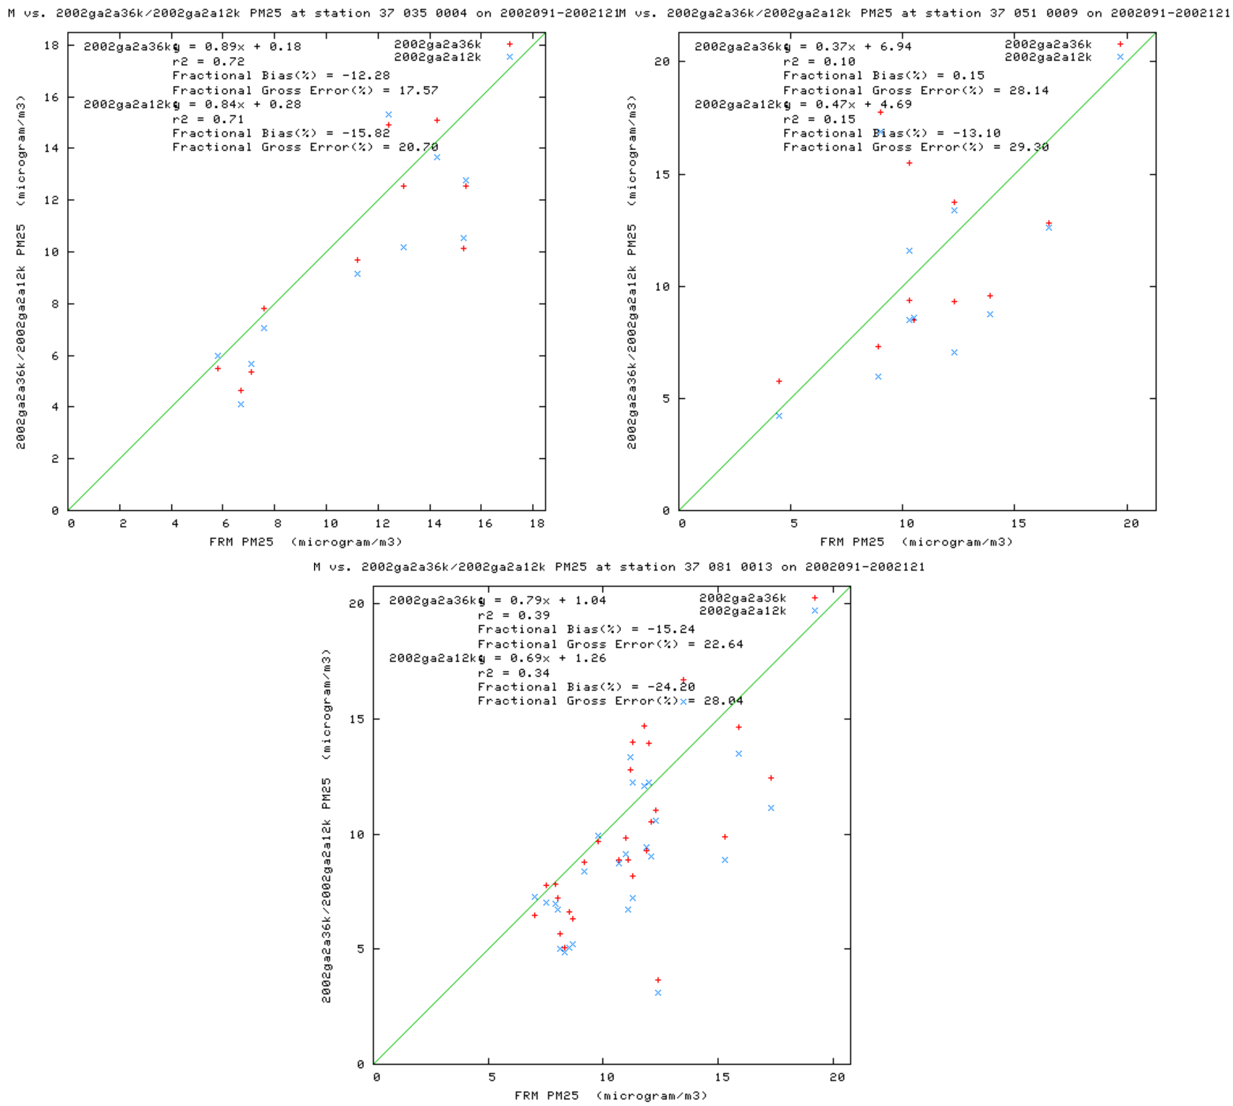

Figure 4-80: Scatter Plot of Observed $PM_{2.5}$ from the FRM network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for the Hickory FRM site (37-035-0004)(top left), the Lexington FRM site (37-057-0002) (top right), and the Mendenhall FRM site (37-081-0013) for the month of April.

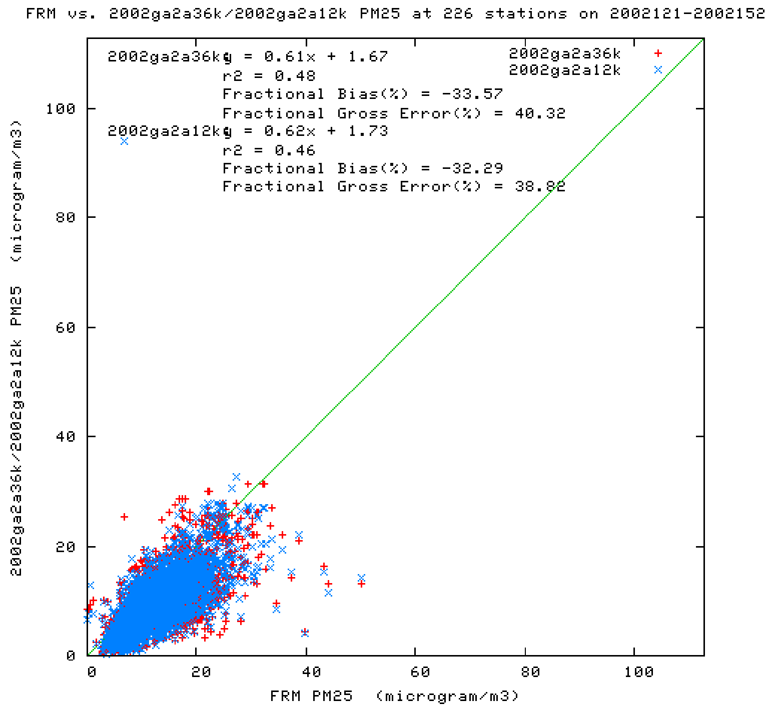
4.2.5 May



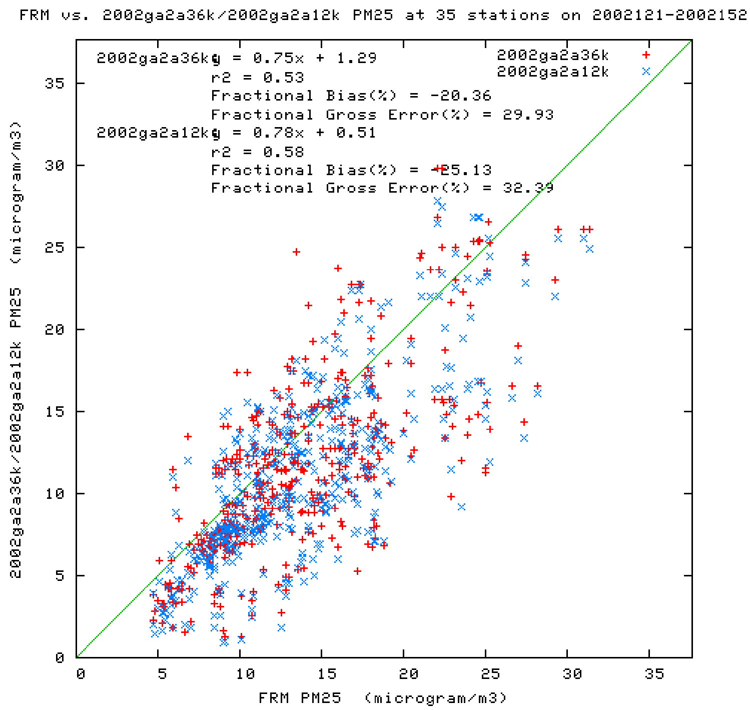


Figure 4-81: Scatter Plot of $PM_{2.5}$ from the FRM network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS FRM sites collectively (top), all North Carolina FRM sites collectively (bottom) for the month of May.

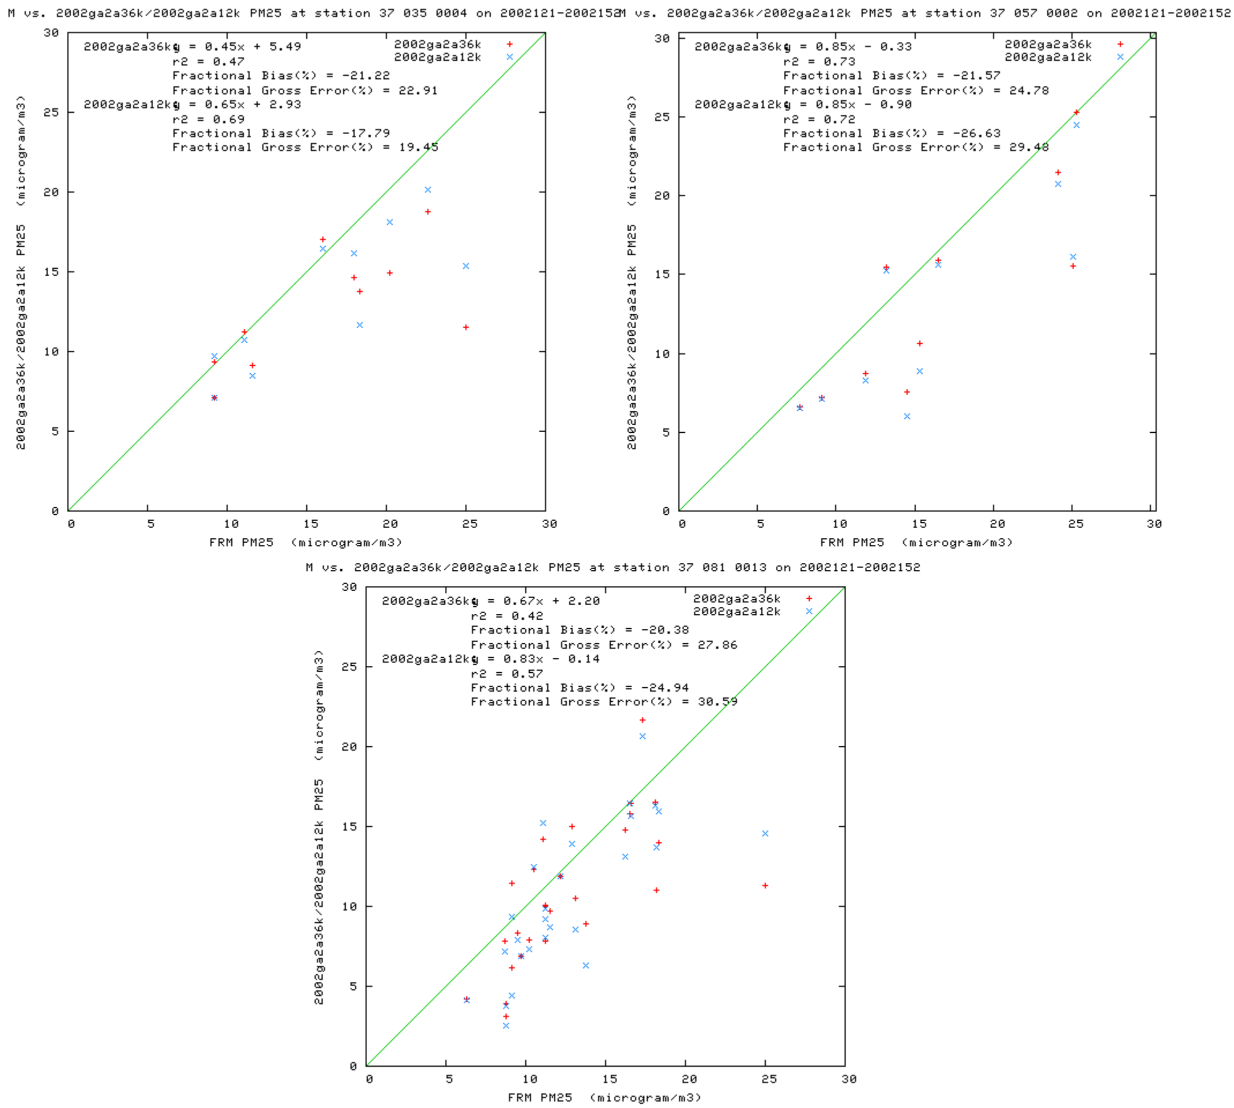

Figure 4-82: Scatter Plot of Observed $PM_{2.5}$ from the FRM network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for the Hickory FRM site (37-035-0004)(top left), the Lexington FRM site (37-057-0002) (top right), and the Mendenhall FRM site (37-081-0013) for the month of May.

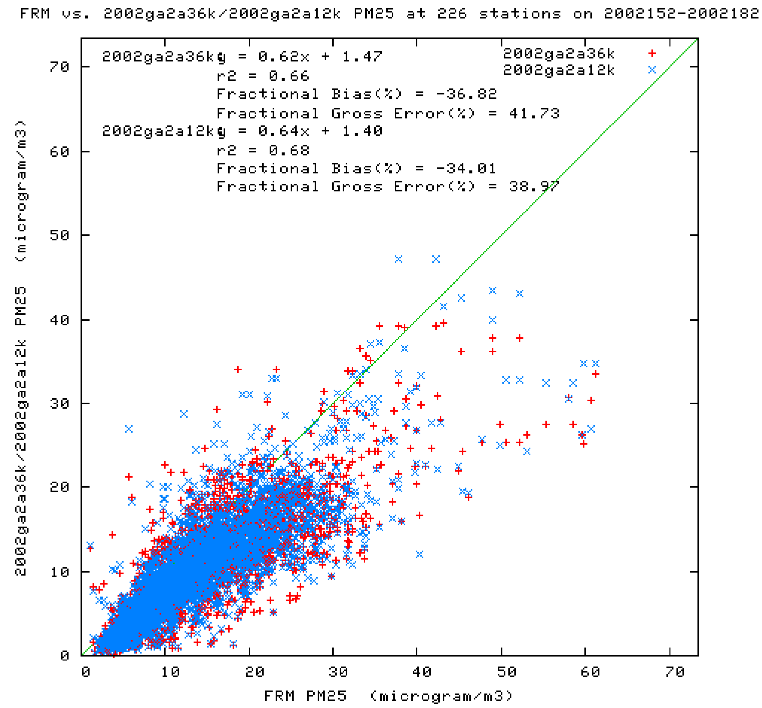
4.2.6 June



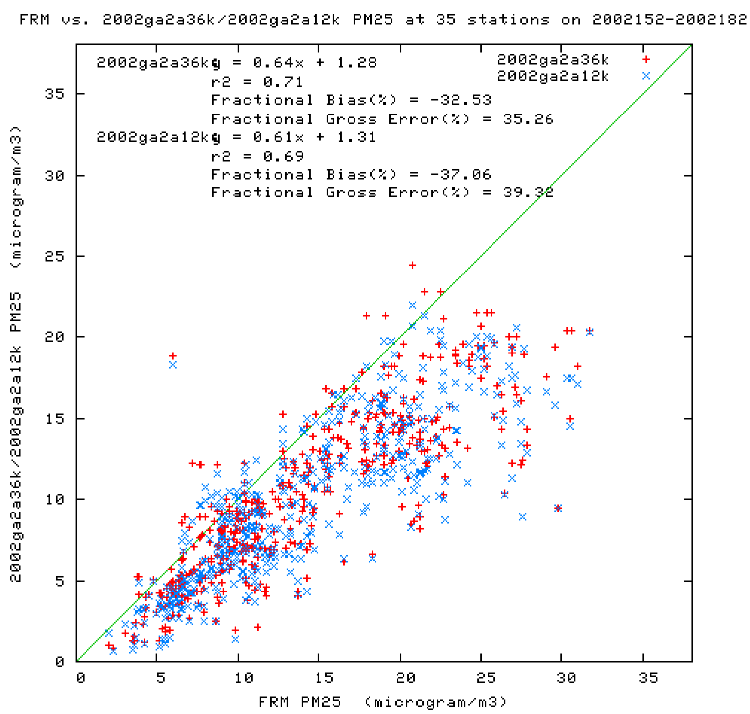


Figure 4-83: Scatter Plot of $PM_{2.5}$ from the FRM network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS FRM sites collectively (top), all North Carolina FRM sites collectively (bottom) for the month of June.

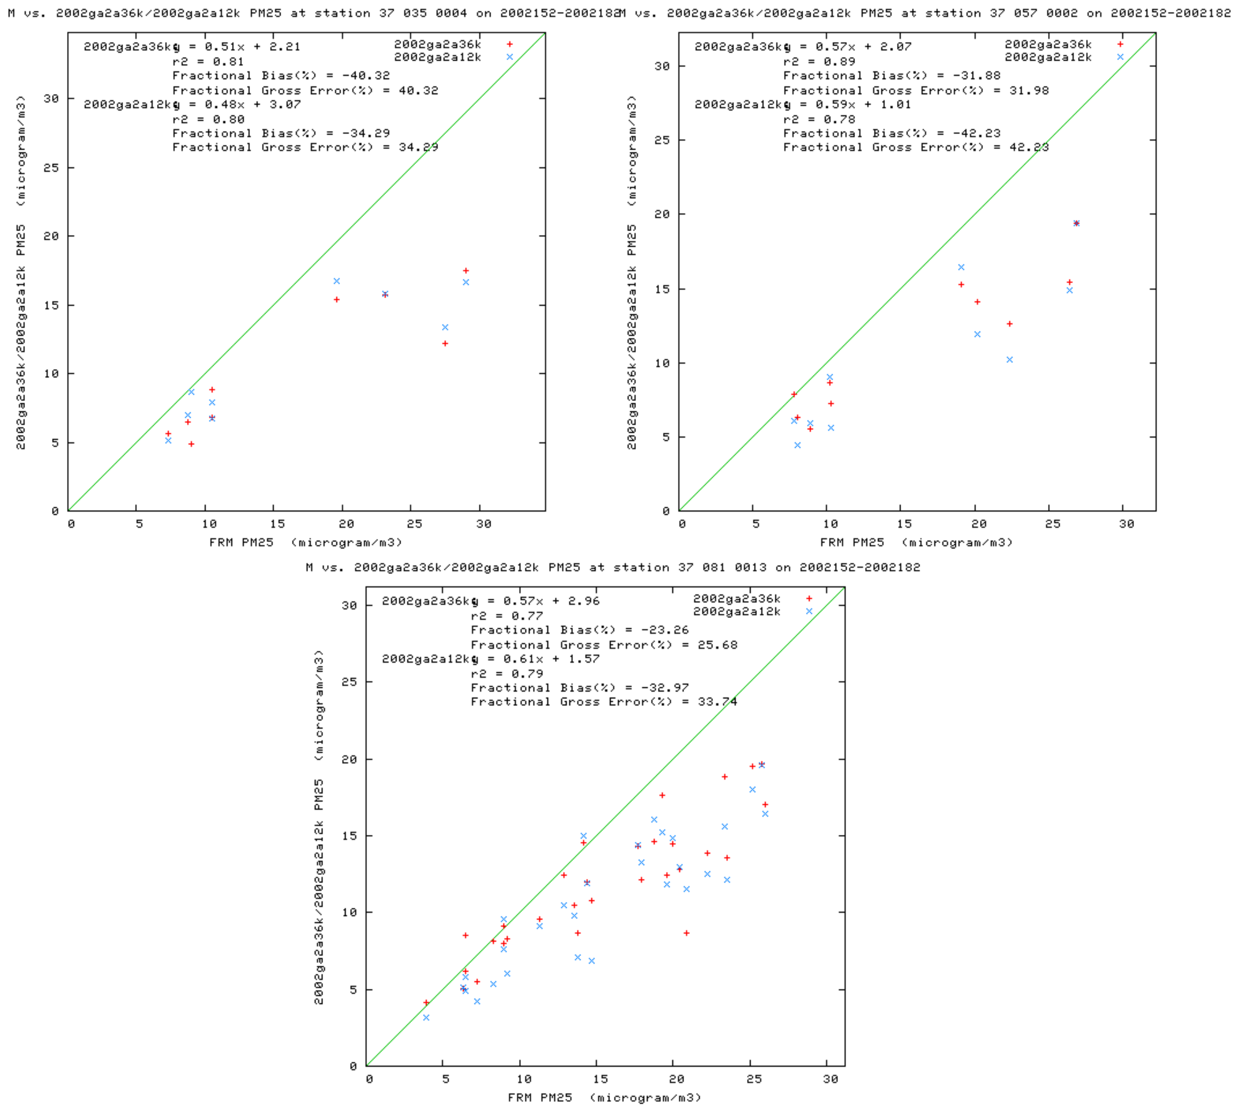

Figure 4-84: Scatter Plot of Observed $PM_{2.5}$ from the FRM network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for the Hickory FRM site (37-035-0004)(top left), the Lexington FRM site (37-057-0002) (top right), and the Mendenhall FRM site (37-081-0013) for the month of June.

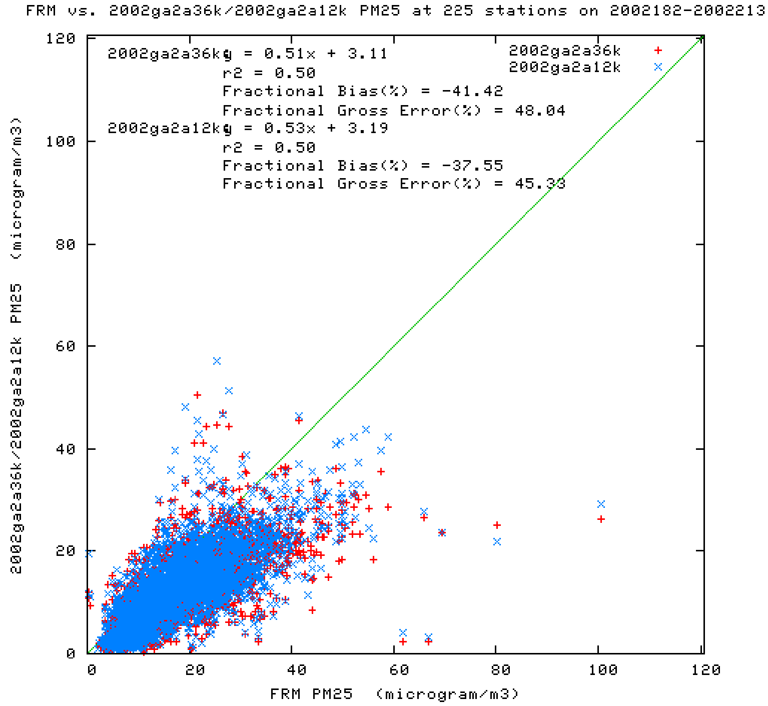
4.2.7 July



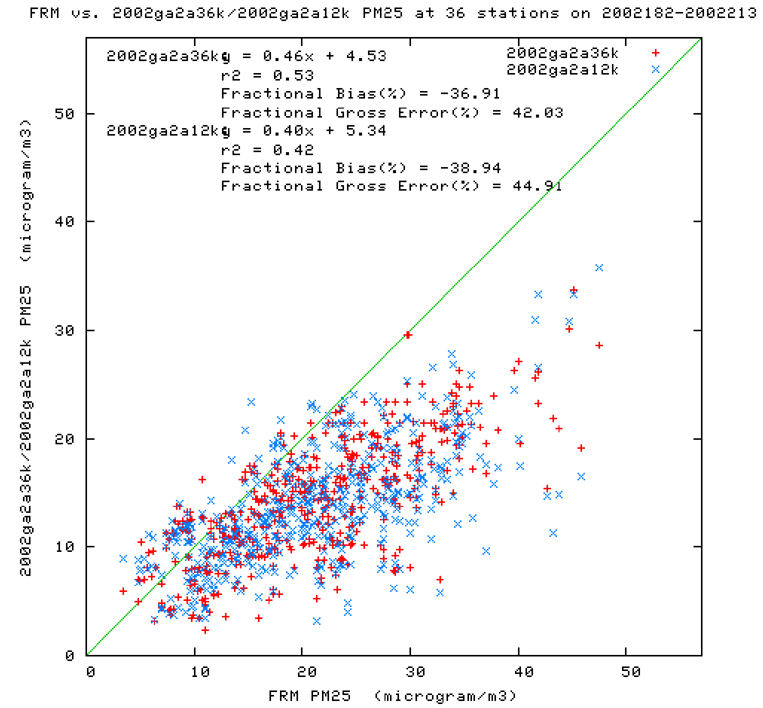


Figure 4-85: Scatter Plot of $PM_{2.5}$ from the FRM network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS FRM sites collectively (top), all North Carolina FRM sites collectively (bottom) for the month of July.

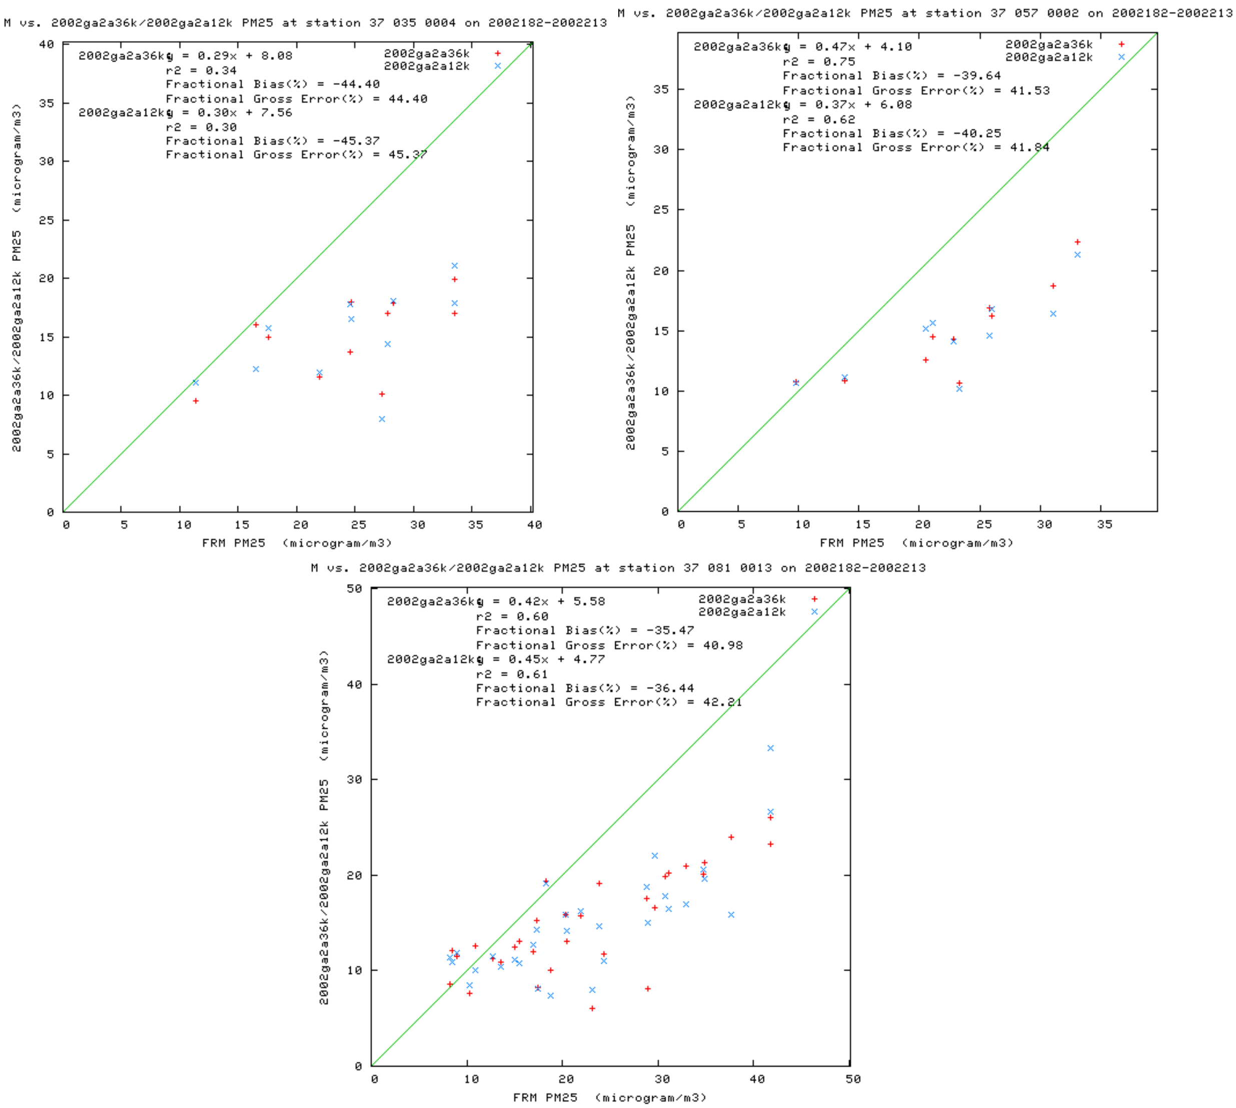

Figure 4-86: Scatter Plot of Observed $PM_{2.5}$ from the FRM network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for the Hickory FRM site (37-035-0004)(top left), the Lexington FRM site (37-057-0002) (top right), and the Mendenhall FRM site (37-081-0013) for the month of July.

4.2.8 August

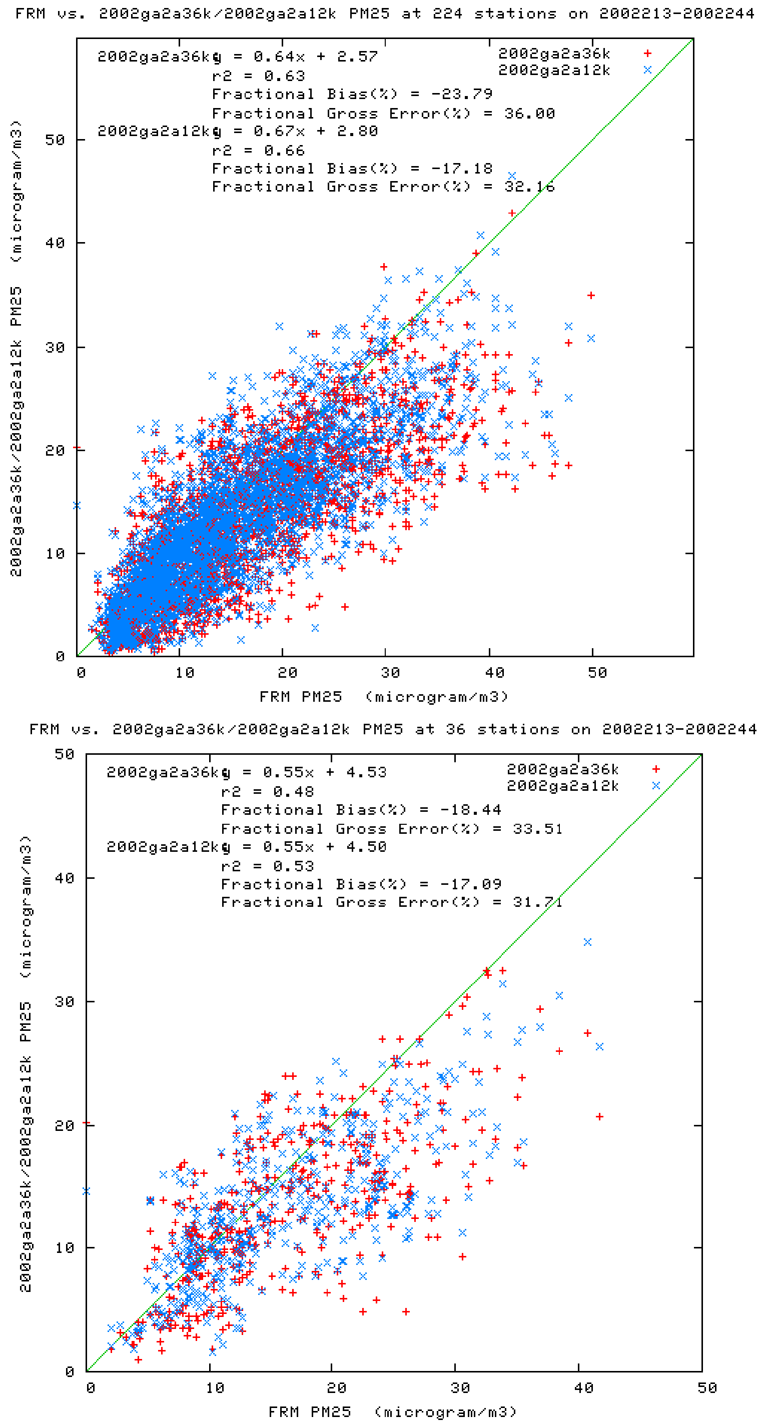

Figure 4-87: Scatter Plot of $PM_{2.5}$ from the FRM network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS FRM sites collectively (top), all North Carolina FRM sites collectively (bottom) for the month of August.

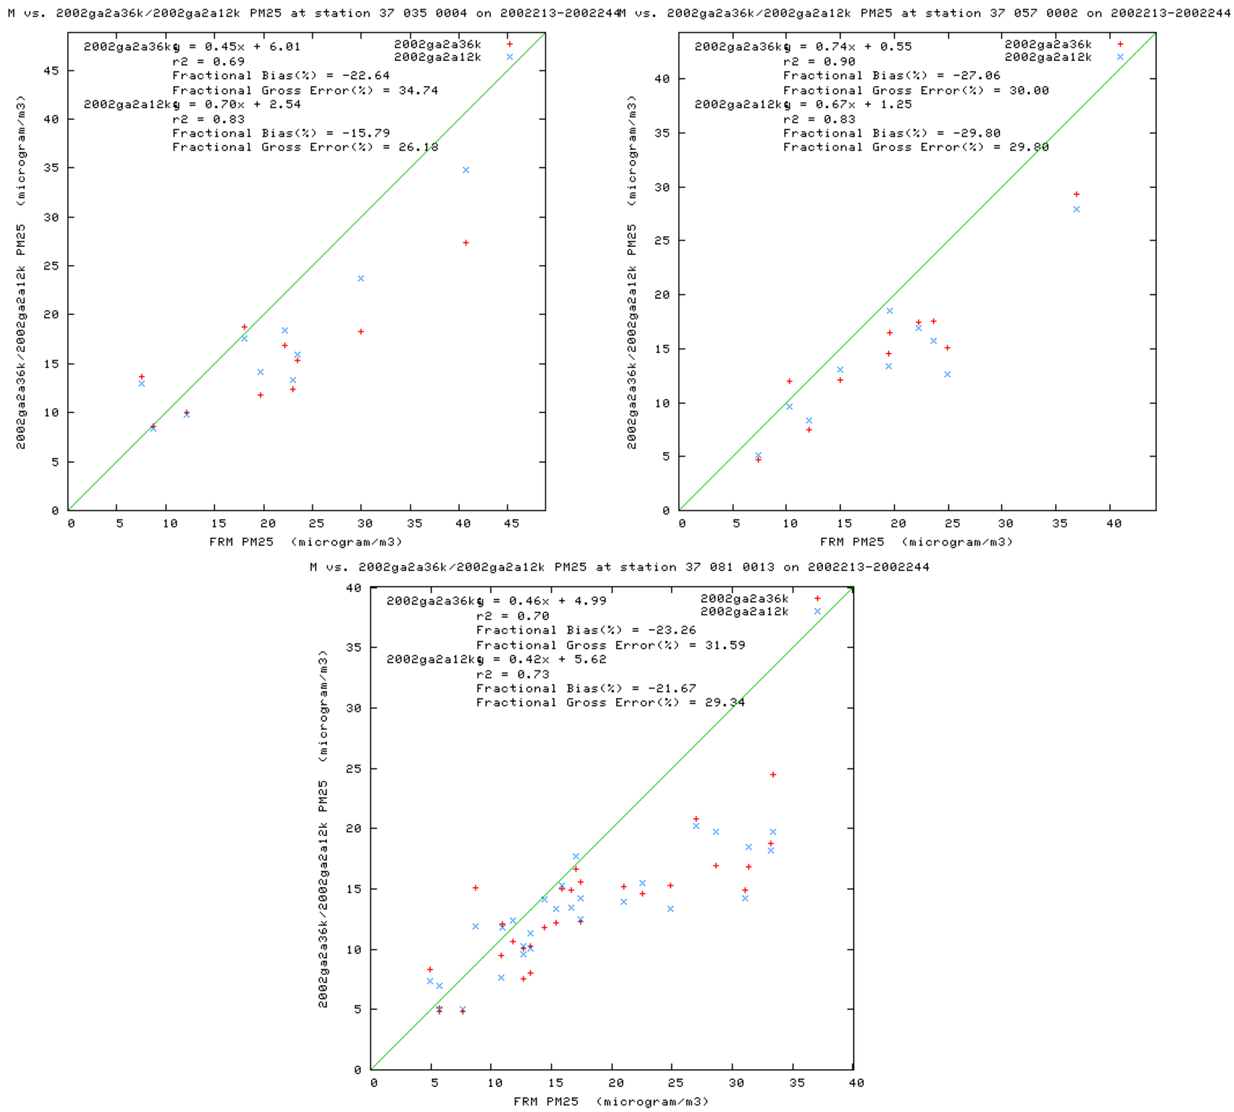

Figure 4-88: Scatter Plot of Observed $PM_{2.5}$ from the FRM network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for the Hickory FRM site (37-035-0004)(top left), the Lexington FRM site (37-057-0002) (top right), and the Mendenhall FRM site (37-081-0013) for the month of August.

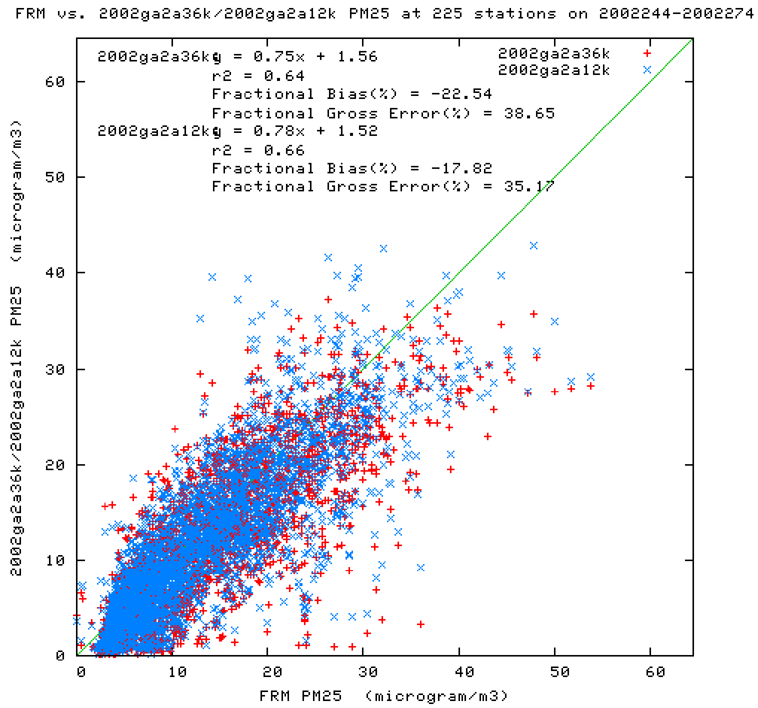
4.2.9 September



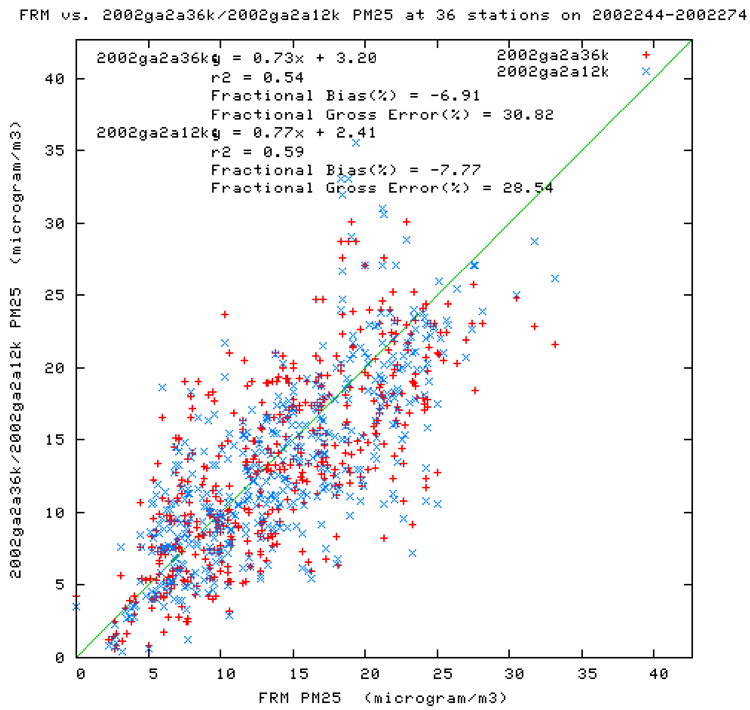


Figure 4-89: Scatter Plot of $PM_{2.5}$ from the FRM network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS FRM sites collectively (top), all North Carolina FRM sites collectively (bottom) for the month of September.

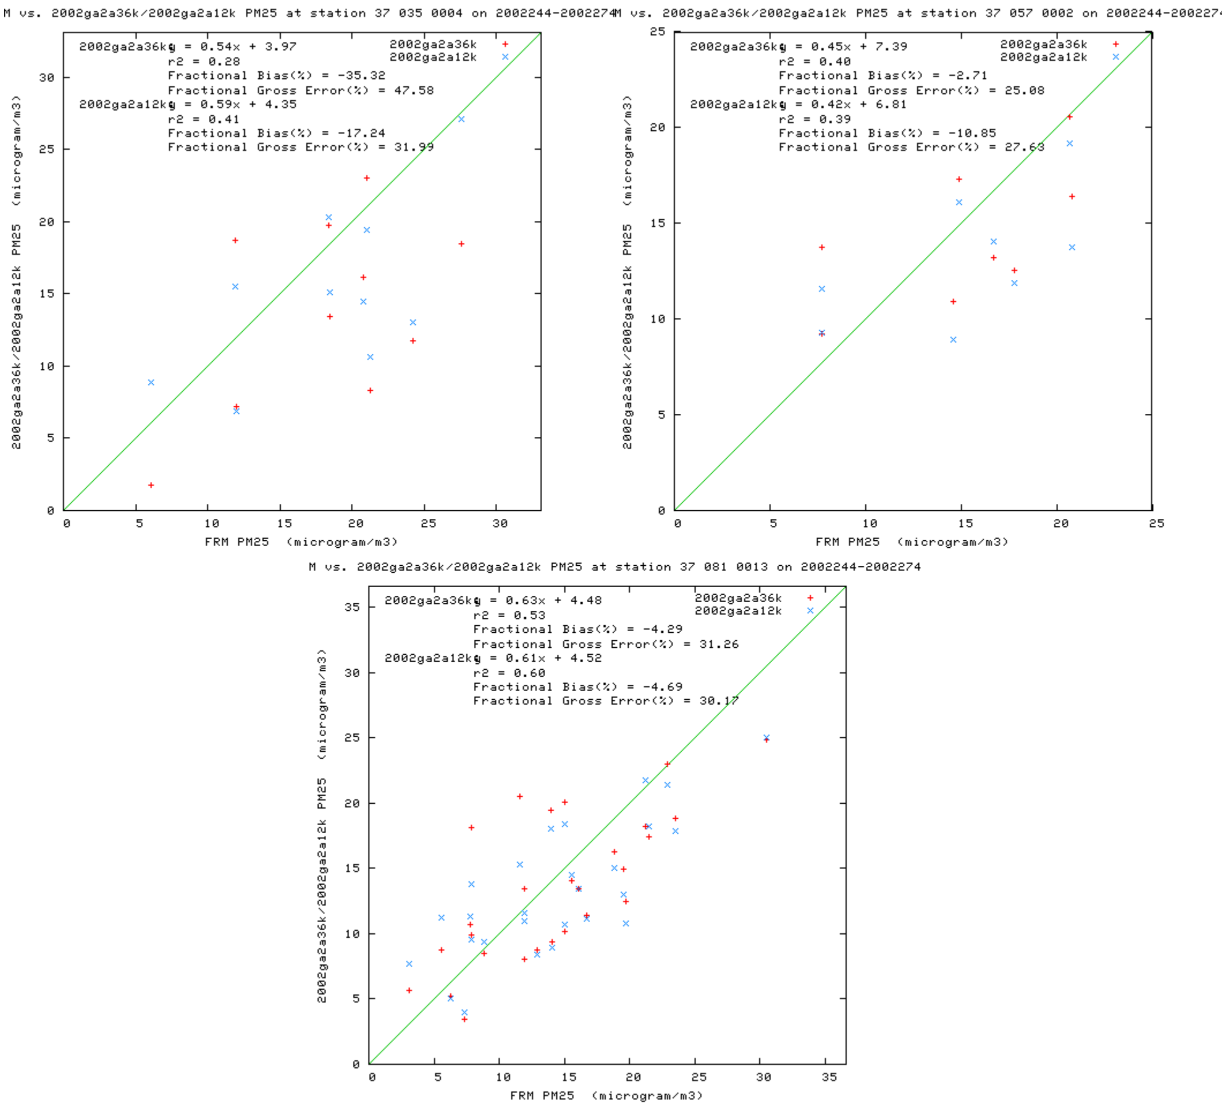

Figure 4-90: Scatter Plot of Observed $PM_{2.5}$ from the FRM network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for the Hickory FRM site (37-035-0004)(top left), the Lexington FRM site (37-057-0002) (top right), and the Mendenhall FRM site (37-081-0013) for the month of September.

4.2.10 October

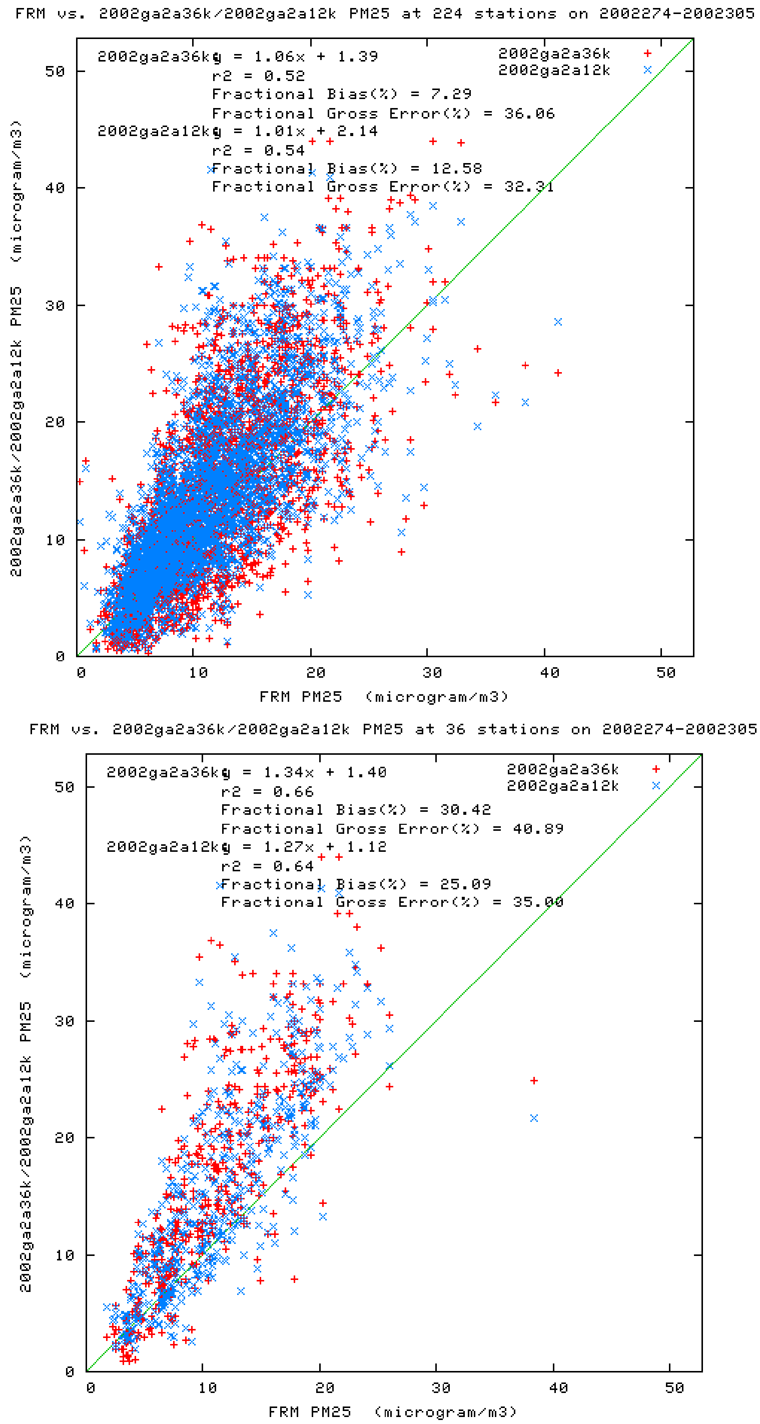

Figure 4-91: Scatter Plot of $PM_{2.5}$ from the FRM network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS FRM sites collectively (top), all North Carolina FRM sites collectively (bottom) for the month of October.

