A construction permit will be required for the flue gas desulfurization system - anticipated submission Spring 2005.

NPDES Permit

NPDES permit modification application for wastewater treatment system submitted February 23, 2006.

A request for authorization to construct the wastewater treatment system is expected to be submitted in the fourth quarter 2006.

Erosion and Sedimentation Control Plan

The first of the erosion and sedimentation plans for the main construction area and laydown yards will be submitted during the second quarter, 2006. Additional plan revisions will be necessary as construction plans are developed.

<u>Cape Fear Plant</u>

Air Permit

A construction permit may be required to conduct a trial of an air pollution control technology. If required, this permit application will be submitted during the second quarter of 2006.

<u>Lee Plant</u>

Air Permit

A construction permit will be required for the installation of the Rotamix system for NOx control. This permit application will be submitted during the second quarter 2006.

8. The results of equipment testing related to compliance with G.S. 143-215.107D.

No equipment testing related to compliance with G.S. 143-215.107D occurred in 2005.

9. The number of tons of oxides of nitrogen (NOx) and sulfur dioxide (SO_2) emitted during the previous calendar year from the coal-fired generating units that are subject to the emissions limitations set out in G.S. 143-215.107D.

The total calendar year 2005 emissions from the affected coal-fired Progress Energy Carolinas units are:

NOx 49,621 tons
SO_2 202,041 tons

10. The emissions allowances described in G.S. 143-215.107D(i) that are acquired by the investor-owned public utility that result from compliance with the emissions limitations set out in G.S. 143-215.107D.

During 2005, PEC did not acquire any allowances as a result of compliance with the emission limitations set out in N.C. General Statute 143-215.107D.

11. Any other information requested by the Commission or the Department of Environment and Natural Resources.

NC Clean Smokestacks Audit Public Staff Data Request No. 5 was issued to Progress Energy Carolinas in February of 2005, and a response was provided on March 4, 2005. NC Clean Smokestacks Commission staff request was issued to Progress Energy Carolinas in April of 2005, and a response was provided on May 2, 2005 with revisions filed on May 6, 2005. NC Clean Smokestacks Audit Public Staff Data Request No. 6 was issued to Progress Energy Carolinas in February of 2006, and a response was provided on March 24, 2006.

Appendix A

Progress Energy Carolinas, Inc's (PEC) Air Quality Improvement Plan Supplement

April 1, 2006

On June 20, 2002, Governor Easley signed into law SB1078, which caps emissions of nitrogen oxides (NOx) and sulfur dioxide (SO_2) from utility owned coal-fired power plants located in North Carolina. PEC's annual NOx emissions must be less than 25,000 tons beginning in 2007 and annual SO_2 emissions must be less than 100,000 tons beginning in 2009 and less than 50,000 tons beginning in 2013. These caps represent a 56% reduction in NOx emissions from 2001 levels and a 74% reduction in SO_2 from 2001 levels for PEC.

PEC owns and operates 18 coal-fired units at seven plants in North Carolina. The locations of these plants are shown on Attachment 1.

Nitrogen Oxides Emissions Control Plan

PEC has been evaluating and installing NOx emissions controls on its coal-fired power plants since 1995 in order to comply with Title IV of the Clean Air Act and the NOx SIP Call rule adopted by the Environmental Management Commission (EMC). Substantial NOx emissions reductions have already been achieved (50,000 tons of NOx in 2004 compared with 112,000 tons in 1997) and further reductions will ensure compliance with the Clean Smokestacks Act 25,000 ton cap in calendar year 2007. This target will be achieved with a mix of combustion controls (which minimize the formation of NOx) such as low-NOx burners and over-fire air technologies, and post-combustion controls (which reduce NOx produced during the combustion of fossil fuel to molecular nitrogen) such as selective catalytic reduction (SCR) and selective non-catalytic reduction (SNCR) technologies.

Attachment 2 details PEC's North Carolina coal-fired electric generating units, their name plate generation capacity, the control technologies already installed, and those planned for installation. As technologies evolve or other circumstances change, a different mix of controls may be selected. Attachment 2 also projects the NOx emissions on a unit-by-unit basis based on the energy demand forecast and expected efficiencies of the NOx emissions controls employed. This information is provided only to show how compliance may be achieved and is not intended in any way to suggest unit-specific emission limits. Actual emissions for each unit may be substantially different in 2007.