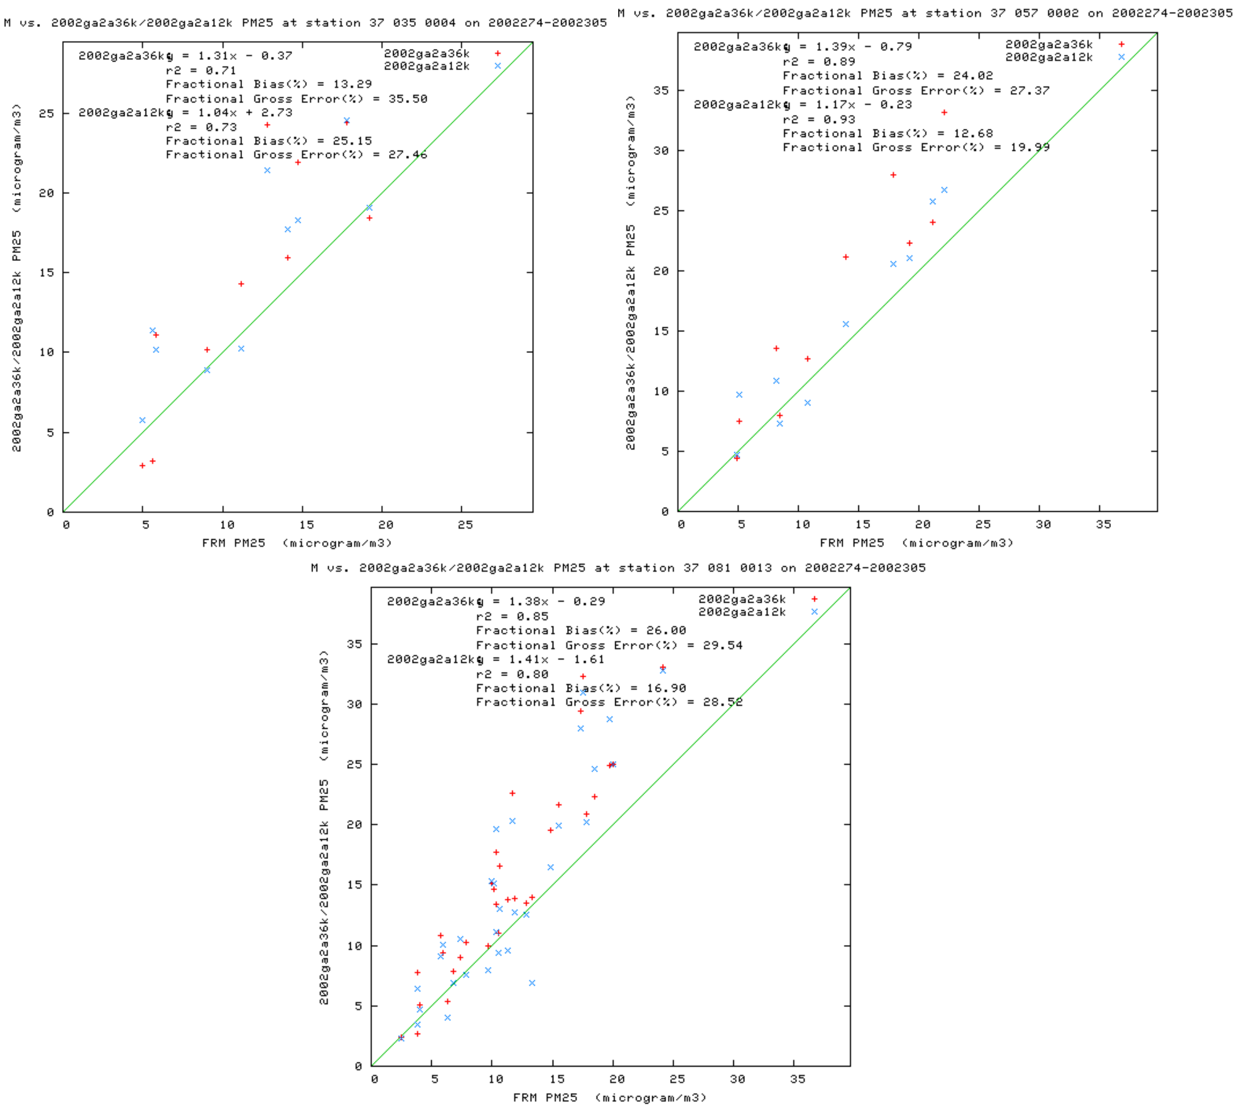

Figure 4-92: Scatter Plot of Observed $PM_{2.5}$ from the FRM network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for the Hickory FRM site (37-035-0004)(top left), the Lexington FRM site (37-057-0002) (top right), and the Mendenhall FRM site (37-081-0013) for the month of October.

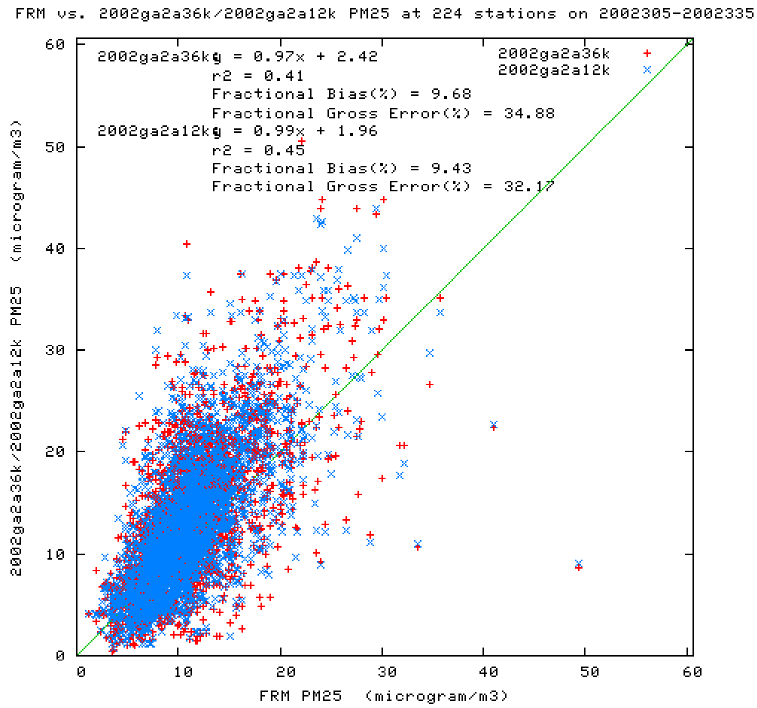
4.2.11 November



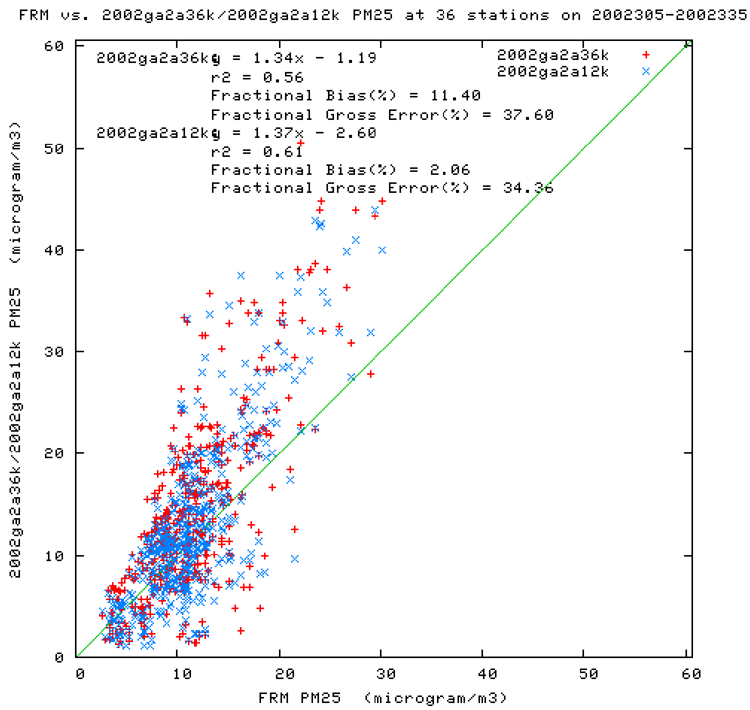


Figure 4-93: Scatter Plot of $PM_{2.5}$ from the FRM network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS FRM sites collectively (top), all North Carolina FRM sites collectively (bottom) for the month of November.

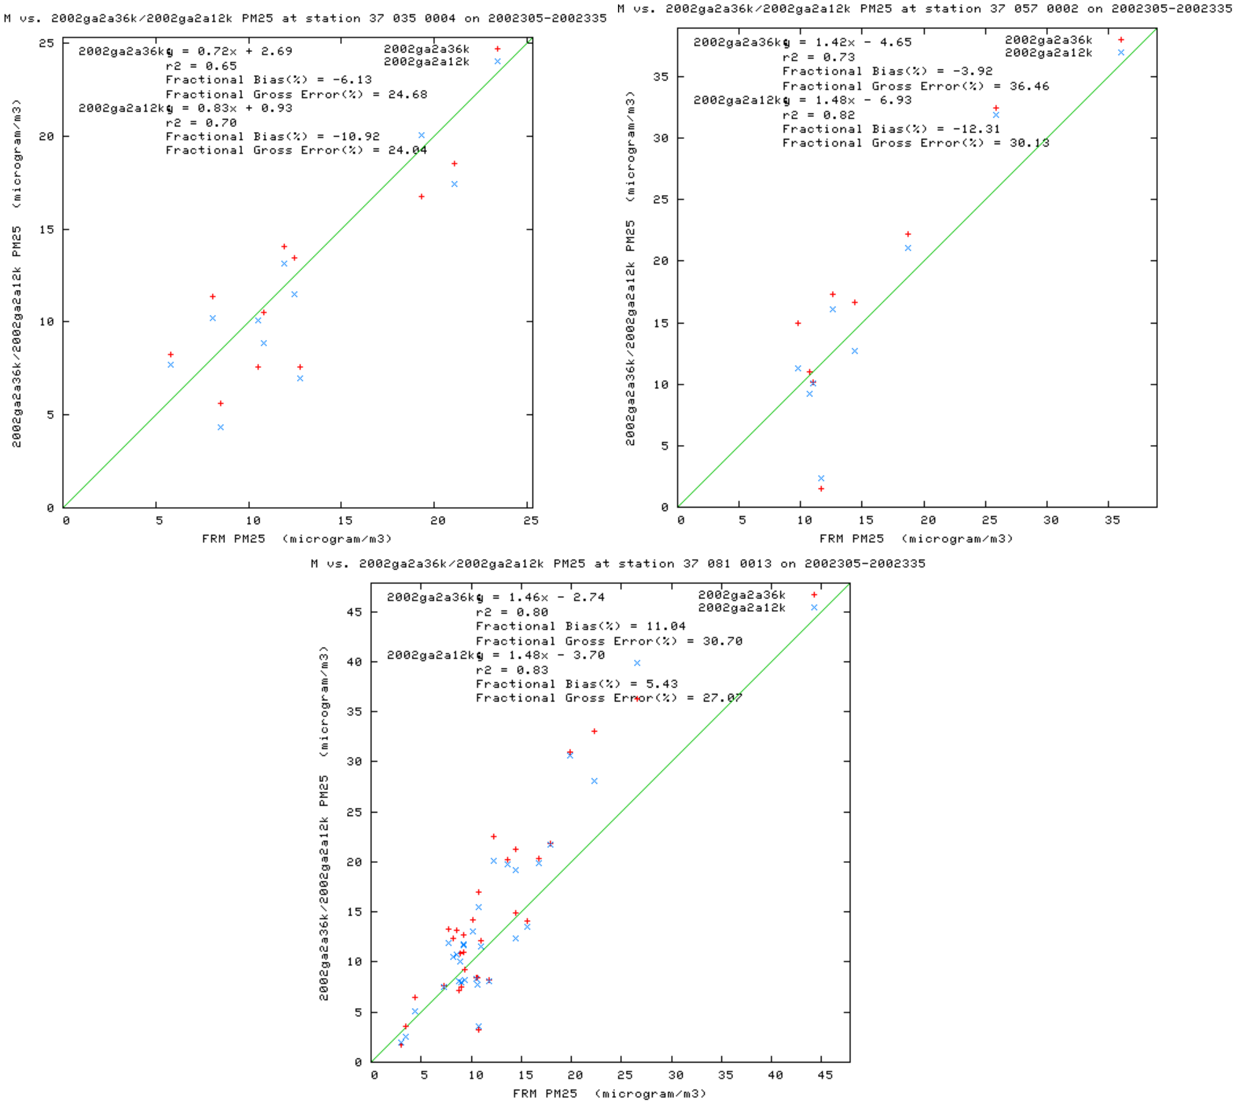

Figure 4-94: Scatter Plot of Observed $PM_{2.5}$ from the FRM network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for the Hickory FRM site (37-035-0004)(top left), the Lexington FRM site (37-057-0002) (top right), and the Mendenhall FRM site (37-081-0013) for the month of November.

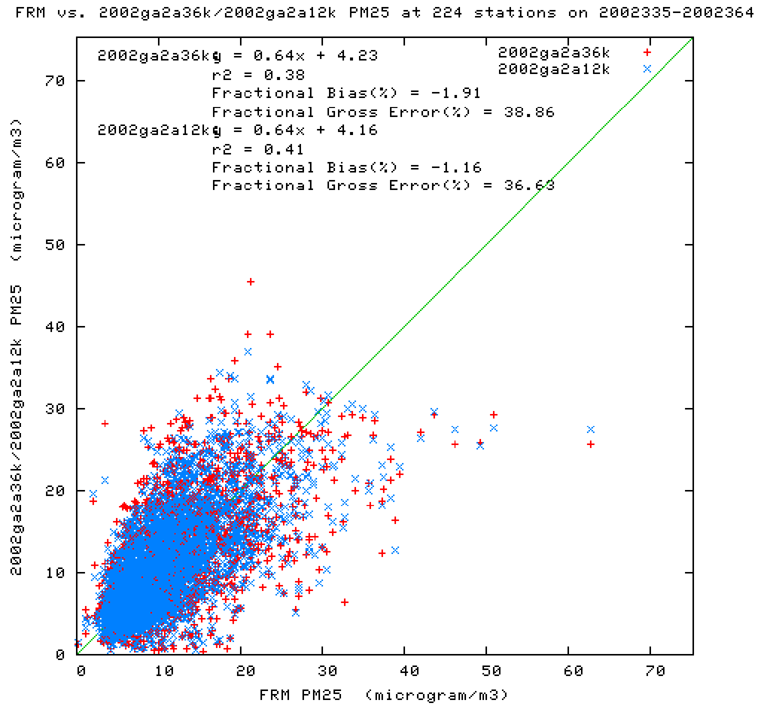
4.2.12 December



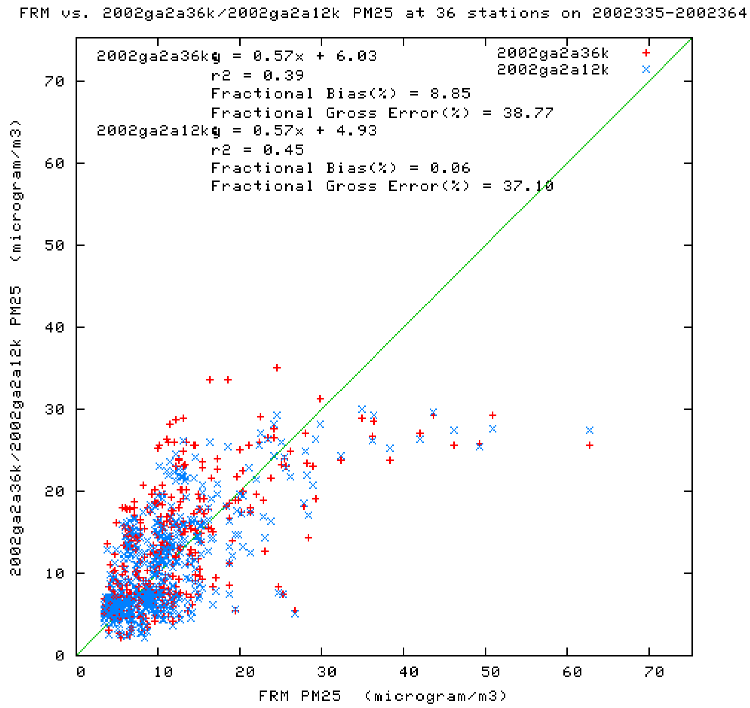


Figure 4-95: Scatter Plot of $PM_{2.5}$ from the FRM network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for all VISTAS FRM sites collectively (top), all North Carolina FRM sites collectively (bottom) for the month of December.

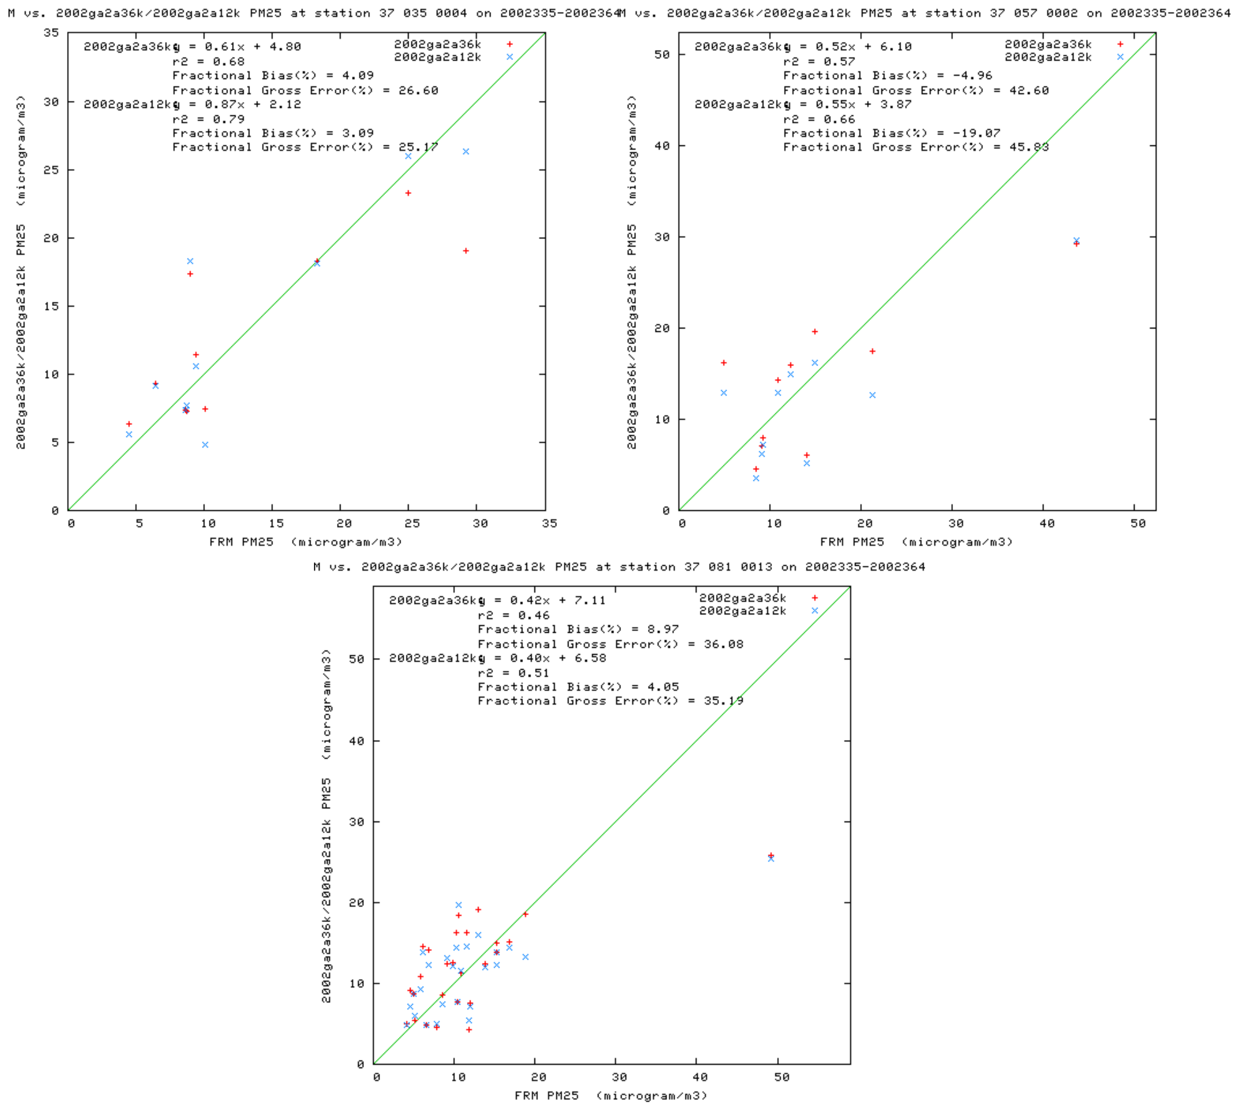

Figure 4-96: Scatter Plot of Observed $PM_{2.5}$ from the FRM network versus the Modeled Sulfate for the 12km domain (blue x's) and the 36km domain (red +'s) for the Hickory FRM site (37-035-0004)(top left), the Lexington FRM site (37-057-0002) (top right), and the Mendenhall FRM site (37-081-0013) for the month of December.

5. Time Series

The time series plots that display model predicted particulate matter component concentrations for the 12km grid resolution (purple line), the 36 km grid resolution (blue line), and observed concentrations (red line) are presented in this section. Observations are reported per the polling frequency of the site presented, and have been paired with their corresponding model predicted value. Time series for five of component species of particulate matter (sulfates, nitrates, ammonium, organic carbon, and elemental carbon) are presented by species, for both the Hickory and Hattie Avenue STN monitoring sites, for each month of the year in Section 5.1. Time series for the total reconstructed fine particulate mass for the STN monitors follows the species plots in Section 5.1.6. Additionally, the total observed $PM_{2.5}$ mass form FRM sites are plotted with the 12km and 36 km grid resolution modeled values in Section 5.2. The annual fractional bias and fractional error for the site for both 12km and 36km grid resolution is presented in top right corner of all the graphs for reference.

Overall, the model captures the cycle of pollutant build up and clean out very well across the major constituents of $PM_{2.5}$. Nitrates performance is the weakest, but the general pattern of increase and decreases is still reasonably captured, with most of the poor performance occurring in the later half of the year. The ammonium cycle is actually captured quite well, especially in the April to May timeframe. The general good performance of the components translates to good performance in the total reconstructed $PM_{2.5}$ mass from the STN sites. The FRM data also shows the model responds appropriately to shift in weather patterns and pollutant patterns, as the FRM modeled response mirrors the observed response quite well.

The negative bias in the model is still apparent in the times series; however, the plots show that the model is doing a good job of capturing the pattern of increases and decreases in $PM_{2.5}$ and it's constituents. This is encouraging because it shows the model chemistry is reacting appropriately to meteorology and is performing well.

5.1 STN Time Series

5.1.1 Sulfates

5.1.1.1 January

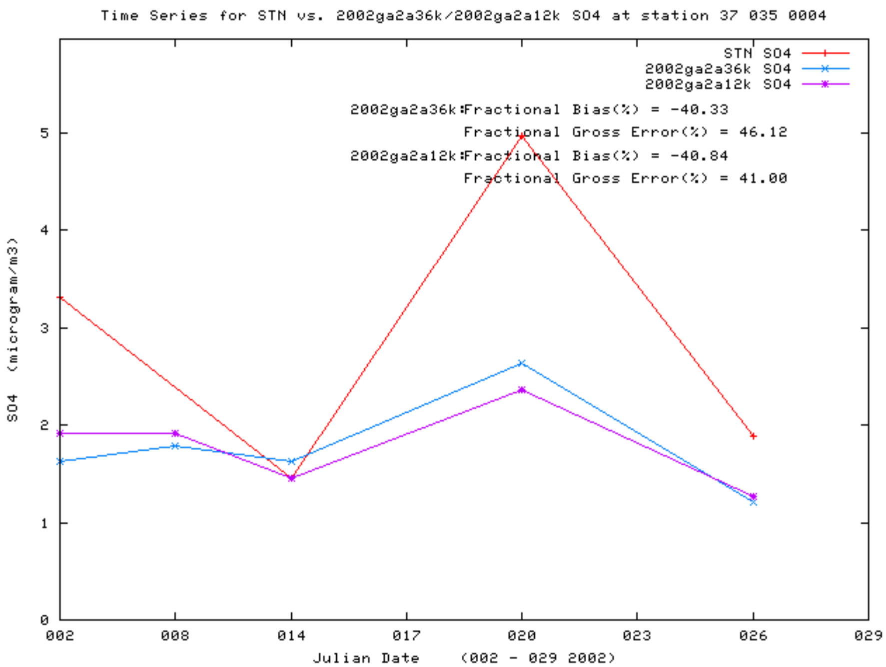

Figure 5-1: January 2002 Time Series of Observed Sulfate levels (red line) and Modeled Sulfate Levels at both 36km (blue line) and 12km (purple line) grind resolution for the Hickory STN monitor (37-035-0004).

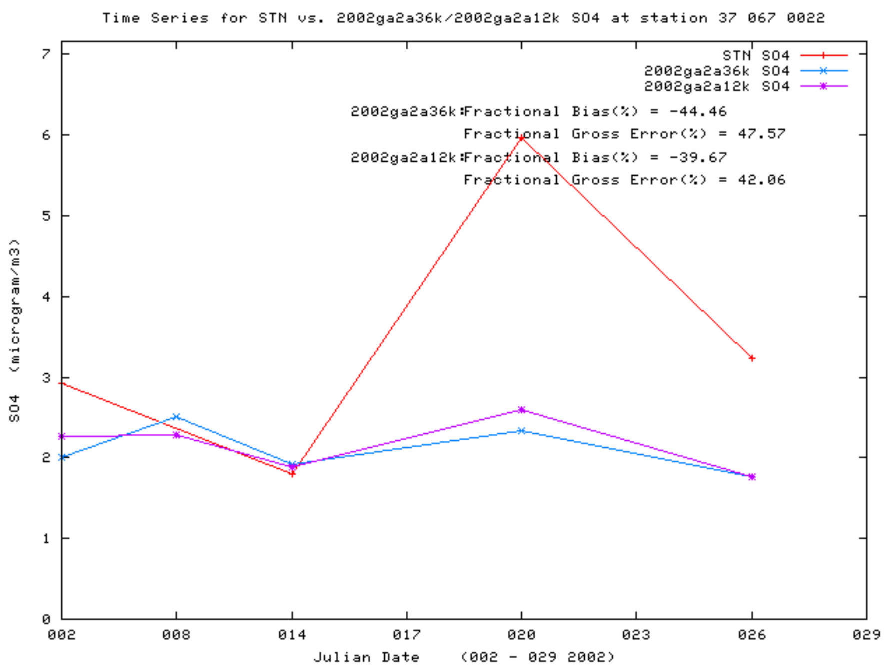

Figure 5-2: January 2002 Time Series of Observed Sulfate levels (red line) and Modeled Sulfate Levels at both 36km (blue line) and 12km (purple line) grind resolution for the Hattie Avenue STN monitor (37-067-0022).

5.1.1.2 February

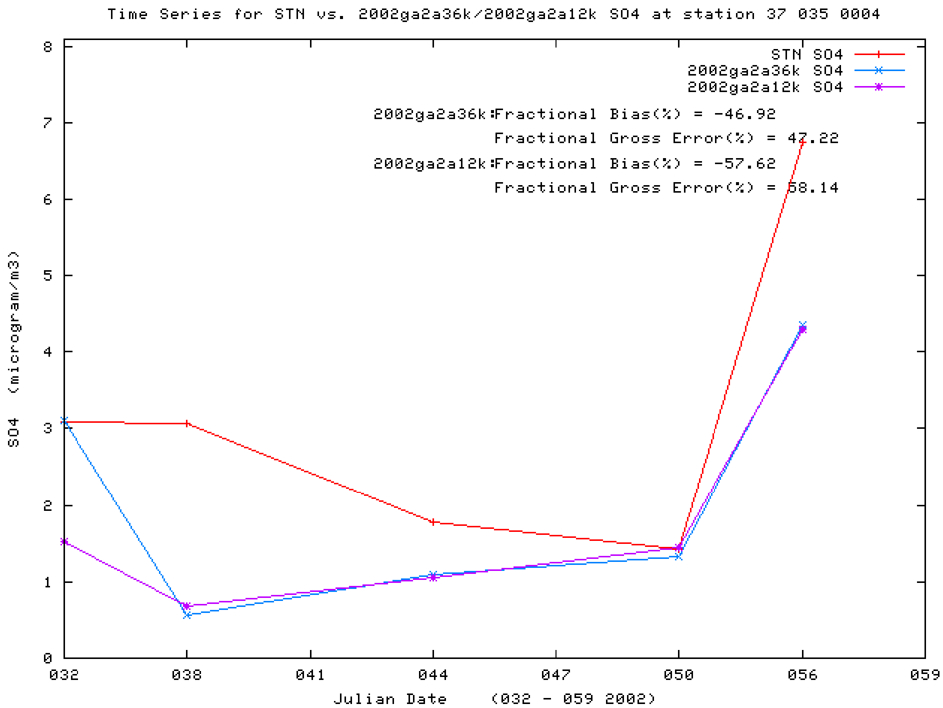

Figure 5-3: February 2002Time Series of Observed Sulfate levels (red line) and Modeled Sulfate Levels at both 36km (blue line) and 12km (purple line) grind resolution for the Hickory STN monitor (37-035-0004).

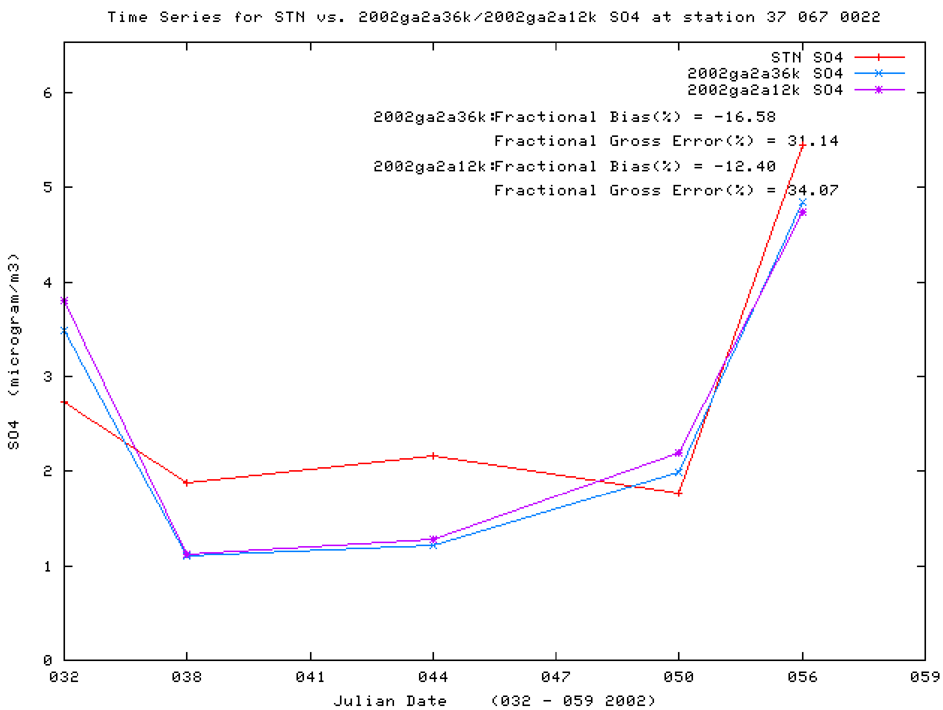

Figure 5-4: February 2002 Time Series of Observed Sulfate levels (red line) and Modeled Sulfate Levels at both 36km (blue line) and 12km (purple line) grind resolution for the Hattie Avenue STN monitor (37-067-0022).

5.1.1.3 March

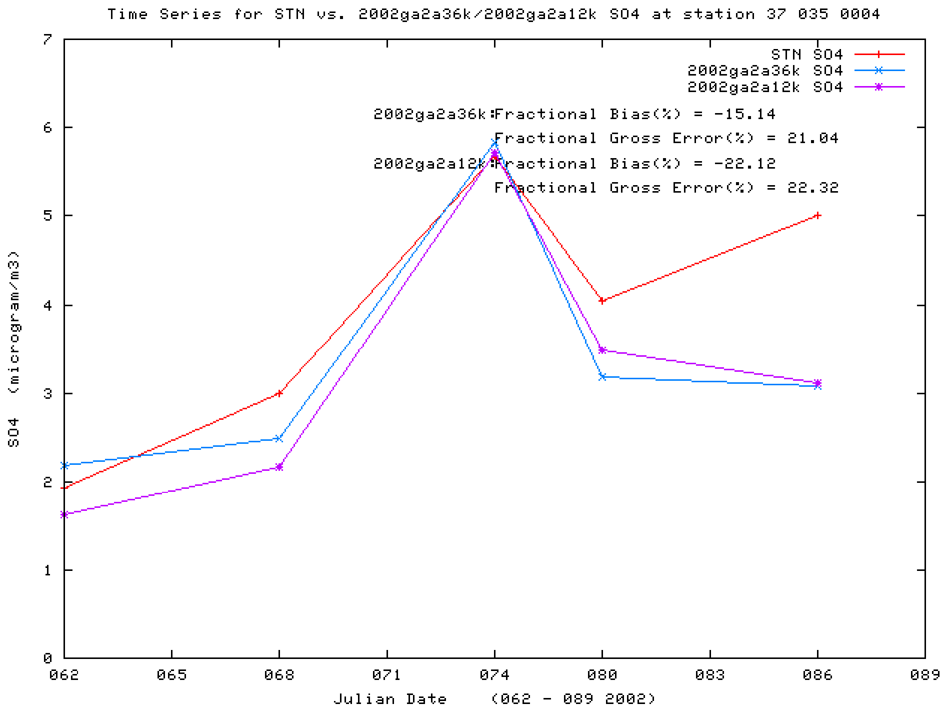

Figure 5-5: March 2002Time Series of Observed Sulfate levels (red line) and Modeled Sulfate Levels at both 36km (blue line) and 12km (purple line) grind resolution for the Hickory STN monitor (37-035-0004).

6. Stacked Bar Charts

The following section provides stacked bar charts comparing observed fine particulate matter composition and modeled fine particulate matter composition. Stacked bar charts have been developed for each of the STN monitoring sites in and near the North Carolina $PM_{2.5}$ nonattainment areas (Hickory and Hattie Avenue).

The stacked bar chart allows a side-by-side comparison of each day's observed and modeled compositional and total light extinction. Within each bar, the yellow portion of the bar represents the mass due to sulfates (SO4), the red portion of the bar represents the mass due to nitrates (NO3), the green portion of the bar represents the mass due to organic carbon (OC), the black the bar represents the portion of mass due to elemental (EC), and finally the grey portion of the bar represents the mass due to ammonium (NH4). The components are presented in the same order for both the observed (left hand bar) and modeled bar (right hand bar), so it is easy to identify days when the predicted mass for the component differs from the observed. The total height of the bar provides the total reconstructed mass of fine particulate matter.

Just glancing through the stacked bars charts reiterates that sulfates are a large contributor to total $PM_{2.5}$ mass in both nonattainment areas. The bar charts also suggest that organic carbon is also a large contributor to $PM_{2.5}$ mass in North Carolina. The bar charts reiterate the general under-prediction seen in previous sections. Both the Hickory and Hattie Avenue sites, the bar charts show that the sulfate mass is generally well captured, with instances of both over and under prediction. Nitrates tend to be over predicted in the early spring and late winter, when the mass is the highest. The bars also suggest that organic carbon is generally under predicted at both sites. Looking across the bars, it appears as though this under prediction of organic carbon and the slight sulfates is the largest contributor to general $PM_{2.5}$ under prediction.

6.1 Hickory (STN)

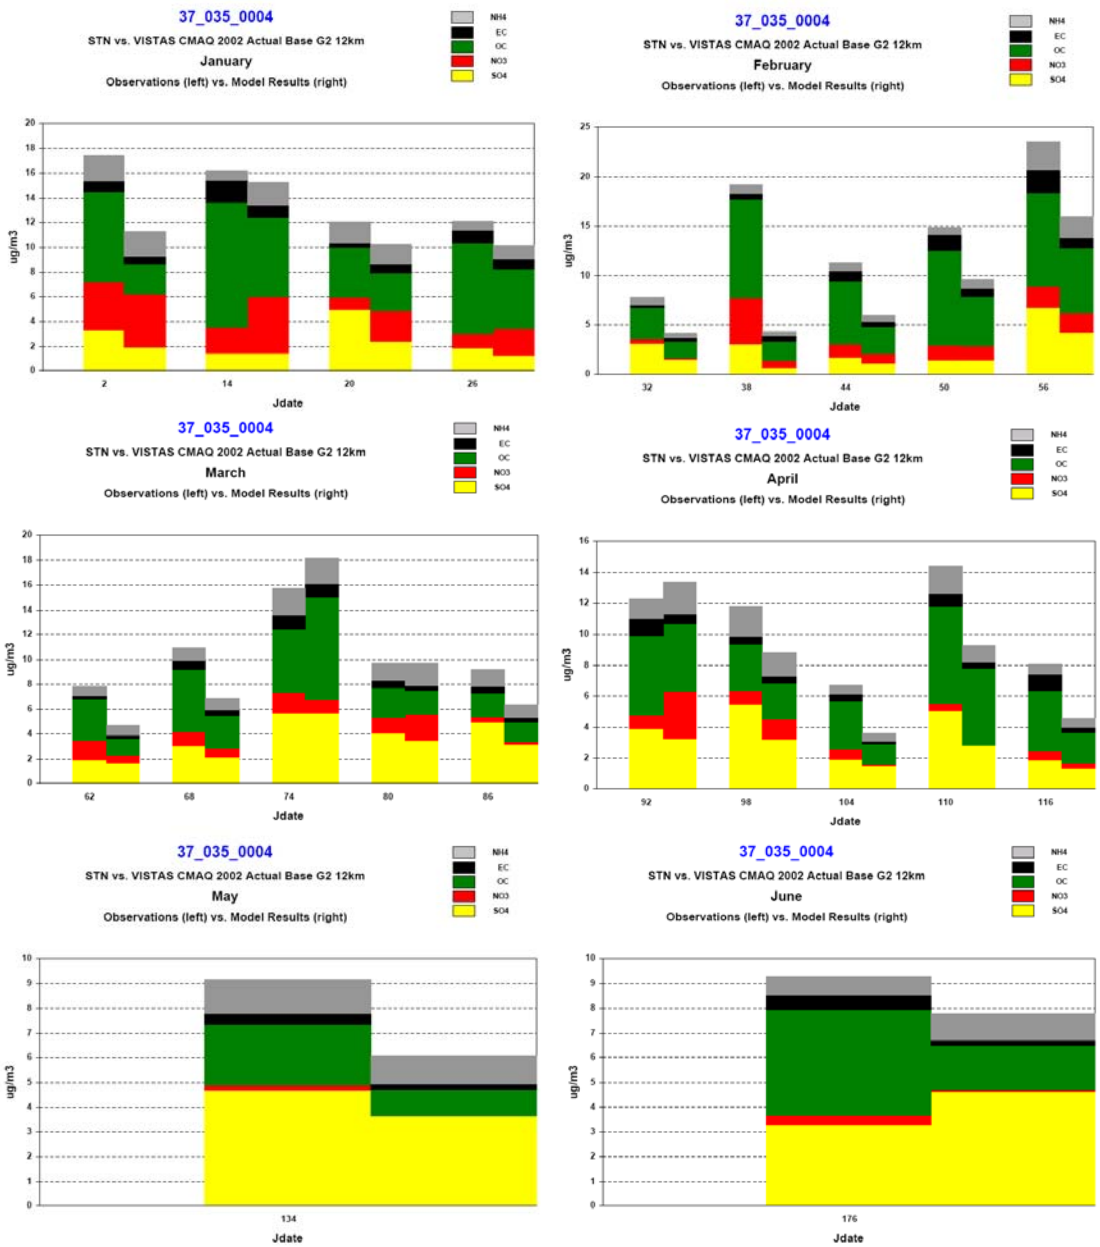

Figure 6-1: Stacked bar chart for the Hickory STN monitoring site (37-035-0004) for January (top left), February (top right), March (center left), April (center right), May (bottom left), and June (bottom right). Observed composition is presented in the left hand bar, with modeled composition represented by the right hand bar.

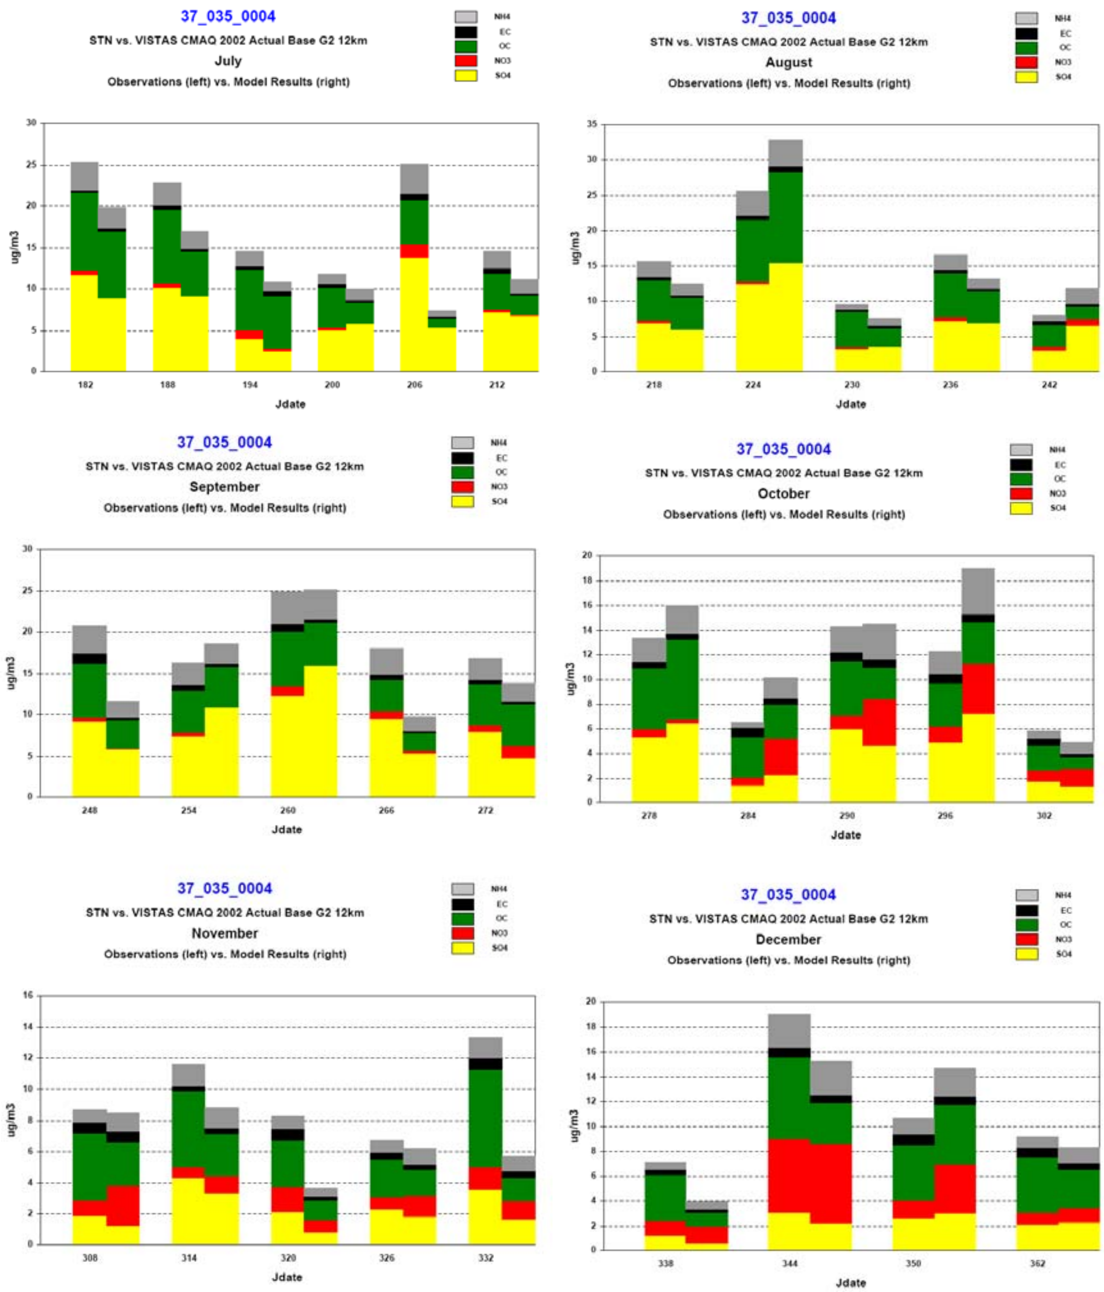

Figure 6-2: Stacked bar chart for the Hickory STN monitoring site (37-035-0004) for July (top left), August (top right), September (center left), October (center right), November (bottom left), and December (bottom right). Observed composition is presented in the left hand bar, with modeled composition represented by the right hand bar.

6.2 Hattie Avenue (STN)

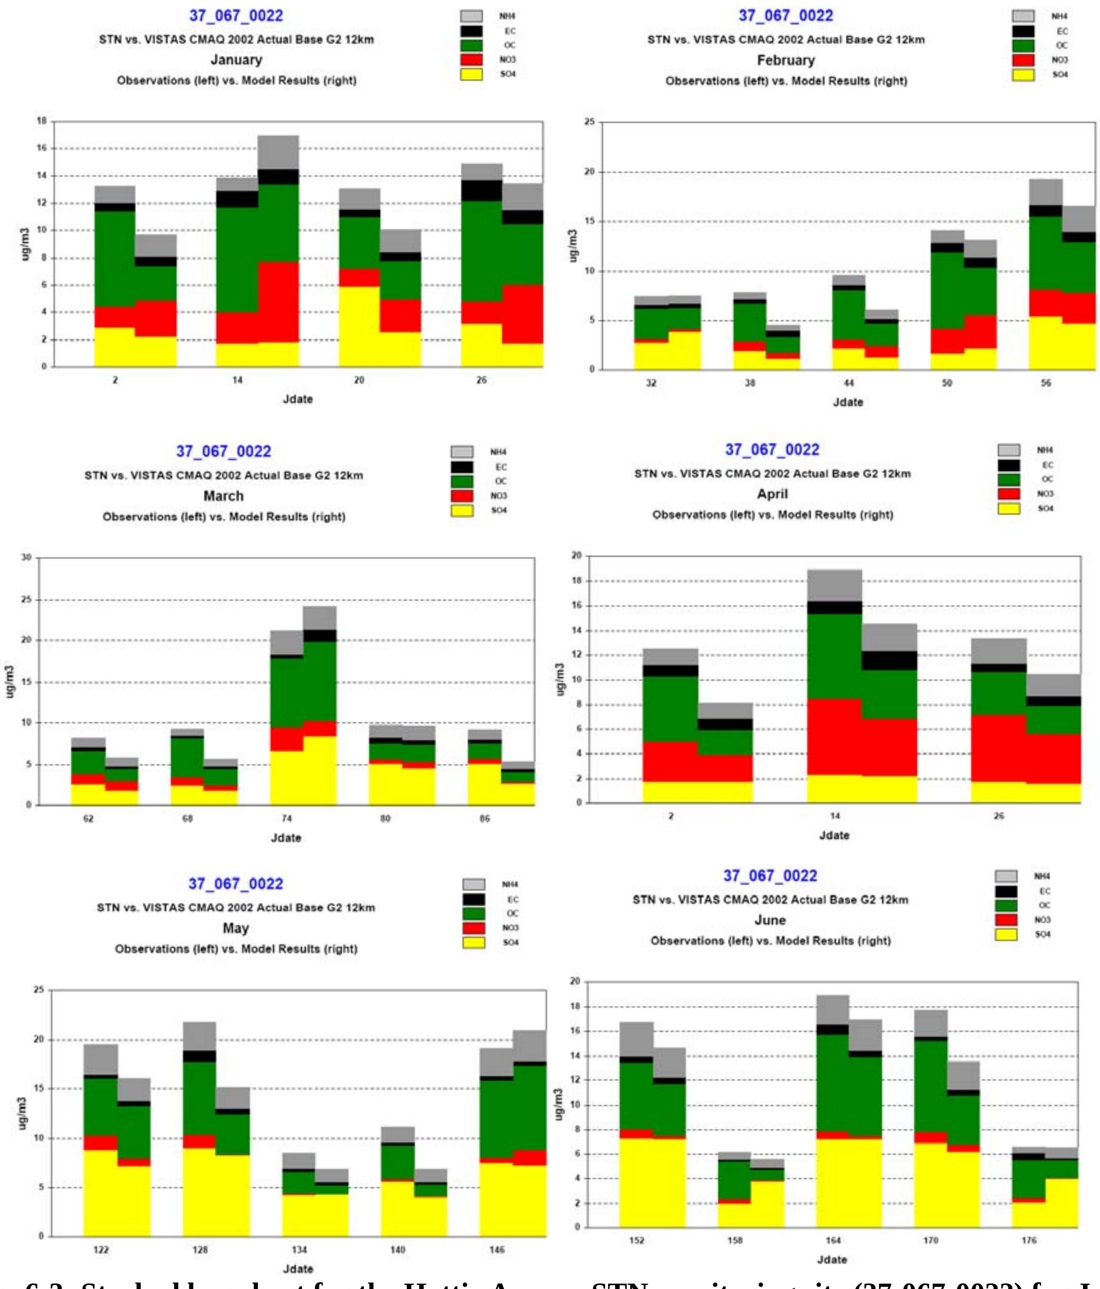

Figure 6-3: Stacked bar chart for the Hattie Avenue STN monitoring site (37-067-0022) for January (top left), February (top right), March (center left), April (center right), May (bottom left), and June (bottom right). Observed composition is presented in the left hand bar, with modeled composition represented by the right hand bar.