Sulfur Dioxide Emissions Control Plan

PEC will be installing wet flue gas desulfurization systems (FGD or "scrubbers") to remove 97% of the SO_2 from the flue gas of its Asheville, Roxboro and Mayo boilers. Screening studies will be conducted for the Cape Fear 5 and 6 and Sutton 3 units to select the most appropriate technology for these plants. Wet scrubbers produce unique waste and by-product streams. Issues related to wastewater permitting and solid waste disposal are being addressed for each site. PEC plans to treat the scrubber wastewater stream at the Asheville Plant using an innovative constructed wetlands treatment system to ensure compliance with discharge limits. A bioreactor technology is being evaluated for the Roxboro Plant. A contract has been executed with a gypsum product end-user that will construct a wallboard facility near the Roxboro plant to use the synthetic gypsum produced by the Roxboro and Mayo plants for the manufacture of drywall products. PEC is also negotiating with another gypsum company for the use of the synthetic gypsum that will be produced at the Asheville plant

Specific units are listed in Attachment 3 with data on projected schedules and projected annual emissions in 2009 and 2013. These projections assume a 97% SO_2 removal efficiency, forecasted energy demand, 3.3 lbs SO_2/Mbtu coal on scrubbed units, and 1.2 lbs SO_2/Mbtu coal on the other units. Please note that these are projected schedules and are subject to revision.

Particular units controlled and control technologies utilized are subject to change depending on future developments in SO_2 removal technologies, energy demand, sulfur content of coal, and other circumstances which may produce a more optimal plan for meeting the SO_2 emissions limits in 2009 and 2013. DENR will be advised as changing circumstances dictate.

Catawba and Davidson Counties Trajectory Analysis

(This page intentionally left blank)

Catawba and Davidson Counties HYSPLIT Back-Trajectory Analysis to Determine $PM_{2.5}$ Source Regions

Michael A. Abraczinskas, K. Wyat Appel, George M. Bridgers, Scott A. Jackson
North Carolina Division of Air Quality
Raleigh, NC

March 8, 2004

1. Introduction

The purpose of this analysis is to access the source regions, in particular according to state boundaries, which contribute significantly to elevated daily Fine Particulate Matter ($PM_{2.5}$) levels in North Carolina. The North Carolina Division of Air Quality (NC DAQ) has identified a specific need to know the regions, specifically according to state boundaries, which contribute significantly to primary and secondary $PM_{2.5}$ in North Carolina. The Environmental Protection Agency (EPA) has established standards for $PM_{2.5}$ at 15 $\mu g/m^3$ for the annual standard and 65 $\mu g/m^3$ for the 24-hour standard.

2. Methodology

An analysis of the National Oceanic and Atmospheric Administration Air Resource Laboratory (NOAA ARL) HYbrid Single-Particle Lagrangian Integrated Trajectory (HYSPLIT; Draxler and Rolph, 2003) model back trajectories was performed in order to access the sources that contribute to elevated $PM_{2.5}$ levels in North Carolina. An analysis of observed 24-hour average $PM_{2.5}$ values throughout from North Carolina's $PM_{2.5}$ monitor network determined that the two monitors with the highest annual $PM_{2.5}$ values in North Carolina are located in Catawba and Davidson Counties. The monitors located in these counties are Federal Reference Method (FRM) monitors and sample $PM_{2.5}$ every three days. Because these monitors had the two highest annual-average $PM_{2.5}$ values, the monitors located in these two counties were chosen as the endpoints for the HYSPLIT back trajectories. The specific location of Catawba County monitor is 35.73°N, 81.36°W, while the Davidson County monitor is located at 35.81°N, 80.26°W.

$PM_{2.5}$ data from January 1, 1999 through June 30, 2002 was analyzed to identify days when the 24-hour average $PM_{2.5}$ value was greater than or equal to 27.9 $\mu g/m^3$. This concentration was chosen since it represents the midpoint of the yellow AQI range (15.5$\mu g/m^3$ – 40.4$\mu g/m^3$) for $PM_{2.5}$, and conversations with EPA representatives have indicated that values above this point could pose a significant health risk. From the three and half years of available $PM_{2.5}$ data from those two monitors, there were a total of 41 days from the Catawba County monitor and 32 days from the Davidson County monitor where the 24-hour average $PM_{2.5}$ value was greater than or equal to 27.9 $\mu g/m^3$. The dates and observed 24-hour average $PM_{2.5}$ of these days are shown in Table 1.

For the days indicated above, HYSPLIT back trajectories were run. Thirty-six hour back trajectories ending at 17UTC, noon Eastern Daylight Time, were run separately for each monitor using the model vertical velocity option. The trajectories were run at three separate heights, specifically 10, 300 and 1000 meters above ground level (AGL). The 10 and 300-meter trajectory levels are heights of lower level circulations, while the 1000-meter trajectory level represents the top of the mixed layer and is generally a transport level. The choice of these levels is based on the experience of NC DAQ meteorologists, who use the HYSPLIT model trajectories as a routine part of their ozone and $PM_{2.5}$ forecast process. 17UTC (Noon EDT) was chosen as the ending time of the trajectories because it represents a time when significant mixing of the boundary and residual layers has occurred, but significant contributions from local-secondary production has not occurred.

3. Results

Table 1 shows the results of the analysis of the back trajectories. Columns 4 and 5 in Table 1 identify the primary and secondary source regions. The primary source region identifies the most significant region(s) contributing to the $PM_{2.5}$ in that county on that day, as determined by the meteorologists. The secondary source region identifies a region(s) that, while is not a primary contributor, does appear to contribute to a significant portion of the $PM_{2.5}$ on that day. Note that while there is always a primary source identified for a given day, there may not be secondary source identified.

Figures 1-4 show composites of the back trajectories originating from the Catawba County site at 10, 300, and 1000 meters AGL for those days when $PM_{2.5}$ concentrations were high. Note that the trajectories are relatively short, indicating regional stagnation and recirculation. Figures 5-8 show similar composites for the Davidson County site.

Analysis of the HYSPLIT back trajectories showed that on the majority of the days the primary source region of the back trajectory was North Carolina. Table 2 shows the distribution of both primary and secondary source regions for the trajectories for both Catawba and Davidson counties. Of the 41 days for which back trajectories were run for the Catawba County monitor, 31 (76%) of them were considered to have North Carolina as the primary source region (Figure 9). Tennessee and Virginia were considered to be primary sources on 9 (22%) and 6 (15%) days, respectively. Significant secondary sources were South Carolina, Tennessee, and Georgia, which contributed on 9 (22%), 8 (20%), and 7 (17%) days respectively (Figure 10). Figure 11 shows the percent of the days in which each region was identified as either a primary or secondary source, or both.

There were 27 (66%) days when North Carolina was identified to be the only primary source region, while there were 4 (10 %) days when North Carolina and another state(s) was identified to be the source region, and 10 (24%) days when North Carolina was not identified as part of the source region. This result is significant, since it indicates that nearly 35 percent of the days when $PM_{2.5}$ was greater than or equal to 27.9 $\mu g/m^3$, back-trajectory analysis indicates transport from neighboring states, in particular Tennessee, Virginia, Georgia and South Carolina.

For the Davidson county monitor, 26 (81%) of the 31 days for which the trajectories were run indicated North Carolina as the primary source (Table 2, Figure 12). Note that there was one day for which a trajectory could not be run due to missing data. Other significant primary sources were Virginia, with 7 (23%) days, and South Carolina and Tennessee, each with 4 (13%) days. Significant secondary sources were South Carolina, Tennessee, and Virginia, each with 5 (16%) days, and Ohio with 4 (13%) days (Figure 13). Of the 31 days for which the back trajectories were run, 17 (55%) of them indicated North Carolina as the only primary source region, while on 14 (45%) days trajectories indicated another state as the primary source region. As with the Catawba County analysis, there were a significant percentage of days when trajectory analysis indicates transport from neighboring states on days when $PM_{2.5}$ was greater than or equal to 27.9 $\mu g/m^3$. The percent of days in which each region contributed as a primary or secondary source (or both), is shown in Figure 14.

Another interesting analysis is examining the 24-hour average $PM_{2.5}$ value and the associated primary source region. The trajectories run for each monitor were divided into an upper third, a middle third, and a lower third based on the observed $PM_{2.5}$ concentration. For the Catawba County monitor the upper third consists of a $PM_{2.5}$ range between 32.8 and 54.7 $\mu g/m^3$, the middle third from 30.0 and 32.7 $\mu g/m^3$, and the lower third from 28.1 to 29.6 $\mu g/m^3$. Note that there are 14 days included in the upper and middle thirds, and only 13 days included in the bottom third (Tables 3-5).