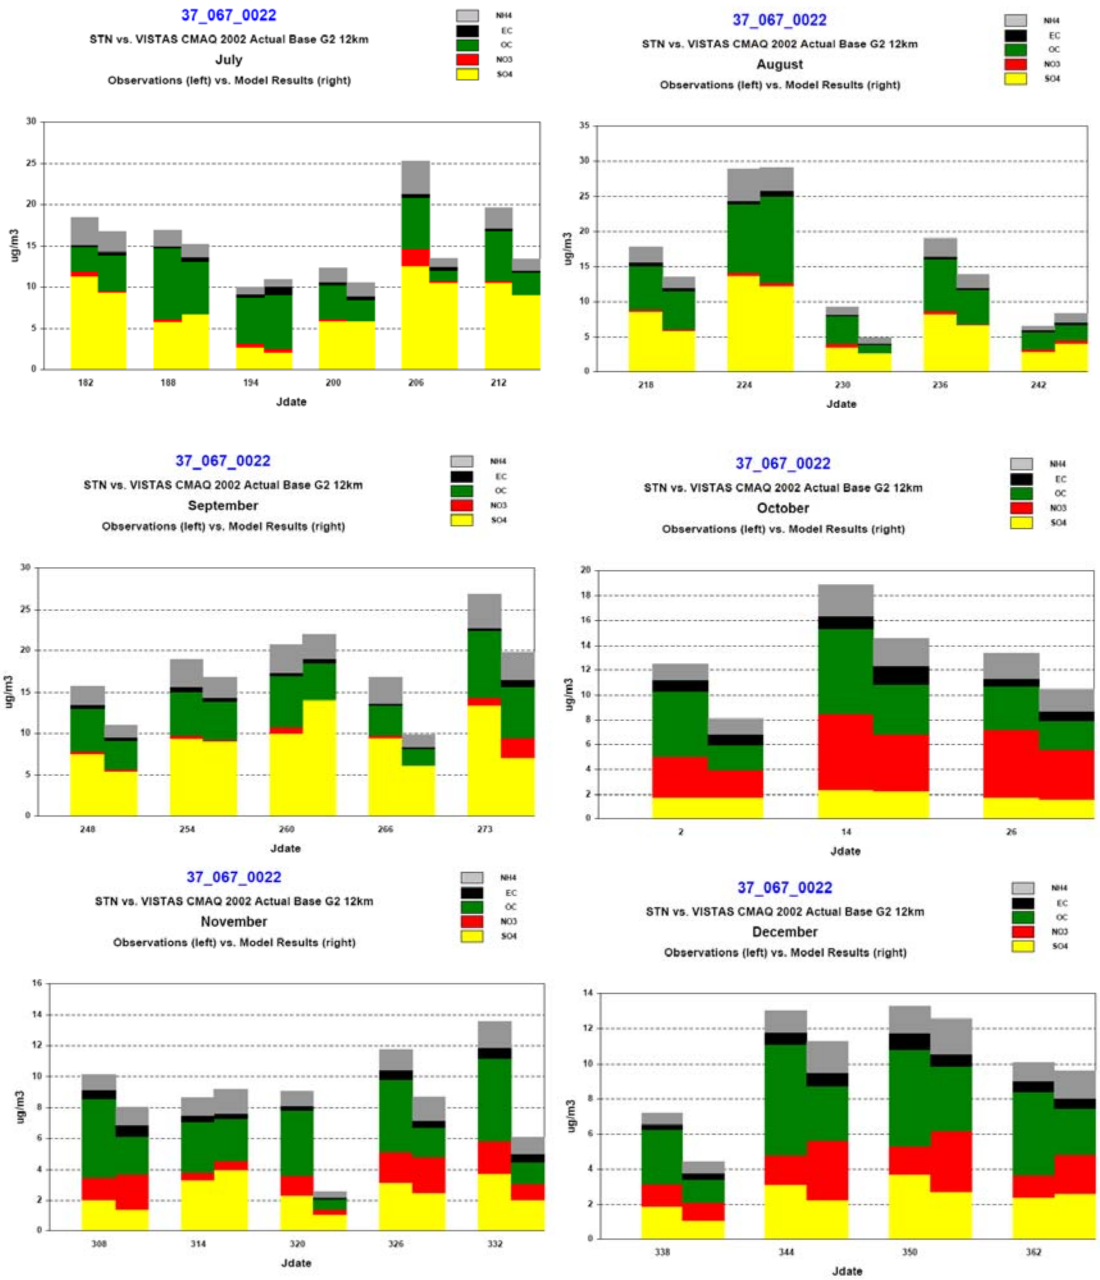

Figure 6-4: Stacked bar chart for the Hattie Avenue STN monitoring site (37-067-0022) for July (top left), August (top right), September (center left), October (center right), November (bottom left), and December (bottom right). Observed composition is presented in the left hand bar, with modeled composition represented by the right hand bar.

Appendix K

Modeling Results

List Of Figures

List Of Tables

Introduction

The air quality modeling results for the 12-kilometer (km) grid modeling domain are presented in this appendix for the attainment demonstration for both the Hickory and the Greensboro-Winston-Salem-High Point (referred to as the Triad area) annual fine particulate matter (PM25) nonattainment areas. These modeling results are displayed as 24-hour average plots of reconstructed PM25 for both the 2002 baseline year and the 2009 attainment year.

A subset of days from 2002 is presented in this appendix, though all days from 2002 are used in developing the relative reduction factor (RRF) and subsequently the future design value (DVF). For model performance evaluation, the USEPA's "Guidance on the Use of Models and Other Analysis for Demonstrating Attainment Goals for Ozone, PM25, and Regional Haze" suggests looking at days with an daily average PM25 concentration greater than 65 micrograms per meter cubed (μg/m^3). However, neither the Hickory nor the Triad PM25 nonattainment area has any observed values greater than or equal to 65 μg/m^3. This lead the North Carolina Division of Air Quality chose to use a cut off of 30 μg/m^3 at any of the monitoring sites in either nonattainment area, as an initial method to select days for examination in the model performance evaluation and in the results section.

To ensure at least four days from each quarter were presented, PM25 values form each quarter were ranked, and the four days with the highest average daily values in each quarter were also chosen. This selection process identified 28 days for presentation in this appendix, and examination in the model performance evaluation (Appendix J). The selected days are presented in Table 1 below.

Each of the following 28 pages presents a single modeling day. The first or top plot on each page is the daily average PM25 plot for the 2002 baseline year. The second or bottom plot is the daily average PM25 plot for the 2009 attainment year. The comparison of the of the attainment year plot to the baseline year plot determines the relative reduction for each of the RRF days in this attainment modeling exercise.

A table is presented immediately below the plots to further detail the change in number of grid cells between ranges approximating the AQI color codes for the daily PM25 standard from 2002 to 2009. The grid cell counts are only calculated for a domain mask that represents the Hickory and Triad nonattainment areas. A statewide view of this domain mask is presented in Figure 1, with a closer view presented in Figure 2.

Finally, a table is included at the bottom of each page that lists the observed monitor values from that particular day. Gray cells indicate days in which the sites had no observed value. Observations can be missing due to the sampling frequency of the site (every day versus every third day) or the monitor was off line for repairs.

Table 1: Days selected for model evaluation and the observed value at each of the monitoring sites in the Hickory and Triad PM Nonattainment areas. Gray cells indicate no monitoring data was available for that day either due to the sampling frequency or the site being off line

1 Attainment Demonstration

This Appendix summarizes the procedures that were used to demonstrate attainment of the annual fine particulate matter (PM2.5) National Ambient Air Quality Standard (NAAQS) in this State Implementation Plan (SIP) package. As described in the US Environmental Protection Agency's (USEPA's) Guidance On The Use Of Models And Other Analyses for Demonstrating Attainment of Air Quality Goals for Ozone, PM2.5, and Regional Haze ("*Attainment Guidance*"), an attainment demonstration consists of (a) analyses which estimate whether selected emissions reductions will result in ambient concentrations that meet the NAAQS, and (b) an identified set of control measures which will result in the required emissions reductions. The necessary emission reductions for both of these attainment demonstration components may be determined by relying on results obtained with air quality models.

Section 3.0 of the *Attainment Guidance* recommends applying both a modeled attainment test and a subsequent screening test to the air quality modeling results to determine if the annual PM2.5 NAAQS will be met. Additional technical or corroboratory analyses may also be used as part of a "supplemental analysis" or a more stringent "weight of evidence" determination to supplement the modeled attainment test and to further support a demonstration of attainment of the NAAQS.

The modeled attainment test, additional corroborative analyses and weight of evidence, and unmonitored area analysis are described in further detail in the remaining portions of this Appendix, detailing how the respective test or analysis was performed and applied to the attainment demonstration.

2 Model Attainment Test

The purpose of a modeling assessment is to determine if control strategies currently being implemented ("on the books") and proposed control strategies will lead to attainment of the NAAQS for PM2.5 by the attainment year of 2009. The modeling is applied in a relative sense, similar to the 8-hour ozone attainment test. However, the PM2.5 attainment test is more complicated and reflects the fact that PM2.5 has many components. In the test, ambient PM2.5 is divided into major components, with a separate relative response factor (RRF) and future design value (DVF) calculated for each of the PM2.5 components. Since the attainment test is calculated on a per species basis, the attainment test for PM2.5 is referred to as the Speciated Modeled Attainment Test (SMAT). The following sections outline the process to determine 2009 projections of PM2.5 will meet the NAAQS from regional modeling, as suggested in the US EPA's Attainment Guidance.

2.1 Determine Baseline Design Values

The first step in any attainment test process is to determine the baseline design value (DVB). In the Attainment Guidance, the US EPA recommends using a DVB that is the average of the three design value periods that straddle the baseline inventory year (e.g., the average of the 2000-2002, 2001-2003, and 2002-2004 design value periods for a 2002 baseline inventory year). This works out to a 5-year weighted average, with the baseline year having the heaviest weight (e.g. {[2000] + 2*[2001] + 3*[2002] + 2*[2003] + [2004]}/9).

For the SMAT process, a mean PM2.5 DVB is determined, as well as component specific DVB for each quarter. The following section will detail the calculation of baseline design values needed for the PM2.5 attainment test.

2.1.1 Mean PM2.5 Baseline Design Values

To begin the SMAT process, a mean PM2.5 DVB is calculated on a quarterly basis for each Federal Reference Method (FRM) monitor in the PM2.5 nonattainment areas. Concentrations are calculated based on calendar quarters (Q1: January - March; Q2: April - June; etc.) as the NAAQS is calculated for a calendar year, and the quarters need to fit evenly within a year. Also, calculating the attainment test on a quarterly basis allows states to examine the differences in PM2.5 composition that occur during the different seasons.

Table 2-1 contains the quarterly average PM2.5 concentration for the FRM monitors in the nonattainment areas. This quarterly data was then averaged, using the weighted scheme suggested by the US EPA, to produce a 5-year weighted DVB. In the case of the Guilford County FRM site (Mendenhall, 37-081-0013), there is less than 5 years of data available, as the site came online late third quarter 2001. Per the Attainment Guidance, when only 3 years of data are available at a site, the baseline design value is then based on a single three-year design value. This is the case for quarters 1 through 3 at the Mendenhall site. Since there are four years of data for fourth quarter, then the baseline design value is based on an average of two design value periods (2001-2003 and 2002-2004). Table 2-2 presents the final mean PM2.5 DVBs for the nonattainment areas.

2.1.2 Speciated Baseline Conditions

The monitored attainment test for PM2.5 utilizes both PM2.5 and individual PM2.5 component species. A separate RRF is calculated for each PM2.5 species. In order to perform the recommended modeled attainment test, States should divide observed mass concentrations of PM2.5 into 7 components (plus passive mass):

1. Mass associated with sulfates (SO4)
2. Mass associated with nitrates (NO3)
3. Mass associated with ammonium (NH4)
4. Mass associated with organic carbon (OC)
5. Mass associated with elemental carbon (EC)
6. Mass associated with particle bound water (PBW)
7. Mass associated with “other” primary inorganic particulate matter (Crustal)
8. And passively collected mass or the mass of the blank filter (0.5 $\mu g/m^3$)

The second part of the process is to use the quarterly mean PM2.5 DVBs (as calculated in Section 2.1.1) with speciated data to calculate the quarterly mean concentrations of these 7 components at the FRM sites. This need to speciate the FRM data presents two issues:

1. FRM measurements and speciated PM2.5 measurements do not always measure the same mass
2. Not all FRM monitoring sites have co-located STN speciation monitors.

The following sections will explain how these issues were overcome to produce the speciated values needed for this attainment demonstration.

2.1.2.1 SANDWICH

As the Attainment Guidance notes, recent data analyses (Frank, 2006) have noted that the FRM monitors do not measure the same components and do not retain all of the PM2.5 that is measured by routine speciation samplers and therefore cannot be directly compared to speciation measurements from the Speciation Trends Network (STN). By design, the FRM mass measurement does not retain all ammonium nitrate and other semi-volatile materials (negative sampling artifacts) and includes particle bound water associated with sulfates, nitrates and other hygroscopic species (positive sampling artifacts). This results in concentrations (and percent contributions to PM2.5 mass), which may be different than the ambient levels of some PM2.5 chemical constituents.

To resolve the differences between FRM and STN total mass, the US EPA has recommended using the "sulfate, adjusted nitrate, derived water, inferred carbonaceous material balance approach" or SANDWICH approach. With the SANDWHICH approach, nitrate mass is adjusted to account for volatilization based on hourly meteorology parameters. Subsequently, quarterly average nitrate, sulfate, elemental carbon, and crustal mass can be calculated, as well as the Degree of Neutralization (DON) of sulfates. Quarterly average NH4 can then be calculated from adjusted the adjusted nitrate mass, sulfate mass, and DON of sulfate. Next the mass of particle bound water can be calculated from the previously obtained DON, sulfate, nitrate, and ammonium values. Finally, organic carbon is calculated by taking the difference between the total PM2.5 mass as measured at the FRM monitor, and the calculated component mass (i.e. OC from mass balance ([OCMmb]) = $PM2.5_{FRM}$ - {[EC] + [SO4] + [NO3] + [NH4] + [water] + [crustal material] + [passive mass]}).

2.1.2.2 Speciated Profiles

While the SANDWICH method reconciles the differences between FRM and STN, a lingering issue is not all FRM monitoring sites have co-located STN monitors to provide speciated data. The US EPA Attainment Guidance suggests four measures that can be taken to resolve the lack of speciated data:

1. Use of concurrent data from a nearby speciated monitor
2. Use of representative data (from a different time period)
3. Use of interpolation techniques to create a spatial field using ambient speciation data
4. Use of interpolation techniques to create spatial fields, and gridded modeling outputs to adjust the species concentrations

Of the four methodologies, the US EPA recommends using one of the spatial interpolation techniques to estimate species concentrations at FRM sites that do not have speciation data (numbers 3 and 4 above). To assist in this task, the EPA is developing software tool called "Modeled Attainment Test Software" (or MATS) that will perform the spatial analysis of described options number 3 and 4. However, the PM2.5 portion of the MATS tool has not been released at this time. In trying to pursue the US EPA recommended course, we have used the speciated profiles from the Clean Air Interstate Rule (CAIR) SMAT tool, which is the predecessor for the MATS program, as an alternative.

The CAIR SMAT tool uses data from both the Interagency Monitoring of Protected Visual Environments (IMPROVE) and the US EPA's Speciation Network (ESPN) to derive mean concentrations for six PM2.5 components. Quarterly average concentrations between Jan 2002 to December 2002 were retained for sites that had at least 11 monitored values per quarter for each of the major PM2.5 species. Major species for ESPN include EC, OC, NH4, SO4, NO3, and crustal material (which includes the five trace elements aluminum, calcium, iron, silicon, and titanium). The major species for IMPROVE are the same except for NH4, which is not routinely measured in the IMPROVE protocol.

The quarterly averaged species concentrations at the IMPROVE and ESPN monitors were used to interpolate concentrations at the PM2.5 FRM monitoring sites using a technique called

Voronoi Neighbor Averaging (VNA). Attachment L1 to this appendix contains the document "Procedures for Estimating Future PM2.5 Values for the CAIR Final Rule by Application of the (Revised) Speciated Modeled Attainment Test (SMAT) Updated- 11/8/04", which describes the interpolation process, and the data speciation process in detail.

As a result of the CAIR SMAT process, quarterly species fraction were generated for the FRM site, which are presented in Table 2-3 below. These fractions were then applied to Observed Quarterly Mean PM2.5 values calculated in Section 2.1.1 to determine quarterly component specific concentrations. Table 2-4 shows the quarterly concentrations for crustal, EC, OC, SO4, NO3, NH4 and PBW assuming a constant passive mass of 0.5 μg/m^3.

2.2 Relative Response Factor Calculation

The next step in the SMAT process is to use base year and future year modeling results to estimate a relative response factor (RRF) for each component of PM2.5 for each quarter. Simply put, the RRF is the quarterly average future year concentration near a monitor divided by the quarterly average base year concentration near the same monitor, or:

$$RRF = \frac{\text{Quarterly Mean Modeled Future Year Concentration "Near" Monitor "X"}}{\text{Quarterly Mean Modeled Base Year Concentration "Near" Monitor "X"}}$$

Instead of focusing on the individual cell containing the monitor, an array of cells that are "near" a monitor are considered in the attainment test. By sampling an array of cells from the modeling, the attainment test allows for variations in the model performance, as the peak concentrations may not occur in the grid cell that contains the monitor, but rather nearby the monitor. Table 2-5 provides the USEPA's recommendations for defining "nearby" cells for grid systems having cells of various sizes. Since the modeling for the North Carolina attainment demonstration was preformed at a 12km grid resolution, a 3x3 grid array was used.

Table 2-5: USEPA's Recommendation for Defining "Near" Cells

Size of Cell (km)	Size of the Array of "Nearby" Cells
<u><</u>5	7 x 7
>5-8	5 x 5
>8-15	3 x 3
>15	1 x 1

For the PM2.5 SMAT, the RRF is calculated for each component, for each quarter. To accomplish this step, daily concentration for each component of PM2.5 is extracted from the base year and future year modeling output near the FRM monitoring sites for each day. The daily component concentrations from the 3x3 array are then averaged to develop a mean daily component mass for each day in both the base and future years. These mean daily component concentrations are then averaged for each quarter to develop base and future year quarterly mean component concentration. The future year quarterly mean component concentrations are then divided by their respective base year quarterly mean component concentrations to develop quarterly RRFs for each component of PM2.5. The quarterly RRFs for the FRM monitors in the North Carolina PM2.5 nonattainment areas are presented below in Table 2-6. In lieu of using RRFs, the estimated future mass of NH4 and PBW will be determined by the estimated future mass of SO4 and NO3, as was done in the CAIR SMAT tool, per the following equations:

NH4 = DON * SO4 + 0.29*NO3

PBW =(-0.002618) + (0.980314*NH4) + (-0.260011* NO3) + (-0.000784* SO4) + (-0.159452* (NH4^2)) + (-0.356957* NO3* NH4) + (0.153894* (NO3^2)) + (0.212891* SO4* NH4) + 0.0444366* SO4* NO3) + (-0.048352* (SO4^2))

			4	1.076	0.753	0.914	0.778	0.889

2.3. Future Year Quarterly Concentration Calculation

The next step in the SMAT process is to calculate future quarterly mean concentration estimates for each component of PM2.5. To accomplish this, the current quarterly mean component concentration (Step 1, Section 2.1.3) is multiplied by the component-specific RRFs obtained in Step 2 (Section 2.2). The quarterly component concentration estimates for the monitors in the North Carolina PM2.5 nonattainment areas are provided below in Table 2-7.

Table 2-7: Blank Corrected Quarterly Component Future Concentrations Estimates for Monitors in the North Carolina Nonattainment Areas

AIRS ID	County	Site Name	Quarter	Crustal	EC	OC	SO4	NO3	NH4	PBW
37-035-0004	Catawba	Hickory	1	0.326	0.621	5.553	2.969	0.606	1.007	0.792
			2	0.714	0.438	5.256	3.994	0.008	1.183	1.161
			3	0.673	0.397	6.148	4.797	0.006	1.379	1.335
			4	0.271	0.458	5.567	2.493	0.462	0.921	0.764
37-057-0002	Davidson	Lexington	1	0.306	0.551	6.330	2.842	0.425	0.962	0.807
			2	1.159	0.433	5.245	4.171	0.008	1.250	1.235
			3	1.064	0.313	4.995	4.927	0.007	1.370	1.297
			4	0.485	0.460	6.090	2.691	0.349	0.895	0.766
37-081-0013	Guilford	Mendenhall	1	0.320	0.531	3.933	2.861	0.315	0.917	0.793
			2	2.804	0.341	3.079	3.200	0.006	0.909	0.875
			3	2.162	0.233	4.531	4.375	0.006	1.111	0.993
			4	1.151	0.452	3.923	2.482	0.346	0.734	0.595

2.4. Future Year Annual Average Estimate

The final step in the SMAT process is to sum the quarterly mean components (from Step 3, Section 2.3) to get annual mean PM2.5 values. Table 2-8 displays the quarterly mean PM2.5 values for the FRM sites in the North Carolina nonattainment areas.

Table 2-8: Quarterly Mean PM2.5 Mass Estimates for 2009

AIRS ID	County	Site Name	Non-Blank Mass Q1	Non-Blank Mass Q2	Non-Blank Mass Q3	Non-Blank Mass Q4
37-035-0004	Catawba	Hickory	11.874	12.754	14.734	10.936
37-057-0002	Davidson	Lexington	12.222	13.501	13.972	11.737
37-081-0013	Guilford	Mendenhall	9.669	11.214	13.410	9.683

The quarterly mean PM2.5 values are then averaged to produce a future year annual average PM2.5 estimate for each FRM site in the nonattainment area (Table 2-9). These values estimated annual PM2.5 values are then compared to the NAAQS (15.0 $\mu g/m^3$). Since the values at the FRM site in the nonattainment areas are < 15.0 $\mu g/m^3$, the test is passed.

Table 2-9: Estimated Annual Mean 2009 PM2.5 Mass Compared to the DVB

AIRS ID	County	Site Name	2002 Annual DVB	2009 Non-Blank Mass	Blank Mass	2009 Annual DVF
37-035-0004	Catawba	Hickory	15.137	12.575	0.050	13.075
37-057-0002	Davidson	Lexington	15.509	12.858	0.050	13.358
37-081-0013	Guilford	Mendenhall	13.095	10.994	0.050	11.494

3 Supplemental Analysis

The Attainment Guidance asserts that all attainment demonstrations should be accompanied by supplemental analysis that further supports the modeling conclusions. This supplemental analysis can include additional analyses of air quality, emissions and meteorological data, and consider modeling outputs other than the results of the attainment test. If the attainment test results fall short of the standard, the results of corroboratory analyses may be used in a weight of evidence determination (WOE) to show that attainment is likely despite modeled results, which may be inconclusive.

The Attainment Guidance defines the guidelines for supplemental analysis/WOE for the annual PM2.5 standard as follows:

- Site with a DVF less than 14.5 $\mu g/m^3$ should submit basic supplemental analysis to confirm the outcome of the model attainment test.
- Sites with a DVF between 14.5 and 15.5 $\mu g/m^3$ should submit a weight of evidence demonstration to aggregate supplemental analysis to support the model attainment demonstration
- Sites with a DVF greater than or equal to 15.5 $\mu g/m^3$ should consider additional control measure to ensure attainment, as more qualitative analysis is unlikely to attainment

All North Carolina PM2.5 nonattainment areas have DVFs lower than 14.5μg/m^3, making the following section an examination of supplemental analysis to corroborate modeling results, rather than a WOE analysis to show attainment. In the following sections we explore refinements to the attainment test, additional modeling studies, and air quality and emissions trend as part of a supplemental analysis for the North Carolina PM2.5 nonattainment areas.

3.1 Additional Air Quality Modeling

The Attainment Guidance suggests several additional modeling exercises that can be performed as part of supplemental/WOE analysis. Suggestions include completing additional analysis on the air quality modeling preformed, or modeling alternative set ups and emissions as part of sensitivity. Each of theses items will be discussed in the following sections.

3.1.1 Air Quality Modeling Metrics

In Section 7.0 of the *Attainment Guidance,* various aspects of air quality models, modeled performance, and uncertainties associated with the length of modeled episodes and limited observational datasets are described. Section 7.1 suggests that some types of "absolute" modeling results may be used to assess general progress towards attainment from the baseline inventory to the projected future inventory. The Attainment Guidance goes on to describe several metrics that can be considered as part of this type of additional analysis, which include:

1. Percent change in total amount of PM2.5 >= 15 μg/m^3 within the nonattainment area
2. Percent change in number of grid cells >= 15 μg/m^3 within the nonattainment area
3. Percent change in grid cell-hours (days) >= 15 μg/m^3 within the nonattainment area
4. Percent change in maximum modeled 24-hour PM2.5 concentrations within the nonattainment area

As the US EPA notes in the Attainment Guidance, care should be taken in interpreting absolute metrics if the model evaluation shows a large under prediction or over prediction of ozone or PM2.5 concentrations, because under (over) prediction of observed concentrations will make it artificially easy (hard) to show progress towards absolute attainment levels. To better coincide with model performance evaluation results, the same subset of days from the modeling were used in the model performance evaluation were used to develop the air quality metrics. This subset of days included all days with an 24-hour PM2.5 concentration greater than 30 μg/m^3 at any of the monitoring sites in either nonattainment area, as well as the four days with the highest average daily values from each quarter. This selection process identified 28 days for presentation in this appendix, and coincides with the days used in the model performance evaluation (Appendix J) and in the model results section (Appendix K). A full listing of the days and the observed 24-hour PM2.5 concentrations from the monitors in the nonattainment areas can be found in either Appendix J or Appendix K.

Because of the complexity of the model extraction for PM2.5, only the second metric is presented for supplemental analysis. The cell counts of modeling data was tallied from both the 2002 baseline and the 2009 attainment year modeling run for the identified days. Data was extracted for only the grid cells that contained portions of the either of the nonattainment areas. Figure 3-1 highlights the 50 cells that encompass the North Carolina nonattainment areas.

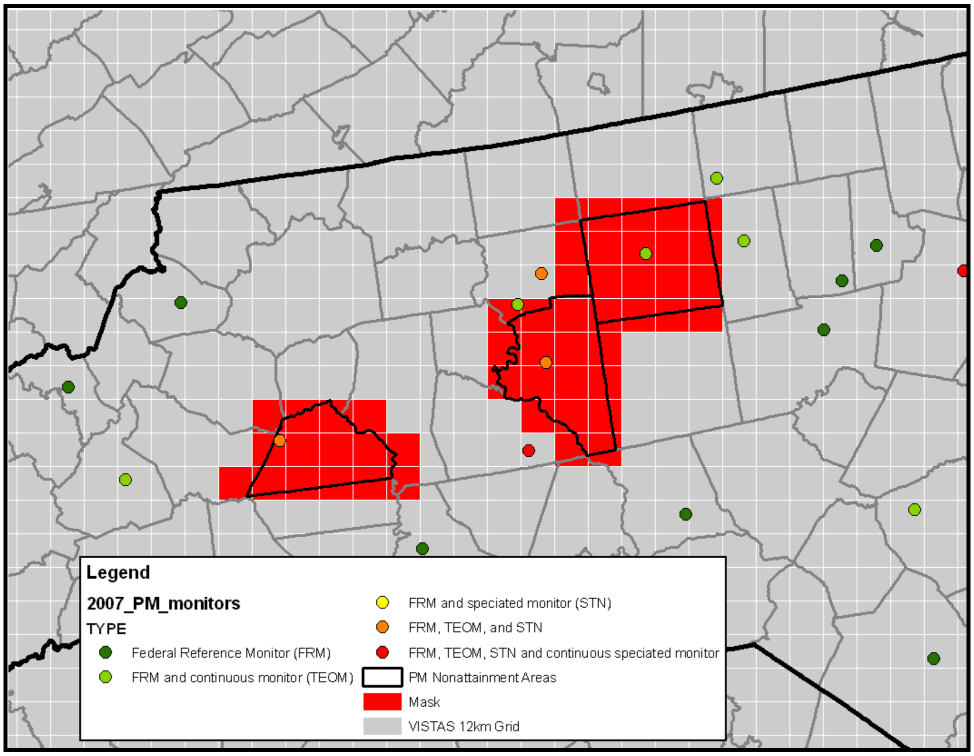

Figure 3-1: Area for which the air quality metrics were applied.

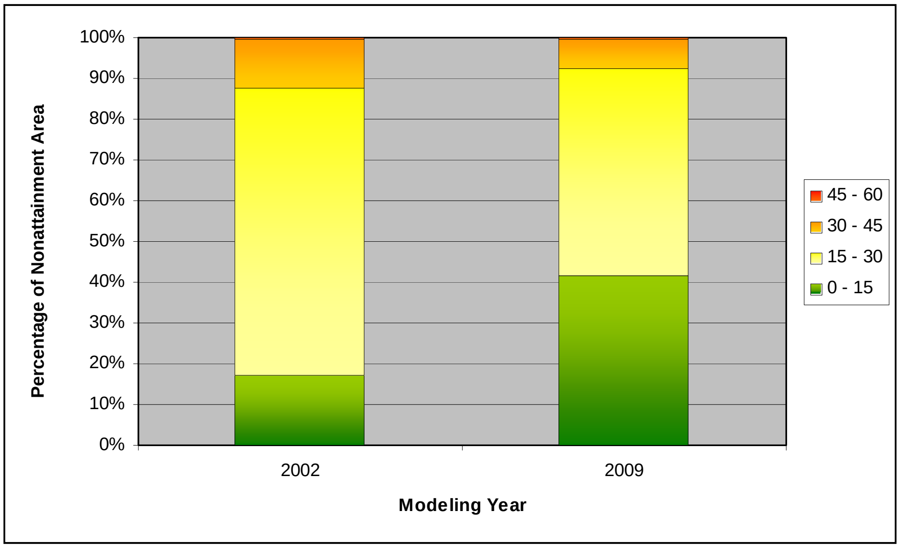
The cell counts were binned based on concentration ranges of 15 μg/m^3 intervals to help illuminate the change in severity on the days in North Carolina with the highest PM2.5 concentrations. Figure 3-2 presents the cell count results both graphically and in tabular form. The graph clearly shows a striking increase in the number of days below 15 μg/m^3. By 2009 only 41.57% of cells fall in the 0 –15 range, a substantial increase from the 17.21% in 2002. Raw cell counts shows a total of 341 cells shifted to the 0 – 15 μg/m^3 range between 2002 and 2009 (Table 3-1).

Figure 3-2 also shows a decrease in the number of cell in the 15 – 30 μg/m^3 bin (269 cell decrease) and the 30 - 45μg/m^3 bin (75 cell decrease). The number of cells in the 45 –60 range remains relatively constant from 2002 to 2009. A closer examination of the daily cell counts shows that all of the cells in the highest concentration category occur on the same day in both the 2002 and 2009 modeling and are likely associated with a fire. Overall, the results from the air quality modeling metric are encouraging. The metric shows a substantial increase in the number of cells below 15 μg/m^3, and an increase in cells below 30μg/m^3.



Concentration	2002	2009
0 - 15	17.21%	41.57%
15 - 30	70.21%	51.00%
30 - 45	12.29%	6.93%
45 - 60	0.29%	0.50%

Figure 3-2: Percentage of Cell in Nonattainment Areas within Concentration Categories for 2002 and 2009. Table of actual values is presented on the right.

Table 3-1: Number of Cells within Concentration Bins. Increases (decreases) in the number of cells within the bins are noted by red (blue) coloration in the last column.

Concentration	2002	2009	Difference
0 - 15	241	582	**341**
15 - 30	983	714	**-269**
30 - 45	172	97	**-75**
45 - 60	4	7	**3**

3.1.2 Other Modeling Results

One way to acquire modeling sensitivity runs is to examine the modeling results from other Regional Planning Organizations or from EPA modeling studies. Other modeling studies may use different physical and chemical modeling options for their meteorological and air quality modeling runs, which would provide a comparison or sensitivity based on these different options.

An air quality modeling exercise that contained results for North Carolina PM2.5 nonattainment area is the USEPA's modeling for the Clean Air Interstate Rule (CAIR). The Technical Support Document for the final CAIR, March 2005, provided modeling results with and without the implementation for the CAIR. Differences between the USEPA's modeling and the attainment demonstration are: 1) the meteorology was for 2001, 2) the DVB was the weighted design values for the 1999-2003 period and 3) the modeling results were for 2010. The DVF was calculated using the CAIR SMAT tool, so methodologies between the CAIR DVF and the values presented in Section 2.4 are the same. These modeling results are listed in Table 3-2 below.

Table 3-2: US EPA CAIR Modeling Results

Future Year	Catawba County	Davidson County
2010	14.07	14.36
2015	13.45	13.61

The USEPA's results were for the highest monitor in a county where more than one monitor is located. The USEPA's modeling results predicts that both the North Carolina nonattainment areas should be below the annual PM2.5 standard by 2010. Although this is one year later than the attainment year for these areas. The USEPA's 2010 CAIR DVFs are 1 $\mu g/m^3$ higher than what the NCDAQ is showing in the attainment demonstration, but still support that both the North Carolina nonattainment areas will attain the annual PM2.5 standard by the attainment year of 2009.

3.2 Air Quality and Emission Trends Analysis

Since the annual PM2.5 designation in 2002, annual average concentrations of PM2.5 have decreased. Values have hovered near the standard at the two nonattaining monitors for roughly the past 5 years, while the Mendenhall monitor has maintained values lower than the NAAQS. Table 3-3 provides the annual average data, with Figure 3-3 providing a graphical representation of the data, with preliminary 2007 annual average values. These preliminary 2007 values show the monitors are still trending towards the NAAQS.

With the data in Table 3-3 and Figure 3-3, please note that the Mendenhall was not in operation from 1999 to 2001, as this site replaced the McLeansville site. Data from the McLeansville site has been substituted in place of the missing data in both Figure 3-3 and Table 3-3, as the two sites are within the required distance to be considered a continuous monitoring site.

Table 3-3: Annual Average PM2.5 values for the past 10 years.

Monitoring Site	County	AIRS ID	Annual Averages									
			1999	2000	2001	2002	2003	2004	2005	2006	2007	2008
Hickory	Catawba	3703500041	17.4	17.6	16.0	15.4	15.0	15.0	15.9	15.2	14.5	12.8
Lexington	Davidson	3705700021	17.3	18.0	16.5	15.9	15.2	15.2	15.4	15.1	14.6	13.7
Mendenhall	Guilford	3708100131				13.7	13.3	14.0	14.0	*14.1*	13.0	11.4

Average of 1st-4th Quarter For Each Year. Values in colored orange are in excess of the Annual PM2.5 NAAQS.

Note: Mendenhall was not in operation from 1999 to 2001

Note: There was an extended loss of monitoring data at the Mendenhall site during the 4th quarter of 2006. The NCDAQ has performed an extensive data imputation study to estimate a 4th quarter average concentration such that an appropriate annual average concentration and design value could be calculated. This study, titled "Mendenhall PM2.5 Data Imputation for 4Q2006" can be found in Appendix C.3

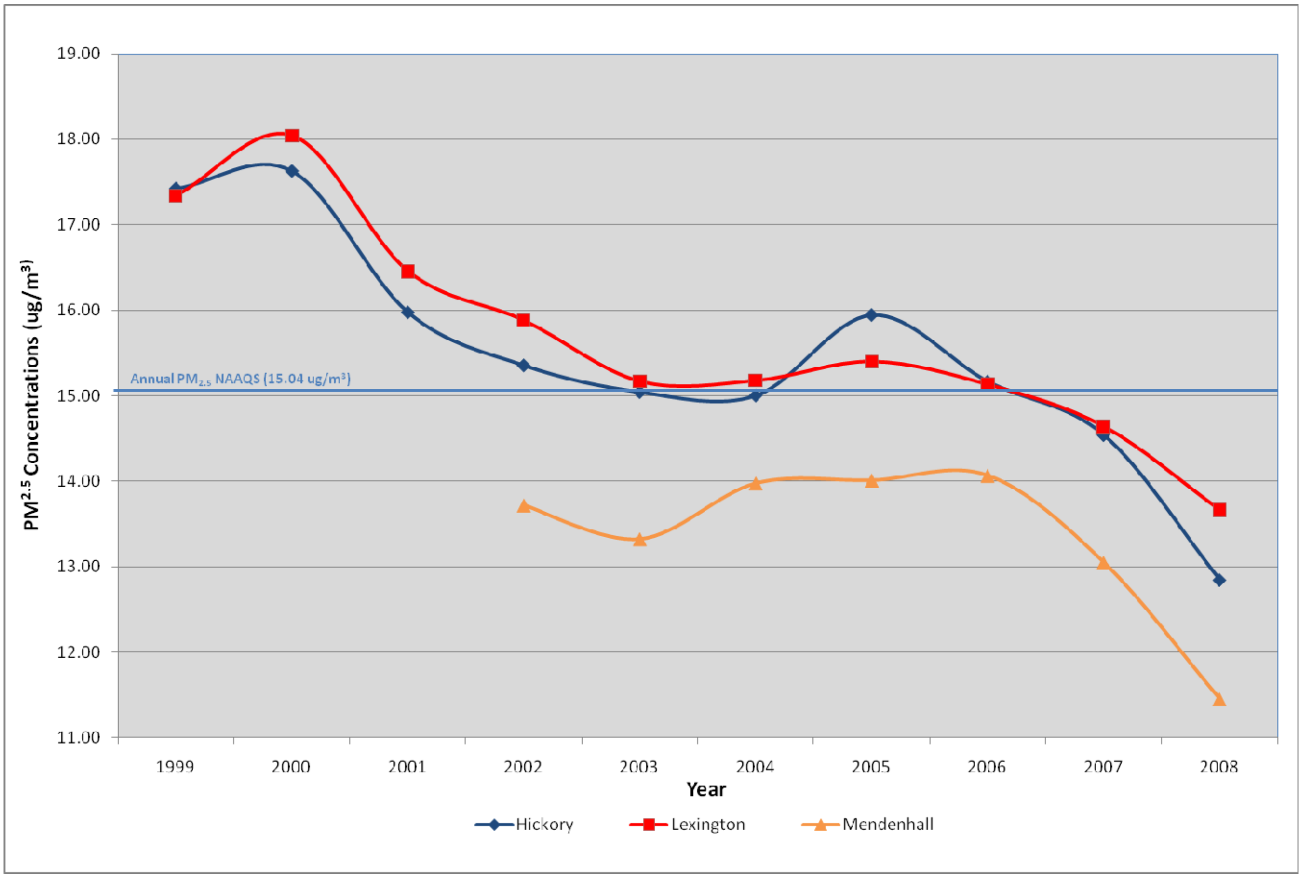


Figure 3-3: Annual PM2.5 Average Values for the Monitors in the Hickory and Triad Nonattainment Areas.

With the improvement in annual average PM2.5values, there has also been an improvement in PM2.5 design values. When one takes into account the period of record, PM2.5 design values have improved significantly over the last 6 years. Like with the annual averages, the three-year design values have also begun to hover near the level of the standard for both the Hickory and Lexington monitors in recent years. It is also important to note the Guilford County monitor (Mendenhall, 37-081-0013) monitor has also maintained design values that meet the NAAQS over the past 3 design value periods (See Table 3-4).

Table 3-4: Three Year Design values for the Monitors in North Carolina's PM2.5 Nonattainment Areas.

Monitoring Site	County	AIRS ID	Design Values							
			1999-2001	2000-2002	2001-2003	2002-2004	2003-2005	2004-2006	2005-2007	2006-2008
Hickory	Catawba	3703500041	17.0	16.3	15.5	15.1	15.3	15.4	15.2	14.2
Lexington	Davidson	3705700021	17.2	16.8	15.8	15.4	15.2	15.2	15.1	14.5
Mendenhall	Guilford	3708100131				13.7	13.8	*14.0*	*13.7*	*12.9*
			Average Over 12 Quarters. Negative & Underlined Indicate Altered Calculation							

Note: Both of the footnotes that apply to Table 3-3 are also applicable with this table.

When evaluating the trends in air quality values it is important to note that there are still significant sulfur dioxide (SO2) emission reductions that are expected between now and the attainment year in the utility sector. The Clean Smokestacks Act requires the two large North Carolina utilities to meet annual SO2 emission budgets for 2007 and a tighter budget for 2009. Units from maintained by both Duke Energy and Progress Energy units are still expected to have controls installed over the next two years. Table 3-5 lists the units that are near the PM2.5 nonattainment areas and shows the year the controls are expected to come on line and the estimated amount of yearly SO2 emissions reductions. In total, over 250,000 tons of SO2 will be reduced annually in central North Carolina alone. As sulfates are one of the larger contributors to total PM2.5 in North Carolina, this substantial reduction in SO2 should result in significant reductions of the observed PM2.5 concentrations, which are already very close to the standard.

Table 3-5: Projected emission reductions Near the North Carolina PM2.5 Nonattainment Areas.

Operator	Facility	Unit	Technology	2007 Plan	Total 2006 Emissions	2009 Projected Emissions '07 Plan SO_2 (Tons)	2009 Projected Total Emissions '07 Plan SO_2 (Tons)	2009 Projected Reductions SO_2 (Tons)

3.3 Supplemental Analysis Conclusions

After examining the totality of the modeling evidence, the North Carolina Division of Air Quality (NC DAQ) is confident the Hickory and Triad PM2.5 nonattainment areas should reach attainment status by the 2009 deadline. US EPA CAIR modeling corroborates NC DAQ modeling results suggesting both nonattainment areas should be below at least 14.5$\mu g/m^3$. In addition, current PM2.5 design values are near NAAQS, with substantial sulfate reductions anticipated in the vicinity of the nonattainment area over the next two years. NC DAQ feels these reductions will more than allow the PM2.5 nonattainment areas to achieve the NAAQS by 2009.

4 Unmonitored Area Analysis

The modeled attainment test does not address future air quality at locations where there is not a $PM_{2.5}$ monitor nearby. To guard against the possibility that air quality levels could exceed the standard in areas with limited monitoring, Section 3.4 of the Attainment Modeling Guidance suggests that additional review is necessary, particularly in nonattainment areas where the $PM_{2.5}$ monitoring network just meets or minimally exceeds the size of the network required. This review is intended to ensure that a control strategy leads to reductions in $PM_{2.5}$ and its constituent pollutants at other locations that could have baseline (and future) design values exceeding the NAAQS, were a monitor deployed there. The test is called an "unmonitored area analysis". The purpose of the analysis is to use a combination of model output and ambient data to identify areas that might exceed the NAAQS if monitors were located there.

The NCDAQ, along with Local and Tribal Programs, currently operates a network of 34 $PM_{2.5}$ monitors. Twenty-nine of these monitors were established as State and Local Air Monitoring Stations (SLAMS). These SLAMS monitors were selected based on specific monitoring objectives (background concentration, area of highest concentration, high population, source impact, transport, and rural impact) as required by the USEPA and siting scales (micro, middle, neighborhood, urban, and regional) established by the USEPA. Of the remaining 8 monitors, 7 are categorized as "Other" or "Special Purpose Monitors" that were established by NCDAQ to evaluate models, study $PM_{2.5}$ formation and transport, and obtain a better understanding of $PM_{2.5}$ in North Carolina. The remaining monitor is a Tribal monitor operated by the Eastern Band of Cherokee Nation.

The NCDAQ believes that the density of its monitoring network more than adequately captures the full extent of the $PM_{2.5}$ air quality concerns in North Carolina. With an average of one monitor per 3711 km^2, this is one of the densest statewide $PM_{2.5}$ monitoring networks in the southeast. A map of each $PM_{2.5}$ monitor and its position relative to the NCDAQ/ASIP 12-km modeling grid is provided in Figure 4-1. As can been seen by the figure, the spatial coverage of the monitors, and their resulting "nearby" 3x3 arrays, covers the majority of the urban areas where $PM_{2.5}$ tends to be higher.

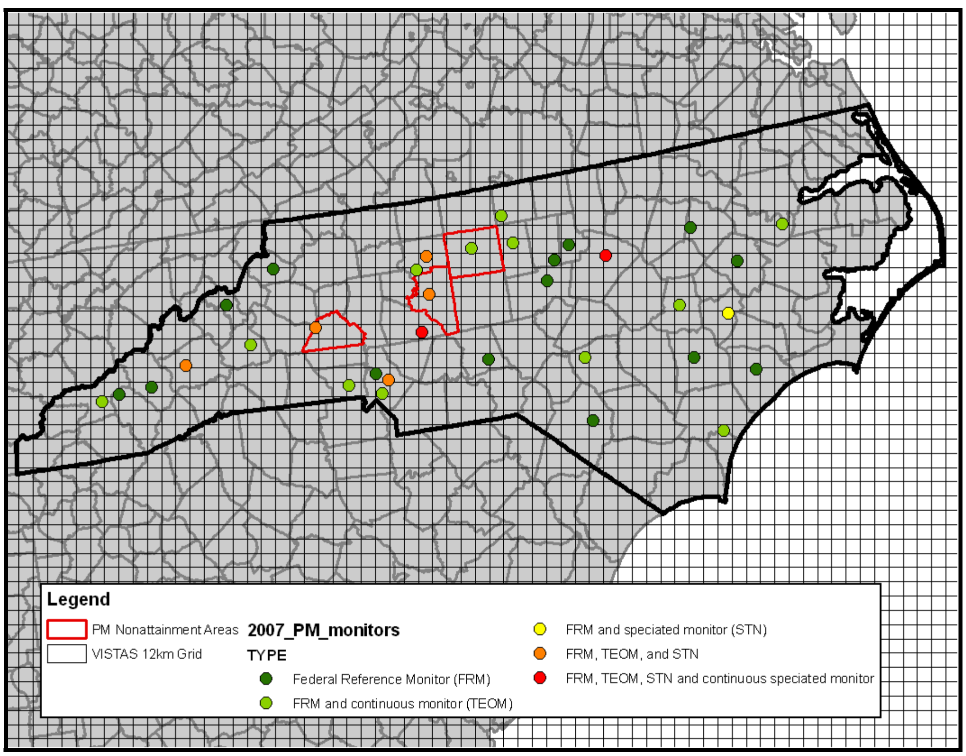

Figure 4-1: PM2.5 Monitors and with Respect to the VISTAS 12km Grid

The adequacy of the NCDAQ $PM_{2.5}$ monitoring network is further demonstrated when plotted against a projected spatial field of annual $PM_{2.5}$ design values. Figure 4-2 presents the 2009 future year $PM_{2.5}$ design value modeling output from this attainment demonstration and the location of each $PM_{2.5}$ monitor in and around North Carolina. This 2009 $PM_{2.5}$ design value spatial field was created by the USEPA's Modeled Attainment Test Software (MATS). It is clear from the MATS analysis that all of the regions of higher, yet attaining, $PM_{2.5}$ design values have numerous representative $PM_{2.5}$ monitors. There are not any identified $PM_{2.5}$ hotspots that would require any additional monitoring considerations in North Carolina.

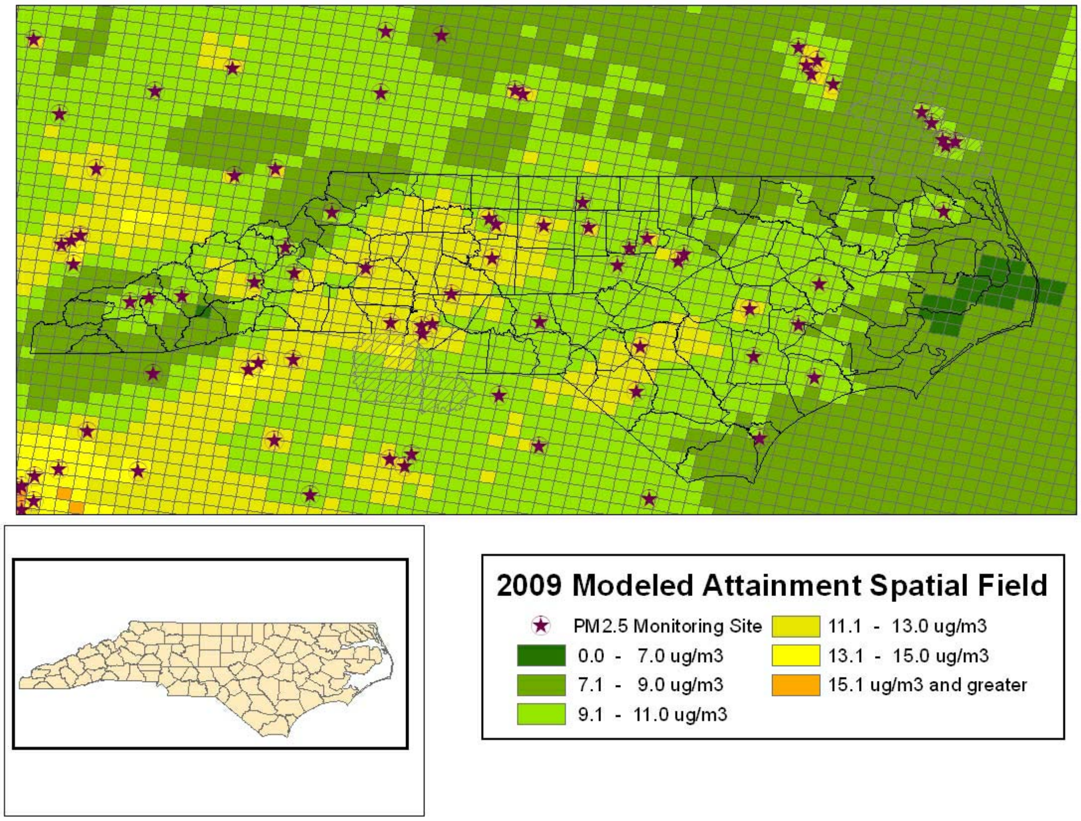

Figure 4-2: PM2.5 Monitors and 2009 Modeled Attainment Spatial Field

Procedures for Estimating Future $PM_{2.5}$ Values for the CAIR Final Rule by Application of the (Revised) Speciated Modeled Attainment Test (SMAT) Updated- 11/8/04

I. Introduction

EPA has issued draft modeling guidance *(EPA, 2001)* that describes a procedure for combining monitoring data with outputs from simulation models to estimate future concentrations of $PM_{2.5}$ mass. The guidance recommends that model predictions be used in a relative sense to estimate changes expected to occur in each major $PM_{2.5}$ species. The procedure is referred to as the Speciated Modeled Attainment Test (SMAT). A preliminary version of SMAT was applied in the Clean Air Interstate Rule (CAIR) proposal modeling *(EPA, 2004)* to estimate future $PM_{2.5}$ nonattainment in the Eastern United States. A revised version of the SMAT technique has been applied in support of the CAIR final rule. Based on comments received from the CAIR proposal, several improvements have been implemented. The revised SMAT procedures are described below.

A. Default SMAT Procedures

The draft modeling guidance includes a sequence of key steps that are recommended for processing $PM_{2.5}$ ambient and modeling data. The following is a brief summary of those steps:

(1) Derive current quarterly mean concentrations for each of the major components of $PM_{2.5}$. This is done by multiplying the monitored quarterly mean concentration of Federal Reference Method (FRM) *(EPA, 1997)* derived $PM_{2.5}$ by the monitored fractional composition of $PM_{2.5}$ species (at speciation monitor sites) for each quarter. (e.g., 20% sulfate x 15 ug/m^3 $PM_{2.5}$ = 3 ug/m^3 sulfate).

(2) For each quarter, apply an air quality model to estimate current and future concentrations for each of the components of $PM_{2.5}$. Take the ratio of future to current predictions for each component. The result is a component-specific *relative reduction factor* (RRF). (e.g., given model predicted sulfate for base is 10 ug/m^3 and future is 8 ug/m^3 then RRF for sulfate is 0.8).

(3) For each quarter, multiply the current quarterly mean component concentration (step 1) times the component-specific RRF obtained in step 2. This leads to an estimated future quarterly mean concentration for each component. (e.g., 3 ug/m^3 sulfate x 0.8 = future sulfate of 2.4 ug/m^3).

(4) Average the four quarterly mean future concentrations to get an estimated future annual mean concentration for each component. Sum the annual mean concentrations of the $PM_{2.5}$ components to obtain an estimated future annual concentration for $PM_{2.5}$.

EPA is using the FRM data for nonattainment designations. Therefore it is critical that the speciated modeled attainment test described above uses FRM data as the base value for projecting future $PM_{2.5}$ concentrations. As can be seen from the list of steps, the modeled attainment test is critically dependent on the availability of species component mass at FRM sites. The modeling guidance recommends using ambient $PM_{2.5}$ speciation data to estimate the relative mass of $PM_{2.5}$ components at each FRM site. The guidance further recommends using the Interagency Monitoring of Protected Visual Environments (IMPROVE) procedure *(IMPROVE, 2000)* for estimating reconstructed fine mass. In this procedure, the $PM_{2.5}$ mass is assumed to be composed of 6 species: ammonium sulfate, ammonium nitrate, organic carbon mass, elemental carbon, crustal and un-attributed mass which is defined as the difference between measured PM2.5 and the sum of the five component species. The relative proportion of each of these 6 species was estimated in the CAIR proposal SMAT analysis.

B. New Species Calculations and Definitions

Recent data analyses as well as a report submited by CAIR commenters *(Glass, 2004)* have noted that the FRM monitors do not measure the same components and do not retain all of the $PM_{2.5}$ that is measured by routine speciation samplers and therefore cannot be directly compared to speciation measurements from EPA's Speciation Network (ESPN). By design, the FRM mass measurement does not retain all ammonium nitrate and other semi-volatile materials (negative sampling artifacts) and includes particle bound water associated with sulfates, nitrates and other hygroscopic species (positive sampling artifacts). This results in concentrations and percent contributions to $PM_{2.5}$ mass which may be different than the ambient levels of some $PM_{2.5}$ chemical constituents. For the purposes of predicting changes in $PM_{2.5}$ chemical components on the $PM_{2.5}$ mass, constructed $PM_{2.5}$ mass should match the composition of mass retained by the FRM. As such, we have made several revisions to the calculation and definition of $PM_{2.5}$ species used in SMAT.

The revised SMAT uses an FRM mass construction methodology which results in reduced nitrates (relative to the amount measured by routine speciation networks), higher mass associated with sulfates (reflecting water included in gravimetric FRM measurements) and a measure of organic carbonaceous mass which is derived from the difference between measured $PM_{2.5}$ and its non-carbon components. This characterization of $PM_{2.5}$ mass also reflects crustal material and other minor constituents. The resulting characterization provides a complete mass balance. It does not have any unknown mass which is sometimes presented as the difference between measured $PM_{2.5}$ mass and the characterized chemical components derived from routine speciation measurements. The net difference between retained mass and measured mass for individual $PM_{2.5}$ chemical components is relatively small when expressed as ug/m3, but can be a large percent for individual constituents.

Below we describe an application of the revised SMAT procedures for a study domain that extends over a large portion of eastern US. The study domain is defined for grids of dimension 36 km X 36 km covering the area enclosed within -100 to -67 longitude and 25 to 49 latitude. Base case and future year model predictions are available for each FRM monitor (and grid cell) that is contained within the domain.

II. $PM_{2.5}$ Mass and Species Data Handling

Speciated $PM_{2.5}$ data from both the IMPROVE and ESPN were used to derive mean concentrations of each of six $PM_{2.5}$ components. No attempt was made to resolve differences in measurement and analysis methodology between the two networks. Since three (or more) years of urban speciation data were not available, calendar year 2002 was used to best correspond[1] to the available 5 years of FRM $PM_{2.5}$ mass data (1999-2003). Quarterly average concentrations between Jan 2002 to December 2002 were retained for sites that had at least 11 monitored values per quarter for each of the major $PM_{2.5}$ species. The quarters were defined as follows: Q1 = January - March 2002; Q2 = April - June 2002; Q3 = July - September 2002; and Q4 = October - December 2002. Major species for ESPN include elemental carbon (EC), organic carbon (OC), ammonium (NH4), sulfate (SO4), nitrate (NO3), and crustal material (which includes the five trace elements aluminum, calcium, iron, silicon, and titanium). The major species for IMPROVE are the same except for ammonium (NH4), which is not routinely measured in the IMPROVE protocol.

All species were used as extracted directly from the Air Quality Subsystem (AQS) with the exception of organic carbon in ESPN. Organic carbon in the ESPN was blank corrected based on measurements from field blanks which indicate a positive bias. The blank corrections were based on a draft report which examined the blank carbon data in the STN network *(Flanagan, 2003)*. The carbon corrections are shown below in Table 1.

Table 1: Organic Carbon Blank Corrections

Sampler Type	**Organic Carbon Correction (ugC/m3)**
URG MASS	**0.29**
R and P 2300	**0.90**
Anderson RAAS	**1.19**
R&P 2025	**0.77**
MetOne SASS	**1.42**

These sampler-specific, network-wide corrections were subtracted from daily measurements of organic carbon and the results multiplied by 1.40 (to convert to organic carbon mass) before aggregating to quarterly and annual levels.

[1]The CAIR proposal SMAT was based on 2001-2002 data (the last 3 quarters of 2001 and the 1st quarter of 2002). There are 2 complete years of speciation data at a some sites, but we used only the latest complete year of data (2002) for this analysis. There were many more speciation sites available in 2002 (compared to 2001) and we did not want to mix a single year of data at most sites with a two year average at a few sites. That may have led to a regional bias in species composition.

For both ESPN and IMPROVE data (for the year Jan 2002- Dec 2002), the following quality checks were made to screen the raw data:

1. Any observations with one or more missing values of any of the major chemical species were removed.

2. All observations on July 6-9, 2002 for the 10 states most affected by the July 2002 Quebec Fires were removed. The 10 states were: DE, CT, VA, MD, NH, MA, NJ, VT, RI, and PA.

3. Only those sites that had a minimum of 11 observations for ALL the major species were retained in the final database.

These conditions result in the following final quarter-by-quarter number of observations and sites from ESPN and IMPROVE for inclusion in the "SMAT" procedure for CAIR.

Table 2: Number of Eastern sites and observations used in the SMAT analysis for 2002

	January 2002—December 2002			
	ESPN		IMPROVE	
	Total Number of Obs.	Number of Sites	Total Number of Obs.	Number of Sites
Quarter 1	2022	98	1206	49
Quarter 2	2419	131	1131	47
Quarter 3	2844	145	1320	54
Quarter 4	2725	149	1637	58

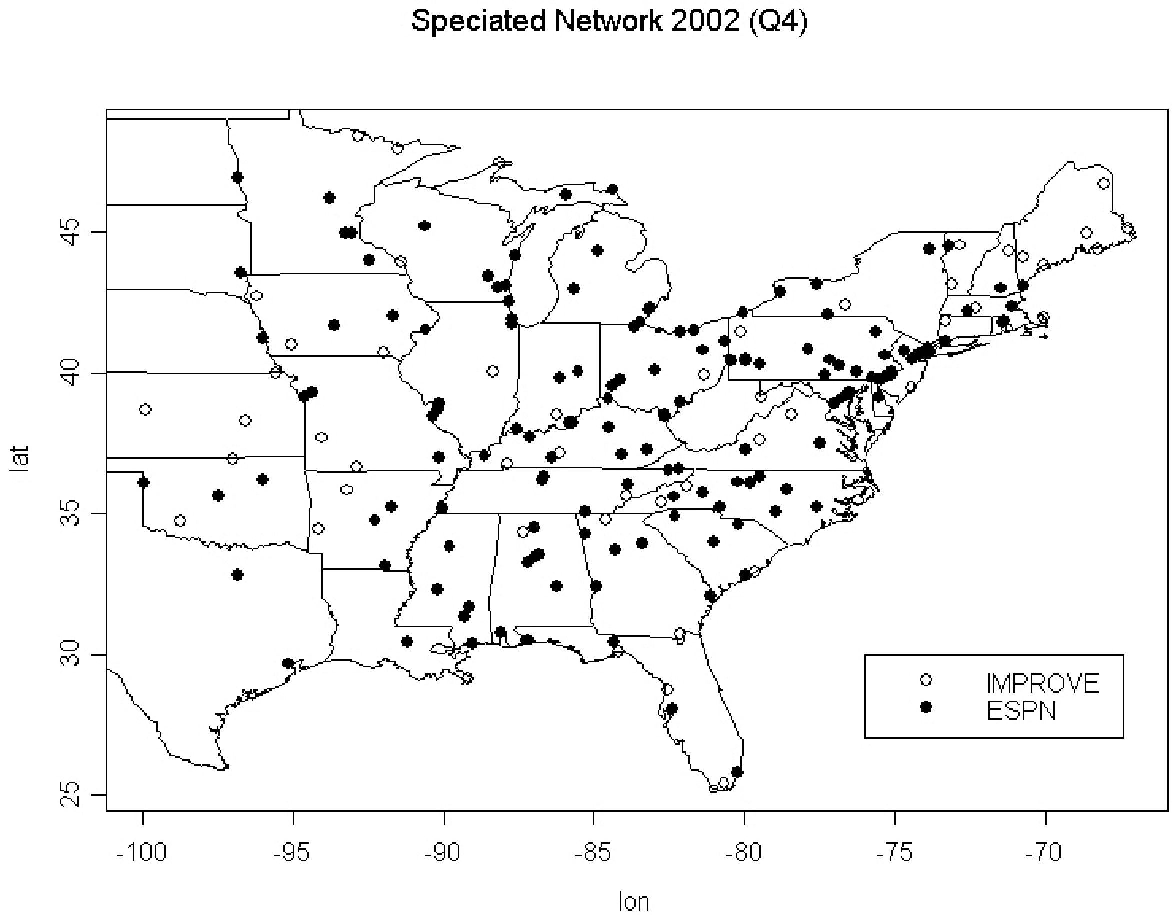

Figure 1- Speciation sites used in the revised SMAT analysis for the 4th quarter of 2002.

To further quality assure the ESPN data, the reconstructed fine mass (RCFM) was compared to measured FRM $PM_{2.5}$ on a quarterly basis[2]. To accomplish this QA check, daily RCFM was calculated for each observation using the following equation:

RCFM = Sulfate + Nitrate + OCM + EC + Crustal + Ammonium

Quarterly average RCFM was calculated using the daily RCFM. These quarterly average RCFM concentrations were then compared to quarterly average FRM $PM_{2.5}$ measurements at co-located sites.

Site-quarter combinations in the ESPN data were removed from the dataset when the quarterly average RCFM was more than 30% higher or 30% lower than the quarterly average

[2]This QA step was not done for the IMPROVE network because IMPROVE sites are not co-located with FRM sites.

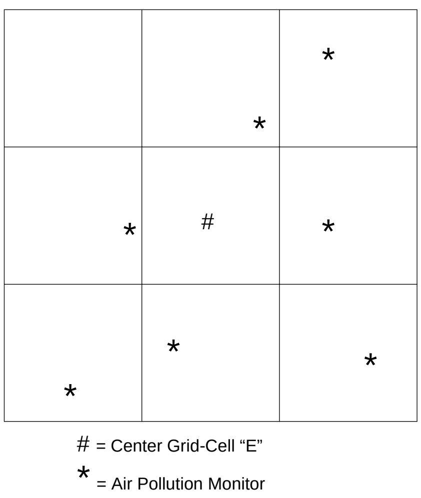
FRM $PM_{2.5}$. This comparison resulted in the removal of 30 site-quarter records from the dataset.

B. Spatial Interpolation of Data

Since roughly 80% of the FRM sites do not have co-located speciation monitors, a spatial interpolation methodology was developed to estimate component species mass at the FRM locations that do not have co-located speciation data. The quarterly average species concentrations at the IMPROVE and ESPN monitors were used to interpolate concentrations at the $PM_{2.5}$ monitoring sites[3]. We previously used a Kriging methodology for SMAT, but have now moved to a technique called Voronoi Neighbor Averaging (VNA) to produce the spatial fields. We are using the revised interpolation technique in order to remain consistent with calculations performed for the health benefits portion of the CAIR. For the benefits analysis, interpolated PM2.5 species data is needed for the entire country (not just the East). We found that VNA gave more spatially consistant results in the West compared to Kriging. We therefore decided to use VNA for the entire country and for all analyses.

All spatial interpolations were conducted using EPA's environmental Benefits Mapping and Analysis Program (BenMAP), about which information can be obtained at http://www.epa.gov/ttn/ecas/benmodels.html (*Abt, 2003*). The VNA interpolation method is contained within the BenMAP program.

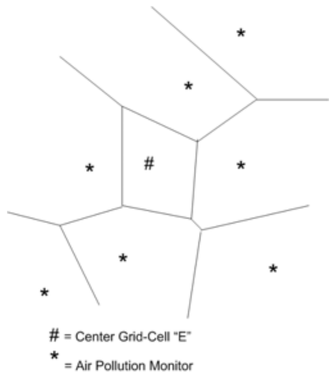
The first step in VNA is to identify the set of neighboring monitors for each of the CMAQ grid cells in the Continental United States. The figure below presents nine grid cells and seven monitors, with the focus on identifying the set of neighboring monitors for grid cell E.



In particular, BenMAP identifies the nearest monitors, or "neighbors," by drawing a polygon, or Voronoi cell, around the center of each county. The polygons have the special

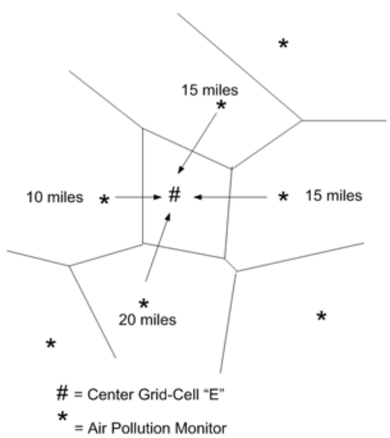
[3]The concentrations are interpolated to the CMAQ 36 km grid cells. Each grid cell has a unique set of interpolated species concentrations. The species concentrations are not interpolated to the location of each monitor within a grid cell.

property that the boundaries are the same distance from the two closest points.



We then choose those monitors that share a boundary with the center of grid cell E. These are the nearest neighbors, and we use these monitors to estimate the air pollution level for this grid cell.

To estimate the concentration of a species in each grid cell, BenMAP calculates an inverse-distance weighted average of the concentrations from each neighboring monitor. The further the monitor is from the grid cell center, the smaller the weight.



The weight for the monitor 30 kilometers from the center of grid cell E is calculated as follows:

$$weight_1 = \frac{\frac{1}{30}}{\left(\frac{1}{30}+\frac{1}{45}+\frac{1}{45}+\frac{1}{55}\right)} = 0.35$$

The weights for the other monitors would be calculated in a similar fashion.

There are several variants to the general VNA method which can be used to allow for differences in the spatial dynamics of different pollutants. These variants include distance limited VNA, inverse distance squared weighting, and nested VNA. Distance limited VNA functions the same as VNA with the exception that neighbors are constrained to be within a given distance from the center of the grid cell. Inverse distance squared weighting uses the inverse of the squared distance from the center of the grid cell in computing the weighted average of neighboring monitors. Nested VNA allows for the use of different weighting algorithms and distance limits depending on data availability. All three of these variants are used in developing the interpolated species concentrations.

Because of the spatial dynamics of different PM species, different adjustments to the generalized VNA method are applied for individual species. For the Eastern U.S., the quarterly average concentrations for nitrates, sulfates, organic carbon mass (measured organic carbon *1.4), and crustal species were interpolated using both IMPROVE and STN monitors with inverse distance squared weighting. Eastern U.S. elemental carbon quarterly concentrations were interpolated using both IMPROVE and STN monitors with inverse distance weighting[4]. Degree of neutralization of sulfate (DON) was calculated at ESPN monitors (IMPROVE does not collect ammonium data) and then interpolated using inverse distance squared weighting.

Interpolated spatial fields of quarterly average sulfate ion, “FRM” nitrate, elemental carbon, organic carbon mass, crustal mass, and the degree of neutralization of sulfate (DON) were created using VNA interpolation. Each of these fields were used in the calculation of component mass as described in the procedures below. Figure 5 is an example of the resulting interpolated surface using the first quarter data for nitrates and figure 6 shows the interpolated fields for third quarter sulfate concentrations.

[4]The elemental carbon data appeared to have stronger urban gradients compared to other species. Therefore, an inverse distance weighting scheme was used to better maintain the observed gradients.

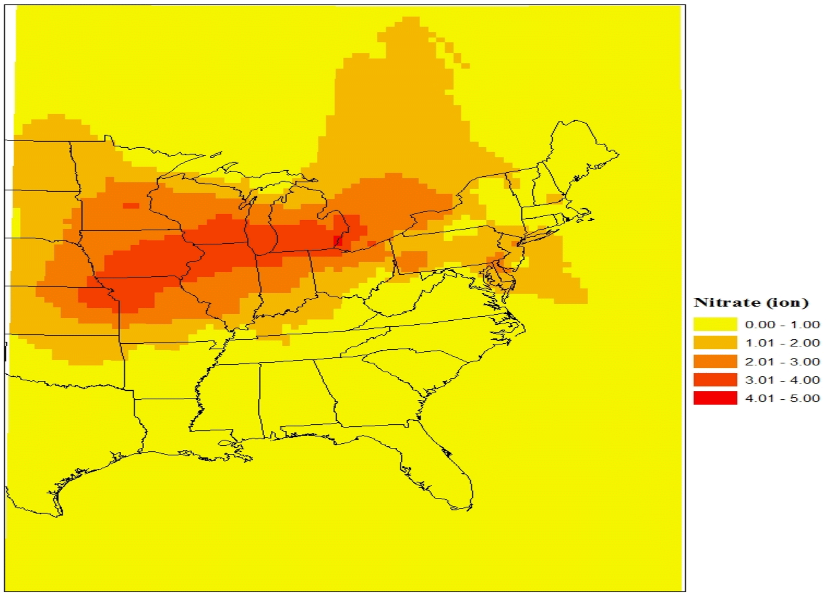


Figure 5. 1st quarter 2002 interpolated nitrate concentration.

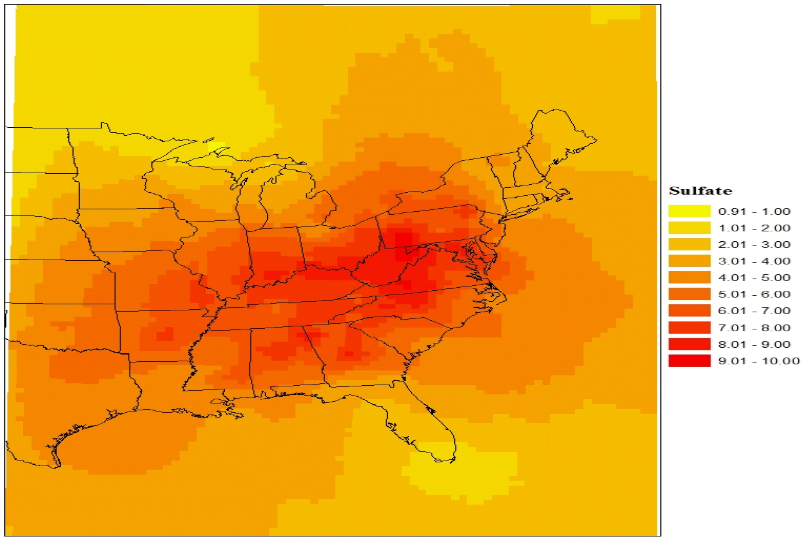

Figure 6. 3rd quarter interpolated sulfate concentration

III. Components of Measured $PM_{2.5}$ Mass

A. Introduction

As stated in the section I, one of the goals of the revised SMAT methodology is to bettter match the speciation data with the FRM $PM_{2.5}$ retained mass. A series of adjustments and calculations were performed in order to derive the estimated species compositions. Those procedures are described below.

To represent composition of measured $PM_{2.5}$ mass (for NAAQS implementation and more precise representation of regulatory $PM_{2.5}$), the following approach is used for revised SMAT:

CFM_{FRM} = [Ammoniated Sulfate Mass] + [Retained Nitrate Mass] + [Retained Carbonaceous Mass] + [Crustal] + [Other Components] [1]

In the above characterization, CFM equals constructed fine mass and all of the listed chemical components reflect those retained during sampling and equilibration on the FRM's Teflon filter. Sulfate and nitrate mass include associated ammonium but which may be different than assumed ammonium sulfate and ammonium nitrate compounds. Also, sulfates, nitrates and carbonaceous mass includes particle bound water associated with these hygroscopic aerosols. For these analyses, Crustal is intended to be a more general term that includes fine soil, and oxides that result from other PM emissions.

B. Derivation of $PM_{2.5}$ Species Used in Revised SMAT

1. Calculated adjusted nitrate by applying formula to daily average data

Retained Nitrate Mass The first step in the procedure for identifying mass components was to estimate the retained nitrate mass on the FRM filters. The FRM does not capture all of the semi-volatile components of the ambient air, such as ammonium nitrate. The retained amount of nitrate ion, however, can be accurately estimated by a simple thermodynamic model that involves 24-hr ambient nitrate speciation concentrations (as measured by a standard speciation sampler using a nylon filter preceded by a HNO3 denuder) together with hourly ambient temperature and humidity. Atmospheric nitrates are higher during the cooler months. Retention on the FRM is also higher during the cooler months and essentially all the nitrates are lost during the summer. The retention does not appear to depend on ambient NH3 or HNO3. More NO3 is retained at low temps and high humidity which varies by sampling location and time of year.

Prediction of FRM Nitrates Because nitrate retention varies by site and season, an ammonium nitrate equilibrium model is used to predict the amount of nitrates retained on the FRM teflon filter. As used by Hering *(Hering, 1999; Zhang, 1992),*

$$\text{delta NO3 (ug/m3)} = 745.7/T_R * 1/24 * \sum_{i=1}^{24} (\mathbf{K}_i^{1/2}) \quad [2]$$

where T_R is the reference temperature for the sampled air volume in degrees Kelvin and $\mathbf{K_i}$ is the dissociation constant for ammonium nitrate evaluated at the ambient temperature for hour i. This volatilization prediction characterizes depletion of some or all of the nitric acid and ammonia vapors ahead of the filter and specifies a 3-5 degree increase in the filtration temperature above ambient.

This model is used to adjust 24-hr ESPN nitrate ion concentrations to estimate FRM NO3 ($NO3_{FRM}$) as follows:

$$NO3_{FRM} = NO3_{ESPN} - \text{delta NO3 (ug/m3)} \quad [3]$$

For each hour of the day, the equilibrium dissociation constant for ammonium nitrate, K_i, was calculated from hourly ambient temperature and hourly ambient relative humidity based on Mozurkewich *(Mozurkewich, 1993)* and as applied by Chang et al.

When RH is less than deliquescence point of ammonium nitrate (61%),

$$\text{Ln } K = 118.87 - (24084/T) - 6.025 \ln T, \quad [4]$$

K in nanobars, T in Kelvins.

When RH is higher than 61%, K is replaced by

$$K' = [P_1 - P_2(1-a) + P_3(1-a)^2]\ (1-a)^{1.75} * K \quad [5]$$

where Ln P1, Ln P2, Ln P3 are specified as
$\text{Ln}(P_1) = -135.94 + 8763/T + 19.12\ln(T)$
$\text{Ln}(P_2) = -122.65 + 9969/T + 16.22\ln(T)$
$\text{Ln}(P_3) = -182.61 + 13875/T + 24.46\ln(T)$

Equation 4 assumes crystallization of ammonium nitrate when RH is less than 61%. Thus, predicted NO3 loss may be underestimated for situations where solids do not form on the filter. For supersaturated solutions and with lower RH, the estimated dissociation for the solution will be larger than K for the solid. However, there is little (or no) data that can be used to give a reliable result for how much larger.

Based on equations [2]-[5], Figure 7 illustrates the potential nitrate loss as a function of temperature and relative humidity. Temperature is presented as degrees F for more convenient interpretation. It shows that at 50 deg F and RH of 80%, approximately 1.6 ug/m3 nitrate would be lost. At RH less < 61% an additional 0.4ug/m3 could be lost. In both cases, the loss cannot exceed the amount of ambient NO3, as depicted by the ESPN NO3.

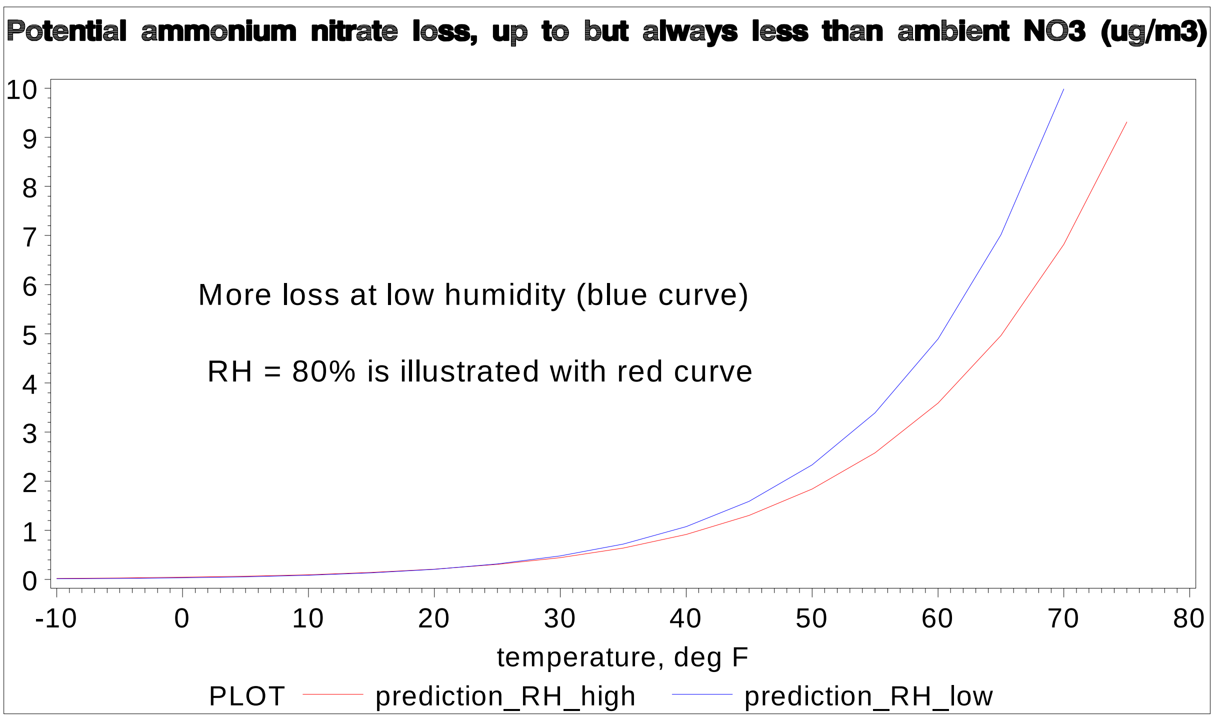

Figure 7- Potential NO3 loss as a function of temperature and relative humidity.

When these predictions are compared with measured FRM nitrates at six eastern US monitoring locations, the annual average prediction errors are <-0.3 - +0.1 ug/m3.

3. Estimated Ammonium associated with sulfates and retained nitrates and sulfates

To determine the mass associated with nitrates, we first assume retained nitrate is probably all ammonium nitrate in the Eastern US. Thus the ammonium associated with nitrates can be derived directly from the measured or predicted $NO3_{FRM}$ as

$$NH4_{NO3} = 0.29 * NO3_{FRM} \quad [6]$$

Similarly, the dry $PM_{2.5}$ mass associated with nitrates is

$$[\text{Retained dry FRM Nitrates}] = 1.29 * NO3_{FRM} \quad [7]$$

FRM nitrates retains water. Discussion of hydrated nitrates (and sulfates) are discussed in the next section.

The difference between total FRM NH4 (amount associated with nitrates and sulfates), termed $NH4_{FRM}$, and the ESPN NH4, termed $NH4_{ESPN,}$, is needed to determine the ammoniated form of sulfates as described by equation 4. Recent measurement study by Collett *(Collett, 2004)* shows that NH4 may not be completely retained during collection on nylon filters preceded by a nitric acid denuder. During sampling conditions associated with nitrate volatilization, ammonium nitrate dissociates but the HNO3 downstream of the denuder is recaptured on the basic nylon media and the result is reported as particle nitrate. On the other hand, the NH4+ volatilizes to gaseous NH3 and apparently passes thru the filter. At several FRM study sites, the ESPN NH4 which is adjusted for evaporated NH4NO3 tends to more closely corresponds to the measured NH4 from the FRM teflon filter. However, for other sites, the measured ESPN NH4 appear to agree with FRM NH4.

Because of uncertainty in retained FRM NH4, NH4adj is estimated as $NH_{4\ ESPN}$ minus ½ the amount that would have evaporated with lost NO3 as follows:

$$NH4_{adj} = NH_{4\ ESPN} - ½ * 0.29 * (NO3_{\ ESPN} - NO3_{FRM}) \quad [8]$$

This essentially assumes that 50 % of the ammonium associated with lost nitrate is also lost.

4. Ammoniated Sulfate Mass.

The mass associated with sulfates is first estimated as its dry mass. All estimated sulfates are assumed to be associated with ammonium, but the form of the sulfate compound and the amount of ammonium must be estimated. The form of the ammoniated sulfate compound(s) and the amount of associated ammonium, however, is somewhat uncertain.

Sulfates may not be fully neutralized in all geographic areas or seasons of the year. During winter-time conditions, when nitrates are prevalent in the ambient aerosol, sulfates tend to be fully neutralized and exist as ammonium sulfate. During the summer when sulfates are higher, nitrates are lower and ammonia is less available for reaction with H2SO4 , the resulting aerosol can be acidic and the form of sulfates can include bisulfate or even H2SO4.

The amount of ammonium associated with the sulfate ion can be estimated as

$$NH4_{(SO4)} = NH4_{adj} - 0.29 * NO3_{FRM}, \quad [9]$$

where 0.29 is the molar ratio of NH4 to NO3 and
$NH4_{FRM}$ and $NO3_{FRM}$ reflect the amounts retained on the FRM filter.

The amount of $NH4_{(SO4)}$ is not allowed to exceed the fully neutralized amount of 0.375 multiplied by the estimated sulfate ion concentration.

Because of uncertainties in NH4 speciation measurements, the spatially interpolated values of NH4 are calculated by deriving the degree of sulfate neutralization (DON) from the estimated $NH4_{(SO4)}$ as

$$DON = NH4_{(SO4)} / SO4. \quad [10]$$

Interpolated values of DON, sulfate and estimated FRM nitrate (adjusted nitrate) are then used to estimate the adjusted ammonium at each FRM site as follows:

$$NH4_{FRM} = DON * SO4 + 0.29*NO3_{FRM}, \quad [11]$$

where: DON, SO4 and NO3FRM are the interpolated (kriged) quarterly average values at each FRM site. $NH4_{FRM}$ is not a directly measured value, but is derived from the measurements of NH4, SO4, and NO3. The interpolated DON values were used to estimate ammonium due to the uncertainty of the ammonium measurements. The accuracy of the ammonium measurement and the amount of ammonium that is retained on the FRM filter is uncertain. Use of the smoothed, interpolated DON values allows for a relatively smooth field of ammonium concentrations.

5. Particle Bound Water

Because ammoniated sulfate and ammonium nitrate are hygroscopic, the retained sulfate and nitrate mass will include water. Particle bound water (PBW) is estimated using the Aerosol Inorganic Model (AIM) *(Clegg, 1998)*. PBW was derived from quarterly average FRM concentrations of sulfate, ammonium, nitrate as describe above. Estimated hydronium ion, H+, needed to achieve ionic balance was derived from the latter values. The model enables the distribution of water and ions to be calculated between liquid, solid and vapor phases for specific temperature and relative humidity conditions. Typical filter equilibration conditions of 35% RH and 22 deg C (295 deg K) temperature were used.

Application of AIM at the specified FRM filter equilibration conditions show that PBW is much more dependent on sulfate concentration compared to nitrate and that the relationship varies somewhat by season to differentiate the relative amounts of sulfate and nitrate aerosol. There is proportionally less estimated PBW water for wintertime aerosol which has higher NH4 and NO3 and lower SO4.

After running the AIM model, it was determined that the particle bound water concentrations are sensitive to the degree of neutralization of the sulfate particles (determined by the relative concentration of $NH4_{FRM}$). Due to the uncertainty in ammonium concentration estimates, we used a relatively smooth field of interpolated ammonium concentrations as input to AIM. This helped to smooth out some of the "bumpiness" in the water concentration predictions.

For computational convenience, a polynomial regression equation was fit to the calculated water mass from AIM and the three input values that fed into AIM (sulfate, nitrate and ammonium). The polynomial equation is then used in all SMAT analyses to estimate water.

The equation is as follows:

```
PBW =(-0.002618) + (0.980314*nh4) + (-0.260011*no3) + (-0.000784*so4)
     + (-0.159452*nh4**2) + (-0.356957*no3*nh4) + (0.153894*no3**2)
     + (0.212891*so4*nh4) + (0.044366*so4*no3) + (-0.048352*so4**2)    [12]
```

where nh4 = $NH4_{FRM}$ and no3 = $NO3_{FRM}$

6. Other Non-Carbon $PM_{2.5}$ Components (blank mass)

The other quantifiable components of $PM_{2.5}$ mass include passively collected mass, represented by the field blank concentration of 0.3-0.5ug/m3 *(EPA, 2002)*. This appears to constitute a contamination of the filter resulting from handling or contact with the FRM cassette. This value is deemed to be an important constituent of $PM_{2.5}$ mass (it is assumed to not be dependent on pollutant emissions). A nominal blank mass value of 0.5 ug/m3 will be considered in mass construction computations presented later. This value is assumed to remain constant through time.

7. Calculation of Carbonaceous Mass

Elsewhere, carbonaceous mass is estimated from blank corrected speciation data, where organic carbonaecous mass is first estimated by multiplying the organic carbon concentrations by 1.4 or alternative factors to account for the oxygen, hydrogen and other elements associated with ambient carbon particles. To that amount is added the elemental carbon concentration. An alternative approach to estimate carbon contribution to $PM_{2.5}$ mass is used for revised SMAT because of (1) many uncertainties in estimating carbonaceous mass from carbon measurements *(Turpin, 2001; Chow, 2004)* (2) differences in carbon measurement protocol between urban and rural monitoring locations, (3) a relatively “bumpy” surface of urban carbon concentrations as derived from these urban and rural organic carbon measurements and (4) lack of carbon measurements at all FRM locations. The revised SMAT approach estimates carbon by mass balance comparing precisely measured FRM $PM_{2.5}$ mass *(EPA, 2003)* with the sum of its non-carbon components. The latter are sulfates, ammonium, nitrates, estimated particle bound water, estimated crustal material plus 0.5 ug/m3 as discussed earlier.

This approach estimates retained carbonacous FRM mass and explicitly accounts for the following important and difficult to estimate carbon mass properties: (1) regional and urban-rural differences in the mix of carbonaceous aerosols, i.e. the amount of oxygen, hydrogen, etc; (2) retained water associated with hygroscopic carbon compounds *(Saxena, 1996; Yua, 2004)*; (3) volatile carbonaceous material measured by speciation samplers, but not retained in FRM mass; and (4) uncertainties associated with blank corrections of measured organic and elemental carbon.

Total Carbonaceous Mass by mass balance **(TCM_{mb})** is defined as ,

$$\mathbf{TCM_{mb}} = PM_{2.5} - \{ [SO4] + [NO3_{FRM}] + [NH4_{FRM}] + [water] + [crustal\ material] + [0.5] \} \quad [13]$$

In this expression, all of the above quarterly average components represent the mass retained on FRM teflon filters.

The mass associated with organic compounds is defined as

$$\mathbf{OCM_{mb}} = \mathbf{TCM_{mb}} - [EC] \quad [14]$$

where EC is elemental carbon.

This approach completely accounts for FRM mass and OCMmb is often greater than the amount that would be derived directly from speciation measurements. Because of uncertainties in speciation measurements and their estimates from interpolated surfaces, a lower limit (floor) for OCMmb was set so that the OCMmb was not unreasonably low. The floor was set so that OCMmb could not be more than 30% lower than measured OCM. We used the Kriged measured values of OCM to calculate the floor. The lower limit is equal to interpolated (measured) OC * 1.4 * 0.7. If the OCMmb concentration was less than the lower limit, it was set equal to the lower limit.

B. Summary of $PM_{2.5}$ Composition Calculations

Equation 15 shows the final composition of PM species as they relate to the measured FRM values for each quarter of 2002. Quarterly average FRM mass is equal to the sum of the seven species plus blank mass.

$$PM2.5_{FRM} = \{ [OCMmb] + [EC] + [SO4] + [NO3_{FRM}] + [NH4_{FRM}] + [water] + [crustal\ material] + [0.5] \} \quad [15]$$

The species data is generated in the following order:

1) Adjusted nitrate is calculated using hourly meteorology and 24-hour average nitrate measurements.

2) Quarterly averages are calculated for adjusted nitrate, sulfate, elemental carbon, degree of sulfate neutralization (DON), crustal mass , and measured OCM[5].

3) Quarterly average ammonium is calculated from the adjusted nitrate, sulfate, and DON values.

4) Calculated ammonium, sulfate, and nitrate values are input into the polynomial water equation to derive particle bound water concentrations.

5) Carbon mass by difference (OMCmb) is calculated from the $PM_{2.5}$ mass, adjusted nitrate, ammonium, sulfate, water, elemental carbon, crustal, and blank mass values.

6) The sum of the 7 species plus blank mass is equal to the FRM mass.

C. Calculation of Quarterly Species Fractions

For each quarter at each FRM site, concentrations for each of the seven species (plus blank mass) are combined with quarterly 2002 $PM_{2.5}$ FRM averages to derive composition fractions in the following manner:

First, the 0.5 ug/m3 of blank mass is subtracted from the FRM $PM_{2.5}$ concentration.

$$PM2.5_{FRM\text{-}Blank} = PM2.5_{FRM} - 0.5\ ug/m3 \qquad [16]$$

The blank mass is subtracted before species fractions are calculated because the blank mass is held constant at 0.5 ug/m3 throughout the analysis. In the example below (table 3a), the measured FRM mass for quarter 3 in 2002 is 22.5 ug/m3. The non-blank FRM mass is 22.0 ug/m3. The mass of the seven species add up to the non-blank mass.

Table 3a

FRM Mass (ug/m3)	**Blank Mass (ug/m3)**	**Non-blank Mass (ug/m3)**	**Sulfate (ug/m3)**	**Nitrate (ug/m3)**	**Organic aerosol (ug/m3)**	**Elemental Carbon (ug/m3)**	**Water (ug/m3)**	**Ammonium (ug/m3)**	**Crustal (ug/m3)**
22.5	0 .5	22.0	8.5	1.1	5.2	0.9	2.3	3.3	0.7

[5]The measured OCM is only used to calculate the "floor" for OCMmb.

Next, species fractions are calculated for each quarter for each specie. In the example below (table 3b), a fraction of non-blank mass is calculated for each of the seven species. Blank mass remains fixed at 0.5 ug/m3.

Table 3b

FRM Mass (ug/m3)	Blank Mass (ug/m3)	Non-blank Mass (ug/m3)	% Sulfate	% Nitrate	% Organic aerosol	% Elemental Carbon	% Water	% Ammonium	% Crustal
22.5	0 .5	22.0	38.6	5.0	23.6	4.1	10.5	15.0	3.2

The percentages in table 3b above are the relative composition for the 3rd quarter of 2002. For the purposes of this analysis, we are assuming that the relative specie composition for each quarter of 2002 is representive of the 1999-2003 time period.

IV. $PM_{2.5}$ Design Values for Projecting to the Future

A. Defining "Current" Year FRM $PM_{2.5}$ Values

The $PM_{2.5}$ component species fractions are applied to "current" $PM_{2.5}$ design values which are then projected to the future. The CAIR proposal SMAT procedure followed the recommendations in the current draft $PM_{2.5}$ modeling guidance. The guidance recommends projecting the highest of the three design values that straddle the base modeling emissions year. In this case the base emissions year is 2001. The three design value periods that straddle 2001 are 1999-2001, 2000-2002, and 2001-2003. The 2001-2003 data was not available when the CAIR proposal was released, so the highest design value of the 2 available years; 1999-2001 or 2000-2002 were used in the CAIR proposal.

In the revised SMAT procedure we are proposing to revise the methodology to calculate the base year design values for projections. We are proposing to use the average of the 3 design value periods that straddle the emissions year. The average of the 3 design values is not a straight five year average. It is, in effect, a weighted average of the annual averages. The design value periods range from 1999-2003. In the average of 1999-2001, 2000-2002, and 2001-2003, 2001 is "weighted" 3 times, 2000 and 2002 are weighted twice, and 1999 and 2003 are weighted once. This has the desired effect of weighting the projected $PM_{2.5}$ values towards the middle year of the five year period, which is the emissions and meteorology year (2001). The average design value methodology also takes into account the emissions and meteorological variability that occurs over the full 5 year period. The average weighted design value is thought to be more representative of the 2001 emissions and meteorology period than the previous methodology of choosing the highest single design value period. This value provides the "best estimate" current year design value for use in future year model projections. It should be noted that in most cases, the "average" design value will not be the same as the 2001-2003 design value that will be used for the purpose of $PM_{2.5}$ designations. The average design value may be higher or lower than the 2001-2003 value.

There are several steps in the derivation of the average $PM_{2.5}$ design values for projections to the future. Quarterly average values are needed for each FRM site. The following steps were used to derive the quarterly average FRM values.

1) The analysis began with quarterly average FRM data for all quarters from 1999-2003.

2) Completeness was defined as site quarters with11 valid samples per quarter. All site quarters with less than 11 samples were removed.

3) A quarterly average 3 year design value was calculated for each design value period in which a site had all 12 quarters with complete data[6] (1999-2001, 2000-2002, and 2001-2003). This results in four quarterly averages for up to three design value periods for each FRM site. Sites had to have complete data for the latest design value period (2001-2003) to be considered in the analysis. Since the $PM_{2.5}$ designation process will use the 2001-2003 data, sites were not used in the analysis if they did not have complete data (as defined in 2 above) for the 2001-2003 period.

4) The (up to) 3 quarterly design value periods were averaged together to get a single quarterly average design value for each site. All complete design value data was used, provided that the 2001-2003 period was complete. A site did not have to have all 3 complete design periods. If 2001-2003 was the only complete period, then that was used as the average design value (even though it isn't truly an average). If 2 complete design value periods were available for a site (1999-2001 and 2001-2003 **or** 2000-2002 and 2001-2003), then those 2 periods were averaged together.

The averaged quarterly average FRM design values were used as the "current" FRM value for each monitoring site. The species fractions from the 2002 speciation data were used to estimate the species concentrations for the current year FRM $PM_{2.5}$ data. The percentage compositions for 2002 are applied to the quarterly average design values as shown in table 4a.. In the example below, the average design value for the 3rd quarter for the site from table 3b is 20.3 ug/m3. This leads to the following concentrations of $PM_{2.5}$ species:

---

[6]Sites were considered to have complete data for the purposes of calculating a 3 year design value if they had 12 complete quarters <u>or</u> were considered to have complete data through data substitution. If a site was complete with data substitution and had 10 or 11 complete quarters, the quarterly design values were calculated using only the complete quarters. Incomplete quarters were not used in the calculations.

Table 4a. Calculation of the "current" species concentrations

Weighted Avg. FRM Mass (ug/m3)	Blank Mass (ug/m3)	Non-blank Mass (ug/m3)	Sulfate (ug/m3)	Nitrate (ug/m3)	Organic aerosol (ug/m3)	Elemental Carbon (ug/m3)	Water (ug/m3)	Ammonium (ug/m3)	Crustal (ug/m3)
20.3	0 .5	19.8	7.64	0.99	4.67	0.81	2.08	2.97	0.63

This procedure is repeated for each $PM_{2.5}$ site and quarter to complete the calculation of current (or baseline) ambient concentrations used as the basis for future estimates of $PM_{2.5}$ mass and its components.

B. Estimating Future Year $PM_{2.5}$

Future concentrations of $PM_{2.5}$ component species are estimated by assuming that the quarterly average component concentration will change in the same proportion as the model predicted change. Model predicted changes in species concentrations (from a current year to a future year) are used to calculate "relative reduction factors". Relative reduction factors are calculated for each grid cell and species as the ratio of the quarterly average future model predictions to the current base model predictions. The relative reduction factor for each species is then multiplied by the estimated current year ambient species mass for the site to estimate future species concentrations.

In the revised SMAT methodology, relative reduction factors are calculated for 5 species; sulfate, nitrate, organic carbon mass, elemental carbon, and crustal mass. The future year concentrations of the 5 components are calculated for each site quarter. The future year ammonium concentrations are calculated from the sulfate, nitrate, and (current year) DON values. Assuming that the DON is unchanged from the current year[7], the ammonium is calculated using the following formula:

$NH4_{future} = DON * SO4_{future} + 0.29*NO3_{future}$,

The $NH4_{future}$, $SO4_{future,}$ and $NO3_{future}$ concentrations were then run through the polynomial water equation to predict a future year water concentration. The future species concentrations at

[7]The DON was assumed to stay constant through time due to the uncertainty in the ammonium measurements. The water calculation is sensitive to the ammonium (and therefore the DON value) concentrations. Keeping the DON constant allows for the future year ammonium and water values to be solely a function of the sulfate and nitrate concentrations. Otherwise, it is possible for sulfate and nitrate to be reduced and water concentrations to increase. This may occur if sulfate becomes more neutralized in the future. But it is somewhat illogical outcome (although scientifically possible) and is highly dependent on an uncertain measurement (ammonium). Therefore we did not allow the DON value to vary with time.

each FRM site were then summed over the seven species plus blank mass[8] to estimate the future quarterly average $PM_{2.5}$ concentration. The four quarterly values are then averaged to obtain the estimated future annual average $PM_{2.5}$ for each FRM site.

V. Summary

The results of the analysis at each of the FRM monitoring sites (with complete data) were used in the CAIR final rule modeling analysis. The revised SMAT technique has several improvements over the original SMAT application in the CAIR proposal. One goal of the revised SMAT methodology was to estimate the $PM_{2.5}$ mass that is retained on the FRM filters. This provides a more unbiased estimate of future $PM_{2.5}$ concentrations which are based on current year FRM measurements. Averaging of multiple design value periods provides a "best estimate" current year design value. Application of revised SMAT with interpolated spatial fields allows us to take advantage of the measurements at each FRM site. In this way, a more complete future year attainment/nonattainment picture can be derived by expanding the predictions of future year design values to all FRM monitoring sites.

Use of SMAT with Spatial Fields for SIPs

The details of this application of revised SMAT are specific to the short term use of the FRM and speciation data (ESPN and IMPROVE) in estimating future year $PM_{2.5}$ concentrations for the CAIR. The use of a single year of speciation data interpolated to a modeling grid is necessary at this time, due to the relatively sparse ambient data sets. The amount of available ambient data will increase significantly in the future. When ambient data is needed for SIP development, there will be at least 3 years of complete speciation data at hundreds of sites. In many areas, the coverage of speciation data may be adequate so that interpolation of the data through spatial fields is not necessary. It is likely that the routinely measured speciation data will never be directly comparable with the FRM data, but our understanding of the biases, artifacts, and sampling issues will continue to improve through time. This application should serve as an example that can be replicated in the short term, but the techniques and assumptions will likely evolve over the long term.

[8] The blank mass value was held constant at 0.5 ug/m3, effectively giving it a relative reduction factor of 1.0.

Appendix M

Adopted State Measures

(This page intentionally left blank)

INTRODUCTION

This Appendix contains the North Carolina rules and legislation that have been adopted that impact fine particulate matter pollution. Below is listed the rules and legislations, with a short description, and the corresponding page numbers where the measure can be found.

(This page intentionally left blank)

15A NCAC 02D .0530 PREVENTION OF SIGNIFICANT DETERIORATION

(a) The purpose of the Rule is to implement a program for the prevention of significant deterioration of air quality as required by 40 CFR 51.166.

(b) For the purposes of this Rule the definitions contained in 40 CFR 51.166(b) and 40 CFR 51.301 shall apply except the definition of "baseline actual emissions."

(1) "Baseline actual emissions" means the rate of emissions, in tons per year, of a regulated new source review (NSR) pollutant, as determined in accordance with Parts (A) through (C) of this Subparagraph:

(A) For an existing emissions unit, baseline actual emissions means the average rate, in tons per year, at which the emissions unit actually emitted the pollutant during any consecutive 24-month period selected by the owner or operator within the 5-year period immediately preceding the date that a complete permit application is received by the Division for a permit required under this Rule. The Director shall allow a different time period, not to exceed 10 years immediately preceding the date that a complete permit application is received by the Division, if the owner or operator demonstrates that it is more representative of normal source operation. For the purpose of determining baseline actual emissions, the following shall apply:

(i) The average rate shall include fugitive emissions to the extent quantifiable, and emissions associated with startups, shutdowns, and malfunctions.

(ii) The average rate shall be adjusted downward to exclude any non-compliant emissions that occurred while the source was operating above any emission limitation that was legally enforceable during the consecutive 24-month period.

(iii) For an existing emission unit (other than an electric utility steam generating unit), the average rate shall be adjusted downward to exclude any emissions that would have exceeded an emission limitation with which the major stationary source must currently comply. However, if the State has taken credit in an attainment demonstration or maintenance plan consistent with the requirements of 40 CFR 51.165(a)(3)(ii)(G) for an emission limitation that is part of a maximum achievable control technology standard that the Administrator proposed or promulgated under part 63 of the Code of Federal Regulations, the baseline actual emissions shall be adjusted to account for such emission reductions.

(iv) For an electric utility steam generating unit, the average rate shall be adjusted downward to reflect any emissions reductions under G. S. 143-215.107D and for which cost recovery is sought pursuant to G. S. 62-133.6.