For the upper third of the days for the Catawba County monitor site, North Carolina was the primary source on 10 days, followed by Tennessee and Virginia with 2 days each. South Carolina, Tennessee, Virginia and Georgia are common secondary source regions. For total days (primary and secondary combined), North Carolina was identified on 10 days, followed by Tennessee on 5 days and South Carolina, Virginia, and Georgia each on 3 days. The results for the middle and lower third of the days are similar to those for the upper third. The same analysis for the Davidson County monitor site yields similar results. Note also that 11 days are included in the upper and middle thirds, while only 10 days are included in the bottom third.

Another analysis that was performed using the back trajectories was to quantify the residence time that the trajectories spent in each state, other than North Carolina. This was accomplished by analyzing each trajectory individually and recording the amount of time the trajectory spent in each individual state. Since trajectories were run at multiple heights, to avoid double counting, only the maximum time that all trajectory heights spent in any one state are reported. Obviously, since the end points of the trajectories are within North Carolina, some time for each trajectory must be spent in North Carolina. The results of the analysis for Davidson and Catawba counties are shown in Tables 6 and 7 respectively. Note that this analysis contains seven events in 2002 for Catawba County and four events in 2002 for Davidson County that are not included in the previous analysis of the trajectories.

For Catawba County, the maximum number of hours the trajectories spent in another state for all events was 258 in Tennessee (recall that an event is a day where the PM2.5

concentration exceeded 27.9 $\mu g/m^3$ at the monitor in that county). This represents 15.6 percent of the total trajectory time (36 hours/event * 46 events = 1656), with an average of 18.4 hours per event. The average represents the average hours the trajectory spent in each state for only those events where the trajectory spent at least some amount of time in the state (zero hour events are not included in the average). Other results include 207 hours (12.5% of total) for South Carolina, with an average of 18.8 hours per event, and 201 hours (12.1% of total) for Kentucky, with an average of 14.4 hours per event.

For Davidson County, the maximum number of hours the trajectories spent in another state for all events was 278 in South Carolina. This was 22.7 percent of the total trajectory time (36 hours/event * 34 days), with an average of 19.9 hours spent in South Carolina for each event. Virginia had a total of 275 hours (22.5% of total) with an average of 14.5 hours per event. Tennessee had a total of 166 hours (13.6 % of total) with an average of 15.1 hours per event.

4. Discussion

Analysis of HYSPLIT back trajectories from two $PM_{2.5}$ monitor locations in North Carolina on days when 24-hour average $PM_{2.5}$ levels were 27.9 $\mu g/m^3$ or greater indicates that while North Carolina is the primary source region for the majority of those days, states neighboring and near North Carolina (including Kentucky, West Virginia, and Ohio) were shown through the trajectory analysis to be potential sources of transported pollution. Back trajectories run from points in Catawba and Davidson Counties in North Carolina show a significant percentage of days for which neighboring states could be considered primary sources for transported pollution. Significant secondary states include South Carolina, Tennessee, and Virginia. Other states with slightly fewer days when back trajectories indicated potential transport include Georgia, Kentucky, and the Ohio Valley.