(v) For a regulated NSR pollutant, when a project involves multiple emissions units, only one consecutive 24-month period shall be used to determine the baseline actual emissions for all the emissions units being changed. A different consecutive 24-month period for each regulated NSR pollutant can be used for each regulated NSR pollutant.

(vi) The average rate shall not be based on any consecutive 24-month period for which there is inadequate information for determining annual emissions, in tons per year, and for adjusting this amount if required by Subparts (ii) and (iii) of this Part.

(B) For a new emissions unit, the baseline actual emissions for purposes of determining the emissions increase that will result from the initial construction and operation of such unit shall equal zero; and thereafter, for all other purposes, shall equal the unit's potential to emit.

(C) For a plantwide applicability limit (PAL) for a stationary source, the baseline actual emissions shall be calculated for existing emissions units in accordance with the procedures contained in Part (A) of this Subparagraph, and for a new emissions unit in accordance with the procedures contained in Part (B) of this Subparagraph.

(2) In the definition of "net emissions increase," the reasonable period specified in 40 CFR 51.166(b)(3)(ii) shall be seven years.

(3) The limitation specified in 40 CFR 51.166(b)(15)(ii) shall not apply.

(c) All areas of the State shall be classified as Class II except that the following areas are Class I:

(1) Great Smoky Mountains National Park;

(2) Joyce Kilmer Slickrock National Wilderness Area;

(3) Linville Gorge National Wilderness Area;

(4) Shining Rock National Wilderness Area;
(5) Swanquarter National Wilderness Area.

(d) Redesignations of areas to Class I or II may be submitted as state proposals to the Administrator of the Environmental Protection Agency (EPA), if the requirements of 40 CFR 51.166(g)(2) are met. Areas may be proposed to be redesignated as Class III, if the requirements of 40 CFR 51.166(g)(3) are met. Redesignations may not, however, be proposed which would violate the restrictions of 40 CFR 51.166(e). Lands within the boundaries of Indian Reservations may be redesignated only by the appropriate Indian Governing Body.

(e) In areas designated as Class I, II, or III, increases in pollutant concentration over the baseline concentration shall be limited to the values set forth in 40 CFR 51.166(c). However, concentration of the pollutant shall not exceed standards set forth in 40 CFR 51.166(d).

(f) Concentrations attributable to the conditions described in 40 CFR 51.166(f)(1) shall be excluded in determining compliance with a maximum allowable increase. However, the exclusions referred to in 40 CFR 51.166(f)(1)(i) or (ii) shall be limited to five years as described in 40 CFR 51.166(f)(2).

(g) Major stationary sources and major modifications shall comply with the requirements contained in 40 CFR 51.166(i) and (a)(7) and by extension in 40 CFR 51.166(j) through (o) and (w). The transition provisions allowed by 40 CFR 52.21 (i)(11)(i) and (ii) and (m)(1)(vii) and (viii) are hereby adopted under this Rule. The minimum requirements described in the portions of 40 CFR 51.166 referenced in this Paragraph are hereby adopted as the requirements to be used under this Rule, except as otherwise provided in this Rule. Wherever the language of the portions of 40 CFR 51.166 referenced in this Paragraph speaks of the "plan," the requirements described therein shall apply to the source to which they pertain, except as otherwise provided in this Rule. Whenever the portions of 40 CFR 51.166 referenced in this Paragraph provide that the State plan may exempt or not apply certain requirements in certain circumstances, those exemptions and provisions of nonapplicability are also hereby adopted under this Rule. However, this provision shall not be interpreted so as to limit information that may be requested from the owner or operator by the Director as specified in 40 CFR 51.166(n)(2).

(h) New natural gas-fired electrical utility generating units shall install best available control technology for NO_X and SO_2.

(i) 40 CFR 51.166(w)(10)(iv)(a) is changed to read: "If the emissions level calculated in accordance with Paragraph (w)(6) of this Section is equal to or greater than 80 percent of the PAL [plant wide applicability limit] level, the Director shall renew the PAL at the same level." 40 CFR 51.166(w)(10)(iv)(b) is not incorporated by reference.

(j) 15A NCAC 02Q .0102 and .0302 are not applicable to any source to which this Rule applies. The owner or operator of the sources to which this Rule applies shall apply for and receive a permit as required in 15A NCAC 02Q .0300 or .0500.

(k) When a particular source or modification becomes a major stationary source or major modification solely by virtue of a relaxation in any enforceable limitation which was established after August 7, 1980, on the capacity of the source or modification to emit a pollutant, such as a restriction on hours of operation, then the provisions of this Rule shall apply to the source or modification as though construction had not yet begun on the source or modification.

(l) The provisions of 40 CFR 52.21(r)(2) regarding the period of validity of approval to construct are incorporated by reference except that the term "Administrator" is replaced with "Director".

(m) Volatile organic compounds exempted from coverage in 40 CFR 51.100(s) shall also be exempted when calculating source applicability and control requirements under this Rule.

(n) The degree of emission limitation required for control of any air pollutant under this Rule shall not be affected in any manner by:

(1) that amount of a stack height, not in existence before December 31, 1970, that exceeds good engineering practice; or
(2) any other dispersion technique not implemented before then.

(o) A substitution or modification of a model as provided for in 40 CFR 51.166(l) shall be subject to public comment procedures in accordance with the requirements of 40 CFR 51.102.

(p) Permits may be issued on the basis of innovative control technology as set forth in 40 CFR 51.166(s)(1) if the requirements of 40 CFR 51.166(s)(2) have been met, subject to the condition of 40 CFR 51.166(s)(3), and with the allowance set forth in 40 CFR 51.166(s)(4).

(q) If a source to which this Rule applies impacts an area designated Class I by requirements of 40 CFR 51.166(e), notice to EPA will be provided as set forth in 40 CFR 51.166(p)(1). If the Federal Land Manager presents a demonstration described in 40 CFR 51.166(p)(3) during the public comment period or public hearing to the Director and if the Director concurs with this demonstration, the permit application shall be denied. Permits may be issued on the basis that the requirements for variances as set forth in 40 CFR 51.166(p)(4), (p)(5) and (p)(7), or (p)(6) and (p)(7) have been satisfied.

(r) A permit application subject to this Rule shall be processed in accordance with the procedures and requirements of 40 CFR 51.166(q). Within 30 days of receipt of the application, applicants shall be notified if the application is complete as to initial information submitted. Commencement of construction before full prevention of significant deterioration approval is obtained constitutes a violation of this Rule.

(s) Approval of an application with regard to the requirements of this Rule shall not relieve the owner or operator of the responsibility to comply fully with applicable provisions of other rules of this Subchapter or Subchapter 02Q of this Title and any other requirements under local, state, or federal law.

(t) When a source or modification subject to this Rule may affect the visibility of a Class I area named in Paragraph (c) of this Rule, the following procedures shall apply:

(1) The Director shall provide written notification to all affected Federal Land Managers within 30 days of receiving the permit application or within 30 days of receiving advance notification of an application. The notification shall be at least 30 days prior to the publication of notice for public comment on the application. The notification shall include a copy of all information relevant to the permit application including an analysis provided by the source of the potential impact of the proposed source on visibility.

(2) The Director shall consider any analysis concerning visibility impairment performed by the Federal Land Manager if the analysis is received within 30 days of notification. If the Director finds that the analysis of the Federal Land Manager fails to demonstrate to his satisfaction that an adverse impact on visibility will result in the Class I area, the Director shall provide in the notice of public hearing on the application, an explanation of his decision or notice as to where the explanation can be obtained.

(3) The Director may require monitoring of visibility in or around any Class I area by the proposed new source or modification when the visibility impact analysis indicates possible visibility impairment.

(u) If the owner or operator of a source is using projected actual emissions to avoid applicability of prevention of significant deterioration requirements, the owner or operator shall notify the Director of the modification before beginning actual construction. The notification shall include:

(1) a description of the project,

(2) identification of sources whose emissions could be affected by the project,

(3) the calculated projected actual emissions and an explanation of how the projected actual emissions were calculated, including identification of emissions excluded by 40 CFR 51.166(b)(40)(ii)(c),

(4) the calculated baseline actual emissions and an explanation of how the baseline actual emissions were calculated, and

(5) any netting calculations if applicable.

If upon reviewing the notification, the Director finds that the project will cause a prevention of significant deterioration evaluation, then the Director shall notify the owner or operator of his findings. The owner or operator shall not make the modification until it has received a permit issued pursuant to this Rule. If a permit revision is not required pursuant to this rule, the owner or operator shall maintain records of annual emissions in tons per year, on a calendar year basis related to the modifications for 10 years following resumption of regular operations after the change if the project involves increasing the emissions unit's design capacity or its potential to emit the regulated NSR pollutant; otherwise these records shall be maintained for five years following resumption of regular operations after the change. The owner or operator shall submit a report to the director within 60 days after the end of each year during which these records must be generated. The report shall contain the items listed in 40 CFR 51.166(r)(6)(v)(a) through (c). The owner or operator shall make the information documented and maintained under this Paragraph available to the Director or the general public pursuant to the requirements in 40 CFR 70.4(b)(3)(viii).

(v) The reference to the Code of Federal Regulations (CFR) in this Rule are incorporated by reference unless a specific reference states otherwise. The version of the Code of Federal Regulations incorporated in this Rule is that as of June 13, 2007 except those provisions noticed as stayed in 69 FR 40274, and does not include any subsequent amendments or editions to the referenced material.

History Note: *Authority G.S. 143-215.3(a)(1); 143-215.107(a)(3); 143-215.107(a)(5); 143-215.107(a)(7); 143-215.108(b); 150B-21.6;*

15A NCAC 02D .0531 SOURCES IN NONATTAINMENT AREAS

(a) For the purpose of this Rule the definitions contained in 40 CFR 51.165(a)(1) and 40 CFR 51.301 shall apply except the definition of "baseline actual emissions."

(1) "Baseline actual emissions" means the rate of emissions, in tons per year, of a regulated new source review (NSR) pollutant, as determined in accordance with Parts (A) through (C) of this Subparagraph:

(A) For an existing emissions unit, baseline actual emissions means the average rate, in tons per year, at which the emissions unit actually emitted the pollutant during any consecutive 24-month period selected by the owner or operator within the 5-year period immediately preceding the date that a complete permit application is received by the Division for a permit required under this Rule. The Director shall allow a different time period, not to exceed 10 years immediately preceding the date that a complete permit application is received by the Division, if the owner or operator demonstrates that it is more representative of normal source operation. For the purpose of determining baseline actual emissions, the following shall apply:

(i) The average rate shall include fugitive emissions to the extent quantifiable, and emissions associated with startups, shutdowns, and malfunctions.

(ii) The average rate shall be adjusted downward to exclude any non-compliant emissions that occurred while the source was operating above any emission limitation that was legally enforceable during the consecutive 24-month period.

(iii) For an existing emission unit (other than an electric utility steam generating unit), the average rate shall be adjusted downward to exclude any emissions that would have exceeded an emission limitation with which the major stationary source must currently comply. However, if the State has taken credit in an attainment demonstration or maintenance plan consistent with the requirements of 40 CFR 51.165(a)(3)(ii)(G) for an emission limitation that is part of a maximum achievable control technology standard that the Administrator proposed or promulgated under part 63 of the Code of Federal Regulations, the baseline actual emissions shall be adjusted to account for such emission reductions.

(iv) For an electric utility steam generating unit, the average rate shall be adjusted downward to reflect any emissions reductions under G.S. 143-215.107D and for which cost recovery is sought pursuant to G.S. 62-133.6.

(v) For a regulated NSR pollutant, when a project involves multiple emissions units, only one consecutive 24-month period shall be used to determine the baseline actual emissions for all the emissions units being changed. A different consecutive 24-month period for each regulated NSR pollutant.

(vi) The average rate shall not be based on any consecutive 24-month period for which there is inadequate information for determining annual emissions, in tons per year, and for adjusting this amount if required by Subparts (ii) and (iii) of this Part.

(B) For a new emissions unit, the baseline actual emissions for purposes of determining the emissions increase that will result from the initial construction and operation of such unit shall equal zero; and thereafter, for all other purposes, shall equal the unit's potential to emit.

(C) For a plantwide applicability limit (PAL) for a stationary source, the baseline actual emissions shall be calculated for existing emissions units in accordance with the procedures contained in Part (A) of this Subparagraph, and for a new emissions unit in accordance with the procedures contained in Part (B) of this Subparagraph.

(2) In the definition of "net emissions increase," the reasonable period specified in 40 CFR 51.165(a)(1)(vi)(C)(1) shall be seven years.

(b) Redesignation to Attainment. If any county or part of a county to which this Rule applies is later designated in 40 CFR 81.334 as attainment for ozone or carbon monoxide, all sources in that county subject to this Rule before the redesignation date shall continue to comply with this Rule.

(c) Applicability. 40 CFR 51.165(a)(2) is incorporated by reference. This Rule applies to the following areas:

(1) Ozone Nonattainment Areas, to major stationary sources and major modifications of sources of volatile organic compounds or nitrogen oxides for which construction commences after the area in which the source is located is designated according to Part (A) or (B) of this Subparagraph:

(A) areas designated in 40 CFR 81.334 as nonattainment for ozone, or

(B) any of the following areas and in that area only when the Director notices in the North Carolina Register that the area is in violation of the ambient air quality standard for ozone:

(i) Charlotte/Gastonia, consisting of Mecklenburg and Gaston Counties; with the exception allowed under Paragraph (l) of this Rule;

(ii) Greensboro/Winston-Salem/High Point, consisting of Davidson, Forsyth, and Guilford Counties and that part of Davie County bounded by the Yadkin River, Dutchmans Creek, North Carolina Highway 801, Fulton Creek and back to Yadkin River; or

(iii) Raleigh/Durham, consisting of Durham and Wake Counties and Dutchville Township in Granville County.

Violations of the ambient air quality standard for ozone shall be determined according to 40 CFR 50.9.

(2) Carbon Monoxide Nonattainment Areas. This Rule applies to major stationary sources and major modifications of sources of carbon monoxide located in areas designated in 40 CFR 81.334 as nonattainment for carbon monoxide and for which construction commences after the area in which the source is located is listed in 40 CFR 81.334 as nonattainment for carbon monoxide.

(d) This Rule is not applicable to:

(1) complex sources of air pollution regulated only under Section .0800 of this Subchapter and not under any other rule in this Subchapter;

(2) emission of pollutants at the new major stationary source or major modification located in the nonattainment area that are pollutants other than the pollutant or pollutants for which the area is nonattainment. (A major stationary source or major modification that is major for volatile organic compounds or nitrogen oxides is also major for ozone.);

(3) emission of pollutants for which the source or modification is not major;

(4) a new source or modification that qualifies for exemption under the provision of 40 CFR 51.165(a)(4); or

(5) emission of compounds listed under 40 CFR 51.100(s) as having been determined to have negligible photochemical reactivity except carbon monoxide.

(e) 15A NCAC 02Q .0102 and .0302 are not applicable to any source to which this Rule applies. The owner or operator of the source shall apply for and receive a permit as required in 15A NCAC 02Q .0300 or .0500.

(f) To issue a permit to a source to which this Rule applies, the Director shall determine that the source meets the following requirements:

(1) The new major stationary source or major modification will emit the nonattainment pollutant at a rate no more than the lowest achievable emission rate;

(2) The owner or operator of the proposed new major stationary source or major modification has demonstrated that all major stationary sources in the State that are owned or operated by this person (or any entity controlling, controlled by, or under common control with this person) are subject to emission limitations and are in compliance, or on a schedule for compliance that is federally enforceable or contained in a court decree, with all applicable emission limitations and standards of this Subchapter that EPA has authority to approve as elements of the North Carolina State Implementation Plan for Air Quality;

(3) The owner or operator of the proposed new major stationary source or major modification will obtain sufficient emission reductions of the nonattainment pollutant from other sources in the nonattainment area so that the emissions from the new major source and associated new minor sources will be less than the emissions reductions by a ratio of at least 1.00 to 1.15 for volatile organic compounds and nitrogen oxides and by a ratio of less than one to one for carbon monoxide. The baseline for this emission offset shall be the actual emissions of the source from which offset credit is obtained. Emission reductions shall not include any reductions resulting from compliance (or scheduled compliance) with applicable rules in effect before the application. The difference between the emissions from the new major source and associated new minor sources of carbon monoxide and the emission reductions shall be sufficient to represent reasonable further progress toward attaining the Ambient Air Quality Standards. The emissions reduction credits shall also conform to the provisions of 40 CFR 51.165(a)(3)(ii)(A) through (G) and (J); and

(4) The North Carolina State Implementation Plan for Air Quality is being carried out for the nonattainment area in which the proposed source is located.

(g) New natural gas-fired electrical utility generating units shall install lowest achievable emission rate technology for NO_X and SO_2.
(h) 40 CFR 51.165(f) is incorporated by reference except that 40 CFR 51.165(f)(10)(iv)(A) is changed to read: "If the emissions level calculated in accordance with Paragraph (f)(6) of this Section is equal to or greater than 80 percent of the PAL level, the Director shall renew the PAL at the same level." 40 CFR 51.165(f)(10)(iv)(B) is not incorporated by reference.
(i) When a particular source or modification becomes a major stationary source or major modification solely by virtue of a relaxation in any enforceable limitation established after August 7, 1980, on the capacity of the source or modification to emit a pollutant, such as a restriction on hours of operation, then the provisions of this Rule shall apply to the source or modification as though construction had not yet begun on the source or modification.
(j) To issue a permit to a source of a nonattainment pollutant, the Director shall determine, in addition to the other requirements of this Rule, that an analysis (produced by the permit applicant) of alternative sites, sizes, production processes, and environmental control techniques for the source demonstrates that the benefits of the source significantly outweigh the environmental and social costs imposed as a result of its location, construction, or modification.
(k) The provisions of 40 CFR 52.21(r)(2) regarding the period of validity of approval to construct are incorporated by reference except that the term "Administrator" is replaced with "Director".
(l) Approval of an application regarding the requirements of this Rule shall not relieve the owner or operator of the responsibility to comply fully with applicable provisions of other rules of this Chapter and any other requirements under local, state, or federal law.
(m) When a source or modification subject to this Rule may affect the visibility of a Class I area named in Paragraph (c) of Rule .0530 of this Section, the following procedures shall be followed:

(1) The owner or operator of the source shall provide an analysis of the impairment to visibility that would occur because of the source or modification and general commercial, industrial and other growth associated with the source or modification;

(2) The Director shall provide written notification to all affected Federal Land Managers within 30 days of receiving the permit application or within 30 days of receiving advance notification of an application. The notification shall be at least 30 days before the publication of the notice for public comment on the application. The notification shall include a copy of all information relevant to the permit application including an analysis provided by the source of the potential impact of the proposed source on visibility;

(3) The Director shall consider any analysis concerning visibility impairment performed by the Federal Land Manager if the analysis is received within 30 days of notification. If the Director finds that the analysis of the Federal Land Manager fails to demonstrate to his satisfaction that an adverse impact on visibility will result in the Class I area, the Director shall provide in the notice of public hearing on the application, an explanation of his decision or notice where the explanation can be obtained;

(4) The Director shall issue permits only to those sources whose emissions will be consistent with making reasonable progress toward the national goal of preventing any future, and remedying any existing, impairment of visibility in mandatory Class I areas when the impairment results from manmade air pollution. In making the decision to issue a permit, the Director shall consider the cost of compliance, the time necessary for compliance, the energy and nonair quality environmental impacts of compliance, and the useful life of the source; and

(5) The Director may require monitoring of visibility in or around any Class I area by the proposed new source or modification when the visibility impact analysis indicates possible visibility impairment.

The requirements of this Paragraph shall not apply to nonprofit health or nonprofit educational institutions.
(n) Paragraphs (f) and (j) of this Rule shall not apply to a new major stationary source or a major modification of a source of volatile organic compounds or nitrogen oxides for which construction commences after the area in which the source is located has been designated according to Part (c)(1)(B) of this Rule and before the area is designated in 40 CFR 81.334 as nonattainment for ozone if the owner or operator of the source demonstrates, using the Urban Airshed Model (UAM), that the new source or modification will not contribute to or cause a violation. The model used shall be that maintained by the Division. The Division shall run the model only after the permit application has been submitted. The permit application shall be incomplete until the modeling analysis is completed. The owner or operator of the source shall apply such degree of control and obtain such offsets necessary to demonstrate the new source or modified source will not cause or contribute to a violation.

(o) If the owner or operator of a source is using projected actual emissions to avoid applicability of nonattainment new source review, the owner or operator shall notify the director of the modification before beginning actual construction. The notification shall include:

(1) a description of the project,

(2) identification of sources whose emissions could be affected by the project,

(3) the calculated projected actual emissions and an explanation of how the projected actual emissions were calculated, including identification of emissions excluded by 40 CFR 51.165(a)(1)(xxviii)(B)(3),

(4) the calculated baseline actual emissions and an explanation of how the baseline actual emissions were calculated, and

(5) any netting calculations if applicable.

If upon reviewing the notification, the Director finds that the project will cause a nonattainment new source review evaluation, then the Director shall notify the owner or operator of his findings. The owner or operator shall not make the modification until it has received a permit issued pursuant to this Rule. If a permit revision is not required pursuant to this Rule, the owner or operator shall maintain records of annual emissions in tons per year on a calendar year basis related to the modifications for 10 years following resumption of regular operations after the change if the project involves increasing the emissions unit's design capacity or its potential to emit the regulated NSR pollutant; otherwise these records shall be maintained for five years following resumption of regular operations after the change. The owner or operator shall submit a report to the director within 60 days after the end of each year during which these records must be generated. The report shall contain the items listed in 40 CFR 51.165(a)(6)(v)(A) through (C). The owner or operator shall make the information documented and maintained under this Paragraph available to the Director or the general public pursuant to the requirements in 40 CFR 70.4(b)(3)(viii).

(p) The version of the Code of Federal Regulations incorporated in this Rule is that as of June 13, 2007 except those provisions noticed as stayed in 69 FR 40274, and does not include any subsequent amendments or editions to the referenced material.

15A NCAC 02D .0532 SOURCES CONTRIBUTING TO AN AMBIENT VIOLATION

(a) This Rule applies to new major stationary sources and major modifications to which Rule .0531 of this Section does not apply and which would contribute to a violation of a national ambient air quality standard but which would not cause a new violation.

(b) For the purpose of this Rule the definitions contained in Section II.A. of Appendix S of 40 CFR Part 51 shall apply.

(c) The Rule is not applicable to:

- (1) complex sources of air pollution that are regulated only under Section .0800 of this Subchapter and not under any other rule of this Subchapter;
- (2) emission of pollutants for which the area in which the new or modified source is located is designated as nonattainment;
- (3) emission of pollutants for which the source or modification is not major;
- (4) emission of pollutants other than sulfur dioxide, total suspended particulates, nitrogen oxides, and carbon monoxide;
- (5) a new or modified source whose impact will increase not more than:
  - (A) 1.0 ug/m3of SO2 on an annual basis,
  - (B) 5 ug/m3of SO2 on a 24-hour basis,
  - (C) 25 ug/m3of SO2 on a 3-hour basis,
  - (D) 1.0 ug/m3of total suspended particulates on an annual basis,
  - (E) 5 ug/m3of total suspended particulates on a 24-hour basis,
  - (F) 1.0 ug/m3of NO2 on an annual basis,
  - (G) 0.5 mg/m3of carbon monoxide on an 8-hour basis,
  - (H) 2 mg/m3of carbon monoxide on a one-hour basis,
  - (I) 1.0 ug/m3of PM10 on an annual basis, or
  - (J) 5 ug/m3of PM10 on a 24-hour basis,

at any locality that does not meet a national ambient air quality standard;

- (6) sources which are not major unless secondary emissions are included in calculating the potential to emit;
- (7) sources which are exempted by the provision in Section II.F. of Appendix S of 40 CFR Part 51;
- (8) temporary emission sources which will be relocated within two years; and
- (9) emissions resulting from the construction phase of the source.

(d) 15A NCAC 2Q .0102 and .0302 are not applicable to any source to which this Rule applies. The owner or operator of the source shall apply for and receive a permit as required in 15A NCAC 2Q .0300 or .0500.

(e) To issue a permit to a new or modified source to which this Rule applies, the Director shall determine that the source will meet the following conditions:

- (1) The sources will emit the nonattainment pollutant at a rate no more than the lowest achievable emission rate.
- (2) The owner or operator of the proposed new or modified source has demonstrated that all major stationary sources in the State which are owned or operated by this person (or any entity controlling, controlled by, or under common control with this person) are subject to emission limitations and are in compliance, or on a schedule for compliance which is federally enforceable or contained in a court decree, with all applicable emission limitations and standards of this Subchapter which EPA has authority to approve as elements of the North Carolina State Implementation Plan for Air Quality.
- (3) The source will satisfy one of the following conditions:
  - (A) The source will comply with Subparagraph (e)(3) of Rule .0531 of this Section when the source is evaluated as if it were in the nonattainment area; or
  - (B) The source will have an air quality offset, i.e., the applicant will have caused an air quality improvement in the locality where the national ambient air quality standard is not met by causing reductions in impacts of other sources greater than any additional impact caused by the source for which the application is being made. The emissions reductions creating the air quality offset shall be placed as a condition in the permit for the source reducing emissions. The requirements of this Part may be partially waived if the source is a resource recovery facility burning municipal solid waste, the source must switch fuels due to lack of adequate fuel supplies, or the source is required to be modified as a result of EPA regulations and no exemption from such regulations is available and if:
    - (i) the permit applicant demonstrates that it made its best efforts to obtain sufficient air quality offsets to comply with this Part;

(ii) the applicant has secured all available air quality offsets; and

(iii) the applicant will continue to seek the necessary air quality offsets and apply them when they become available.

(f) At such time that a particular source or modification becomes a major stationary source or major modification solely by virtue of a relaxation in any enforceable limitation established after August 7, 1980, on the capacity of the source or modification to emit a pollutant, such as a restriction on hours of operation, then the provisions of this Rule shall apply to the source or modification as though construction had not yet begun on the source or modification.

(g) The version of the Code of Federal Regulations incorporated in this Rule is that as of January 1, 1989, and does not include any subsequent amendments or editions to the referenced material.

History Note: *Filed as a Temporary Amendment Eff. March 8, 1994 for a period of 180 days or until the permanent rule becomes effective, whichever is sooner;*

Amended Eff. July 1, 1994; December 1, 1993; December 1, 1992; October 1, 1989.

SECTION .1900 - OPEN BURNING

15A NCAC 02D .1901 OPEN BURNING: PURPOSE: SCOPE

(a) Open Burning Prohibited. A person shall not cause, allow, or permit open burning of combustible material except as allowed by Rule .1903 and Rule .1904 of this Section.

(b) Purpose. The purpose of this Section is to control air pollution resulting from the open burning of combustible materials and to protect the air quality in the immediate area of the open burning.

(c) Scope. This Section applies to all operations involving open burning. This Section does not authorize any open burning which is a crime under G.S. 14-136 through G.S. 14-140.1, or affect the authority of the Division of Forest Resources to issue or deny permits for open burning in or adjacent to woodlands as provided in G.S. 113-60.21 through G.S. 113-60.31. This Section does not affect the authority of any local government to regulate open burning through its fire codes or other ordinances. The issuance of any open burning permit by the Division of Forest Resources or any local government does not relieve any person from the necessity of complying with this Section or any other air quality rule.

History Note: *Authority G.S. 143-215.3(a)(1); 143-215.107(a)(5);*
Eff. July 1, 1996;
Amended Eff. July 1, 2007; June 1, 2004.

15A NCAC 02D .1902 DEFINITIONS

For the purpose of this Section, the following definitions apply:

(1) "Air Curtain Burner" means a stationary or portable combustion device that directs a plane of high velocity forced draft air through a manifold head into a pit or container with vertical walls in such a manner as to maintain a curtain of air over the surface of the pit and a recirculating motion of air under the curtain.

(2) "Air Quality Action Day Code 'Orange' or above" means an air quality index greater than 100 as defined in 40 CFR Part 58, Appendix G.

(3) "Air quality forecast area" means for

  (a) Asheville air quality forecast area: Buncombe, Haywood, Henderson, Jackson, Madison, Swain, Transylvania, and Yancey Counties;

  (b) Charlotte air quality forecast area: Cabarrus, Gaston, Iredell South of Interstate 40, Lincoln, Mecklenburg, Rowan, and Union Counties;

  (c) Hickory air quality forecast area: Alexander, Burke, Caldwell, and Catawba Counties;

  (d) Fayetteville air quality forecast area: Cumberland and Harnett Counties;

  (e) Rocky Mount air quality forecast area: Edgecombe and Nash Counties;

  (f) Triad air quality forecast area: Alamance, Caswell, Davidson, Davie, Forsyth, Guilford, Randolph, Rockingham, and Stokes Counties; and

  (g) Triangle air quality forecast area: Chatham, Durham, Franklin, Granville, Johnston, Person, Orange, Vance, and Wake Counties.

(4) "Smoke management plan" means the plan developed following the North Carolina Division of Forest Resources' smoke management program and approved by the North Carolina Division of Forest Resources. The purpose of the smoke management plan is to manage smoke from prescribed burns of public and private forests to minimize the impact of smoke on air quality and visibility.

(5) "Dangerous materials" means explosives or containers used in the holding or transporting of explosives.

(6) "HHCB" means the Health Hazards Control Branch of the Division of Epidemiology.

(7) "Initiated" means start or ignite a fire or reignite or rekindle a fire.

(8) "Land clearing" means the uprooting or clearing of vegetation in connection with construction for buildings; right-of-way maintenance; agricultural, residential, commercial, institutional, or industrial development; mining activities; or the initial clearing of vegetation to enhance property value; but does not include routine maintenance or property clean-up activities.

(9) "Log" means any limb or trunk whose diameter exceeds six inches.

(10) "Nonattainment area" means an area identified in 40 CFR 81.334 as nonattainment.

(11) "Nuisance" means causing physical irritation exacerbating a documented medical condition, visibility impairment, or evidence of soot or ash on property or structure other than the property on which the burning is done.

(12) "Occupied structure" means a building in which people may live or work or one intended for housing farm or other domestic animals.

(13) "Off-site" means any area not on the premises of the land-clearing activities.

(14) "Open burning" means the burning of any matter in such a manner that the products of combustion resulting from the burning are emitted directly into the atmosphere without passing through a stack, chimney, or a permitted air pollution control device.

(15) "Operator" as used in .1904(b)(6) and .1904(b)(2)(D) of this Section, means the person in operational control over the open burning.

(16) "Person" as used in 02D .1901(c), means:

  (a) the person in operational control over the open burning; or

  (b) the landowner or person in possession or control of the land when he has directly or indirectly allowed the open burning or has benefited from it.

(17) "Pile" means a quantity of combustible material assembled together in a mass.

(18) "Public pick-up" means the removal of refuse, yard trimmings, limbs, or other plant material from a residence by a governmental agency, private company contracted by a governmental agency or municipal service.

(19) "Public road" means any road that is part of the State highway system; or any road, street, or right-of-way dedicated or maintained for public use.

(20) "RACM" means regulated asbestos containing material as defined in 40 CFR 61.142.

(21) "Refuse" means any garbage, rubbish, or trade waste.

(22) "Regional Office Supervisor" means the supervisor of personnel of the Division of Air Quality in a regional office of the Department of Environment and Natural Resources.

(23) "Salvageable items" means any product or material that was first discarded or damaged and then all, or part, was saved for future use, and include insulated wire, electric motors, and electric transformers.

(24) "Synthetic material" means man-made material, including tires, asphalt materials such as shingles or asphaltic roofing materials, construction materials, packaging for construction materials, wire, electrical insulation, and treated or coated wood.

(25) "Permanent site" means for an air curtain burner, a place where an air curtain burner is operated for more than nine months.

History Note: *Authority G.S. 143-212; 143-213; 143-215.3(a)(1);*
Eff. July 1, 1996;
Amended Eff. July 1, 2007; December 1, 2005; June 1, 2004; July 1, 1998.

.15A NCAC 02D .1903 OPEN BURNING WITHOUT AN AIR QUALITY PERMIT

(a) All open burning is prohibited except open burning allowed under Paragraph (b) of this Rule or Rule .1904 of this Section. Except as allowed under Paragraphs (b)(3) through (b)(9) of this Rule, open burning shall not be initiated in an air quality forecast area that the Department, or the Forsyth County Environmental Affairs Department for the Triad air quality forecast area, has forecasted to be in an Air Quality Action Day Code "Orange" or above during the time period covered by that forecast.

(b) The following types of open burning are permissible without an air quality permit:

(1) open burning of leaves, tree branches or yard trimmings, excluding logs and stumps, if the following conditions are met:

(A) The material burned originates on the premises of private residences and is burned on those premises;

(B) There are no public pickup services available;

(C) Non-vegetative materials, such as household garbage, lumber, or any other synthetic materials are not burned;

(D) The burning is initiated no earlier than 8:00 a.m. and no additional combustible material is added to the fire between 6:00 p.m. on one day and 8:00 a.m. on the following day;

(E) The burning does not create a nuisance; and

(F) Material is not burned when the Division of Forest Resources has banned burning for that area.

(2) open burning for land clearing or right-of-way maintenance if the following conditions are met:

(A) The wind direction at the time that the burning is initiated and the wind direction as forecasted by the National Weather Service at the time that the burning is initiated are away from any area, including public roads within 250 feet of the burning as measured from the edge of the pavement or other roadway surface, which may be affected by smoke, ash, or other air pollutants from the burning;

(B) The location of the burning is at least 1,000 feet from any dwelling, group of dwellings, or commercial or institutional establishment, or other occupied structure not located on the property on which the burning is conducted. The regional office supervisor may grant exceptions to the setback requirements if:

(i) a signed, written statement waiving objections to the open burning associated with the land clearing operation is obtained and submitted to, and the exception granted by, the regional office supervisor before the burning begins from a resident or an owner of each dwelling, commercial or institutional establishment, or other occupied structure within 1,000 feet of the open burning site. In the case of a lease or rental agreement, the lessee or renter shall be the person from whom permission shall be gained prior to any burning; or

(ii) an air curtain burner that complies with Rule .1904 of this Section, is utilized at the open burning site.

Factors that the regional supervisor shall consider in deciding to grant the exception include all the persons who need to sign the statement waiving the objection have signed it, the location of the burn, and the type, amount, and nature of the combustible substances. The regional supervisor shall not grant a waiver if a college, school, licensed day care, hospital, licensed rest home, or other similar institution is less than 1000 feet from the proposed burn site when such institution is occupied.

(C) Only land cleared plant growth is burned. Heavy oils, asphaltic materials such as shingles and other roofing materials, items containing natural or synthetic rubber, or any materials other than plant growth shall not be burned; however, kerosene, distillate oil, or diesel fuel may be used to start the fire;

(D) Initial burning begins only between the hours of 8:00 a.m. and 6:00 p.m., and no combustible material is added to the fire between 6:00 p.m. on one day and 8:00 a.m. on the following day;

(E) No fires are initiated or vegetation added to existing fires when the Division of Forest Resources has banned burning for that area; and

(F) Materials are not carried off-site or transported over public roads for open burning unless the materials are carried off-site or transported over public roads to facilities permitted according to Rule .1904 of this Section for the operation of an air curtain burner at a permanent site;

(3) camp fires and fires used solely for outdoor cooking and other recreational purposes, or for ceremonial occasions, or for human warmth and comfort and which do not create a nuisance and do not use synthetic materials or refuse or salvageable materials for fuel;

(4) fires purposely set to public or private forest land for forest management practices for which burning is acceptable to the Division of Forest Resources and which follows the smoke management plan as outlined in the Division of Forest Resources' smoke management program;

(5) fires purposely set to agricultural lands for disease and pest control and fires set for other agricultural or apicultural practices for which burning is currently acceptable to the Department of Agriculture;

(6) fires purposely set for wildlife management practices for which burning is currently acceptable to the Wildlife Resource Commission;

(7) fires for the disposal of dangerous materials when it is the safest and most practical method of disposal;

(8) fires purposely set by manufacturers of fire extinguishing materials or equipment, testing laboratories, or other persons, for the purpose of testing or developing these materials or equipment in accordance with a standard qualification program;

(9) fires purposely set for the instruction and training of fire-fighting personnel at permanent fire-fighting training facilities;

(10) fires purposely set for the instruction and training of fire-fighting personnel when conducted under the supervision of or with the cooperation of one or more of the following agencies:

(A) the Division of Forest Resources;

(B) the North Carolina Insurance Department;

(C) North Carolina technical institutes; or

(D) North Carolina community colleges, including:

(i) the North Carolina Fire College; or

(ii) the North Carolina Rescue College;

(11) fires not described in Subparagraphs (9) or (10) of this Paragraph, purposely set for the instruction and training of fire-fighting personnel, provided that:

(A) The regional office supervisor of the appropriate regional office and the HHCB have been notified according to the procedures and deadlines contained in the appropriate regional notification form. This form may be obtained by writing the appropriate regional office at the address in Rule .1905 of this Section and requesting it, and

(B) The regional office supervisor has granted permission for the burning. Factors that the regional office supervisor shall consider in granting permission for the burning include type, amount, and nature of combustible substances. The regional office supervisor shall not grant permission for the burning of salvageable items, such as insulated wire and electric motors or if the primary purpose of the fire is to dispose of synthetic materials or refuse. The regional office supervisor of the appropriate regional office shall not consider previously demolished structures as having training value. However, the regional office supervisor of the appropriate regional office may allow an exercise involving the burning of motor vehicles burned over a period of time by a training unit or by several related training units. Any deviations from the dates and times of exercises, including additions, postponements, and deletions, submitted in the schedule in the approved plan shall be communicated verbally to the regional office supervisor of the appropriate regional office at least one hour before the burn is scheduled; and

(12) fires for the disposal of material generated as a result of a natural disaster, such as tornado, hurricane, or flood, if the regional office supervisor grants permission for the burning. The person desiring to do the burning shall document and provide written notification to the regional office supervisor of the appropriate regional office that there is no other practical method of disposal of the waste. Factors that the regional office supervisor shall consider in granting permission for the burning include type, amount, location of the burning, and nature of combustible substances. The regional office supervisor shall not grant permission for the burning if the primary purpose of the fire is to dispose of synthetic

materials or refuse or recovery of salvageable materials. Fires authorized under this Subparagraph shall comply with the conditions of Subparagraph (b)(2) of this Rule.

(c) The authority to conduct open burning under this Section does not exempt or excuse any person from the consequences, damages or injuries that may result from this conduct. It does not excuse or exempt any person from complying with all applicable laws, ordinances, rules or orders of any other governmental entity having jurisdiction even though the open burning is conducted in compliance with this Section.

History Note: *Authority G.S. 143-215.3(a)(1); 143-215.107(a)(5);*
Eff. July 1, 1996;
Amended Eff. July 1, 2007; December 1, 2005; June 1, 2004; July 1, 1998.

15A NCAC 02D .1904 AIR CURTAIN BURNERS

(a) Air quality permits are required for air curtain burners subject to 40 CFR 60.2245 through 60.2265, 60.2810 through 60.2870, 60.2970 through 60.2975, or 60.3062 through 60.3069 or located at permanent sites or where materials are transported in from another site. Air quality permits are not required for air curtain burners located at temporary land clearing or right-of-way maintenance sites for less than nine months unless they are subject to 40 CFR 60.2245 through 60.2265, 60.2810 through 60.2870, 60.2970 through 60.2975, or 60.3062 through 60.3069. The operation of air curtain burners in particulate and ozone nonattainment areas shall cease in any area that has been forecasted by the Department, or the Forsyth County Environmental Affairs Department for the Triad air quality forecast area, to be in an Air Quality Action Day Code "Orange" or above during the time period covered by that forecast.

(b) Air curtain burners shall comply with the following conditions and stipulations:

(1) The wind direction at the time that the burning is initiated and the wind direction as forecasted by the National Weather Service during the time of the burning shall be away from any area, including public roads within 250 feet of the burning as measured from the edge of the pavement or other roadway surface, which may be affected by smoke, ash, or other air pollutants from the burning;

(2) Only collected land clearing and yard waste materials may be burned. Heavy oils, asphaltic materials, items containing natural or synthetic rubber, tires, grass clippings, collected leaves, paper products, plastics, general trash, garbage, or any materials containing painted or treated wood materials shall not be burned. Leaves still on trees or brush may be burned;

(3) No fires shall be started or material added to existing fires when the Division of Forest Resources has banned burning for that area;

(4) Burning shall be conducted only between the hours of 8:00 a.m. and 6:00 p.m.;

(5) The air curtain burner shall not be operated more than the maximum source operating hours-per-day and days-per-week. The maximum source operating hours-per-day and days-per-week shall be set to protect the ambient air quality standard and prevention of significant deterioration (PSD) increment for particulate. The maximum source operating hours-per-day and days-per-week shall be determined using the modeling procedures in Rule .1106(b), (c), and (f) of this Subchapter. This Subparagraph shall not apply to temporary air curtain burners;

(6) An air curtain burner with an air quality permit shall have onsite at all times during operation of the burner a visible emissions reader certified according to 40 CFR Part 60, Method 9 to read visible emissions, and the facility shall test for visible emissions within five days after initial operation and within 90 days before permit expiration;

(7) Air curtain burners shall meet manufacturer's specifications for operation and upkeep to ensure complete burning of material charged into the pit. Manufacturer's specifications shall be kept on site and be available for inspection by Division staff;

(8) Except during start-up, visible emissions shall not exceed ten percent opacity when averaged over a six-minute period except that one six-minute period with an average opacity of more than ten percent but no more than 35 percent shall be allowed for any one-hour period. During start-up, the visible emissions shall not exceed 35 percent opacity when averaged over a six-minute period. Start-up shall not last for more than 45 minutes, and there shall be no more than one start-up per day. Instead of complying with the opacity standards in this Subparagraph, air curtain burners subject to:

   (A) 40 CFR 60.2245 through 60.2265 shall comply with the opacity standards in 40 CFR 60.2250;

   (B) 40 CFR 60.2810 through 60.2870 shall comply with the opacity standards in 40 CFR 60.2860;

   (C) 40 CFR 60.2970 through 60.2975 shall comply with the opacity standards in 40 CFR 60.2971; or

   (D) 40 CFR 60.3062 through 60.3069 shall comply with the opacity standards in 40 CFR 60.3066;

(9) The owner or operator of an air curtain burner shall not allow ash to build up in the pit to a depth higher than one-third of the depth of the pit or to the point where the ash begins to impede combustion, whichever occurs first. The owner or operator of an air curtain burner shall allow the ashes to cool and water the ash prior to its removal to prevent the ash from becoming airborne;

(10) The owner or operator of an air curtain burner shall not load material into the air curtain burner such that it will protrude above the air curtain;

(11) Only distillate oil, kerosene, diesel fuel, natural gas, or liquefied petroleum gas may be used to start the fire; and

(12) The location of the burning shall be at least 500 feet from any dwelling, group of dwellings, or commercial or institutional establishment, or other occupied structure not located on the property on which the burning is conducted. The regional office supervisor may grant exceptions to the setback requirements if a signed, written statement waiving objections to the air curtain burning is obtained from a resident or an owner of each dwelling, commercial or institutional establishment, or other occupied structure within 500 feet of the burning site. In case of a lease or rental agreement, the lessee or renter, and the property owner shall sign the statement waiving objections to the burning. The statement shall be submitted to and approved by the regional office supervisor before initiation of the burn. Factors that the regional supervisor shall consider in deciding to grant the exception include: all the persons who need to sign the statement waiving the objection have signed it; the location of the burn; and the type, amount, and nature of the combustible substances.

Compliance with this Rule does not relieve any owner or operator of an air curtain burner from the necessity of complying with other rules in this Section or any other air quality rules.

(c) Recordkeeping Requirements. The owner or operator of an air curtain burner at a permanent site shall keep a daily log of specific materials burned and amounts of material burned in pounds per hour and tons per year. The logs at a permanent air curtain burner site shall be maintained on site for a minimum of two years and shall be available at all times for inspection by the Division of Air Quality. The owner or operator of an air curtain burner at a temporary site shall keep a log of total number of tons burned per temporary site. Additionally, the owner or operator of air curtain burner subject to:

(1) 40 CFR 60.2245 through 60.2265 shall comply with the monitoring, recordkeeping, and reporting requirements in 40 CFR 60.2245 through 60.2265;

(2) 40 CFR 60.2810 through 60.2870 shall comply with the monitoring, recordkeeping, and reporting requirements in 40 CFR 60.2810 through 60.2870;

(3) 40 CFR 60.2970 through 60.2975 shall comply with the monitoring, recordkeeping, and reporting requirements in 40 CFR 60.2970 through 60.2975; or

(4) 40 CFR 60.3062 through 60.3069 shall comply with comply with the monitoring, recordkeeping, and reporting requirements in 40 CFR 60.3062 through 60.3069.

(d) Title V Considerations. Burners that have the potential to burn 8,100 tons of material or more per year may be subject to Section 15A NCAC 2Q .0500, Title V Procedures.

(e) Prevention of Significant Deterioration Consideration. Burners that burn 16,200 tons per year or more may be subject to 15A NCAC 02D .0530, Prevention of Significant Deterioration.

(f) A person may use a burner using a different technology or method of operation than an air curtain burner as defined under Rule .1902 of this Section if he demonstrates to the Director that the burner is at least as effective as an air curtain burner in reducing emissions and if the Director approves the use of the burner. The Director shall approve the burner if he finds that it is at least as effective as an air curtain burner. This burner shall comply with all the requirements of this Rule.

(g) In addition to complying with the requirements of this Rule, an air curtain burner subject to:

(1) 40 CFR Part 60, Subpart CCCC that commenced construction after November 30, 1999, or that commenced reconstruction or modification on or after June 1, 2001, shall also comply with 40 CFR 60.2245 through 60.2265, or

(2) 40 CFR Part 60, Subpart EEEE that commenced construction after December 9, 2004, or that commenced reconstruction or modification on or after June 16, 2006, shall also comply with 40 CFR 60.2970 through 60.2975.

History Note: *Authority G.S. 143-215.3(a)(1); 143-215.107(a)(5), (10); 143-215.66; 143-215.108; 40 CFR 60.2865;*
Eff. July 1, 1996;
Amended Eff. July 1, 2007; December 1, 2005; August 1, 2004.

15A NCAC 02D .1905 REGIONAL OFFICE LOCATIONS

Inquiries, requests and plans shall be handled by the appropriate Department of Environment and Natural Resources regional offices. They are:

(1) Asheville Regional Office, 2090 Highway 70, Swannanoa, North Carolina 28778
(2) Winston-Salem Regional Office, 585 Waughtown Street, Winston-Salem, North Carolina 27107;
(3) Mooresville Regional Office, 610 East Center Avenue, Suite 301, Mooresville, North Carolina 28115;
(4) Raleigh Regional Office, 3800 Barrett Drive, Raleigh, North Carolina 27611;
(5) Fayetteville Regional Office, Systel Building, 225 Green Street, Suite 714, Fayetteville, North Carolina 28301;
(6) Washington Regional Office, 943 Washington Square Mall, Washington, North Carolina 27889; and
(7) Wilmington Regional Office, 127 Cardinal Drive Extension, Wilmington, North Carolina 28405.

History Note: Authority G.S. 143-215.3(a)(1);
Eff. July 1, 1996;
Amended Eff. December 1, 2005.

15A NCAC 02D .1906 DELEGATION TO COUNTY GOVERNMENTS

(a) The governing body of any county or municipality or group of counties or municipalities may establish a partial air pollution control program to implement and enforce this Section provided that:

(1) It has the administrative organization, staff, financial and other resources necessary to carry out such a program;

(2) It has adopted appropriate ordinances, resolutions, and regulations to establish and maintain such a program; and

(3) It has otherwise complied with G.S. 143-215.112 "Local Air Pollution Control Programs."

(b) The governing body shall submit to the Director documentation demonstrating that the requirements of Paragraph (a) of this Rule have been met. Within 90 days after receiving the submittal from the governing body, the Director shall review the documentation to determine if the requirements of Paragraph (a) of this Rule have been met and shall present his findings to the Commission. If the Commission determines that the air pollution program is adequate, it shall certify the local air pollution program to implement and enforce this Section within its area of jurisdiction.

(c) County and municipal governments shall not have the authority to issue permits for air curtain burners at a permanent site as defined in 15A NCAC 02D .1904.

(d) The three certified local air pollution programs, the Western North Carolina Regional Air Quality Control Agency, the Forsyth County Environmental Affairs Department, and Mecklenburg County Air Quality, a Division of Land Use and Environmental Services Agency, shall continue to enforce open burning rules as part of their local air pollution programs.

History Note: *Authority G.S. 143-215.3(a)(1); 143-215.112;*
Eff. July 1, 1996;
Amended Eff. December 1, 2005; June 1, 2004.

15A NCAC 02D .1907 MULTIPLE VIOLATIONS ARISING FROM A SINGLE EPISODE

(a) Multiple violations arising from a single episode of open burning may result in multiple civil penalties. Factors the Director shall consider in determining the number of violations per episode of open burning include:

(1) the type of material burned,
(2) the amount of material burned,
(3) the location of the burn, and
(4) any other factor relevant to air pollution control or air quality.

(b) Each pile of land clearing or road maintenance debris that does not comply with the specifications of 15A NCAC 02D .1903(b)(2) shall constitute a separate violation.

History Note: Authority G.S. 143-215.3(a)(1); 143-215.107(a)(5);
Eff. July 1, 2007.

SECTION .2400 – CLEAN AIR INTERSTATE RULES

15A NCAC 02D .2401 PURPOSE AND APPLICABILITY

(a) Purpose. The purpose of this Section is to implement the federal Clean Air Interstate Rule and thereby reduce the interstate transportation of fine particulate matter and ozone.

(b) Applicability. This Section applies to the following, which are CAIR NOx units, CAIR SO2 units, and CAIR NOx Ozone Season units to the extent they are subject to the NOx annual trading program, SO2 trading program, and NOx ozone season trading program, respectively, in this Section:

(1) any stationary, fossil-fuel-fired boiler or stationary, fossil-fuel-fired combustion turbine serving at any time, since the later of November 15, 1990 or the start-up of a unit's combustion chamber, a generator with nameplate capacity of more than 25 MWe producing electricity for sale, provided that if a stationary boiler or stationary combustion turbine that does not meet these requirements begins to combust fossil fuel or to serve a generator with nameplate capacity of more than 25 MWe producing electricity for sale, the unit shall become subject to this Section under this Subparagraph on the first date on which the unit both combusts fossil fuel and serves such generator;

(2) notwithstanding Subparagraph (b)(1) of this Rule, a unit that meets the requirements in 40 CFR 96.104(b)(1)(i), (b)(2)(i), or (b)(2)(ii), 96.204(b)(1)(i), (b)(2)(i), or (b)(2)(ii), 96.304(b)(1)(i), (b)(2)(i), or (b)(2)(ii), shall not be subject to this Section under this Subparagraph and shall become subject to this Section under this Subparagraph as provided in 40 CFR 96.104(b)(1)(ii) or (b)(2)(iii), 96.204(b)(1)(ii) or (b)(2)(iii), or 96.304(b)(1)(ii) or (b)(2)(iii);

(3) solely for the purposes of the NOx ozone season trading program, fossil fuel-fired stationary boilers, combustion turbines, or combined cycle systems having a maximum design heat input greater than 250 million Btu per hour except stationary combustion turbines constructed before January 1, 1979, that have a federally enforceable permit that restricts:

  (A) its potential emissions of nitrogen oxides to no more than 25 tons between May 1 and September 30;

  (B) it to burning only natural gas or oil; and

  (C) its hours of operation as described in 40 CFR 96.4(b)(1)(ii) and (iii); or

(4) solely for the purposes of the NOx ozone season trading program, fossil-fuel fired stationary boilers, combustion turbines, or combined cycle systems serving a generator with a nameplate capacity greater than 25 MW electrical and selling any amount of electricity.

(c) Retired unit exemption. Any unit that is permanently retired and is not an opt-in unit under Rule .2411 of this Section shall be exempted from the annual trading program for:

(1) nitrogen oxides if it complies with the provisions of 40 CFR 96.105,

(2) sulfur dioxide if it complies with the provisions of 40 CFR 96.205, or

(3) ozone season nitrogen oxides if it complies with the provisions of 40 CFR 96.305.

(d) Effect on other authorities. No provision of this Section, any application submitted or any permit issued pursuant to Rule .2406 of this Section, or any exemption under 40 CFR 96.105, 96.205, or 96.305 shall be construed as exempting any source or facility covered under this Section or the owner or operator or designated representative of any source or facility covered under this Section from complying with any other requirements of this Subchapter or Subchapter 15A NCAC 02Q or the Clean Air Act. The Environmental Management Commission may specify through rulemaking a specific emission limit lower than that established under this Rule for a specific source if compliance with the lower emission limit is required to attain or maintain the ambient air quality standard for ozone or fine particulate (PM2.5) or any other ambient air quality standard in Section 15A NCAC 02D .0400.

History Note: Authority G.S. 143-215.3(a); 143-215.107(a)(5), (10);
Eff. July 1, 2006;
Amended Eff. May 1, 2008.

15A NCAC 02D .2402 DEFINITIONS

(a) For the purpose of this Section, the definitions in 40 CFR 96.102, 96.202 and 96.302 shall apply except that solely for the purposes of units subject to Rule .2401(b)(3), .2401(b)(4), or .2405(a)(2) of this Section, the term "fossil-fuel-fired" means:

(1) sources that began operation before January 1, 1996, where fossil fuel actually combusted either alone or in combination with any other fuel, comprised more than 50 percent of the annual heat input on a Btu basis during 1995, or, if a source had no heat input in 1995, during the last year of operation of the unit before 1995;

(2) sources that began operation on or after January 1, 1996 and before January 1, 1997, where fossil fuel actually combusted either alone or in combination with any other fuel, comprised more than 50 percent of the annual heat input on a Btu basis during 1996; or

(3) sources that began operation on or after January 1, 1997;

   (A) Where fossil fuel actually combusted either alone or in combination with any other fuel, comprised more than 50 percent of the annual heat input on a Btu basis during any year as determined by the owner or operator of the source and verified by the Director; or

   (B) Where fossil fuel combusted either alone or in combination with any other fuel, is projected to comprise more than 50 percent of the annual heat input on a Btu basis during any year, provided that the unit shall be "fossil-fuel-fired" as of the date, during such year, on which the source begins combusting fossil fuel.

(b) Notwithstanding the provisions of the definition of "commence commercial operation" in 40 CFR 96.302, for a unit under Rules .2401(b)(3), .2401(b)(4) or .2405(a)(2) of this Section, and not serving a generator producing electricity for sale, the unit's date of commencement of operation shall also be the unit's date of commencement of commercial operation.

(c) Notwithstanding the provisions of the definition of "commence operation" in 40 CFR 96.302, and solely for the purposes of 40 CFR Part 96 Subpart HHHH, for a unit that is not a CAIR NOx Ozone Season unit, under Rules .2401(b)(3), .2401(b)(4), or .2405(a)(2) of this Section on the later of November 15, 1990 or the date the unit commenced or commences operation as defined in the first provision of this definition in 40 CFR 96.302 and that subsequently becomes or became such a CAIR NOx Ozone Season unit, the unit's date for commencement of operation shall be the date on which the unit becomes or became a CAIR NOx Ozone Season unit under Rule .2401(b)(3), .2401(b)(4), or .2405(a)(2) of this Section. For a unit with a date of commencement of operation as defined in the first sentence of this Subparagraph and that subsequently undergoes a physical change (other than replacement of the unit by a unit at the same source), such date shall remain the date of commencement of operation of the unit, which shall continue to be treated as the same unit. For a unit with a date of commencement of operation as defined in the first sentence of this Paragraph and that subsequently is replaced by a unit at the same source (e.g., repowered), such date shall remain the replaced unit's date of commencement of operation, and the replacement unit shall be treated as a separate unit with a separate date for commencement of operation as defined in this Paragraph.

(d) For the purposes of this Section, the following definitions apply:

(1) "Modification" means modification as defined in 15A NCAC 02D .0101.

(2) "Reconstruction" means the replacement of components of an existing unit that meets the requirements of 40 CFR 60.15(b)(1).

(3) "Replacement" means, solely for the purposes of Rules .2403 and .2405 of this Section, removing an existing unit and putting in its place at the same facility a functionally equivalent new unit.

(e) For the purpose of this Section, the abbreviations and acronyms listed in 40 CFR 96.103, 96.203, 96.303 shall apply.

History Note: Authority G.S. 143-215.3(a); 143-215.107(a)(5), (10);
Eff. July 1, 2006;
Amended Eff. May 1, 2008.

15A NCAC 02D .2403 NITROGEN OXIDE EMISSIONS

(a) Allocations. The annual allocations of nitrogen oxide allowances are:

FACILITY	ALLOCATIONS FOR 2009-2014 (TONS)	ALLOCATIONS FOR 2015 AND LATER (TONS)
Craven County Wood Energy, LP	498	424
Duke Energy, Belews Creek	10,837	9,220
Duke Energy, Buck	1,355	1,153
Duke Energy, Cliffside	2,932	2,495
Duke Energy, Dan River	792	674
Duke Energy, G.G. Allen	4,338	3,691
Duke Energy, Lincoln	230	196
Duke Energy, Marshall	9,667	8,225
Duke Energy, Riverbend	1,709	1,454
Dynegy-Rockingham Power	194	165
Edgecombe GenCo	807	687
Elizabethtown Power	86	73
Lumberton Power	121	103
Primary Energy, Roxboro	164	140
Primary Energy, Southport	401	341
Progress Energy, Asheville	2,103	1,789
Progress Energy, Blewett	8	7
Progress Energy, Cape Fear	1,244	1,059
Progress Energy, Lee	1870	1591
Progress Energy, L.V. Sutton	2,146	1,826
Progress Energy, Mark's Creek Richmond Co.	374	318
Progress Energy, Mayo	4,004	3,407
Progress Energy, Roxboro	11,578	9,851
Progress Energy, Weatherspoon	674	573
PWC-Butler Warner Generation Plant	77	65
Rosemary Power Station, Halifax	42	36
Southern Power Company Plant Rowan County	25	22
Westmoreland Partners, LLC, Roanoke Valley Energy Facility	1269	1080

In the event that EPA determines that Craven County Wood Energy is not subject to the provisions of this Section, its allocation shall go to the new source growth pool.

(b) Compliance. The emissions of nitrogen oxides of a CAIR NOx source shall not exceed the number of allowances that it has in its compliance account established and administered under Rule .2408 of this Section.

(c) Emission measurement requirements. The emissions measurements recorded and reported according to 40 CFR Part 96 Subpart HH shall be used to determine compliance by each CAIR NOx source with its emissions limitation according to 40 CFR 96.106(c) including 96.106(c)(5) and (6).

(d) Excess emission requirements. The provisions of 40 CFR 96.106(d) shall be used for excess emissions.

(e) Liability. The owner or operator of any unit or source covered under this Section shall be subject to the provisions of 40 CFR 96.106(f).

(f) Modification and reconstruction, replacement, retirement, or change of ownership. The modification or reconstruction of a CAIR NOx unit shall not make that CAIR NOx unit a "new" CAIR NOx unit under Rule .2412 of this Section. The

CAIR NOx unit that is modified or reconstructed shall not change the emission allocation under Paragraph (a) of this Rule. If one or more CAIR NOx units at a facility covered under this Rule is replaced, the new CAIR NOx unit shall not receive an allocation under Rule .2412 of this Section, nor shall it change the allocation of the facility. If the owner of a facility changes, the emission allocations under this Rule and revised emission allocations made under Rule .2413 of this Section shall remain with the facility. If a CAIR NOx unit is retired, the owner or operator and the designated representatives of the CAIR NOx unit shall follow the procedures in 40 CFR 96.105. The allocations of a retired CAIR NOx unit shall remain with the owner or operator of the retired CAIR NOx unit until a reallocation occurs under Rule .2413 of this Section when the allocation shall be removed and given to other CAIR NOx units if the retired CAIR NOx unit is still retired using the procedure in Rule .2413 of this Section.

History Note: *Authority G.S. 143-215.3(a); 143-215.65; 143-215.66; 143-215.107(a)(5), (10);*
Eff. July 1, 2006;
Amended Eff. May 1, 2008.

15A NCAC 02D .2404 SULFUR DIOXIDE

(a) Applicability. This Rule applies only to units that meet the description in Rule .2401(b)(1) or (2) of this Section.

(b) Allocations. The annual allocation of sulfur dioxide allowances shall be determined by EPA. The allocations for CAIR SO_2 units are in 40 CFR 73.10.

(c) Compliance. The emissions of sulfur dioxides of a source described in Paragraph (a) of this Rule shall not exceed the number of allowances that it has in its compliance account established and administered under Rule .2408 of this Section.

(d) Emission measurement requirements. The emissions measurements recorded and reported according to 40 CFR Part 96 Subpart HHH shall be used to determine compliance by each CAIR SO_2 source with its emissions limitation according to 40 CFR 96.206(c) including 96.206(c)(5) and (6).

(e) Excess emission requirements. The provisions of 40 CFR 96.206(d) shall be used for excess emissions.

(f) Liability. The owner or operator of any unit or source covered under this Section shall be subject to the provisions of 40 CFR 96.206(f).

History Note: *Authority G.S. 143-215.3(a); 143-215.65; 143-215.66; 143-215.107(a)(5), (10);*
Eff. July 1, 2006;
Amended Eff. May 1, 2008.

15A NCAC 02D .2405 NITROGEN OXIDE EMISSIONS DURING OZONE SEASON

(a) Allocations. The ozone season allocations of nitrogen oxide allowances are:

(1) Facilities that meet the description in Rule .2401(b)(1) or (b)(2) of this Section.

FACILITY	ALLOCATIONS FOR 2009-2014 (TONS)	ALLOCATIONS FOR 2015 AND LATER (TONS)
Craven County Wood Energy, LP	211	179
Duke Energy, Belews Creek	4,917	4,184
Duke Energy, Buck	656	558
Duke Energy, Cliffside	1,350	1,148

Primary Energy, Southport	213	181
Progress Energy, Asheville	899	765
Progress Energy, Blewett	7	6
Progress Energy, Cape Fear	527	448
Progress Energy, Lee	905	770
Progress Energy, L.V. Sutton	1,023	871
Progress Energy, Mark's Creek Richmond Co.	335	285
Progress Energy, Mayo	1,735	1,476
Progress Energy, Roxboro	5,069	4,314
Progress Energy, Weatherspoon	346	295
PWC-Fayetteville	53	45
Rosemary Power Station, Halifax	26	22
Southern Power Company Plant Rowan County	25	20
Westmoreland Partners, LLC, Roanoke Valley Energy Facility	511	434

In the event that EPA determines that Craven County Wood Energy is not subject to the provisions of this Section, its allocation shall go to the new source growth pool.

(2) Facilities that meet the description in Rule .2401(b)(3) or (b)(4) of this Section.

FACILITY	ALLOCATON FOR 2009-2014 (TONS)	ALLOCATIONS FOR 2015 AND LATER (TONS)
Blue Ridge Paper Products	839	839

FACILITY	ALLOCATON FOR 2009-2014 (TONS)	ALLOCATIONS FOR 2015 AND LATER (TONS)
International Paper Corp., Columbus Co.	307	307
Kapstone Kraft Paper corporation	346	346
Coastal Carolina Clean Power, LLC	113	113
UNC-Chapel Hill	241	241
Weyerhaeuser, New Bern Mill	193	193
Domtar Paper Co.	404	404

(b) Ozone season defined. The ozone season is from May 1 through September 30 of each year.
(c) Change in status. If a unit at a facility named in Subparagraph (a)(2) of this Rule meets the description under Subparagraphs (b)(1) or (b)(2) of Rule .2401 of this Section, it shall lose its allocation under Subparagraph (a)(2) of this Rule and shall receive an allocation under Rule .2412 of this Section as a new unit until it receives an allocation under Rule .2413 of this Section.
(d) Compliance. The nitrogen oxide ozone season emissions of a CAIR NOx Ozone Season source shall not exceed the number of allowances that it has in its compliance account established and administered under Rule .2408 of this Section. For purposes of making deductions for excess emissions for the ozone season in 2008 under the NOx SIP Call (Section 15A NCAC 02D .1400), the Administrator shall deduct allowances allocated under this Rule for the ozone season in 2009.
(e) Emission measurement requirements. The emissions measurements recorded and reported according to 40 CFR Part 96 Subpart HHHH shall be used to determine compliance by each CAIR NOx Ozone Season source with its emissions limitation according to 40 CFR 96.306(c) including 96.306(c)(5) and (6).
(f) Excess emission requirements. The provisions of 40 CFR 96.306(d) shall be used for excess emissions.
(g) Liability. The owner or operator of any unit or source covered under this Section shall be subject to the provisions of 40 CFR 96.306(f).
(h) Modification and reconstruction, replacement, retirement, or change of ownership. The modification or reconstruction of a CAIR NOx Ozone Season unit shall not make that CAIR NOx Ozone Season unit a "new" CAIR NOx Ozone Season unit under Rule .2412. The CAIR NOx Ozone Season unit that is modified or reconstructed shall not change the emission allocation under Paragraph (a) of this Rule. If one or more CAIR NOx Ozone Season units at a facility is replaced, the new CAIR NOx Ozone Season unit shall not receive an allocation under Rule .2412 of this Section, nor shall it change the allocation of the facility. If the owner of a facility changes, the emission allocations under this Rule and revised emission allocations made under Rule .2413 of this Section shall remain with the facility. If a CAIR NOx Ozone Season unit is retired, the owner or operator, and designated representatives, of the CAIR NOx Ozone Season unit shall follow the procedures in 40 CFR 96.305. The allocations of a retired CAIR NOx Ozone Season unit shall remain with the owner or operator of the retired CAIR NOx Ozone Season unit until a reallocation occurs under Rule .2413 of this Section when the allocation shall be removed and given to other CAIR NOx Ozone Season units if the retired CAIR NOx Ozone Season unit is still retired using the procedure in Rule .2413 of this Section.

History Note: *Authority G.S. 143-215.3(a); 143-215.65; 143-215.66; 143-215.107(a)(5), (10);*
Eff. July 1, 2006;
Amended Eff. May 1, 2008.

15A NCAC 02D .2406 PERMITTING

(a) The owner or operator of any source covered under this Section shall submit permit applications to comply with the requirements of this Section following the procedures and requirements in 15A NCAC 02Q .0500 (Title V permitting procedures) and in:

(1) 40 CFR 96.106(a), 96.121, and 96.122 for each CAIR NOx source;
(2) 40 CFR 96.206(a), 96.221, and 96.222 for each CAIR SO_2 source; and
(3) 40 CFR 96.306(a), 96.321, and 96.322 for each CAIR NOx Ozone Season source.

(b) The Director shall review applications submitted under Paragraph (a) of this Rule and issue permits for compliance with this Section following the procedures and requirements in 15A NCAC 02Q .0500 (Title V permitting procedures) and in:

(1) 40 CFR 96.106(a), 96.120, 96.123, and 96.124 for each CAIR NOx source;
(2) 40 CFR 96.206(a), 96.220, 96.223, and 96.224 for each CAIR SO_2 source; and
(3) 40 CFR 96.306(a), 96.320, 96.323, and 96.324 for each CAIR NOx Ozone Season source.

History Note: Authority G.S. 143-215.3(a); 143-215.107(a)(5), (10); 143-215.108;
Eff. July 1, 2006.

15A NCAC 02D .2407 MONITORING, REPORTING, AND RECORDKEEPING

(a) The owner or operator of a unit covered under this Section shall comply with the monitoring, recordkeeping, and reporting requirements in:

(1) 40 CFR 96.106(b) and (e) and in 40 CFR Part 96, Subpart HH for each CAIR NOx unit;

(2) 40 CFR 96.206(b) and (e) and in 40 CFR Part 96, Subpart HHH for each CAIR SO2 unit; and

(3) 40 CFR 96.306(b) and (e) and in 40 CFR Part 96, Subpart HHHH for each CAIR Ozone Season NOx unit.

(b) To approve or disapprove monitors used to show compliance with Rules .2403, .2404, or .2405 of this Section, the Division shall follow the procedures in:

(1) 40 CFR 96.171 for nitrogen oxides,

(2) 40 CFR 96.271 for sulfur dioxides, and

(3) 40 CFR 96.371 for ozone season nitrogen oxides.

History Note: Authority G.S. 143-215.3(a); 143-215.65; 143-215.66; 143-215.107(a)(5), (10);
Eff. July 1, 2006.

15A NCAC 02D .2408 TRADING PROGRAM AND BANKING

(a) EPA to administer. The United States Environmental Protection Agency (EPA) shall administer the allowance tracking system according to the procedures in:

(1) 40 CFR Part 96, Subpart FF and Subpart GG for nitrogen oxides;
(2) 40 CFR Part 96, Subpart FFF and Subpart GGG for sulfur dioxide; and
(3) 40 CFR Part 96, Subpart FFFF and Subpart GGGG for ozone season nitrogen oxides.

(b) Compliance account. The owners and operators of each source covered under this Section shall have a compliance account in the EPA administered tracking system that satisfies the requirements of:

(1) 40 CFR 96.151 for nitrogen oxides,
(2) 40 CFR 96.251 for sulfur dioxides, and
(3) 40 CFR 96.351 for ozone season nitrogen oxides.

(c) General account. Any person may apply to open a general account to hold and transfer allowances by using the procedures and meeting the requirements in:

(1) 40 CFR 96.151(b) for nitrogen oxides and may close that account using the procedures in 40 CFR 96.157,
(2) 40 CFR 96.251(b) for sulfur dioxides and may close that account using the procedures in 40 CFR 96.257, and
(3) 40 CFR 96.351(b) for ozone season nitrogen oxides and may close that account using the procedures in 40 CFR 96.357.

(d) Allowance transfers.

(1) Any person who has a compliance or general account established under 40 CFR 96.151 may transfer allowances using the procedures in 40 CFR 96.160.
(2) Any person who has a compliance or general account established under 40 CFR 96.251 may transfer allowances using the procedures in 40 CFR 96.260.
(3) Any person who has a compliance or general account established under 40 CFR 96.351 may transfer allowances using the procedures in 40 CFR 96.360.

(e) Submittal of information. Persons with accounts shall submit information to EPA following the requirements of:

(1) 40 CFR 96.152 for nitrogen oxides,
(2) 40 CFR 96.252 for sulfur dioxides, and
(3) 40 CFR 96.352 for ozone season nitrogen oxides.

(f) Banking. Any person who has a compliance account or a general account may bank allowances for future use or transfer under:

(1) 40 CFR 96.155 for nitrogen oxides,
(2) 40 CFR 96.255 for sulfur dioxides, and
(3) 40 CFR 96.355 for ozone season nitrogen oxides.

(g) Appeal Procedures. The appeal procedures for decisions of the Administrator are set forth in

(1) 40 CFR 96.108 for nitrogen oxides,
(2) 40 CFR 96.208 for sulfur dioxides, and
(3) 40 CFR 96.308 for ozone season nitrogen oxides.

History Note: *Authority G.S. 143-215.3(a); 143-215.107(a)(5), (10);*
Eff. July 1, 2006.

15A NCAC 02D .2409 DESIGNATED REPRESENTATIVE

(a) Designated representative. The owners and operators of any source covered under this Section shall select a designated representative according to 40 CFR 96.110 for each CAIR NOx source, 96.210 for each CAIR SO_2 source, and 96.310 for each CAIR NOx Ozone Season source. The designated representative shall have the responsibilities and duties set out in 40 CFR 96.110 for a CAIR NOx source, 96.210 for a CAIR SO_2 source, and 96.310 for a CAIR NOx Ozone Season source.

(b) Alternate designated representative. The owners and operators of any source covered under this Section shall select an alternate designated representative according to 40 CFR 96.111 for each CAIR NOx source, 96.211 for each CAIR SO_2 source, and 96.311 for each CAIR NOx Ozone Season source. The alternate designated representative shall have the responsibilities and duties set out in 40 CFR 96.111 for a CAIR NOx source, 96.211 for CAIR SO_2 source, and 96.311 for a CAIR NOx Ozone Season source.

(c) Changing designated representative and alternate designated representative. The owner or operator of any source covered under this Section may change the designated representative or the alternate designated representative using:

(1) 40 CFR 96.112 for a CAIR NOx source;

(2) 40 CFR 96.212 for a CAIR SO_2 source; and

(3) 40 CFR 96.312 for a CAIR NOx Ozone Season source.

(d) A CAIR designated representative or alternative CAIR designated representative may delegate his or her authority to make an electronic submission to the Administrator using:

(1) 40 CFR 96.115 for a CAIR NOx source;

(2) 40 CFR 96.215 for a CAIR SO2 source; and

(3) 40 CFR 96.315 for a CAIR NOx Ozone Season source.

(e) Changes in owners and operators. Whenever the owner or operator of a source or unit covered under this Section changes, the following provisions shall be followed:

(1) 40 CFR 96.112(c) for a CAIR NOx source;

(2) 40 CFR 96.212(c) for a CAIR SO_2 source; and

(3) 40 CFR 96.312(c) for a CAIR NOx Ozone Season source.

(f) Certificate of representation. A complete certificate of representation for a CAIR designated representative or an alternate CAIR designated representative shall meet the requirements of 40 CFR 96.113 for nitrogen oxides, 40 CFR 96.213 for sulfur dioxide, and 40 CFR 96.313 for ozone season nitrogen oxides.

(g) Objections concerning CAIR designated representative. Objections concerning CAIR designated representative shall be handled according to the procedures in 40 CFR 96.114 for nitrogen oxides, 40 CFR 96.214 for sulfur dioxide, and 40 CFR 96.314 for ozone season nitrogen oxides.

History Note: *Authority G.S. 143-215.3(a); 143-215.107(a)(5), (10);*
Eff. July 1, 2006;
Amended Eff. May 1, 2008.

15A NCAC 02D .2410 COMPUTATION OF TIME

Time periods shall be determined as described in:

(1) 40 CFR 96.107 for nitrogen oxides;

(2) 40 CFR 96.207 for sulfur dioxide, and

(3) 40 CFR 96.307 for ozone season nitrogen oxides.

History Note: Authority G.S. 143-215.3(a); 143-215.107(a)(5), (10);
Eff. July 1, 2006.

15A NCAC 02D .2411 OPT-IN PROVISIONS

(a) Opting in. The owners and operators of a unit may opt into:

(1) the nitrogen oxide trading program by following the procedures in and meeting the requirements of 40 CFR Part 96 Subpart II,

(2) the sulfur dioxide trading program by following the procedures in and meeting the requirements of 40 CFR Part 96 Subpart III, and

(3) the ozone season nitrogen oxide trading program by following the procedures in and meeting the requirements of 40 CFR Part 96 Subpart IIII.

(b) Permitting. The Director shall permit opt-in units under Paragraph (a) of this Rule according to 15A NCAC 02Q .0500; and

(1) 40 CFR 96.184 and 96.185 for nitrogen oxides and shall allocate allowances according to 40 CFR 96.188,

(2) 40 CFR 96.284 and 96.285 for sulfur dioxides and shall allocate allowances according to 40 CFR 96.288, and

(3) 40 CFR 96.384 and 96.385 for ozone season nitrogen oxides and shall allocate allowances according to 40 CFR 96.388.

(c) Withdrawing. The owners and operators of an opt-in unit under Paragraph (a) of this Rule may withdraw from the trading program according to:

(1) 40 CFR 96.186 for nitrogen oxides,

(2) 40 CFR 96.286 for sulfur dioxides, and

(3) 40 CFR 96.386 for ozone season nitrogen oxides.

(d) Change in regulatory status. If an opt-in unit becomes:

(1) a CAIR NOx unit under 40 CFR 96.104, then 40 CFR 96.187 shall apply,

(2) a CAIR SO_2 unit under 40 CFR 96.204, then 40 CFR 96.287 shall apply, or

(3) a CAIR ozone season NOx unit under 40 CFR 96.304, then 40 CFR 96.387 shall apply.

History Note: *Authority G.S. 143-215.3(a); 143-215.107(a)(5), (10); 143-215.108;*
Eff. July 1, 2006.

15A NCAC 02D .2412 NEW UNIT GROWTH

(a) For nitrogen oxide emissions, the total nitrogen oxide allowances available for allocation in the new unit set-aside for each control period in 2009 through 2014 shall be 2638 tons and the total nitrogen oxide allowances available for allocation in each control period in 2015 and thereafter shall be 1154 tons. Except for the reference to 40 CFR 96.142(b), the procedures in 40 CFR 96.142(c)(2) through (4) shall be used to create allocations for units covered under this Section that commenced operations on or after January 1, 2001 and that are not covered in the table in Rule .2403 of this Section.

(b) For ozone season nitrogen oxides emissions, the total ozone season nitrogen oxide allowances available for allocation in the new unit set-aside for each control period in 2009 through 2014 shall be 1234 tons and the total ozone season nitrogen oxide allowances available for allocation in each control period in 2015 and thereafter shall be 555 tons. Except for the reference to 40 CFR 96.142(b) the procedures in 40 CFR 96.342(c)(2) through (4) shall be used to create allocations for units covered under this Section that commenced operations on or after January 1, 2001 and that are not listed in the table in Rule .2405 of this Section.

(c) New unit allowances in Paragraph (a) of this Rule that are not allocated in a given year shall be redistributed to units under .2401(b)(1) and (2) according to the provisions of 40 CFR 96.142(d) and 96.342(d) except that the divisor used in calculating individual unit allocations:

(1) for nitrogen oxide allowances shall be 2638 tons for each control period in 2009 through 2014 and 1154 tons in each control period in 2015 and thereafter, and

(2) for ozone season nitrogen oxide allowances shall be 1234 tons for each control period in 2009 through 2014 and 555 tons for each control period in 2015 and thereafter.

(d) The Director shall report the allocations to new units to EPA in accordance with 40 CFR 51.123(o)(2) and (aa)(2).

History Note: *Authority G.S. 143-215.3(a); 143-215.107(a)(5), (10);*
Eff. July 1, 2006;
Amended Eff. May 1, 2008.

15A NCAC 02D .2413 PERIODIC REVIEW AND REALLOCATIONS

In 2010 and every five years thereafter, the Environmental Management Commission shall review the emission allocations of units covered under Rules .2403 and .2405 of this Section and decide if any revisions are needed. In making this decision the Environmental Management Commission shall consider the following:

(1) the size of the allocation pool for new unit growth under Rule .2412 of this Section;

(2) the amount of emissions allocations requested by units under Rule .2412 of this Section;

(3) the amount of emissions allocations available through the respective trading programs under Rule .2408 of this Section;

(4) the impact of reallocation on existing units;

(5) the impact of reallocations on units covered under Rule .2412 of this Section;

(6) impact on future growth; and

(7) other relevant information on the impacts of reallocation.

Any revisions of allocations shall be consistent with the requirements in 40 CFR 51.123(o)(2)(ii) and (aa)(2)(iii) or 96.141 and 96.341.

History Note: *Authority G.S. 143-215.3(a); 143-215.107(a)(5), (10);*
Eff. July 1, 2006.

GENERAL ASSEMBLY OF NORTH CAROLINA
SESSION 2001

SESSION LAW 2002-4
SENATE BILL 1078

AN ACT TO IMPROVE AIR QUALITY IN THE STATE BY IMPOSING LIMITS ON THE EMISSION OF CERTAIN POLLUTANTS FROM CERTAIN FACILITIES THAT BURN COAL TO GENERATE ELECTRICITY AND TO PROVIDE FOR RECOVERY BY ELECTRIC UTILITIES OF THE COSTS OF ACHIEVING COMPLIANCE WITH THOSE LIMITS.

The General Assembly of North Carolina enacts:

SECTION 1. Article 21B of Chapter 143 of the General Statutes is amended by adding a new section to read:

"**§ 143-215.107D. Emissions of oxides of nitrogen (NOx) and sulfur dioxide (SO2) from certain coal-fired generating units.**

(a) As used in this section:

(1) 'Coal-fired generating unit' means a coal-fired generating unit, as defined by 40 Code of Federal Regulations § 96.2 (1 July 2001 Edition), that is located in this State and has the capacity to generate 25 or more megawatts of electricity.

(2) 'Investor-owned public utility' means an investor-owned public utility, as defined in G.S. 62-3.

(b) An investor-owned public utility that owns or operates coal-fired generating units that collectively emitted more than 75,000 tons of oxides of nitrogen (NOx) in calendar year 2000:

(1) Shall not collectively emit from the coal-fired generating units that it owns or operates more than 35,000 tons of oxides of nitrogen (NOx) in any calendar year beginning 1 January 2007.

(2) Shall not collectively emit from the coal-fired generating units that it owns or operates more than 31,000 tons of oxides of nitrogen (NOx) in any calendar year beginning 1 January 2009.

(c) An investor-owned public utility that owns or operates coal-fired generating units that collectively emitted 75,000 tons or less of oxides of nitrogen (NOx) in calendar year 2000 shall not collectively emit from the coal-fired generating units that it owns or operates more than 25,000 tons of oxides of nitrogen (NOx) in any calendar year beginning 1 January 2007.

(d) An investor-owned public utility that owns or operates coal-fired generating units that collectively emitted more than 225,000 tons of sulfur dioxide (SO2) in calendar year 2000:

(1) Shall not collectively emit from the coal-fired generating units that it owns or operates more than 150,000 tons of sulfur dioxide (SO2) in any calendar year beginning 1 January 2009.

(2) Shall not collectively emit from the coal-fired generating units that it owns or operates more than 80,000 tons of sulfur dioxide (SO2) in any calendar year beginning 1 January 2013.

(e) An investor-owned public utility that owns or operates coal-fired generating units that collectively emitted 225,000 tons or less of sulfur dioxide (SO2) in calendar year 2000:

(1) Shall not collectively emit from the coal-fired generating units that it owns or operates more than 100,000 tons of sulfur dioxide (SO2) in any calendar year beginning 1 January 2009.

(2) Shall not collectively emit from the coal-fired generating units that it owns or operates more than 50,000 tons of sulfur dioxide (SO2) in any calendar year beginning 1 January 2013.

(f) Each investor-owned public utility to which this section applies may determine how it will achieve the collective emissions limitations imposed by this section. Compliance with the emissions limitations set out in this section does not alter the obligation of any person to comply with any other federal or State law, regulation, or rule related to air quality or visibility. This subsection shall not be construed to limit the authority of the Commission to impose specific limitations on the emission of oxides of nitrogen (NOx) and sulfur dioxide (SO2) from an individual coal-fired generating unit owned or operated by an investor-owned public utility.

(g) A coal-fired generating unit that is subject to the collective emissions limitations set out in this section on 1 July 2002 shall remain subject to the collective emissions limitations whether or not it thereafter continues to be owned or operated by an investor-owned public utility.

(h) The Commission shall require that any permit or modified permit issued for a coal-fired generating unit that is subject to this section include conditions that provide for testing, monitoring, record keeping, and reporting adequate to assure compliance with the requirements of this section.

(i) The Governor may enter into an agreement with an investor-owned public utility under which the investor-owned public utility voluntarily agrees to transfer to the State any emissions allowances acquired or that may be acquired by the investor-owned public utility pursuant to 42 U.S.C. §§ 7651-7651o, as implemented by 40 Code of Federal Regulations §§ 73.1 through 73.90 (1 July 2001 Edition); 42 U.S.C. 7410(a)(2)(D)(i)(I), as implemented by 40 Code of Federal Regulations § 51.121 (1 July 2001 Edition), related federal regulations, and the associated State Implementation Plan; 42 U.S.C. § 7426, as implemented by 40 Code of Federal Regulations

§ 52.34 (1 July 2001 Edition) and related federal regulations; or any similar program established under federal law that result from compliance with the emissions limitations set out in this section. An agreement entered into pursuant to this subsection shall be binding and shall be enforceable by specific performance. If the Governor enters into an agreement that provides for the transfer of emissions allowances to the State, the Governor shall file verified copies of the agreement with the Attorney General, the Secretary of State, the State Treasurer, the Secretary of Environment and Natural Resources, and the Utilities Commission. The State Treasurer shall hold all emissions allowances that are transferred to the State as provided in this subsection in trust for the people of this State and shall sell, trade, transfer, or otherwise dispose of the emissions allowances only as the General Assembly shall provide by law.

(j) An investor-owned public utility that is subject to the emissions limitations set out in this section shall submit to the Utilities Commission and to the Department on or before 1 April of each year a verified statement pursuant to subsection (i) of G.S. 62-133.6."

SECTION 2. G.S. 143-215.108 reads as rewritten:

"**§ 143-215.108. Control of sources of air pollution; permits required.**

(a)~~After the effective date applicable to any air quality or emission control standards established pursuant to G.S. 143-215.107 and except~~ Except as provided in subsections (a1) and (a2) of this section, no person shall do any of the following things or carry out any of the following activities which contravene or will be likely to contravene ~~such~~ standards established pursuant to G.S. 143-215.107 or set out in G.S. 143-215.107D ~~until or~~ unless ~~such~~ that person ~~shall have applied for and shall have received~~ has obtained from the Commission a permit therefor and ~~shall have~~ has complied with ~~such conditions, if any, as are prescribed by such~~ any conditions of this permit:

(1) Establish or operate any air contaminant source;
(2) Build, erect, use or operate any equipment which may result in the emission of air contaminants or which is likely to cause air pollution;
(3) Alter or change the construction or method of operation of any equipment or process from which air contaminants are or may be emitted;
(4) Enter into an irrevocable contract for the construction and installation of any air-cleaning device, or allow or cause such device to be constructed, installed, or operated.

(a1)The Commission may by rule establish procedures that meet the requirements of section 502(b)(10) of Title V (42 U.S.C. § 7661a(b)(10)) and 40 Code of Federal Regulations § 70.4(b)(12) (1 July 1993 Edition) to allow a permittee to make changes within a permitted facility without requiring a revision of the permit.

(a2)The Commission may adopt rules that provide for a minor modification of a permit. At a minimum, rules that provide for a minor modification of a permit shall meet the requirements of 40 Code of Federal Regulations § 70.7(e)(2) (1 July 1993 Edition). If the Commission adopts rules that provide for a minor modification of a permit, a permittee shall not make a change in the permitted facility while the application for the minor modification is under review unless the change is authorized under the rules adopted by the Commission.

(b) The Commission shall act upon all applications for permits so as to effectuate the ~~purpose~~ purposes of this ~~section,~~ Article by reducing existing air pollution and preventing, so far as reasonably possible, any increased pollution of the air from any additional or enlarged sources.

(c) The Commission shall have the power:

(1) To grant and renew a permit with ~~such~~ any conditions attached ~~as~~ that the Commission believes necessary to achieve the purposes of this ~~section~~ Article or the requirements of the Clean Air Act and implementing regulations adopted by the United States Environmental Protection Agency;

...."

SECTION 3. G.S. 143-215.107(a)(8) reads as rewritten:

"(8) To develop and adopt standards and plans necessary to implement programs to control acid deposition and to regulate the use of sulfur dioxide (SO2) allowances and ~~nitrogen~~ oxides of nitrogen (NOx) emissions in accordance with Title IV and implementing regulations adopted by the United States Environmental Protection Agency."

SECTION 4. G.S. 143-215.114A(a) reads as rewritten:

"(a)A civil penalty of not more than ten thousand dollars ($10,000) may be assessed by the Secretary against any person who:

(1) Violates any classification, standard or limitation established pursuant to ~~G.S. 143-215.107;~~G.S. 143-215.107.

(2) Is required but fails to apply for or to secure a permit required by G.S. 143-215.108 or who violates or fails to act in accordance with the terms, conditions, or requirements of such ~~permit;~~permit.

(3) Violates or fails to act in accordance with the terms, conditions, or requirements of any special order or other appropriate document issued pursuant to ~~G.S. 143-215.110;~~G.S. 143-215.110.

(4) Fails to file, submit, or make available, as the case may be, any documents, data or reports required by this Article or Parts 1 or 7 of Article 21 of this ~~Chapter;~~Chapter.

(5) Violates a rule of the Commission or a local governing body implementing this Article or Parts 1

or 7 of ~~Article 21;~~Article 21.

(6) Violates the offenses set out in G.S. 143-215.114B.

(7) Violates the emissions limitations set out in G.S. 143-215.107D."

SECTION 5. G.S. 143-215-114A is amended by adding a new subsection to read:

"(b1)The Secretary may assess a civil penalty of not more than ten thousand dollars ($10,000) per day for a violation of the emissions limitations set out in G.S. 143-215.107D as provided in this subsection. If at the end of any calendar year, an investor-owned public utility has violated an emissions limitation set out in G.S. 143-215.107D, the violation shall be considered to be continuous from the day that the collective emissions first exceeded the emissions limitation set out in G.S. 143-215.107D through the end of the calendar year and the Secretary may assess a separate civil penalty for each day."

SECTION 6. G.S. 143-215.114B(f) reads as rewritten:

"(f)Any person who negligently violates any classification, standard or limitation established pursuant to ~~G.S. 143-215.107;~~ G.S. 143-215.107 or by G.S. 143-215.107D any term, condition, or requirement of a permit issued pursuant to G.S. 143-215.108 or of a special order or other appropriate document issued pursuant to G.S. 143-215.110 or any rule of the Commission implementing any of the said section, shall be guilty of a Class 2 misdemeanor which may include a fine not to exceed fifteen thousand dollars ($15,000) per day of violation, provided that such fine shall not exceed a cumulative total of two hundred thousand dollars ($200,000) for each period of 30 days during which a violation continues."

SECTION 7. G.S. 143-215.114B(g) reads as rewritten:

"(g)Any person who knowingly and willfully violates any classification, standard, or limitation established in the rules of the Commission pursuant to ~~G.S. 143-215.107 or~~ G.S. 143-215.107; the emissions limitations set out in G.S. 143-215.107D; any term, condition, or requirement of a permit issued pursuant to ~~G.S. 143-215.108~~ G.S. 143-215.108; or of a special order or other appropriate document issued pursuant to G.S. 143-215.110, shall be guilty of a Class H felony, which may include a fine not to exceed one hundred thousand dollars ($100,000) per day of violation, provided that this fine shall not exceed a cumulative total of five hundred thousand dollars ($500,000) for each period of 30 days during which a violation continues. For the purposes of this subsection, the phrase "knowingly and willfully" shall mean intentionally and consciously as the courts of this State, according to the principles of common law, interpret the phrase in the light of reason and experience."

SECTION 8. G.S. 143-215.114B(h)(1) reads as rewritten:

"(1) Any person who knowingly violates any classification, standard, or limitation established in the rules of the Commission pursuant to ~~G.S. 143-215.107 or~~ G.S. 143-

215.107; the emissions limitations set out in G.S. 143-215.107D; any term, condition, or requirement of a permit issued pursuant to ~~G.S. 143-215.108~~ G.S. 143-215.108; or of a special order or other appropriate document issued pursuant to G.S. 143-215.110 and who knows at that time that he thereby places another person in imminent danger of death or serious bodily injury shall be guilty of a Class C felony, which may include a fine not to exceed two hundred fifty thousand dollars ($250,000) per day of violation, provided that this fine shall not exceed a cumulative total of one million dollars ($1,000,000) for each period of 30 days during which a violation continues."

SECTION 9. Article 7 of Chapter 62 of the General Statutes is amended by adding a new section to read:

"**§ 62-133.6. Environmental compliance costs recovery.**

(a) As used in this section:

(1) 'Coal-fired generating unit' means a coal-fired generating unit, as defined by 40 Code of Federal Regulations § 96.2 (1 July 2001 Edition), that is located in this State and has the capacity to generate 25 or more megawatts of electricity.

(2) 'Environmental compliance costs' means only those capital costs incurred by an investor-owned public utility to comply with the emissions limitations set out in G.S. 143-215.107D that exceed the costs required to comply with 42 U.S.C. § 7410(a)(2)(D)(i)(I), as implemented by 40 Code of Federal Regulations § 51.121 (1 July 2001 Edition), related federal regulations, and the associated State or Federal Implementation Plan, or with 42 U.S.C. § 7426, as implemented by 40 Code of Federal Regulations § 52.34 (1 July 2001 Edition) and related federal regulations. The term 'environmental compliance costs' does not include:

a. Costs required to comply with a final order or judgment rendered by a state or federal court under which an investor-owned public utility is found liable for a failure to comply with any federal or state law, rule, or regulation for the protection of the environment or public health.

b. The net increase in costs, above those proposed by the investor-owned public utility as part of its plan to achieve compliance with the emissions limitations set out in G.S. 143-215.107D, that are necessary to comply with a settlement agreement, consent decree, or similar resolution of litigation arising from any alleged failure to comply with any federal or state law, rule, or regulation for the protection of the environment or public health.

c. Any criminal or civil fine or penalty, including court costs imposed or assessed for a violation by an investor-owned public utility of any federal or state law, rule, or regulation for the protection of the environment or public health.

d. The net increase in costs, above those proposed by the investor-owned public utility as part of its plan to achieve the emissions limitations set out in G.S. 143-215.107D, that are necessary to comply with any limitation on emissions of oxides of nitrogen (NOx) or sulfur dioxide (SO2) that are imposed on an individual coal-fired generating unit by the Environmental Management Commission or the Department of Environment and Natural Resources to address any nonattainment of an air quality standard in any area of the State.

(3) 'Investor-owned public utility' means an investor-owned public utility, as defined in G.S. 62-3.

(b) The investor-owned public utilities shall be allowed to accelerate the cost recovery of their estimated environmental compliance costs over a seven-year period, beginning 1 January 2003 and ending 31 December 2009. For purposes of this subsection, an investor-owned public utility subject to the provisions of subsections (b) and (d) of G.S. 143-215.107D shall amortize environmental compliance costs in the amount of one billion five hundred million dollars ($1,500,000,000) and an investor-owned public utility subject to the provisions of subsections (c) and (e) of G.S. 143-215.107D shall amortize environmental compliance costs in the amount of eight hundred thirteen million dollars ($813,000,000). During the rate freeze period established in subsection (e) of this section, the investor-owned public utilities shall, at a minimum, recover through amortization seventy percent (70%) of the environmental compliance costs set out in this subsection. The maximum amount for each investor-owned public utility's annual accelerated cost recovery during the rate freeze period shall not exceed one hundred fifty percent (150%) of the annual levelized environmental compliance costs set out in this subsection. The amounts to be amortized pursuant to this subsection are estimates of the environmental compliance costs that may be adjusted as provided in this section. The General Assembly makes no judgment as to whether the actual environmental compliance costs will be greater than, less than, or equal to these estimated amounts. These estimated amounts do not define or limit the scope of the expenditures that may be necessary to comply with the emissions limitations set out in G.S. 143-215.107D.

(c) The investor-owned public utilities shall file their compliance plans, including initial cost estimates, with the Commission and the Department of Environment and Natural Resources not later than 10 days after the date on which this section becomes effective. The Commission shall consult with the Secretary of Environment and Natural Resources and shall consider the advice of the Secretary as to whether an investor-owned public utility's proposed compliance plan is adequate to achieve the emissions limitations set out in G.S. 143-215.107D.

(d) Subject to the provisions of subsection (f) of this section, the Commission shall hold a hearing to review the environmental compliance costs set out in subsection (b) of this section. The Commission may modify and revise those costs as necessary to ensure that they are just, reasonable, and prudent based on the most recent cost information available and determine the annual cost recovery amounts that each investor-owned public utility shall be required to record and recover during calendar years 2008 and 2009. In making its decisions pursuant to this subsection, the Commission shall consult with the Secretary of Environment and Natural Resources to receive advice as to whether the investor-owned public utility's actual and proposed modifications and permitting and construction schedule are adequate to achieve the emissions limitations set out in G.S. 143-215.107D. The Commission shall issue an order pursuant to this subsection no later than 31 December 2007.

(e) Notwithstanding G.S. 62-130(d) and G.S. 62-136(a), the base rates of the investor-owned public utilities shall remain unchanged from the date on which this section becomes effective through 31 December 2007. The Commission may, however, consistent with the public interest:

(1) Allow adjustments to base rates, or deferral of costs or revenues, due to one or more of the following conditions occurring during the rate freeze period:
 a. Governmental action resulting in significant cost reductions or requiring major expenditures including, but not limited to, the cost of compliance with any law, regulation, or rule for the protection of the environment or public health, other than environmental compliance costs.
 b. Major expenditures to restore or replace property damaged or destroyed by force majeure.
 c. A severe threat to the financial stability of the investor-owned public utility resulting from other extraordinary causes beyond the reasonable control of the investor-owned public utility.
 d. The investor-owned public utility persistently earns a return substantially in excess of the rate of return established and found reasonable by the Commission in the investor-owned public utility's last general rate case.

(2) Approve any reduction in a rate or rates applicable to a customer or class of customers during the rate freeze period, if requested to do so by an investor-owned public utility that is subject to the emissions limitations set out in G.S. 143-215.107D.

(f) In any general rate case initiated to adjust base rates effective on or after 1 January 2008, the investor-owned public utility shall be allowed to recover its actual environmental compliance costs in accordance with Article 7 of this Chapter less the cumulative amount of accelerated cost recovery recorded pursuant to subsection (b) of this section.

(g) Consistent with the public interest, the Commission is authorized to approve proposals submitted by an investor-owned public utility to implement optional, market-based rates and services, provided the proposal does not increase base rates during the period of time referred to in subsection (e) of this section.

(h) Nothing in this section shall prohibit the Commission from taking any actions otherwise appropriate to enforce investor-owned public utility compliance with applicable statutes or Commission rules or to order any appropriate remedy for such noncompliance allowed by law.

(i) An investor-owned public utility that is subject to the emissions limitations set out in G.S. 143-215.107D shall submit to the Commission and to the Department of Environment and Natural Resources on or before 1 April of each year a verified statement that contains all of the following:

(1) A detailed report on the investor-owned public utility's plans for meeting the emissions limitations set out in G.S. 143-215.107D.

(2) The actual environmental compliance costs incurred by the investor-owned public utility in the previous calendar year, including a description of the construction undertaken and completed during that year.

(3) The amount of the investor-owned public utility's environmental compliance costs amortized in the previous calendar year.

(4) An estimate of the investor-owned public utility's environmental compliance costs and the basis for any revisions of those estimates when compared to the estimates submitted during the previous year.

(5) A description of all permits required in order to comply with the provisions of G.S. 143-215.107D for which the investor-owned public utility has applied and the status of those permits or permit applications.

(6) A description of the construction related to compliance with the provisions of G.S. 143-215.107D that is anticipated during the following year.

(7) A description of the applications for permits required in order to comply with the provisions of G.S. 143-215.107D that are anticipated during the following year.

(8) The results of equipment testing related to compliance with G.S. 143-215.107D.

(9) The number of tons of oxides of nitrogen (NOx) and sulfur dioxide (SO2) emitted

during the previous calendar year from the coal-fired generating units that are subject to the emissions limitations set out in G.S. 143-215.107D.

(10) The emissions allowances described in G.S. 143-215.107D(i) that are acquired by the investor-owned public utility that result from compliance with the emissions limitations set out in G.S. 143-215.107D.

(11) Any other information requested by the Commission or the Department of Environment and Natural Resources.

(j) The Secretary shall review the information submitted pursuant to subsection (i) of this section and determine whether the investor-owned public utility's actual and proposed modifications and permitting and construction schedule are adequate to achieve the emissions limitations set out in G.S. 143-215.107D and shall advise the Commission as to the Secretary's findings and recommendations.

(k) Any information, advice, findings, recommendations, or determinations provided by the Secretary pursuant to this section shall not constitute a final agency decision within the meaning of Chapter 150B of the General Statutes and shall not be subject to review under that Chapter."

SECTION 10. It is the intent of the General Assembly that the State use all available resources and means, including negotiation, participation in interstate compacts and multistate and interagency agreements, petitions pursuant to 42 U.S.C. § 7426, and litigation to induce other states and entities, including the Tennessee Valley Authority, to achieve reductions in emissions of oxides of nitrogen (NOx) and sulfur dioxide (SO2) comparable to those required by G.S. 143-215.107D, as enacted by Section 1 of this act, on a comparable schedule. The State shall give particular attention to those states and other entities whose emissions negatively impact air quality in North Carolina or whose failure to achieve comparable reductions would place the economy of North Carolina at a competitive disadvantage.

SECTION 11. The Environmental Management Commission shall study the desirability of requiring and the feasibility of obtaining reductions in emissions of oxides of nitrogen (NOx) and sulfur dioxide (SO2) beyond those required by G.S. 143-215.107D, as enacted by Section 1 of this act. The Environmental Management Commission shall consider the availability of emissions reduction technologies, increased cost to consumers of electric power, reliability of electric power supply, actions to reduce emissions of oxides of nitrogen (NOx) and sulfur dioxide (SO2) taken by states and other entities whose emissions negatively impact air quality in North Carolina or whose failure to achieve comparable reductions would place the economy of North Carolina at a competitive disadvantage, and the effects that these reductions would have on public health, the environment, and natural resources, including visibility. In its conduct of this study, the Environmental Management Commission may consult with the Utilities Commission and the Public Staff. The Environmental Management Commission shall report its findings and recommendations to the General Assembly and the Environmental Review Commission annually beginning 1 September 2005.