Davidson	7/18/2001	37.7	NC / SC	SE. TN / N. GA	**Low**: SC and some NC; **Mid**: NC and Northern GA; **Upper**: NC, Eastern TN, N. GA
Davidson	7/5/1999	36.6	NC	Eastern TN (significant)	**Low**: All in NC; **Mid**: Origin in NE TN; **Upper**: Crosses KY, WV, VA
Davidson	6/2/2000	34.9	NC	Eastern TN	Missing Data
Davidson	6/29/2000	34.1	NC / N. GA / N. SC	Aloft from Ohio Valley	**Low**: NC, SC, and GA; **Mid**: NC and GA (ATL); **Upper**: Ohio Valley
Davidson	8/7/1999	33.8	NC	SW. VA	**Low**: NC; **Mid**: NC and SW VA; **Upper**: NC (CLT)
Davidson	7/2/2000	32.7	NC (CLT)	North Central SC	**Low**: Completely in NC; **Mid**: NC and Upstate SC; **Upper**: NC and Upstate SC
Davidson	8/28/1999	32.1	NC	SW. VA (less sig)	**Low**: NC; **Mid**: NC and SW VA; **Upper** NC and SW VA
Davidson	11/11/1999	31.8	TN		**Low, Mid, and Upper**: Long transport from Tennessee
Davidson	8/16/2000	31.2	NC / VA	Ohio Valley	Missing Data
Davidson	8/19/1999	31.1	NC / VA	Ohio Valley	**Low**: NC, VA, and WV; **Mid**: Eastern VA; **Upper**: NC, SW VA, and Ohio Valley
Davidson	10/27/2000	31.1	VA		**Low, Mid, and Upper**: Virginia
Davidson	1/21/1999	31.0	NC (CLT, I-85)	Upstate SC	**Low**: All in NC; **Mid and Upper**: long transport from the west
Davidson	11/8/2000	30.7	NC		**Low:** Short over NC; **Mid and Upper**: Long transport from the south (SC, GA, FL)
Davidson	7/20/1999	30.6	NE. TN, SW. VA, NC		**Low**: NC and Upstate SC; **Mid**: E. TN and NC **Upper**: VA, KY, and TN
Davidson	8/16/1999	30.1	NC		**Low, Mid, and Upper**: All completely in NC (short trajectories)
Davidson	6/11/1999	29.8	NC (PP, I-40)	Tidewater of VA (minimal)	**Low, Mid, and Upper** all over NC and originate in the Atlantic
Davidson	2/9/2000	29.4	NC	I-95 Virginia	**Low**: NC and VA; **Mid**: NC and VA; **Upper**: NC (over the mountains)
Davidson	5/30/1999	29.1	NC (CLT)	NC	**Low, Mid, and Upper** all in NC and very northern SC
Davidson	8/8/2001	29.0	Ohio Valley	WV / VA / NC	**Low**: NC and SW VA; **Mid**: VA and WV; **Upper:** VA, WV and Ohio Valley
Davidson	10/30/1999	28.5	NC		Missing Data
Davidson	8/17/2001	28.5	NC / SC	GA (ATL)	**Low**: NC (CLT) and SC; **Mid**: Mostly SC, some NC; **Upper**: NC and GA (ATL)
Davidson	7/8/1999	28.4	NC	Upstate SC, Eastern TN (3rd)	**Low**: NC; **Mid**: Upstate SC; **Upper**: NE Tennessee
Davidson	10/18/2000	28.0	NC	Eastern TN	**Low**: Completely in NC; **Mid**: Completely in NC; **Upper**: long transport from TN
Davidson	8/14/2001	27.9	NC / VA	WV	**Low**: NC and SW VA; **Mid**: NC, Central VA, and WV; **Upper**: VA, WV, and Ohio Valley

Table 1. Days when observed $PM_{2.5}$ values in Catawba and Davidson Counties was above 27.8 ug/m^3. Indicated in the table is the county, date, $PM_{2.5}$ observed value, the primary and secondary sources as determined by the NC DAQ meteorologists, and any notes made by the meteorologists concerning that days trajectories. Purple shading indicates observed values greater than 39.9 ug/m^3, red shading between 35.0 ug/m^3 and 39.9 ug/m^3, orange shading between 30.0 ug/m^3 to 34.9 ug/m^3, yellow shading between 27.9 ug/m^3 and 29.9 ug/m^3. Blue shading indicates known fire events in North Carolina. On days with missing EDAS data, surface maps were used to determine the source region(s).