SECTION 12. The General Assembly anticipates that measures implemented to achieve the reductions in emissions of oxides of nitrogen (NOx) and sulfur dioxide (SO2) required by G.S. 143-215.107D, as enacted by Section 1 of this act, will also result in significant reductions in the emissions of mercury from coal-fired generating units. The Division of Air Quality of the Department of Environment and Natural Resources shall study issues related to monitoring emissions of mercury and the development and implementation of standards and plans to implement programs to control emissions of mercury from coal-fired generating units. The Division shall evaluate available control technologies and shall estimate the benefits and costs of alternative strategies to reduce emissions of mercury. The Division shall annually report its interim findings and recommendations to the Environmental Management Commission and the Environmental Review Commission beginning 1 September 2003. The Division shall report its final findings and recommendations to the Environmental Management Commission and the Environmental Review Commission no later than 1 September 2005. The costs of implementing any air quality standards and plans to reduce the emission of mercury from coal-fired generating units below the standards in effect on the date this act becomes effective, except to the extent that the emission of mercury is reduced as a result of the reductions in the emissions of oxides of nitrogen (NOx) and sulfur dioxide (SO2) required to achieve the emissions limitations set out in G.S. 143-215.107D, as enacted by Section 1 of this act, shall not be recoverable pursuant to G.S. 62-133.6, as enacted by Section 9 of this act.

SECTION 13. The Division of Air Quality of the Department of Environment and Natural Resources shall study issues related to the development and implementation of standards and plans to implement programs to control emissions of carbon dioxide (CO2) from coal-fired generating units and other stationary sources of air pollution. The Division shall evaluate available control technologies and shall estimate the benefits and costs of alternative strategies to reduce emissions of carbon dioxide (CO2). The Division shall annually report its interim findings and recommendations to the Environmental Management Commission and the Environmental Review Commission beginning 1 September 2003. The Division shall report its final findings and recommendations to the Environmental Management Commission and the Environmental Review Commission no later than 1 September 2005. The costs of implementing any air quality standards and plans to reduce the emission of carbon dioxide (CO2) from coal-fired generating units below the standards in effect on the date this act becomes effective, except to the extent that the emission of carbon dioxide (CO2) is reduced as a result of the reductions in the emissions of oxides of nitrogen (NOx) and sulfur dioxide (SO2) required to achieve the emissions limitations set out in G.S. 143-215.107D, as enacted by Section 1 of this act, shall not be recoverable pursuant to G.S. 62-133.6, as enacted by Section 9 of this act.

SECTION 14. On or before 1 June of each year, the Department of Environment and Natural Resources and the Utilities Commission shall report on the implementation of this act to the Environmental Review Commission and the Joint Legislative Utility Review Committee. The first report required by this section shall be submitted no later than 1 June 2003.

SECTION 15. If any section or provision of this act is declared unconstitutional or invalid by the courts, the unconstitutional or invalid section or provision does not affect the validity of this act as a whole or any part of this act other than the part declared to be unconstitutional or invalid.

SECTION 16. This act is effective when it becomes law except that G.S. 143-215.107D(i), as enacted by Section 1 of this act, is effective retroactively to 1 June 2002.

In the General Assembly read three times and ratified this the 19th day of June, 2002.

N.C. Utilities Commission
OFFICIAL COPY

March 27, 2009

Ms. Renne C. Vance, Chief Clerk
North Carolina Utilities Commission
4325 Mail Service Center
Raleigh, NC 27699-4325

Subject: Docket No. E-7, Sub 718
Duke Energy Carolinas, LLC NO_x and SO_2 Compliance Plan Annual Update

Record No. NC CAP 008

Dear Ms. Vance:

Duke Energy Carolinas, LLC is required by Senate Bill 1078 ("North Carolina Clean Air Legislation") to file information on or before April 1 of each year to update the North Carolina Utilities Commission ("Commission") of the progress to date, upcoming activities and expected plans to achieve the emissions limitations set out in G.S. 143-215.107D. Enclosed for filing are the original and thirty (30) copies of Duke Energy Carolinas' Compliance Plan Annual Update for 2009 that fully describe the Company's efforts to comply with the North Carolina Clean Air Legislation.

The current plan to meet the emission requirements for NO_x and SO_2 includes:

NO_x Control – Duke Energy Carolinas has completed installing controls for NO_x reductions originally planned under the North Carolina Clean Air Legislation. The combination of SCR, SNCR, and low NO_x burners, along with year round operation of these controls, has achieved and continues to maintain annual emissions below Duke Energy Carolinas' final annual target of 31,000 tons of NO_x per year.

SO_2 Control – The installation of wet scrubbers on our twelve largest generating units continues to be our plan for compliance with the 2009 and 2013 SO_2 caps under the North Carolina Clean Air Legislation. During 2008, we completed installation of wet scrubbers on both units at the Belews Creek Station, and we will complete the scrubber controls for the five units at Plant Allen in 2009. As a result of these projects, Duke Energy Carolinas expects to operate well below its 2009 SO_2 emission limit of 150,000 tons. With the final scrubber work at Cliffside Unit 5 to be completed in 2010, we expect to complete our SO_2 controls several years ahead of the 2013 final deadline in the Clean Air Legislation.

Exhibits A and B outline current unit specific technology selections, projected operational dates, expected emission rates, and the corresponding tons of emissions that demonstrate compliance with the legislative requirements to the best of Duke Energy Carolinas' knowledge at this time.

www.duke-energy.com

The current estimate of Environmental Compliance Costs for these pollution control projects is included in Exhibit C and reflects some improvement since last year.

Duke Energy Carolinas will continue to examine the technology selection, implementation schedule and associated costs. Annual updates will be provided to the Commission as required. If you have questions regarding any aspect of our plan, please do not hesitate to contact my office at 919-235-0955.

Sincerely,

George T. Everett

Duke Energy Carolinas, LLC

General Assembly of North Carolina Session 2001
Senate Bill 1078 – Improve Air Quality/Electric Utilities (NC Clean Air Legislation)
2009 Annual Data Submittal

1. **A detailed report on the investor-owned public utility's plans for meeting the emissions limitations set out in G.S. 143-215.107D.**

   Exhibits A and B outline the plan for technology selections by facility and unit, actual and projected operational dates, actual and expected emission rates, and the corresponding tons of emissions that demonstrate compliance with the provisions of G.S. 143-215.107D. Changes to the expected plan for meeting these emissions limitations as compared to past compliance plans are described below:

   NO_x Compliance

   - Emission Rate Changes – Expected rates for certain units have been adjusted in this 2009 update based on operating experience in 2008 with installed controls and targeted future performance.

   SO_2 Compliance

   - Emission Rate Changes – Expected rates have been adjusted in this 2009 update based on operating experience in 2008 and targeted future performance.
   - Unit Retirements – Retirement of Dan River 1 & 2 as discussed in the Certificate of Public Convenience and Necessity ("CPCN") Order for the Dan River Combined Cycle Project (Docket E-7 Sub 832) are now reflected in the 2013 SO_2 compliance plan.

2. **The actual environmental compliance costs incurred by the investor-owned public utility in the previous calendar year, including a description of the construction undertaken and completed during that year.**

   In the 2008 calendar year, Duke Energy Carolinas spent **$268,883,600** on activities in support of compliance with the provisions of G.S. 143-215.107D. Exact amounts associated with each project are provided in Exhibit C, and a description of the associated activities is provided below:

   Allen Steam Station FGD

   - Completed wastewater treatment system
   - Completed duct installation and insulation
   - Completed stack and flue liners
   - Installed and commissioned all major equipment for Unit 1 absorber operation
   - Completed limestone unloading and storage system
   - Received, installed and placed auxiliary transformers in service

<u>Belews Creek Steam Station FGD</u>

- Completed startup activities and achieved substantial completion milestone for the Unit 1 FGD
- Completed construction, commissioning and startup activities for the Unit 2 FGD and achieved substantial completion milestone
- Completed all systems performance testing
- Achieved overall project completion and closeout milestone

<u>Cliffside Steam Station Unit 5 FGD</u>

- Signed Amended and Restated Engineering, Procurement and Construction ("EPC") Agreement with Shaw, Stone & Webster
- Completed site bulk excavation and initial site preparation
- Completed dewatering building foundation
- Completed Unit 5 absorber vessel and absorber building foundations
- Completed chimney concrete shell
- Completed fabrication of all Unit 5 flue liners
- Received and set Unit 5 recycle pump motors

<u>Allen Steam Station SNCR, Unit 5</u>

- Completed installation and commissioning of the Unit 5 SNCR equipment

3. **The amount of the investor-owned public utility's environmental compliance costs amortized in the previous calendar year.**

As discussed in the December 20, 2007 order associated with rates and environmental compliance costs (Docket E-7 Sub 829), no additional amounts were amortized related to construction work activity in the 2008 calendar year in support of compliance with the provisions of G.S. 143-215.107D. **$1,050,000,000** was amortized in total for the program through year-end 2007.

4. **An estimate of the investor-owned public utility's environmental compliance costs and the basis for any revisions of those estimates when compared to the estimates submitted during the previous year.**

The estimated 'environmental compliance costs' as defined in G.S. 143-215.107D are provided in Exhibit C. While there has been no significant change to the scope or timing associated with any of these projects, forecasts for active projects have been updated as compared to the 2008 filing. The net overall reduction is $16,672,700 or approximately 1% of the previously forecasted costs and can mostly be attributed to unused contingency or risk items included in the previous forecast.

5. **A description of all permits required in order to comply with the provisions of G.S. 143-215.107D for which the investor-owned public utility has applied and the status of those permits or permit applications.**

<u>Allen Steam Station FGD</u>

- Request to revise NPDES Permit to include FGD wastewater – Submitted 1/24/2006; received revision 9/11/2006

- Submittal to DENR/ACOE regarding stream crossing of entrance road – Received permits 5/25/2006
- Air Permit Application – Submitted 4/10/2006; received Permit 6/30/2006
- Authorization to Construct (ATC) application for Wastewater Treatment System – Submitted 9/14/2006; received Permit to Construct 12/15/2006
- NOTE: all erosion control permits are in EPC contractor's scope for the Allen FGD Project and were received in 2006 (7/13/2006 and 12/18/2006). EPC contractor also received permit from NCDOT to improve Highway NC273 at the Allen FGD entrance road on 12/3/2008. Stack contractor also applied for air permit associated with flue liner fabrication on 11/1/2006 and received on 2/2/2007.

Belews Creek Steam Station FGD

- Request to revise NPDES Permit to include FGD wastewater – Submitted 6/30/2004; received Permit Revision 5/16/2005
- Initial Erosion Control Permit – Submitted 2/4/2005; received Permit 3/7/2005
- Landfill Site Suitability Application – Submitted 3/30/2005; received Site Suitability Approval Letter 6/19/2006
- Air Permit Application for Belews Creek FGD project – Submitted 4/18/2005; received Air Permit 2/6/2006
- Authorization to Construct (ATC) application for Wastewater Treatment System – Submitted 7/21/2005; received Permit to Construct 12/27/2005
- Authorization to Construct (ATC) application for Constructed Wetlands – Submitted 7/21/2005; received Permit to Construct 12/27/2005
- Revised Landfill Construction Plan Application – Submitted 9/30/2005; received Permit to Construct 6/29/2006
- Air Permit – Notice of Intent to Construct – Submitted 10/11/2005; received Permit to Construct 10/24/2005
- Authorization to Construct Sanitary Waste Lagoon – Submitted 3/23/2006; received Permit to Construct 9/1/2006
- Existing Sewage Lagoon Approval to Decommission – Submitted 10/31/2006; received permit 1/25/2007
- Permit to operate the FGD Residue Landfill – Submitted Certification Report on 9/28/2007; received permit 1/24/2008
- Erosion Control Permit to construct Used Oil Building – Submitted August 2008; received permit 10/10/2008
- Building Permit to construct Used Oil Building – Submitted August 2008; received permit 10/21/2008
- NOTE: Revisions to Erosion Control Permit submitted on various dates; most recent revised permit received 3/30/2006

Cliffside Steam Station Unit 5 FGD

- Air Permit Application for Cliffside Unit 5 FGD project – Submitted 12/16/2005; received 12/15/2006
- Request to revise NPDES Permit (including new Cliffside Unit 6) – Submitted 4/30/2007; Received Permit Revision 8/13/2007
- FAA Permit for Stack – received permit 10/30/2007

- Landfill Site Suitability Application – Submitted 1/7/2008; received 11/18/2008
- Authorization to Construct (ATC) application for Wastewater Treatment System – received Permit to Construct 9/22/2008
- Building Permits from Cleveland & Rutherford Counties for WFGD Control Room – received 1/26/2009
- Landfill Construction Plan Application – Submitted 12/18/08; expect approval in March 2009

Marshall Steam Station FGD

- Landfill Construction Plan Application – Submitted 4/1/04; received 2/4/05
- Sedimentation and Erosion Control Plan Permits
  - Limestone/Gypsum Conveyor – Submitted 6/17/04; received 7/9/04
  - Limestone/Gypsum Conveyor Expansion – Submitted 12/15/04; received 12/30/04
  - *Constructed Wetland Treatment System – Submitted 7/26/04; received 8/18/04*
  - Gypsum Landfill – Submitted 3/31/04; received 4/21/04
- Authorization to Construct (ATC) application for Solids Removal System – Submitted 11/19/04; received 12/22/04
- Authorization to Construct (ATC) application for Constructed Wetlands – Submitted 5/21/04; received 8/10/04
- Air Permit Revisions (for material handling issues) – Submitted 9/2/05; received 12/7/05
- Landfill Permit Documents (to line landfill) – Submitted 12/15/05; received 6/5/06
- Permit to Operate Marshall FGD Landfill – Submitted 10/27/06; received 11/21/06

6. **A description of the construction related to compliance with the provisions of G.S. 143-215.107D that is anticipated during the following year.**

Allen Steam Station FGD

- Begin operation of the Unit #1 absorber
- Begin operation of the Unit #3 absorber
- Complete gypsum handling system
- Complete final drawing turnover and archival
- Complete modification to Highway NC273 at the Allen FGD entrance road
- Complete generating unit tie-ins for Units 1-5

Cliffside Steam Station Unit 5 FGD

- Complete erection of the Unit 5 absorber vessel
- Complete initial tie-in to the Unit 5 stack and installation of blanking plates
- Receive and set Unit 5 auxiliary transformer and backfeed power
- Construct wastewater treatment facility
- Erect limestone and gypsum material handling equipment
- Complete steel erection for dewatering building, absorber building and reagent prep building
- Receive equipment and begin ball mill assembly

7. **A description of the applications for permits required in order to comply with the provisions of G.S. 143-215.107D that are anticipated during the following year.**

No additional applications for permits are expected.

8. **The results of equipment testing related to compliance with G.S. 143-215.107D.**

No additional equipment related testing occurred in 2008. The SNCR and SCR tests that occurred in prior years that were used in evaluating technology selections are repeated in this 2009 report for reference.

Allen Steam Station SNCR, Unit 1

- SNCR Equipment installation was completed in May 2003 followed by equipment acceptance testing in late 2003. During this test run, it was determined that the SNCR system met all commercial performance guarantees with approximately a 25% reduction in NOx with ammonia slip of less than 5 ppm at full load.
- During the 2004 ozone season, Allen Unit 1 achieved a 0.162# NO_x/MMBTU outlet rate, 5% better than the 0.17#/MMBTU target established for the unit.

Belews Creek Steam Station SCR

- SCR Equipment installation was completed in 2003 in support of the EPA/SIP Call requirements for NO_x reduction. While Belews Creek had operational problems in the first half of the 2004 ozone season, many of these issues were addressed on Belews Creek Unit 1 by August, 2004. Subsequently, tests performed during the months of August and September showed that when the SCR Equipment was in service during this time, emissions averaged 0.07# NO_x/MMBTU.

9. **The number of tons of oxides of nitrogen (NO_x) and sulfur dioxide (SO_2) emitted during the previous calendar year from the coal-fired generating units that are subject to the emissions limitations set out in G.S. 143-215.107D.**

   In the 2008 calendar year, **29,052.3** tons of NO_x and **132,405.8** tons of SO_2 were emitted from the North Carolina based Duke Energy Carolinas coal-fired units located in North Carolina and subject to the emissions limitations set out in G.S 143-215.107D.

10. **The emissions allowances described in G.S. 143-215.107D(i) that are acquired by the investor-owned public utility that result from compliance with the emissions limitations set out in G.S. 143-215.107D.**

    No emissions allowances have been acquired by Duke Energy Carolinas resulting from compliance with the emissions limitations set out in G.S. 143-215.107D.

11. **Any other information requested by the Commission or Department of Environment and Natural Resources.**

    No additional information has been requested to be included in this annual data submittal.

Expected Duke Energy Carolinas Compliance for NC Clean Air Legislation as of 4/1/2009

[1] SNCR Technology in service on Marshall Unit 3 was replaced by SCR Technology in 2008 in support of 8-hour ozone attainment demonstration in the Charlotte region. Similar to other SCR additions to comply with other laws besides the North Carolina Clean Air Legislation, costs associated with this Marshall Unit 3 SCR project are not "environmental compliance costs" within the meaning of that term as used in the North Carolina Clean Air Legislation.

Technology
Burners -- Overfired Air or Separated Overfired Air with associated Mill Classifier installations
SCR -- Selective Catalytic Reduction
SNCR -- Selective Non-Catalytic Reduction

Progress Energy

August 17, 2009

Mr. Dee Freeman
Secretary
North Carolina Department of Environment and Natural Resources
1601 Mail Service Center
Raleigh, NC 27699-1601

Dear ~~Secretary Freeman~~: Dee

In accordance with amended G.S. 62-110.1, Progress Energy Carolinas, Inc. (PEC, Company) submits the attached revised report regarding the current status of and future plans for compliance with the provisions of the North Carolina Clean Smokestacks Act.

As I have noted before, we regularly review and refine our compliance strategy, weighing a number of factors such as system load projections, new natural gas supply, natural gas-fired generation options, coal unit retirements, updated load and energy forecasts, updated fuel costs, updated capital and operating costs, and federal and state environmental legislative and regulatory developments. As a result of recent resource planning studies taking all of these drivers into account, PEC has determined that retirement of a coal-fired plant and replacement of that plant with combined-cycle natural gas-fired units represents a cost- effective resource plan for our system. Accomplishing this retirement and replacement by 2013 eliminates the need for a sulfur dioxide scrubber on Sutton Unit 3 in order to comply with the 2013 Clean Smokestacks Act limits. This revised strategy is described in the attached updated Clean Smokestacks report.

I want to thank you and your staff for your assistance and support of SB 1004, which will help facilitate our plans for natural-gas fired generation. We look forward to continuing our positive working relationship with the Department to facilitate fulfillment of the Company's obligations with this important law.

Please contact me at (919) 546-3775 if you have any questions.

Sincerely,

Caroline Choi
Director, Energy Policy and Strategy

VERIFICATION

STATE OF NORTH CAROLINA)
)
COUNTY OF WAKE)

NOW, BEFORE ME, the undersigned, personally came and appeared, Paula Sims, who first duly sworn by me, did depose and say:

That she is Paula Sims, Senior Vice President-Power Operations of Carolina Power & Light Company, d/b/a Progress Energy Carolinas, Inc.; she has the authority to verify the foregoing Progress Energy Carolinas, Inc. North Carolina Clean Smokestacks Act Calendar Year 2008 Progress Report - Revision; that she has read said revised Report and knows the contents thereof; are true and correct to the best of her knowledge and beliefs.

Paula Sims
Senior Vice President-Power Operations
Progress Energy Carolinas, Inc.

Subscribed and sworn to me
this 17 day of August, 2009.

Notary Public

Revised 2008 CSA Report

Progress Energy Carolinas, Inc. (PEC)
North Carolina Clean Smokestacks Act
Calendar Year 2008 Progress Report

On June 20, 2002, North Carolina Senate Bill 1078, also known as the "Clean Smokestacks Act," was signed into effect. This law requires significant reductions in the emissions of nitrogen oxides (NOx) and sulfur dioxide (SO_2) from utility owned coal-fired power plants located in North Carolina. Section 9(i), which is now incorporated as Section 62-133.6(i) of the North Carolina General Statutes, requires that an annual progress report regarding compliance with the Clean Smokestacks Act be submitted on or before April 1 of each year. The report must contain the following elements, taken verbatim from the statute:

1. A detailed report on the investor-owned public utility's plans for meeting the emissions limitations set out in G.S. 143-215.107D.
2. The actual environmental compliance costs incurred by the investor-owned public utility in the previous calendar year, including a description of the construction undertaken and completed that year.
3. The amount of the investor-owned public utility's environmental compliance costs amortized in the previous calendar year.
4. An estimate of the investor-owned public utility's environmental compliance costs and the basis for any revisions of those estimates when compared to the estimates submitted during the previous year.
5. A description of all permits required in order to comply with the provisions of G.S. 143-215.107D for which the investor-owned public utility has applied and the status of those permits or permit applications.
6. A description of the construction related to compliance with the provisions of G.S. 143-215.107D that is anticipated during the following year.
7. A description of the applications for permits required in order to comply with the provisions of G.S. 143-215.107D that are anticipated during the following year.
8. The results of equipment testing related to compliance with G.S. 143-215.107D.
9. The number of tons of oxides of nitrogen (NOx) and sulfur dioxide (SO_2) emitted during the previous calendar year from the coal-fired generating units that are subject to the emissions limitations set out in G.S. 143-215.107D.
10. The emissions allowances described in G.S. 143-215.107D(i) that are acquired by the investor-owned public utility that result from compliance with the emissions limitations set out in G.S. 143-215.107D.
11. Any other information requested by the Commission or the Department of Environment and Natural Resources.

Information responsive to each of these report elements follows. The responses are given by item number in the order in which they are presented above.

1. A detailed report on the investor-owned public utility's plans for meeting the emissions limitations set out in G.S. 143-215.107D.

Under G.S. § 143-215.107D(f), "each investor-owned public utility…may determine how it will achieve the collective emissions limitations imposed by this section." PEC originally submitted its compliance plan on July 29, 2002. Appendix A contains an updated version of this plan, effective July 31, 2009. We continue to evaluate various design, technology and generation options that could affect our future compliance plans.

2. **The actual environmental compliance costs incurred by the investor-owned public utility in the previous calendar year, including a description of the construction undertaken and completed that year.**

In 2008, Progress Energy Carolinas, Inc. incurred actual capital costs of $114,164,000.

Mayo

Engineering, procurement, and construction work continued throughout 2008. Major accomplishments included completion of the absorber, completion of the chimney, beginning construction of the waste water treatment system, and beginning commissioning and start-up activities. At year end, the project was 83% complete. Construction occurred on schedule to support final tie-in of the scrubber in March, 2009 with initial operation in early April, 2009.

Roxboro

The scrubbers on Units 2 and 4 operated successfully throughout the year. Construction of the scrubbers on Units 1 and 3 was completed with Unit 3 going into service on May 6, 2008 and Unit 1 going into service on December 16, 2008. At the end of 2008, the Roxboro project was 96% complete.

3. **The amount of the investor-owned public utility's environmental compliance costs amortized in the previous calendar year.**

Progress Energy Carolinas, Inc. amortized $15,000,000 in 2008.

4. **An estimate of the investor-owned public utility's environmental compliance costs and the basis for any revisions of those estimates when compared to the estimates submitted during the previous year.**

Appendix B contains the capital costs incurred toward compliance with G.S. § 143-215.107D through 2008 and the projected costs for future years through 2013. The costs shown are the net costs to PEC, excluding the portion for which the Power Agency is responsible. The estimated total capital costs, including escalation, are currently projected to be $1.068 billion. This represents a decrease of $334 million from the April 2009 cost estimate of $1.402 billion.

We regularly review and refine our compliance strategy, weighing a number of factors such as system load projections, new natural gas supply, natural gas-fired generation options, coal unit retirements, updated load and energy forecasts, updated fuel costs, updated capital and operating costs, and federal and state environmental legislative and regulatory developments. As a result of recent resource planning studies taking all of these drivers into account, PEC has determined that retirement of a coal-fired plant and replacement of that plant with a combined-cycle natural gas-fired unit represents a cost-effective resource plan for our system. Accomplishing this retirement and replacement by 2013 eliminates the need for a sulfur dioxide scrubber on Sutton Unit 3 in order to comply with the 2013 Clean Smokestacks Act limits.

With this plan, additional controls are not needed at Sutton 3 to meet the 2013 Clean Smokestacks Act limits, therefore that unit is no longer shown in Appendix B and the compliance costs have been reduced accordingly.

5. **A description of all permits required in order to comply with the provisions of G.S. 143-215.107D for which the investor-owned public utility has applied and the status of those permits or permit applications.**

Progress Energy applied for or received the following permits in 2008:

Roxboro Plant

Air Permit

Agency approval was received on April 23, 2008, which incorporated revised limits for SO_2 and NOx based on scrubber stack dispersion analysis.

Authorization to Construct

A request for an Authorization to Construct for revisions to the waste water system to temporarily reroute the backwash discharge line from the flush pond to the settling pond was submitted on April 10, 2008 and approved on April 18, 2008.

Mayo Plant

Erosion and Sediment Control Plan

Revision I to the Erosion and Sediment Control Plan for an increase in disturbed land for additional lay down area for the flue gas desulfurization system was submitted on April 17, 2008 and was approved on May 8, 2008.

Revision J to the Erosion and Sediment Control Plan for an increase in disturbed land (additional borrow area) was submitted on October 28, 2008 and was approved on December 17, 2008.

6. **A description of the construction related to compliance with the provisions of G.S. 143-215.107D that is anticipated during the following year.**

Mayo

The SO_2 scrubber at Mayo has been completed and began operation in early April, 2009. The bioreactor was placed into service in June, 2009. The remaining construction activities at Mayo for 2009 involve resolution of project punch-list items.

Roxboro

During 2009, the remaining construction activities at Roxboro involve final grading, paving and roadwork, resolution of project punch-list items, and additional construction related to the waste water treatment settling and flush ponds.

7. **A description of the applications for permits required in order to comply with the provisions of G.S. 143-215.107D that are anticipated during the following year.**

The following permit applications and permit approvals are anticipated for 2009:

Roxboro Plant

Authorization to Construct

A request for addendum for the Authorization to Construct for repairs to the gypsum settling pond and flush pond for the waste water treatment system was submitted on January 12, 2009. Agency approval was obtained on May 15, 2009.

A request for Authorization to Construct for an additional settling pond for the waste water treatment system was submitted on March 11, 2009. Agency approval was obtained on June 15, 2009.

Erosion and Sedimentation Control Plan

Additional plan revisions may be necessary as construction plans are further developed.

Mayo Plant

Air Permit

A renewal application for the Title V Air Permit was submitted on November 30, 2007. This application contained an update to include NSPS requirements for the emergency quench water pump. Agency approval for the quench water pump was obtained on May 27, 2009.

A permit application submitted for changes to the air permit on January 15, 2009 included revisions to the limestone silo control device arrangement and installation of a dry sorbent injection system for SO_3 control. Agency approval was obtained on May 27, 2009.

NPDES Permit

A revision to the NPDES permit to include limestone and gypsum truck traffic in support of scrubber operation was requested on February 11, 2009 with approval expected in the third quarter 2009.

Authorization to Construct

A request for an addendum to the Authorization to Construct for the waste water treatment system was submitted on September 12, 2008, which revises the design of the HDPE liner and base of the settling pond. Approval of this request was issued on February 23, 2009.

Erosion and Sedimentation Control Plan

Plan revisions may be necessary as construction plans are further developed.

8. The results of equipment testing related to compliance with G.S. 143-215.107D.

Performance testing of the scrubbers on Roxboro Units 3 and 4 was completed in 2008. The testing confirmed that each scrubber achieved its performance guarantee of 97% SO_2 removal efficiency.

Testing of the scrubber at Mayo is planned for later this year.

9. The number of tons of oxides of nitrogen (NOx) and sulfur dioxide (SO_2) emitted during the previous calendar year from the coal-fired generating units that are subject to the emissions limitations set out in G.S. 143-215.107D.

The affected coal-fired PEC units have achieved a 59% reduction in NOx and a 56% reduction in SO_2 since 2002. The total calendar year 2008 emissions from the affected coal-fired Progress Energy Carolinas units are:

NOx 24,190 tons
SO_2 94,221 tons

10. The emissions allowances described in G.S. 143-215.107D(i) that are acquired by the investor-owned public utility that result from compliance with the emissions limitations set out in G.S. 143-215.107D.

During 2008, PEC did not acquire any allowances as a result of compliance with the emission limitations set out in N.C. General Statute 143-215.107D.

11. Any other information requested by the Commission or the Department of Environment and Natural Resources.

There have been no additional requests for information from the North Carolina Utilities Commission or the Department of Environment and Natural Resources since the last report.

Appendix A

Progress Energy Carolinas, Inc's (PEC) Air Quality Improvement Plan Supplement

July 31, 2009

On June 20, 2002, Governor Easley signed into law SB1078, which caps emissions of nitrogen oxides (NOx) and sulfur dioxide (SO_2) from utility owned coal-fired power plants located in North Carolina. Under the law, G.S. § 143-215.107D, PEC's annual NOx emissions must not exceed 25,000 tons beginning in 2007 and annual SO_2 emissions must not exceed 100,000 tons beginning in 2009 and 50,000 tons beginning in 2013. These caps represent a 56% reduction in NOx emissions from 2001 levels and a 74% reduction in SO_2 emissions from 2001 levels for PEC.

PEC owns and operates 18 coal-fired units at seven plants in North Carolina. The locations of these plants are shown on Attachment 1. Under G.S. § 143-215.107D(f), "each investor-owned public utility…may determine how it will achieve the collective emissions limitations imposed by this section."

Nitrogen Oxides Emissions Control Plan

PEC has been evaluating and installing NOx emissions controls on its coal-fired power plants since 1995 in order to comply with Title IV of the Clean Air Act and the NOx SIP Call rule adopted by the Environmental Management Commission (EMC). Substantial NOx emissions reductions have been achieved (24,383 tons of NOx in 2007 compared with 112,000 tons in 1997), and compliance with the Clean Smokestacks Act's 25,000 ton cap was achieved in calendar year 2007. This target was achieved with a mix of combustion controls (which minimize the formation of NOx), such as low-NOx burners and over-fire air technologies, and post-combustion controls (which reduce NOx produced during the combustion of fossil fuel to molecular nitrogen), such as selective catalytic reduction (SCR) and selective non-catalytic reduction (SNCR) technologies.

Attachment 2 details PEC's North Carolina coal-fired electric generating units, their summer net generation capability, and installed NOx control technologies.

Sulfur Dioxide Emissions Control Plan

PEC has installed wet flue gas desulfurization systems (FGD or "scrubbers") to remove 97% of the SO_2 from the flue gas at its Asheville, Mayo and Roxboro boilers.

Wet scrubbers produce unique waste and byproduct streams. Issues related to wastewater permitting and solid waste disposal are being addressed for each site. PEC is treating the scrubber wastewater stream at the Asheville Plant using an innovative constructed wetlands treatment system to ensure compliance with discharge limits. A bioreactor technology will be used for the Roxboro and Mayo Plants.

A contract has been executed with a gypsum product end-user that will construct a facility near the Roxboro Plant to use the synthetic gypsum produced by the Roxboro and Mayo Plants for the manufacture of drywall products. PEC also has entered into an agreement that enables PEC to sell synthetic gypsum produced at the Asheville Plant.

We regularly review and refine our compliance strategy, weighing a number of factors such as system load projections, new natural gas supply, natural gas-fired generation options, coal unit retirements, updated load and energy forecasts, updated fuel costs, updated capital and operating costs, and federal and state environmental legislative and regulatory developments. As a result of recent resource planning studies taking all of these drivers into account, PEC has determined that retirement of a coal-fired plant and replacement of that plant with a combined-cycle natural gas-fired unit represents a cost-effective resource plan for our system. Accomplishing this retirement and replacement by 2013 eliminates the need for a sulfur dioxide scrubber on Sutton Unit 3 in order to comply with the 2013 Clean Smokestacks Act limits.

With this plan, additional controls are not needed at Sutton 3 to meet the 2013 Clean Smokestacks Act limits, therefore that unit is no longer shown in Appendix B and the compliance costs have been reduced accordingly.

Attachment 3 details PEC's North Carolina coal-fired electric generating units, their summer net generation capability, installed SO_2 control technologies and those planned for installation. As technologies evolve or other circumstances change, a different mix of controls may be selected. Attachment 3 also projects annual SO_2 emissions on a unit-by-unit basis based on the energy demand forecast and expected efficiencies of the SO_2 emissions controls employed. These projections are based on the planned removal technologies and PEC's current fuel and operating forecasts. This information is provided only to show how compliance may be achieved and is not intended in any way to suggest unit-specific emission limits. Actual emissions for each unit may be substantially different.

Contingency Measures Documentation

(This page intentionally left blank)

TABLE OF CONTENTS

LIST OF TABLES

LIST OF FIGURES

(This page intentionally left blank)

1 Introduction

Section 172(c)(9) requires that the nonattainment State Implementation Plan (SIP) contain specific measures that would take effect upon a State's failure to attain the fine particulate matter ($PM_{2.5}$) standard in a given area. These contingency measures must be fully adopted rules or control measures that are ready to be implemented quickly upon failure to meet the standard by the attainment date. Additionally, the contingency measures must be beyond the modeled controls needed to demonstrate attainment of the standard. Finally, the SIP should contain trigger mechanisms for the contingency measures, specify a schedule for implementation, and indicate that the measures will be implemented without further action by the State or by the United States Environmental Protection Agency (USEPA).

In the April 25, 2007, Clean Air Fine Particle Implementation Rule (72 FR 20586), the USEPA stated that the measures should provide for emission reductions equivalent to about one year of reductions needed for Reasonable Further Progress (RFP). However, since North Carolina is able to model attainment of the $PM_{2.5}$ National Ambient Air Quality Standard (NAAQS) within five years of designation, RFP is not required. The USEPA's guidance to the North Carolina Division of Air Quality (NCDAQ) was to have contingency measures that amounted to one-seventh of the emission reductions that occurred between the base year 2002 and the attainment year 2009, or approximately one year's worth of emission reductions.

The NCDAQ modeled the emission reductions that occurred as a result of the North Carolina Clean Smokestacks Act (CSA) legislation, which requires coal-fired power plants in North Carolina to reduce annual sulfur dioxide (SO_2) emissions by 49% by 2009 and by 74% by 2013 and to reduce the annual nitrogen oxides (NO_x) emissions by 78% by 2009. These emission reductions went well beyond what was needed to attain the annual $PM_{2.5}$ NAAQS of 15.0 microgram per cubic meter ($\mu g/m^3$), evident by the predicted future design values being over 1.5 $\mu g/m^3$ below the $PM_{2.5}$ NAAQS. Therefore, the NCDAQ thought it was unreasonable to require contingency measures of such a large quantity when the State had already reduced a significant amount of the precursor pollutants throughout the State.

Another suggestion by the USEPA was to do sensitivity modeling to determine approximately the level of emission reductions needed to model 15.0 $\mu g/m^3$ and use one-seventh of this emission reduction level to determine the amount of contingency measures needed. The NCDAQ did not believe it was a wise use of State resources to perform further modeling when both nonattainment areas have already attained the annual $PM_{2.5}$ NAAQS.

Therefore, the NCDAQ has documented the expected 2009 utility emissions, based on the latest CSA compliance plans, which go beyond what was modeled in the attainment demonstration, as well as the estimated emission reductions expected in 2010. All of these emission reductions will take place without further action from the State. Since the purpose of the contingency measures is to provide for the implementation of measures in the event an area fails to attain the NAAQS, the NCDAQ believes it has met the spirit of this requirement.

2 Region for Contingency Measures

Since the most significant man-made emissions contributor to $PM_{2.5}$ formation in North Carolina is the precursor pollutant SO_2, the NCDAQ has elected to have only SO_2 contingency measures. Under the section for RFP in the Implementation Rule, geographic coverage of emission sources is discussed (72 FR 20636). Due to the regional nature of $PM_{2.5}$, it makes senses that sources of SO_2 outside of the nonattainment area may be impacting the $PM_{2.5}$ concentrations in the nonattainment area. Therefore, the USEPA is allowing states to consider emission reductions from emission sources up to 200 kilometer (km) beyond the nonattainment area for contingency measures. The NCDAQ has elected to go beyond the nonattainment areas for its contingency measure plan.

For the Hickory nonattainment area's contingency measures, the NCDAQ has elected to include all counties that are within, or bisected by, a 75 km circle from the nonattainment area boundary. Figure 2-1 displays the region that contingency measures are being considered for the Hickory nonattainment area. The yellow and blue lines represents a 75 km and 200 km radius, respectively, from the nonattainment area boundary. The emissions from all counties that are shaded are considered in the analysis. For simplicity, these counties will be referred to as the region of influence for the Hickory nonattainment area.

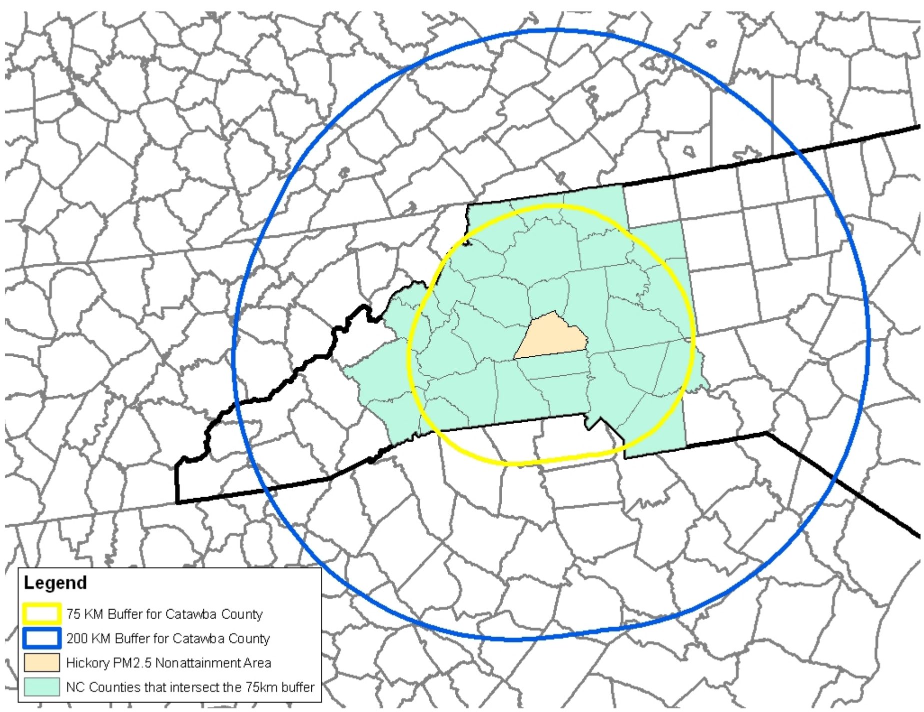

Figure 2-1. The shaded counties represent the region where SO_2 contingency measures were considered for the Hickory nonattainment area.

Similarly, for the Greensboro/Winston-Salem/High Point nonattainment area (referred to as the Triad area), all counties within, or bisected by, a 75 km circle from the nonattainment area boundary are considered for contingency measures. Figure 2-2 displays the region that contingency measures are being considered for the Triad nonattainment area. Again, the yellow and blue lines represents a 75 km and 200 km radius, respectively, from the nonattainment area boundary. The emissions from all counties that are shaded are considered in the analysis. For simplicity, these counties will be referred to as the region of influence for the Triad nonattainment area.

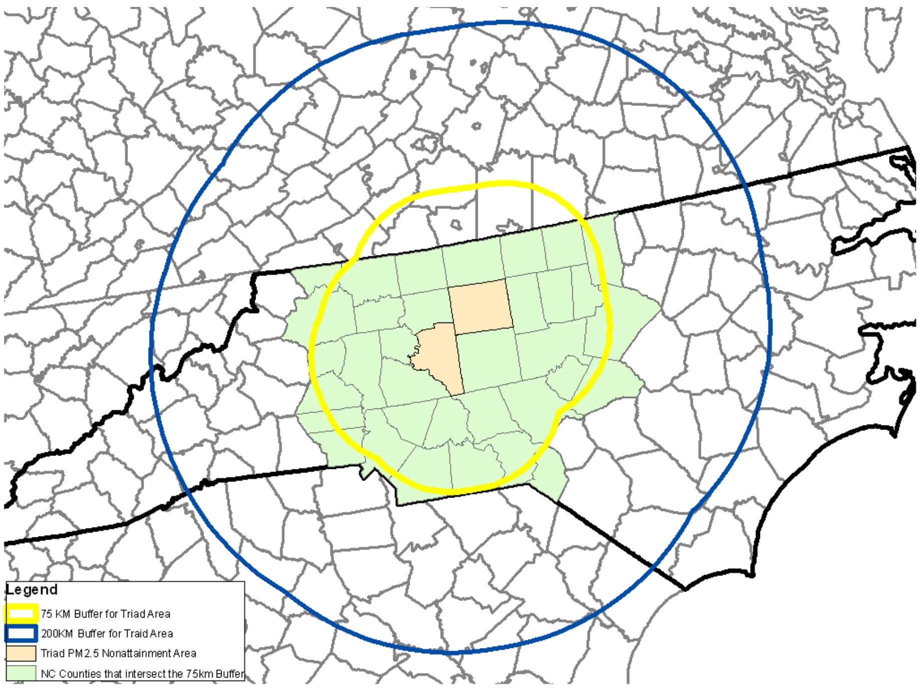

Figure 2-2. The shaded counties represent the region where SO_2 contingency measures were considered for the Triad nonattainment area.

3 2002 Baseline SO_2 Emissions

Table 3-1 displays the 2002 baseline SO_2 emissions, by source sector, for the counties located within the region of influence for the Hickory nonattainment area. The total 2002 baseline SO_2 emissions for the region of influence is 215,080 tons per year. Table 3-2 displays the 2002 baseline SO_2 emissions, by source sector, for the counties located within the region of influence for the Triad nonattainment area. The total 2002 baseline SO_2 emissions for the region of influence is 401,290 tons per year.

4 Contingency Measures

As stated above, the NCDAQ has elected to have only SO_2 contingency measures. As can be seen in Tables 3-1 and 3-2, the vast majority of the SO_2 emissions come from point sources (approximately 96%). Therefore, the NCDAQ only looked at the point source sector for emissions reductions, and specifically the coal-fired power plants since they make up the majority of the point source SO_2 emissions.

In June 2002, the North Carolina General Assembly enacted the CSA, requiring coal-fired power plants to reduce annual SO_2 emissions by 49% by 2009 and 74% by 2013. Additionally, this legislation required reductions in annual nitrogen oxide emissions. One of the first state laws of its kind in the nation, this legislation provides a model for other states in controlling multiple air pollutants from older coal-fired power plants. The reduction in emissions achieved through the CSA are not allowed to be traded in the National emissions trading program, but rather are held in trust by the citizens of North Carolina.

Since the first phase-in year is 2009, which coincides with the attainment year for the $PM_{2.5}$ nonattainment areas, some of the SO_2 reductions expected from the CSA were modeled as part of the attainment demonstration. However, not all of the units expecting to have controls operational in 2009 were modeled at full compliance. Additionally, one facility's controls will be fully implemented during the middle of 2010. Since these additional emission reductions were not modeled as part of the attainment demonstrations and will take place in 2010 without further action from the State or the USEPA, they can be considered as contingency measures. Additionally, when the attainment demonstration modeling project started, the latest compliance plan for CSA was the 2006 plan. The utility companies now have a better understanding of what the SO_2 emissions will be in 2009 and are reflected in the 2009 CSA compliance plan. The difference between the emissions modeled and the current expectations for the 2009 emissions are further emission reductions that are expected to occur that were not modeled as part of the attainment demonstration.

All the Duke Energy and Progress Energy units that are in the area of influence for both nonattainment areas were reviewed to determine the difference in the 2009 emissions modeled and the current expectation based on the latest CSA compliance plan. The units that were considered for the analysis of emission reductions to occur in 2010 include:

- Duke Energy Allen Steam Station, units 1 through 5, located in Gaston County;
- Duke Energy Cliffside, unit 5, located in Rutherford County; and
- Progress Energy Mayo, unit 1, located in Person County.

The table below shows the 2009 emissions modeled based on the 2006 CSA compliance plan, the expected 2009 emissions based on the latest CSA compliance plan and the difference between them. The 2006 CSA compliance plan is attached to this appendix and the 2009 CSA compliance plan can be found in Appendix M.

Table 4-1 Comparison of Modeled 2009 Emissions to Expected 2009 Emissions

Unit	Area of Influence	2009 Modeled Emissions	Expected 2009 Emissions	Difference
Duke Energy Facilities				
Allen Unit 1	Both Areas	2,659	1,336	-1,323
Allen Unit 2		2,488	1,842	-646
Allen Unit 3		9,864	5,694	-4,170
Allen Unit 4		10,746	6,556	-4,190
Allen Unit 5		4,215	4,333	118
Belews Unit 1	Triad Area	5,927	5,476	-451
Belews Unit 2		4,579	4,535	-44
Buck Unit 3	Both Areas	1,542	1,017	-525
Buck Unit 4		983	642	-341
Buck Unit 5	Both Areas	4,412	4,472	60
Buck Unit 6		4,410	4,784	374
Dan River Unit 1	Triad Area	2,184	1,919	-265
Dan River Unit 2		2,336	2,081	-255
Dan River Unit 3		5,202	5,062	-140
Cliffside Unit 1	Hickory Area	1,170	488	-682
Cliffside Unit 2		1,198	469	-729
Cliffside Unit 3		2,243	1,385	-858
Cliffside Unit 4		2,213	1,414	-799
Cliffside Unit 5		31,193	28,476	-2717
Marshall Unit 1	Both Areas	1,952	1,742	-210
Marshall Unit 2		1,940	1,742	-198
Marshall Unit 3		3,539	3,439	-100
Marshall Unit 4		3,333	3,354	21
Riverbend Unit 4	Both Areas	3,635	3,344	-291
Riverbend Unit 5		3,641	3,219	-422
Riverbend Unit 6		5,799	5,320	-479
Riverbend Unit 7		5,942	5,260	-682
Progress Energy Facilities				
Asheville Unit 1	Hickory Area	864	1,003	139
Asheville Unit 2		886	770	-116
Cape Fear Unit 5	Triad Area	6,249	4,829	-1,420
Cape Fear Unit 6		7,725	6,705	-1,020
Mayo Unit 1	Triad Area	14,361	5,232	-9,129
Roxboro Unit 1	Triad Area	1,741	1,341	-400
Roxboro Unit 2		2,853	2,687	-166
Roxboro Unit 3		2,928	2,716	-212
Roxboro Unit 4		2,363	3,120	757
Total Emissions		169,315	137,804	-31511

This difference of 31,511 tons per year of SO_2 emissions represents emissions that were not modeled but are expected to occur in 2009 within the area of influences of the two nonattainment areas combined. The expected versus modeled SO_2 emissions will be 25,749 tons per year lower within the Triad's area of influence and 18,766 tons per year lower within the Hickory's area of influence.

To estimate the additional amount of SO_2 emissions that will be reduced in 2010, the 2009 annual SO_2 emissions that were listed in the 2009 CSA compliance plan were subtracted from the 2013 annual emissions. For the unit that the control equipment is expected to come on-line in the middle of 2010, only a half-year compliance was considered, i.e., half of the controlled emissions plus half of the uncontrolled emissions. The 2013 annual emissions represent full implementation of the control measures and is a conservative surrogate for estimating 2010 SO_2 emissions since 2013 energy demands will be higher than 2010 and therefore the expected emissions for 2013 will be slightly higher than 2010. Table 4-2 displays the expected compliance period, the expected 2009 emissions, the estimated 2010 emissions, area impacted and the estimated emission reductions for the units considered for the contingency measures.

Table 4-2 Estimated Emission Reductions Expected from Clean Smokestacks Act

Unit	Compliance Period	Area of Influence	2009 SO2 (tons/year)	2010 SO2 (tons/year)	Reductions (tons/year)
Allen –1	Early 2009	Both areas	1,336	660	- 676
Allen – 2	Early 2009		1,842	644	-1,198
Allen – 3	Late 2009		5,694	1,239	-4,455
Allen – 4	Late 2009		6,556	1,321	-5,235
Allen – 5	Mid 2009		4,333	1,134	-3,199
Cliffside – 5	Mid 2010	Hickory	28,476	15,667	-12,809
Mayo – 1	Late 2009	Triad	5,232	1,969	-3,263

To demonstrate that the expected emission reductions have an impact on the nonattainment areas, the NCDAQ relied on the back trajectory analysis that was done for the $PM_{2.5}$ nonattainment boundary recommendation package. For the details of how these trajectory analyses were created, please refer to the documentation used for the boundary recommendation package attached to this appendix.

Figure 4-1 displays the location of the utilities subject to the CSA. Figures 4-2 and 4-3 displays the back trajectory analysis for the Hickory and Lexington $PM_{2.5}$ monitors, respectively. The back trajectories were overlaid on a map with the utility locations displayed with red dots. It is clear from these figures that the air masses pass over or near large utility plants on days when high $PM_{2.5}$ levels were observed at the monitors.