County	Date	PM 2.5	Primary	Secondary	Notes
Catawba	11/2/2000	54.7	NC (Fire Event)	Ohio Valley	**Low and Mid**: Completely in NC; **Upper**: Long transport from the Ohio Valley
Catawba	11/8/2000	50.1	NC (Fire Event)	SC / E. GA / FL (minor)	**Low, Mid, and Upper**: Short trajectories in NC, then long transport from the south
Catawba	1/21/1999	41.0	NC	Upstate, North Central GA	**Low**: all in NC; **Mid**: NC, Upstate SC, and N. GA; **Upper**: long transport from the southwest
Catawba	6/21/2001	40.0	NC	SC (minor)	**Low**: NC and Upstate SC; **Mid**: Completely NC; **Upper**: All NC except for couple hours in TN
Catawba	10/21/2000	38.0	NC	N. SC and E. TN	**Low**: NC and Upstate SC; **Mid**: Eastern TN and N. GA; **Upper**: Central TN and Northern MS
Catawba	10/27/2000	36.7	SW. VA / WV	Southern Ohio Valley	**Low**: SW VA and Eastern KY; **Mid and Upper**: SW VA, Western WV, Southern Ohio Valley
Catawba	7/23/1999	36.1	NE. TN / OV / SW. VA		**Low and Mid**: Northern TN; **Upper**: long transport from the northwest
Catawba	8/7/2000	34.2	NC	Eastern TN, GA (ATL)	**Low and Mid**: NC and Northern GA; **Upper**: Eastern TN and Northern GA
Catawba	3/31/1999	30.0	NC	Northern SC	**Low**: NC; **Mid**: NC, minor SC and VA; **Upper**; Upstate SC
Catawba	2/9/2000	33.5	NC	Eastern TN, Northern GA	**Low**: NC and very minor VA; **Mid**: NC and very minor SC; **Upper**: NC, E. TN, and N. GA
Catawba	6/5/1999	33.2	NC		**Low, Mid, and Upper**: NC (CLT and Triad)
Catawba	8/7/1999	33.1	NC	SW. VA	**Low and Mid**: Mostly NC, few hours in SW VA; **Upper**: Mostly in NC, few hours in NE TN
Catawba	1/1/2000	33.0	Millenium		**Low, Mid, and Upper**: NC and transport from the west
Catawba	2/21/2001	32.8	Eastern TN	Northern GA	**Low**: Eastern TN and Northern GA; **Mid**: NE TN, SW VA (minor), and TN; **Upper**: TN and KY
Catawba	7/8/2000	32.7	NC		**Low and Mid**: Completely in NC; **Upper**: NC and Upstate SC (minor, mostly NC)
Catawba	7/17/1999	32.3	NC	Upstate SC	**Low and Mid**: NC and Upstate SC; **Upper**: All in NC
Catawba	8/2/2001	32.0	NC		**Low, Mid, and Upper**: Trajectories completely in NC
Catawba	6/8/1999	31.7	NE. TN / SW. VA / KY		**Low**: NE TN and SW VA; **Mid and Upper**: NE TN, SW VA, KY;
Catawba	8/16/1999	31.1	NC		**Low and Mid**: Completely in NC; **Upper**: NC and Upstate SC (CLT area)
Catawba	8/13/1999	31.0	NC	SC	**Low**: Completely in NC; **Mid**: NC and Upstate SC (CLT); **Upper**: NC
Catawba	6/2/2000	31.0	Eastern TN	N. GA and NC	missing data
Catawba	7/20/1999	30.9	NC / E. TN		**Low**: Completely in NC; **Mid and Upper**: Eastern TN
Catawba	5/3/2000	30.8	NC	VA and SC	**Low**: majority NC and VA; **Mid**: NC (half), VA (half); **Upper**: mostly NC, minor SC
Catawba	7/23/2000	30.6	NC		**Low, Mid, and Upper**: Completely in NC
Catawba	9/7/2001	30.4	NC	NE. TN	**Low and Mid**: Completely in NC; **Upper**: NC and NE Tennessee
Catawba	8/26/2001	30.2	NC	Eastern TN and SC (minor)	**Low**: Completely in NC; **Mid**: Mostly in NC, few hours in Upstate SC; **Upper**: Eastern TN
Catawba	1/30/1999	30.0	NC		**Low, Mid, and Upper**: NC and VA (few hours);
Catawba	2/17/1999	30.0	NC / N. GA / Upstate SC		missing data
Catawba	8/19/1999	29.6	Ohio Valley / SW. VA		**Low**: NC, SW VA, and WV; **Mid**: NC, VA, and WV; **Upper**: NC, NE TN, SW VA, and E. KY
Catawba	7/2/2000	29.4	NC	SC	**Low**: NC (CLT); **Mid**: NC and Upstate SC; **Upper**: NC and Central SC
Catawba	7/18/2001	29.3	NC	SE. TN and N. GA	**Low**: NC and Northern GA; **Mid and Upper**: Southeast TN and Northest MS
Catawba	7/5/2000	29.1	Eastern and Central TN		**Low, Mid, and Upper**: Transport from Central and Eastern Tennessee
Catawba	11/18/2001	29.0	NC	VA / Ohio Valley (upper)	**Low and Mid**: NC and VA; **Upper**: SW VA, KY, and Southern Ohio Valley
Catawba	8/10/1999	28.4	NC	E. TN	**Low and Mid**: All in NC; **Upper**: transport from KY and TN
Catawba	6/4/2002	28.4	SC	NC	**Low**: Upstate SC and NC; **Mid**: SC and NC; **Upper**: SC and NC
Catawba	7/5/1999	28.2	NE. TN	SW. VA / KY	**Low**: NE TN; **Mid**: NE TN and SW VA; **Upper**: SW VA and KY
Catawba	6/11/2000	28.2	NC / NE. TN / SC		**Low and Mid**: Majority Upstate SC, some NC; **Upper**: NC and some NE TN and Upstate SC
Catawba	8/16/2000	28.2	NE. TN / SW. VA	KY	missing data
Catawba	10/18/2000	28.2	NC	NE and Central TN	**Low**: Completely in NC; **Mid and Upper**: Eastern and Central TN
Catawba	8/4/1999	28.1	NC / VA		**Low, Mid, and Upper**: NC and SW VA
Catawba	9/31/01	28.1	NC	SW. VA and E. KY	**Low and Mid**: Completely in NC; **Upper**: SW VA and SE KY

Table 1 Continued

Table 2. Number of days that the HYSPLIT back trajectories indicated a region as a primary or secondary source for locations in Catawba and Davidson Counties in North Carolina.

Catawba County					***Davidson County***			
State/Area	**Primary (days)**	**Secondary (days)**	**Total (days)**		**State/Area**	**Primary (days)**	**Secondary (days)**	**Total (days)**
North Carolina	31	2	33		North Carolina	26	2	28
South Carolina	3	9	12		South Carolina	4	5	9
Tennessee	9	8	17		Tennessee	4	5	9
Virginia	6	5	11		Virginia	7	5	12
Georgia	1	7	8		Georgia	1	2	3
Kentucky	1	3	4		Kentucky	1	0	1
Ohio Valley	2	3	5		Ohio Valley	1	4	5
NC Only	27				NC Only	17		
NC + Other	4				NC + Other	9		
No NC	10				No NC	5		

Table 3. Number of days in the highest one-third of 24-hour average $PM_{2.5}$ values for all days for which HYSPLIT trajectories were run. Specific $PM_{2.5}$ values were 32.8 – 54.7 µg/m^3 for Catawba County and 34.9 – 46.8 µg/m^3 for Davidson County.

Catawba County – Upper Third					***Davidson County – Upper Third***			
State/Area	**Primary (days)**	**Secondary (days)**	**Total (days)**		**State/Area**	**Primary (days)**	**Secondary (days)**	**Total (days)**
North Carolina	10	0	10		North Carolina	8	1	9
South Carolina	0	3	3		South Carolina	2	2	4
Tennessee	2	3	5		Tennessee	2	3	5
Virginia	2	1	3		Virginia	2	0	2
Georgia	0	3	3		Georgia	0	1	1
Kentucky	0	0	0		Kentucky	1	0	1
Ohio Valley	1	1	2		Ohio Valley	0	1	1

Table 4. Number of days in the middle one-third of 24-hour average $PM_{2.5}$ values for all days for which HYSPLIT trajectories were run. Specific $PM_{2.5}$ values were 30.0 – 32.8 μg/m^3 for Catawba County and 30.6 – 34.1 μg/m^3 for Davidson County.

Catawba County – Middle Third					***Davidson County – Middle Third***			
State/Area	**Primary (days)**	**Secondary (days)**	**Total (days)**		**State/Area**	**Primary (days)**	**Secondary (days)**	**Total (days)**
North Carolina	10	0	10		North Carolina	9	0	9

Georgia	0	1	1		Georgia	0	1	1
Kentucky	0	2	2		Kentucky	0	0	0
Ohio Valley	1	1	2		Ohio Valley	1	0	1

Table 6. Total number of hours back trajectories spent in states other than North Carolina for all events for the Davidson County $PM_{2.5}$ monitor. Hours are based on the maximum of all trajectory heights, and therefore do not double count. Percent of total hours based on maximum hours of all events (1224 hours). Average hours based on average of each event, excluding zero hour events.

Appendix O:

Insignificance of NH_3 and VOCs to PM2.5 Attainment in North Carolina

(This page intentionally left blank)

1 Significance of Precursors Contributing to Fine Particulate Formation

The United States Environmental Protection Agency (USEPA) revised the National Ambient Air Quality Standards (NAAQS) for particulate matter in 1997 establishing fine particulates (particulate matter with aerodynamic diameter ≤ 2.5 micrometers or PM2.5) as a benchmark. The revised NAAQS for particulate matter set a daily standard of 65 $\mu g/m^3$ and an annual standard of 15.0 $\mu g/m^3$. The daily PM2.5 standard was more recently revised in 2006 by lowering it to 35 $\mu g/m^3$ based on a review of the air quality criteria and the NAAQS, but the annual PM2.5 standard was retained at 15.0 $\mu g/m^3$. Both of these revisions to the NAAQS for particulate matter are published in 40 CFR 50.7 and 40 CFR 50, Appendix N.