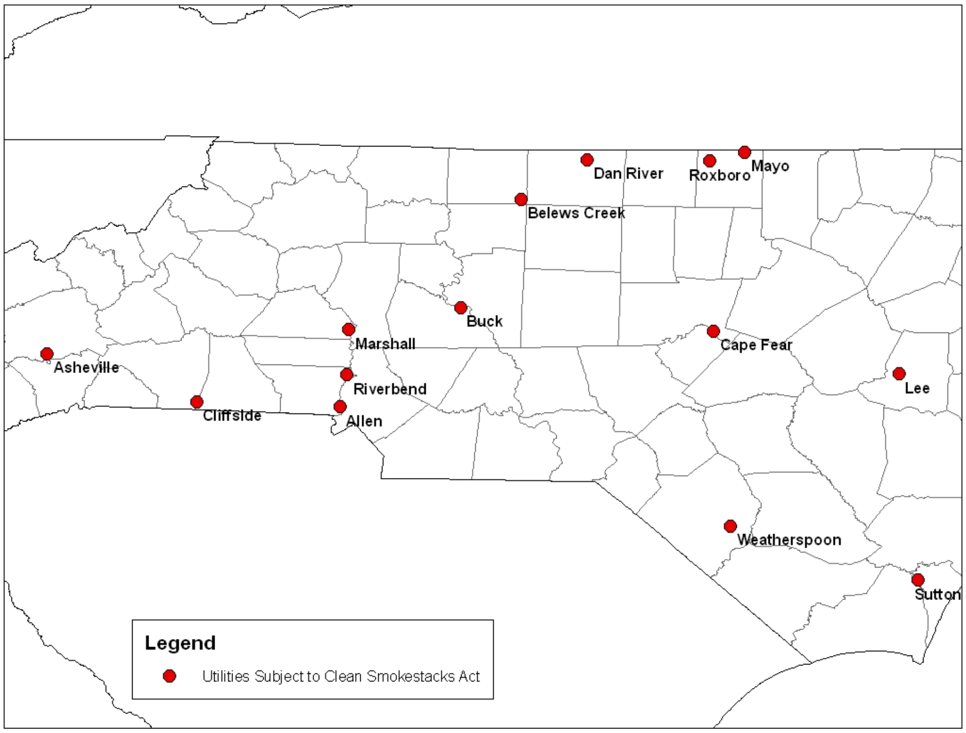

Figure 4-1. Location of the Utilities Subject to the CSA.

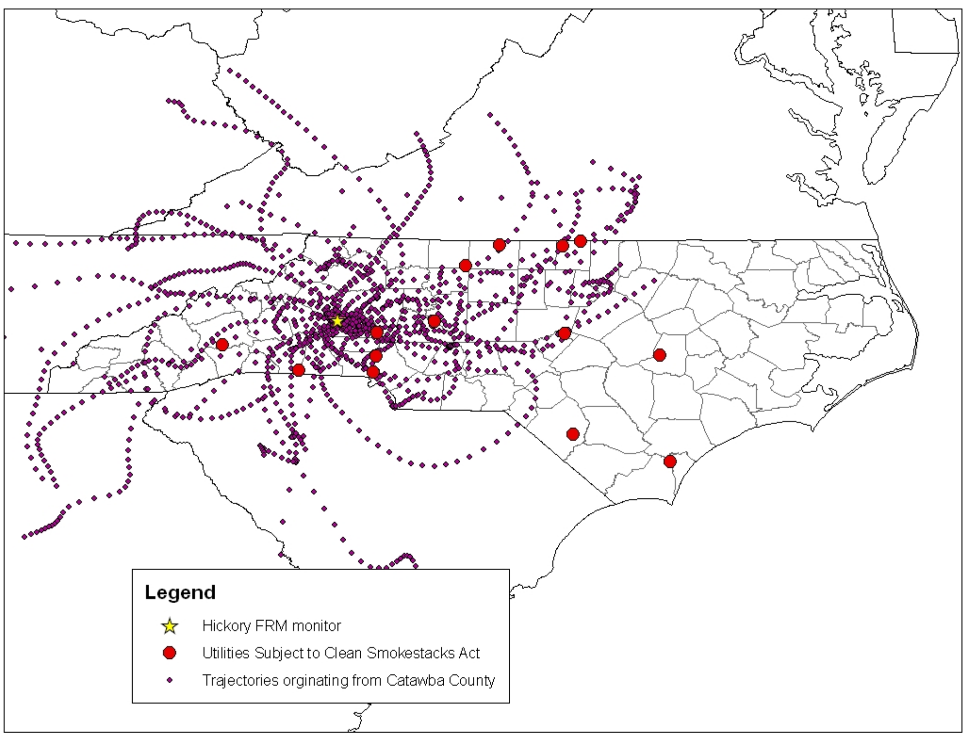

Figure 4-2. Back Trajectory Analysis for Hickory $PM_{2.5}$ Monitor.

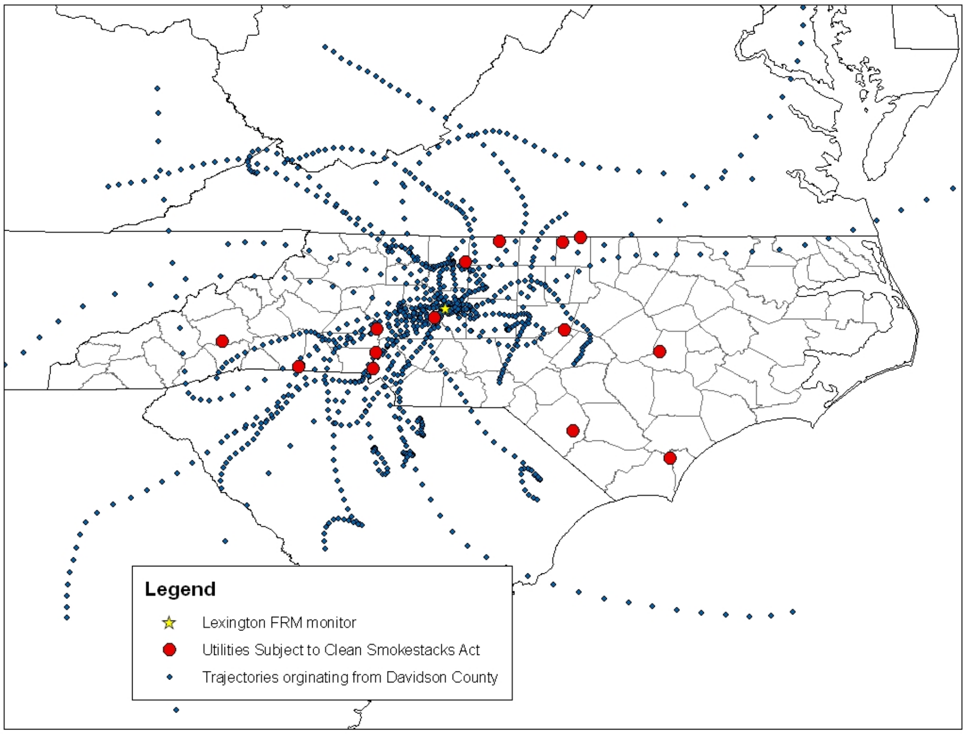

Figure 4-3. Back Trajectory Analysis for Lexington $PM_{2.5}$ Monitor.

4.1 Hickory Area Contingency Measure Reductions

In order to estimate the total emission reductions from point sources in 2010, the other point sources located within the region of influence had to be grown from 2009 to 2010. The NCDAQ estimated that the other point sources within the region of influence would grow approximately 50 tons.

The total reduction that is expected beyond the emissions that were modeled in the attainment demonstration is 18,766 tons in 2009 emissions and approximately 27,500 tons per year that are expected to occur between 2009 and 2010, for a total of over 46,000 tons per year of SO_2 emissions reduced. This is approximately a twenty-two percent reduction from the 2002 baseline SO_2 emissions for the Hickory region of influence, which is a significant reduction of emissions. This reduction in emissions beyond what was modeled should satisfy the contingency measure requirement for this nonattainment area.

4.2 Triad Area Contingency Measure Reductions

Again, in order to estimate the total emission reductions from point sources in 2010 for the Triad region of influence, the other point sources located within the region of influences had to be grown from 2009 to 2010. The NCDAQ estimated that the other point sources within the region of influence would grow approximately 85 tons.

The total reduction that is expected beyond the emissions that were modeled in the attainment demonstration is 25,749 tons in 2009 emissions and approximately 18,000 tons per year that are expected to occur between 2009 and 2010, for a total of over 43,000 tons per year of SO_2 emissions reduced. This is approximately an eleven percent reduction from the 2002 baseline SO_2 emissions for the Triad area of influence, which again is a significant reduction of emissions. This reduction in emissions beyond what was modeled should satisfy the contingency measure requirement for this nonattainment area.

5 Conclusions

The NCDAQ believes that existing control measures required by the North Carolina Clean Smokestacks Act results in a sufficient amount of SO_2 emission reductions to adequately meet the contingency measure requirements of Section 172(c)(9). The Hickory area is expected to achieve over 46,000 tons per year of SO_2 reduction and the Triad area is expected to achieve over 43,000 tons per year SO2 reductions. Considering the purpose of contingency measures is to require further emission reductions in case a nonattainment area does not attain the NAAQS by the prescribed attainment date and both nonattainment areas in have already attained the $PM_{2.5}$ NAAQS, the NCDAQ firmly believes that North Carolina has more than fulfilled the contingency measure requirement.

March 30, 2006

Ms. Geneva S. Thigpen, Chief Clerk
North Carolina Utilities Commission
4325 Mail Service Center
Raleigh, NC 27699-4325

2006
Clerk's Office
N.C. Utilities Commission

Subject: Docket No. E-7, Sub 718
Duke Power Compliance Plan Annual Update NO_x Control

Record No. NC CAP 005

Dear Ms. Thigpen:

Duke Power is required by Senate Bill 1078 to file information on or before 1 April of each year to update the Commission on progress to date, upcoming activities and expected strategies to achieve the emissions limitations set out in G.S. 143-215.107D. Enclosed for filing are the original and thirty (30) copies of Duke Power's Compliance Plan Annual Update for 2006 that fully describe the company's efforts to comply with this clean air legislation.

The current plan to meet the emission requirements for NO_x and SO_2 includes:

NO_x Control – The installation of Selective Catalytic Reduction (SCR) on Cliffside Steam Station Unit 5 and Belews Creek Steam Station Units 1&2 has been completed. Our NOx plans include installation of Selective Non-Catalytic Reduction (SNCR) at 15 units, and burner work at our remaining sites with the exception of Cliffside Units 1-4. With these installations, Duke can demonstrate compliance with our 2007 and 2009 NOx caps under Senate Bill 1078.

SO_2 Control – The installation of wet scrubbers on our twelve largest generating units continues to be our plan. We have worked with the Department of Environment and Natural Resources on a plan to accelerate the scrubber installation schedule at Plant Allen. Acceleration of the Allen scrubbers maintains our design and construction continuity and helps assure Duke Power can meet the recently finalized Clean Air Interstate Rule. Costs for our scrubber projects have gone up at Plant Allen due to increases in material (steel and petroleum-based products) and labor costs. Explanations for these increases have been shared with the Public Staff.

Exhibits A and B outline current unit specific technology selections, projected operational dates, expected emission rates, and the corresponding tons of emissions that demonstrate compliance with the legislative requirements to the best of Duke Power's knowledge at this time. The projected estimates of 'environmental compliance costs' for these pollution control projects are included in Exhibit C.

Duke Power will continue to examine the technology selection, implementation schedule and associated costs. Annual updates will be provided to the NC Utilities Commission as required. If you have questions regarding any aspect of our plan, please do not hesitate to contact my office at 919-235-0955.

Sincerely,

George T. Everett

Duke Power Company

General Assembly of North Carolina Session 2001
Senate Bill 1078 – Improve Air Quality/Electric Utilities (NC Clean Air Legislation)
2006 Annual Data Submittal

1. A detailed report on the investor-owned public utility's plans for meeting the emissions limitations set out in G.S. 143-215.107D.

Exhibits A and B outline the plan as of this date for technology selections by facility and unit, projected operational dates, expected emission rates, and the corresponding tons of emissions that demonstrate compliance with the provisions of G.S. 143-215.107D. Changes to the expected plan for meeting these emissions limitations as compared to past compliance plans are highlighted in these exhibits and described below:

<u>NO_x Compliance</u>

- Technology Change – The Dan River Unit 3 SNCR project has been deleted from the plan because of the expected high cost to install and operate a single unit SNCR system.
- Schedule Changes – Numerous project schedule changes are included in this 2006 update:
  - The Buck Units 3&4 Burner projects were accelerated from 2008 to the spring of 2007 to better support compliance with the Phase I cap of 35,000 tons per year.
  - The Buck Unit 5 SNCR project was accelerated to the fall of 2006 to better align with the Buck Unit 6 SNCR schedule and allow for the most effective outage and work sequencing.
  - The Dan River Units 2&3 Burner projects were delayed until the fall of 2006 because of the elimination of the pollution control project (PCP) exemption in July 2005 and its effect on the permitting process.
  - The Riverbend Unit 4 SNCR project was accelerated to the spring of 2007 for outage optimization and to better support compliance with the Phase I cap of 35,000 tons per year.
  - The Riverbend Units 6&7 SNCR projects were accelerated to the fall of 2006 for outage optimization.
- Rate Changes – Expected rates have been adjusted in this 2006 update based on 2005 operational performance, project schedule changes and other factors:
  - Allen Units 1-5 expected rates were adjusted based on 2005 ozone season performance; Allen Units 1&3 SNCR operation demonstrated that 0.16 could be achieved with system optimization.
  - The Belews Creek Units 1&2 expected rates were also lowered based on 2005 ozone season results.
  - The Buck Units 3&4 rates were adjusted as a result of the Burner project accelerations.

- Buck Units 5&6 expected rates were lowered based on 2005 ozone season performance along with SNCR equipment guarantees.
- Cliffside Units 1&2 expected rates increased based on 2005 ozone season performance.
- The Cliffside 5 expected rate decreased slightly based on 2005 ozone season performance of the SCR equipment.
- The Dan River Unit 2 expected rate was adjusted slightly based on expected performance.
- The Dan River Unit 3 expected rate was changed based on expected performance of the burner equipment, the burner outage schedule and the deletion of the SNCR equipment.
- The Marshall Unit 2 expected rate changed due to the timing of the SNCR installation outage and 2005 ozone season performance.
- The Marshall Units 3&4 expected rates changed based on the 2005 ozone season performance and the current SNCR installation outage schedule; the 2009 expected rates for these units reflect expected further optimization of the SNCR equipment.
- The Riverbend expected rates were adjusted based on the SNCR installation schedule changes and lower SNCR equipment guarantees.

Because the expected 2009 NO_x emissions are so close to the 31,000 ton limit, Duke will continue to evaluate options to improve performance, including the addition of SCR on Marshall Unit 3 and reconsideration of a Dan River Unit 3 SNCR system.

<u>SO_2 Compliance</u>

- New Pulverized Coal (PC) Units – This 2006 update includes the proposed addition of two new 800 MW coal units in 2011 and 2012 at the Cliffside Steam Station. The 2013 expected compliance plan includes these units along with the associated retirement of Cliffside Units 1-4 if the new units are put in service.
- Schedule Changes – Both the Belews Creek Unit 2 and Cliffside Unit 5 FGD (Scrubber) operational dates were adjusted in this plan. The Belews Creek Unit 2 operational date has shifted slightly from the fall of 2007 until early 2008; the Cliffside 5 operational date has shifted out to 2010 to better align with the proposed operational dates for the new units.
- Rate Changes – Expected rate changes have been adjusted in this 2006 update based on changes to operational dates and other considerations:
  - The Allen expected rates were adjusted based on the new sequencing of FGD operational dates in 2009; Allen Units 1, 2 & 5 are now expected to be operational in the spring of 2009 and supported by one FGD absorber while Units 4&5 are expected to be operational in the fall of 2009 and supported by the second FGD absorber.
  - The Buck rates were adjusted based on the expected use of a lower sulfur coal
  - The Cliffside rates were adjusted based on the expected use of a higher sulfur coal and the FGD operational date change for Unit 5.

2. **The actual environmental compliance costs incurred by the investor-owned public utility in the previous calendar year, including a description of the construction undertaken and completed during that year.**

In the 2005 calendar year, Duke Power Company spent $346,420,000 on activities in support of compliance with the provisions of G.S. 143-215.107D. Exact amounts associated with each project are provided in Exhibit C, and a description of the associated activities is provided below:

Allen Steam Station FGD

- Initiated Phase II portion of project including preliminary engineering, project scope development, plant interface studies, contract exhibits and project estimates

Belews Creek Steam Station FGD

- Executed the Engineering, Procurement and Construction (EPC) agreement with the Consortium of ALSTOM Power Inc. and Shaw/Stone & Webster (Alstom/Shaw)
- Mobilized the project's construction management team to the Belews Creek site and initiated construction activities
- Completed the installation of a new fuel oil tank and the removal of the existing fuel oil and elevated water storage tanks from the area planned for the main portions of the FGD system
- Removed the existing hill from the area planned for the main portions of the FGD system (approximately 300,000 cubic yards of soil and rock)
- Initiated construction of the major foundations for the FGD system
- Completed approximately 20% of the overall project (approximately 10% of the construction activities)

Cliffside Steam Station Unit 5 FGD

- Continued preliminary construction planning and development of conceptual site layout

Marshall Steam Station FGD

- Completed fabrication and installation of absorber outlet ducts and flue liners
- Completed site earthwork for gypsum landfill, wetlands (including plantings)
- Completed all remaining major building and equipment foundations including wetlands equalization basin, transformers, switchgear and major tanks
- Completed structural steel erection for absorber, reagent prep, dewatering buildings, transfer towers 1&2, limestone unloading & stackout, and duct support sections 1 through 11
- Completed assembly of ball mills, absorber recycle pumps, hydrocyclones, dewatering belt filters, limestone unloading and major field-erected tanks
- Completed installation of underground piping, above group piping systems and makeup water station tie-ins

- Completed majority of transformers setting, switchgear and underground ductbank work
- Completed majority of material handing equipment installation
- Completed erection of all wastewater treatment tanks and sludge press building

Allen Steam Station SNCR, Unit 2

- Completed preliminary engineering

Allen Steam Station SNCR, Unit 3

- Completed installation of Unit 3 SNCR equipment and supporting plant air equipment

Allen Steam Station SNCR, Unit 4

- Completed detailed engineering and received mechanical, electrical and installation drawings
- Procured material in preparation for 2006 installation

Allen Steam Station SNCR, Unit 5

- Completed preliminary engineering

Buck Steam Station SNCR, Unit 5

- Completed preliminary engineering

Buck Steam Station SNCR, Unit 6

- Completed preliminary engineering

Dan River Steam Station Burners, Unit 2

- Completed detailed engineering and material procurement in preparation for 2006 installation

Dan River Steam Station Classifiers, Unit 2

- Completed installation of advanced static classifier technology in fall of 2005

Dan River Steam Station Burners, Unit 3

- Completed detailed engineering and material procurement in preparation for 2006 installation

Dan River Steam Station Classifiers, Unit 3

- Completed installation of advanced static classifier technology in fall of 2005

Marshall Steam Station SNCR, Unit 1

- Completed detailed engineering and received mechanical, electrical and installation drawings
- Procured material in preparation for 2006 installation

Marshall Steam Station SNCR, Unit 2

- Completed preliminary engineering

Marshall Steam Station SNCR, Unit 3

- Completed installation of SNCR equipment

Marshall Steam Station SNCR, Unit 4

- Continued preliminary engineering and planning for project

Riverbend Steam Station SNCR, Unit 4

- Completed preliminary engineering

Riverbend Steam Station Burners, Unit 5

- Incurred final costs associated with project to install burners on unit in early 2005

Riverbend Steam Station SNCR, Unit 5

- Completed preliminary engineering

Riverbend Steam Station Burners, Unit 6

- Completed installation of SOFA technology on unit in spring of 2005

Riverbend Steam Station Classifiers, Unit 6

- Completed installation of advanced static classifier technology in spring of 2005

Riverbend Steam Station SNCR, Unit 6

- Completed preliminary engineering

Riverbend Steam Station SNCR, Unit 7

- Completed preliminary engineering

3. **The amount of the investor-owned public utility's environmental compliance costs amortized in the previous calendar year.**

In the 2005 calendar year, **$311,236,000** was amortized related to construction work activity in support of compliance with the provisions of G.S. 143-215.107D. **$637,429,142** in total has now been amortized for the program through year-end 2005.

4. **An estimate of the investor-owned public utility's environmental compliance costs and the basis for any revisions of those estimates when compared to the estimates submitted during the previous year.**

The estimated 'environmental compliance costs' as defined in G.S. 143-215.107D are provided in Exhibit C. Changes to the expected costs as compared to past compliance plans are highlighted in this exhibit and described below:

- Allen FGD Project – The Allen FGD estimate has increased since 2005 and is attributable to ramp up in the power generation and/or environmental retrofit construction market, and continued escalation of labor costs. The Cliffside 5 FGD estimate is also affected by these issues, but is expected to be offset by savings if this project is executed in conjunction with the proposed construction of new generating units at the Cliffside station.
- SNCR Projects – In addition to the deletion of the Dan River Unit 3 SNCR project, refinement of the SNCR work scope at each location has resulted in a lower overall estimated cost. The most significant change to this scope over the last year has been to remove the Riverbend central reagent (urea) distribution center scope of work and replace with individual station storage and dilution water equipment.
- Dan River Unit 3 Burner Project – The Dan River Unit 3 Burner project experienced some costs increases estimated at $470,000 due to the delay in installation discussed above.

5. **A description of all permits required in order to comply with the provisions of G.S. 143-215.107D for which the investor-owned public utility has applied and the status of those permits or permit applications.**

<u>Belews Creek Steam Station FGD</u>

- NPDES Permit Modification – Submitted 6/30/04; received 5/16/05
- Initial Erosion Control Permit – Submitted 2/4/05; received 3/7/05
- Landfill Site Suitability Application – Submitted 3/30/05; expect Site Suitability by April 2006
- Air Permit Application for Belews Creek FGD project – Submitted 4/18/05; received 2/6/06
- Request to revise NPDES Permit to include FGD wastewater – Submitted 6/30/04; received permit revision 5/16/05
- Authorization to Construct (ATC) application for Wastewater Treatment System – Submitted 7/21/05; received 12/27/05
- Authorization to Construct (ATC) application for Constructed Wetlands – Submitted 7/21/05; expect final permit April 2006
- Revised Landfill Construction Plan Application – Submitted 9/30/05; expect permit July 2006
- Air Permit – Notice of Intent to Construct – Submitted 10/11/05; received 10/24/05
- NOTE: Revisions to Erosion Control Permit submitted on various dates; most recent revised permit received 12/20/05

Cliffside Steam Station Unit 5 FGD

- Air Permit Application – Submitted 12/16/05
- NOTE: A complimentary PSD permit application was submitted on this same 12/16/05 date for the proposed new generating units at the Cliffside site. If this associated PSD air permit is not approved or withdrawn, it will be necessary to submit a revised Air Permit Application for a standalone Unit 5 FGD.

Marshall Steam Station FGD

- Landfill Construction Plan Application – Submitted 4/1/04; received 2/4/05
- Sedimentation and Erosion Control Plan Permits
  - Limestone/Gypsum Conveyor – Submitted 6/17/04; received 7/9/04
  - Limestone/Gypsum Conveyor Expansion – Submitted 12/15/04; received 12/30/04
  - Constructed Wetland Treatment System – Submitted 7/26/04; received 8/18/04
  - Gypsum Landfill – Submitted 3/31/04; received 4/21/04
- Authorization to Construct (ATC) application for Solids Removal System – Submitted 11/19/04; received 12/22/04
- Authorization to Construct (ATC) application for Constructed Wetlands – Submitted 5/21/04; received 8/10/04

Allen Steam Station SNCR, Unit 3

- Air Permit Application – Submitted 7/15/04; Received 2/5/05

Allen Steam Station SNCR, Unit 4

- Air Permit Application – Submitted 7/15/05; Received 1/15/06

Marshall Steam Station SNCR, Unit 1

- Air Permit Application – Submitted 9/18/05; Received 12/20/05

Marshall Steam Station SNCR, Unit 2

- Air Permit Application – Submitted 9/18/05; Received 12/20/05

Marshall Steam Station SNCR, Unit 3

- Air Permit Application – Submitted 5/14/04; Received 10/13/04

Riverbend Steam Station SNCR, Unit 4

- Air Permit Application – Submitted 3/20/05; Received 8/1/05

Riverbend Steam Station Burners, Unit 5

- Air Permit Application – Submitted 4/2/04; Received 4/30/04

Riverbend Steam Station SNCR, Unit 5

- Air Permit Application – Submitted 3/20/05; Received 8/1/05

Riverbend Steam Station Burners, Unit 6

- Air Permit Application – Submitted 5/14/03; Received September 2003

Riverbend Steam Station SNCR, Unit 6

- Air Permit Application – Submitted 11/5/05; Received 1/1/06

Riverbend Steam Station SNCR, Unit 7

- Air Permit Application – Submitted 11/5/05; Received 1/1/06

6. A description of the construction related to compliance with the provisions of G.S. 143-215.107D that is anticipated during the following year.

Allen Steam Station FGD

- Finalize EPC agreement with the Alstom/Shaw consortium
- Relocate existing plant services including ash sluice lines, diesel oil tank, electrical and potable water lines
- Relocate existing rail spurs and switches
- Construct new FGD entrance road from state highway
- Begin earthwork and grading for project, including initial site clearing
- Begin installation of piles and foundations
- Install new ductwork tie-ins to Unit 2

Belews Creek Steam Station FGD

- Complete the construction of the major foundations for the FGD system
- Complete the construction of the concrete shell for the two new chimneys
- Complete all construction on approximately 5% of the sub-systems that make up the total FGD system
- Complete construction of the Constructed Wetlands (part of the wastewater treatment system)
- Initiate commissioning activities on the completed sub-systems of the total FGD system
- Achieve a completion status of 75% on the overall project (65% of construction activities)

Cliffside Steam Station Unit 5 FGD

- Continue engineering study to finalize the project scope, funding and implementation schedule

Marshall Steam Station FGD

- Mobilize large crane for ductwork installation
- Complete initial tie-in of the Unit 4 ductwork and install blanking plate
- Complete ductwork installation using large crane
- Complete construction, turnover and commissioning of Unit 4 and common systems

- Complete final tie-in of the Unit 4 ductwork and removal of blanking plate
- Begin testing and tuning of Unit 4 and common systems
- Achieve Substantial Completion for Unit 4 and common systems
- Complete initial tie-in of the Unit 3 ductwork and install blanking plate
- Complete construction, turnover and commissioning of Unit 3 systems
- Complete final tie-in of the Unit 3 ductwork and removal of blanking plate
- Begin testing and tuning of Unit 3 and common systems
- Achieve Substantial Completion for Unit 3 systems

Allen Steam Station SNCR, Unit 2

- Complete detailed engineering for SNCR equipment and reagent storage
- Begin material procurement activities in support of installation in early 2007
- Complete procurement and construction of reagent storage equipment

Allen Steam Station SNCR, Unit 4

- Complete installation of SNCR equipment, including incremental compressed air and dilution water systems, in time to support 2006 ozone season operation

Allen Steam Station SNCR, Unit 5

- No significant activity expected in 2006

Buck Steam Station Burners, Unit 3

- Complete detailed engineering and material procurement activities in support of installation in early 2007

Buck Steam Station Classifiers, Unit 3

- No significant activity expected in 2006

Buck Steam Station Burners, Unit 4

- Complete detailed engineering and material procurement activities in support of installation in early 2007

Buck Steam Station Classifiers, Unit 4

- No significant activity expected in 2006

Buck Steam Station SNCR, Unit 5

- Complete detailed engineering and material procurement activities in support of installation in late 2006
- Substantially complete installation of SNCR equipment including incremental air, dilution water and storage needs in time to support 2007 operation

Buck Steam Station SNCR, Unit 6

- Complete detailed engineering and material procurement activities in support of installation in late 2006
- Substantially complete installation of SNCR equipment including incremental air, dilution water and storage needs in time to support 2007 operation

Dan River Steam Station Burners, Unit 1

- No significant activity expected in 2006

Dan River Steam Station Burners, Unit 2

- Substantially complete installation of burners

Dan River Steam Station Burners, Unit 3

- Substantially complete installation of burners

Marshall Steam Station SNCR, Unit 1

- Complete installation of SNCR equipment in time to support 2006 ozone season operation

Marshall Steam Station SNCR, Unit 2

- Complete detailed engineering for SNCR equipment and reagent storage
- Begin material procurement activities in support of installation in early 2007
- Complete procurement and construction of reagent storage equipment

Marshall Steam Station SNCR, Unit 4

- Complete detailed engineering for SNCR equipment
- Begin material procurement activities in support of installation in early 2007

Riverbend Steam Station SNCR, Unit 4

- Complete detailed engineering for SNCR equipment
- Begin material procurement activities in support of installation in early 2007

Riverbend Steam Station SNCR, Unit 5

- Complete detailed engineering for SNCR equipment
- Begin material procurement activities in support of installation in late 2007

Riverbend Steam Station SNCR, Unit 6

- Complete detailed engineering and material procurement activities in support of installation in late 2006
- Substantially complete installation of SNCR equipment including reagent storage needs in time to support 2007 operation

Riverbend Steam Station SNCR, Unit 7

- Complete detailed engineering and material procurement activities in support of installation in late 2006
- Substantially complete installation of SNCR equipment including incremental air and dilution water needs in time to support 2007 operation

7. A description of the applications for permits required in order to comply with the provisions of G.S. 143-215.107D that are anticipated during the following year.

Allen Steam Station FGD

- Authorization to Construct (ATC) application for Wastewater Treatment System – Plan to submit August 2006; expect to receive February 2007
- Air Permit Application – Plan to submit April 2006; expect to receive approval July 2006
- Request to revise NPDES Permit to include FGD wastewater – Submitted 1/24/2006; expect to receive revision May 2006
- Submittal to DENR/ACOE regarding stream crossing of entrance road – Plan to submit March 2006
- NOTE: all erosion control permits are in EPC contractor's scope for the Allen FGD Project

Belews Creek Steam Station FGD

- Authorization to Construct (ATC) application for Sanitary Waste Lagoon – Plan to submit March 2006; expect to receive September 2006

Cliffside Steam Station Unit 5 FGD

- NOTE: A complimentary PSD permit application was submitted on 12/16/05 for the proposed new generating units at the Cliffside site. If this associated PSD air permit is not approved or withdrawn, it will be necessary to submit a revised Air Permit Application for a standalone Unit 5 FGD. This application would be made in the 3rd or 4th Quarter of 2006.

Allen Steam Station SNCR, Unit 2

- Air Permit Application – Plan to submit July 2006; expect to receive approval January 2007

Allen Steam Station SNCR, Unit 4

- Authorization to Construct (ATC) application for the dilution water piping – Plan to submit to the City of Belmont March 2006

Buck Steam Station Burners, Unit 3

- Air Permit Application – Plan to submit March 2006; expect to receive approval February 2007

Buck Steam Station Burners, Unit 4

- Air Permit Application – Plan to submit March 2006; expect to receive approval February 2007

Buck Steam Station SNCR, Unit 5

- Air Permit Application – Plan to submit March 2006; expect to receive approval July 2006

Buck Steam Station SNCR, Unit 6

- Air Permit Application – Plan to submit March 2006; expect to receive approval July 2006

Dan River Steam Station Burners, Unit 1

- Air Permit Application – Submitted 2/23/06; expect to receive approval August 2006

Dan River Steam Station Burners, Unit 2

- Air Permit Application – Submitted 2/23/06; expect to receive approval September 2006

Dan River Steam Station Burner Project, Unit 3

- Air Permit Application – Submitted 2/23/06; expect to receive approval September 2006

Marshall Steam Station SNCR, Unit 4

- Air Permit Application – Plan to submit September 2006; expect to receive approval January 2007

8. The results of equipment testing related to compliance with G.S. 143-215.107D.

No additional equipment related testing occurred in 2005. The SNCR and SCR tests that occurred in prior years that were used in evaluating technology selections are repeated in this 2006 report for reference.

Allen Steam Station SNCR, Unit 1

- SNCR Equipment installation was completed in May 2003 followed by equipment acceptance testing in late 2003. During this test run, it was determined that the SNCR system met all commercial performance guarantees with approximately a 25% reduction in NOx with ammonia slip of less than 5 ppm at full load
- During the 2004 ozone season, Allen Unit 1 achieved a 0.162# NO_x/MMBTU outlet rate, 5% better than the 0.17#/MMBTU target established for the unit.

Belews Creek Steam Station SCR

- SCR Equipment installation was completed in 2003 in support of the EPA/SIP Call requirements for NO_x reduction. While Belews Creek had operational problems in the first half of the 2004 ozone season, many of these issues were addressed on Belews Creek Unit 1 by August, 2004. Subsequently, tests performed during the months of August and September showed that when the SCR Equipment was in service during this time, emissions averaged 0.07# NO_x/MMBTU

9. The number of tons of oxides of nitrogen (NO_x) and sulfur dioxide (SO_2) emitted during the previous calendar year from the coal-fired generating units that are subject to the emissions limitations set out in G.S. 143-215.107D.

In the 2005 calendar year, 56,073.3 tons of NO_x and 298,780.5 tons of SO_2 were emitted from the North Carolina based Duke Power Company coal-fired units located in North Carolina and subject to the emissions limitations set out in G.S 143-215.107D.

10. The emissions allowances described in G.S. 143-215.107D(i) that are acquired by the investor-owned public utility that result from compliance with the emissions limitations set out in G.S. 143-215.107D.

No emissions allowances have been acquired by Duke Power Company resulting from compliance with the emissions limitations set out in G.S. 143-215.107D.

11. Any other information requested by the Commission or Department of Environment and Natural Resources.

No additional information has been requested to be included in this annual data submittal.

Expected Duke Power Company Compliance for NC Clean Air Plan as of 4/1/2006 (Exhibit A)

NO_x							
				2007 Compliance		2009 Compliance	
Facility	Unit	Technology	Operational Date	Expected Rate #/MMBTUs	Tons	Expected Rate #/MMBTUs	Tons

Riverbend	5	SNCR&Burners	2008	0.240	516	0.170	401
Riverbend	6	SNCR&Burners	2006	0.150	570	0.150	565
Riverbend	7	SNCR	2006	0.150	549	0.150	578
			Expected Total:		32,533		30,909 *** NOTE 1 ***
			Compliance Limit:		35,000		31,000

*** NOTE 1 *** Because the expected 2009 NO_x emissions are so close to the 31,000 ton limit, Duke will continue to evaluate options to improve performance, including SCR on Marshall Unit 3 and/or SNCR on Dan River Unit 3.

Technology:
Burners -- Overfired Air or Separated Overfired Air with associated Mill Classifier installations
SCR -- Selective Catalytic Reduction
SNCR -- Selective Non-Catalytic Reduction

Raleigh, NC 27699-4325

Re: Annual NC Clean Smokestacks Act Compliance Report
Docket No. E-2, Sub 815

Dear Mrs. Thigpen:

Progress Energy Carolinas, Inc. submits the attached report for calendar year 2005 regarding the status of compliance with the provisions of the North Carolina Clean Smokestacks Act. Section 9(i) of the Act requires that an annual report of compliance progress be submitted to the Commission by April 1 of each year for the previous calendar year.

Very truly yours,

Len S. Anthony /mhm

Progress Energy

March 30, 2006

Mr. William G. Ross, Jr.
Secretary
North Carolina Department of Environment and Natural Resources
1601 Mail Service Center
Raleigh, NC 27699-1601

Dear Secretary Ross:

Progress Energy Carolinas, Inc. (PEC) submits the attached report for calendar year 2005 regarding the status of compliance with the provisions of the North Carolina Clean Smokestacks Act. Section 9(i) of the Act requires that an annual compliance progress report be submitted by April 1 of each year for the previous calendar year. PEC appreciates the efforts of your staff to work with us and looks forward to continuing our positive working relationship to facilitate fulfillment of PEC's obligations with this important law.

Please don't hesitate to contact me at (919) 546-3775 if you have any questions.

Sincerely,

Caroline Choi
Director, Environmental Services

[Page 2 intentionally left blank]

Progress Energy Carolinas, Inc.
North Carolina Clean Smokestacks Act
Calendar Year 2005 Progress Report

On June 20, 2002, North Carolina Senate Bill 1078, also known as the "Clean Smokestacks Act," was signed into effect. This law requires significant reductions in the emissions of nitrogen oxides (NOx) and sulfur dioxide (SO_2) from utility owned coal-fired power plants located in North Carolina. Section 9(i) of the bill, which is now incorporated as Section 62-133.6(i) of the North Carolina General Statutes, requires that an annual progress report regarding compliance with the Clean Smokestacks Law be submitted on or before April 1 of each year. The report must contain the following elements, taken verbatim from the statute:

1. A detailed report on the investor-owned public utility's plans for meeting the emissions limitations set out in G.S. 143-215.107D.
2. The actual environmental compliance costs incurred by the investor-owned public utility in the previous calendar year, including a description of the construction undertaken and completed that year.
3. The amount of the investor-owned public utility's environmental compliance costs amortized in the previous calendar year.
4. An estimate of the investor-owned public utility's environmental compliance costs and the basis for any revisions of those estimates when compared to the estimates submitted during the previous year.
5. A description of all permits required in order to comply with the provisions of G.S. 143-215.107D for which the investor-owned public utility has applied and the status of those permits or permit applications.
6. A description of the construction related to compliance with the provisions of G.S. 143-215.107D that is anticipated during the following year.
7. A description of the applications for permits required in order to comply with the provisions of G.S. 143-215.107D that are anticipated during the following year.
8. The results of equipment testing related to compliance with G.S. 143-215.107D.
9. The number of tons of oxides of nitrogen (NOx) and sulfur dioxide (SO_2) emitted during the previous calendar year from the coal-fired generating units that are subject to the emissions limitations set out in G.S. 143-215.107D.
10. The emissions allowances described in G.S. 143-215.107D(i) that are acquired by the investor-owned public utility that result from compliance with the emissions limitations set out in G.S. 143-215.107D.
11. Any other information requested by the Commission or the Department of Environment and Natural Resources.

Information responsive to each of these report elements follows. The responses are given by item number in the order in which they are presented above.

1. **A detailed report on the investor-owned public utility's plans for meeting the emissions limitations set out in G.S. 143-215.107D.**

The plan for Progress Energy Carolinas, Inc. was originally submitted on July 29, 2002. Appendix A contains an updated version of this plan, effective April 1, 2006. We continue to evaluate various design, technology and generation options that could affect our future compliance plans.

2. **The actual environmental compliance costs incurred by the investor-owned public utility in the previous calendar year, including a description of the construction undertaken and completed that year.**

The actual capital costs incurred by Progress Energy in 2005 were $181,274,000.

We successfully placed in service our first wet scrubber on Asheville Unit 1 in November 2005. A significant amount of work was performed at the Asheville plant in 2005 in order to place the Unit 1 scrubber in service. This work included the installation of electrical power and control cables and circuits, piping, pumps, valves, oxidation air compressors, instruments and controls (including the scrubber distributed control system), agitators, absorber tower outlet hood, spray headers, trays and other tower internals, limestone and gypsum handling equipment, and gypsum dewatering equipment. Work efforts also included constructing the wetlands and industrial wastewater treatment system for treating scrubber blowdown wastewater, completing ductwork from the precipitator to the scrubber tower and from the scrubber tower to the stack, and installing new induced draft fans and various other process equipment. Much of the equipment noted above was also installed for the Asheville Unit 2 scrubber, which will be placed in service in 2006.

In addition to the scrubber projects at Asheville, detailed design, engineering and procurement activities began for the Asheville Unit 1 SCR, which will be installed and operational in late 2007. Based on the changes in forecasted energy demand, the in-service date for these NOx controls was accelerated from 2008 to ensure compliance with the Act's annual tonnage cap. Detailed design and engineering activities included preparation of various specifications and bill of materials, civil engineering of foundation systems, structural engineering of flue gas path components and associated structural steel, and mechanical engineering for various piping systems. Work on the Asheville Unit 1 SCR also included issuing purchase orders for the SCR catalyst, ammonia injection grids, static mixers, urea to ammonia system equipment, ash handling system changes, and sonic horns.

At the Roxboro plant, environmental projects work increased significantly in 2005. Engineering, procurement and construction began or continued for each of the four units. The new electrical switchgear building that will provide power for much of the common scrubber equipment was completed. Various power distribution panels and load centers located in the electrical switchgear building were placed into service. Purchase orders were issued for most of the major equipment. Structural steel was erected, along with various floor elevations for the new limestone preparation/gypsum dewatering building. Erection began on the limestone ball mills and the limestone storage silos. Two new concrete chimney shells (one for Units 1 and 2 and one for Units 3 and 4) were constructed. Many of the fiberglass reinforced plastic sections that make up the flue gas liners were fabricated off site to be ready for installation beginning in early 2006. Foundations were completed for all four absorber towers and their adjacent pump buildings. The ceramic tile-lined concrete absorber tower for the Unit 2 scrubber was built. Excavation began for the limestone storage pile and conveying equipment. Erection also started on the pipe bridge between the absorber towers and the limestone preparation/gypsum dewatering building.

At the Mayo plant, initial general arrangement drawings for the wet scrubber were developed. Engineering studies were completed for the scrubber distributed controls system, electrical power distribution, and induced draft fans options. Work began on the water supply, scrubber blowdown wastewater treatment, and boiler/ductwork transient analysis studies. Engineering was also performed to support the modeling required to determine the height of the new chimney. A purchase order was issued for the absorber recycle pumps. The procurement of these pumps requires a long lead time; they were purchased in 2005 to ensure availability and minimize cost increases. A milestone project schedule was developed. There were no construction activities in 2005.

At the Lee plant, preliminary engineering, design, and procurement activities were initiated for the installation of low-NOx burners in 2006. The PSD permit application was prepared and submitted to the Division of Air Quality for review and approval. There were no construction activities in 2005.

At the Sutton Plant, preliminary engineering, design, and procurement activities were initiated for the installation of low-NOx burners in 2006. There were no construction activities in 2005.

3. The amount of the investor-owned public utility's environmental compliance costs amortized in the previous calendar year.

Progress Energy Carolinas, Inc. amortized $147 million in 2005.

4. An estimate of the investor-owned public utility's environmental compliance costs and the basis for any revisions of those estimates when compared to the estimates submitted during the previous year.

Appendix B contains the capital costs incurred toward compliance with G.S. 143-215.107D in 2005 and the projected costs for future years through 2013, which show the net cost to PEC excluding the portion for which the Power Agency is responsible. The estimated total capital costs, including escalation, are currently projected to be between $1.1B and $1.4B, with the current point estimate being $1.36B. This represents an increase of 52% from the 2005 cost estimate of $895 million. Prior reports have discussed the cost impact of project scope changes such as the use of a wet scrubber at Asheville in lieu of a dry scrubber, the capability to burn higher sulfur coals, and increased sulfur removal efficiency; all of which provide increased fuel flexibility for the Asheville, Roxboro, and Mayo plants. These additional cost increases reflect 1) increased costs for materials of construction, such as steel, concrete, and electrical power and control cables; 2) the need for a greater volume of these materials than originally forecast; 3) increased costs for equipment, such as pumps, fans, and electrical transformers; 4) the addition of wastewater treatment facilities, which were not included in the original program estimate; and 5) adjusting future project costs based on the actual project costs for our first completed scrubber and the current detailed cost estimates for the scrubbers under construction. It should be noted that significant design work remains to be completed, especially for the SO_2 controls at Mayo, Cape Fear, and Sutton. Our current estimates are subject to further adjustment as the engineering for these projects is completed.

The cost increases that we are experiencing are not unique to PEC. Other utilities with major construction projects for environmental controls are experiencing similar increases. Significant cost increases are also being experienced on other, non-utility, large construction projects in North Carolina, especially in the Raleigh area. For example, the project costs for the expansion of Terminal C at the Raleigh Durham International Airport were recently reported to have increased by 23% over the last 3 years due to inflation and rising building costs; projected costs for new Wake County schools were recently reported to have increased by 18-20% a year compared with an overall inflation rate of 2.7 to 3.4% due to higher prices for construction materials; the project costs for the planned commuter rail service from Raleigh to Durham were recently reported to have increased by 9% since 2004 (not adjusted for inflation); and the costs for the new Raleigh convention center currently under construction were recently reported to have increased by 12% due to the volatility of equipment and material prices in the construction market.

Independent cost indices, such as the Chemical Engineering Plant Cost Index, also show that the costs for construction labor and materials have increased sharply. The net overall plant escalation from December 2002 through November 2005 was 19%, which is substantially higher than the 2.0 to 2.5% per year (7.7% over the same December 2002-November 2005 period) escalation rates used for the original program cost estimates.

5. A description of all permits required in order to comply with the provisions of G.S. 143-215.107D for which the investor-owned public utility has applied and the status of those permits or permit applications.

Progress Energy applied for the following permits in 2005:

Asheville Plant

Erosion and Sedimentation Control Plan

Several updates were submitted for the erosion and sedimentation control plan:

- Rev H for the wastewater treatment discharge pipeline, truck scale, truck wash station was approved April 6, 2005.
- Rev 1 for the river pumps conduit was approved June 2, 2005.
- Rev I for the Unit 1 SCR was approved November 14, 2005.

NPDES Permit

An Authorization to Construct (ATC) the wastewater treatment system for the pretreatment of flue gas desulfurization wastewater was approved March 29, 2005 –ATC No. 0000396A03.

The ATC engineer's certifications for pretreatment and constructed wetlands were submitted November 8, 2005.

Roxboro Plant

Air Permit

An update to the air permit for coal handling and limestone handling was submitted on August 25, 2005. This permit was issued on February 9, 2006.

Erosion and Sedimentation Control Plan

Several updates were submitted for the erosion and sedimentation control plan:

- Rev G for the gypsum storage area was approved January 21, 2005
- Rev H was rolled in with Rev G (revision H was a response to questions on revision G) and so was also approved January 21, 2005.
- Rev I for the emergency access road, fire protection piping, conduit, temporary haul road was approved May 17, 2005.
- Rev J for the makeup water pipeline, gypsum conveyor foundations, settling pond and bioreactor site was approved September 13, 2005

Wetlands Permitting

An Army Corps of Engineers permit and water quality certification to fill wetlands for gypsum storage area was received September 6, 2005.

NPDES permit

An NPDES permit for the wastewater treatment system was received August 10, 2005.

Submissions were made for the Authorization to Construct (ATC) the wastewater treatment system on October 3, November 1 and December 2, 2005. Approval for construction of the settling basin is expected in March 2006. Approval for the construction of the bioreactor is expected in the second quarter of 2006.

Dam/Impoundment Safety

Progress Energy's letter to the NCUC identifying work in the ash pond was approved December 5, 2005.

Lee Plant

Air Permit

A prevention of significant deterioration (PSD) permit application for the installation of low NOx burners was submitted on December 7, 2005. A draft permit was received February 13, 2006 and is expected to be final in March 2006.

Sutton Plant

Air Permit

Air permit 01318T18 for the installation of Low NOx Burners was received February 21, 2005.

6. A description of the construction related to compliance with the provisions of G.S. 143-215.107D that is anticipated during the following year.

Appendix C presents the planned construction schedule for compliance with G.S. 143-215.107D. Please note that this is a projected schedule of construction activity through 2013 that is subject to modification. The schedule will be updated as part of this report each year.

The planned construction activities at Asheville in 2006 include the completion of the mechanical, electrical and controls systems for the Unit 2 scrubber. This includes completion of the flue gas ductwork from the precipitator to the absorber tower, and installation, checkout and commissioning of the major equipment including the distributed controls system and absorber recycle pumps. Systems common to both Units 1 and 2 were commissioned during the checkout and startup activities for the Unit 1 scrubber. The unit 2 scrubber is expected to be placed into service at the end of May

Construction activities will also begin for the Asheville Unit 1 SCR project. These activities include installation of foundations for the new SCR structural steel; fabrication, delivery and erection of the SCR support steel; fabrication and delivery of the inlet and outlet ducts for the SCR and the SCR reactor modules; and various mechanical and electrical activities to support placing this SCR in service in 2007.

At Roxboro, the significant construction activities for the Unit 2 scrubber include installation of the absorber recycle pumps, hydroclones, oxidation air compressors, absorber tower outlet hood, flue gas ductwork from the precipitator to the absorber tower and from the absorber tower to the chimney, spray headers, trays and other tower internals, agitators, and various process piping and tanks. Flue liners for each boiler will be installed in the chimney. The structural steel for the absorber recycle pump building will be erected. Systems common to the scrubbers for all units such as the gypsum handling conveyors, limestone handling and preparation equipment (conveyors, feeders, silos, and ball mills), dewatering equipment (belt filters), wastewater treatment settling ponds and bio-reactor will be installed. Various mechanical, electrical and controls equipment that support the scrubber process will also be installed. Installation of the gypsum conveyor from the dewatering building to the storage pile will begin. Construction activities for the Unit 3 and Unit 4 scrubbers will include the erection of the absorber tower for each unit and installation of the flue gas liners in the Units 3 and 4 chimneys. Installation will begin for various electrical power and control cables and circuits along with the installation of various process equipment and piping. Minimal construction activities for Unit 1 will be performed. Construction of these systems and the scrubber blowdown wastewater treatment system will continue through 2008.

7. **A description of the applications for permits required in order to comply with the provisions of G.S. 143-215.107D that are anticipated during the following year.**

Several recent changes to permitting processes in the state have dramatically increased the lead time to prepare and review environmental permits necessary for Clean Smokestacks projects. A recent court decision [D.C. Circuit Court of Appeals Decision in *New York v. EPA*, No. 02-1387 (June 24, 2005)] eliminated the provision exempting pollution control equipment from new source review. For Progress Energy Carolinas, this results in increased costs for consultants and modeling. For the NC Division of Air Quality (DAQ), this results in longer permit application processing times. For example, the application for the installation of a low-NOx burner, which formerly took 3-4 months, now requires review under the PSD program, a process typically lasting a year or more. The staff at the DAQ has expedited this process for the recent permit submission for the Lee plant. We appreciate the collaborative efforts the DAQ staff has made to assure our construction and installation schedules remain on track. However, the longer permit processing times continue to be a serious concern for future projects as not every permit can reasonably be expedited. PEC wishes to work collaboratively with the DAQ to prevent such delays from occurring.

The following permit applications and permit approvals are anticipated for 2006:

Asheville Plant

Air Permit

Revisions to the air permit may be necessary to test and, if necessary, install technology to reduce emissions of SO_3.

Erosion and Sedimentation Control Plan

Revision J for the construction of the demineralizer pipe, pump and ductbank was approved in January 2006.

Roxboro Plant

Air Permit

Revisions to the air permit will be necessary to address fugitive emissions of hydrogen sulfide from the wastewater treatment system.

NPDES Permit

The ATC for the gypsum settling pond was received March 3, 2006.
Receipt of the ATC for the bioreactor is anticipated in the second quarter 2006.

Erosion and Sedimentation Control Plan

- Rev K for the haul road, transformers, main plant area wastewater pipe trench and gypsum conveyor foundations was approved in February 2006
- Rev L for burying the wastewater pipeline - approval is anticipated second quarter 2006

Additional revisions to the plan may be necessary.

Mayo Plant

Air Permit