Areas designated as "nonattainment" for fine particulates by the USEPA must submit formal implementation plans detailing how attainment will be met as outlined in the Clean Air Act (CAA). These implementation plans must outline the measures that will be taken to curtail the concentrations of various pollutants that are assumed to have significant contributions to fine particulate nonattainment, including sulfur dioxide (SO_2), nitrogen oxides (NOx), and PM2.5.

The USEPA, in 72 FR 20586, requires states to "evaluate and consider control strategies for sources of SO_2, direct PM2.5, and NOx emissions in all nonattainment areas." However, the rule does allow states to make technical demonstrations to reverse the inclusion of NOx as precursor of PM2.5, or deem the precursor insignificant, based on geographical regions, emissions, etc. This then eliminates the need to examine NOx control measures for purposes of reducing PM2.5 concentrations. Although NOx is a relatively minor precursor of PM2.5 in North Carolina, the State of North Carolina is foregoing a technical demonstration of NOx insignificance and will follow the requirements in 72 FR 20586 to include NOx as a precursor for addressing attainment of the 1997 and 2006 revisions of the PM2.5 NAAQS.

The two remaining species that comprise PM2.5, ammonia (NH_3) and volatile organic carbons (VOCs) have been deemed as insignificant contributors to the total mass of PM2.5 by the USEPA. With regards to NH_3, 72 FR 20586 states NH_3 "is presumed not to be a PM2.5 attainment plan precursor, meaning that the State is not required to address [NH_3] in its attainment plan or evaluate sources of [NH_3] emissions for reduction measures." Likewise, the final rule for VOCs states that "States are not required to address VOC in PM2.5 implementation plans and evaluate control measures for such pollutants unless the State or EPA makes a technical demonstration that emissions of VOCs from sources in the State significantly contribute to PM2.5 concentrations in a given nonattainment area."

2 NH_3 and VOC Insignificance

The State of North Carolina agrees with the USEPA's presumptive exclusion of NH_3 and VOCs with regards to the PM2.5 implementation plan. Therefore, emission controls for NH_3 and VOCs are not considered as a part of the North Carolina Division of Air Quality's (NCDAQ's) PM2.5 attainment demonstration plan.

I. INTRODUCTION/BACKGROUND

The Visibility Improvement – State and Tribal Association of the Southeast (VISTAS) has contracted with E.H. Pechan & Associates, Inc. (Pechan) to prepare a 2002 mobile source emissions inventory. The purpose of this emissions inventory is to support the modeling and assessment of speciated particulate matter with an aerodynamic diameter less than or equal to 2.5 micrometers ($PM_{2.5}$). Through this contract, Pechan first prepared an inventory review document. This document summarized several regional and national emission inventory efforts and identified strengths and weaknesses associated with the use of these inventories in regional haze modeling. This document also summarized data submittals by State and local air agencies within the VISTAS region that could be used in the VISTAS 2002 mobile source emissions inventory.

Since that time, the State and local air agencies have updated their submittals for the mobile source sectors, including both onroad vehicles and nonroad engines. In July of 2003, Pechan delivered sets of inputs to the NONROAD model option files and MOBILE6.2 input files and vehicle miles traveled (VMT) data for each State and local agency to review. For the onroad sector, the MOBILE6.2 input files and VMT data represented Pechan's processing of the State and local inputs in a consistent manner for use in calculating the 2002 onroad emissions inventory. The MOBILE6.2 input files and VMT data included as much of the local data supplied by the State and local agencies as possible, with missing information filled in with appropriate default data. The data delivered by Pechan for the State and local agencies to review related to the nonroad sector was primarily in the form of temperature and fuel data that would be used as inputs to the NONROAD model. It should be noted that the nonroad sector inputs were completed first and did not include some of the later temperature and fuel updates that did get incorporated in the onroad data.

The State and local agencies were given a brief period to review, comment upon, and make updated submittals to the onroad and nonroad inputs that were delivered in July 2003. After receiving these comments and updated data, Pechan updated the appropriate MOBILE6.2 input files, VMT data, and nonroad inputs with the revised State and local data. Pechan then calculated 2002 onroad and nonroad emissions from these inputs. Pechan presented the preliminary results of these emission inventories at a VISTAS meeting on August 28, 2003. These draft August 2003 emission estimates, including inputs and methodology, were documented in a draft report circulated to VISTAS in October 2003. This October 2003 report also included documentation of draft 2002 refueling emissions from onroad and nonroad sources. The VISTAS States were asked to review this document, as well as the supporting files provided by Pechan, and provide comments or revisions by December 2003. Onroad and nonroad 2002 emissions for the VISTAS States have since been calculated based on the updates provided by the States. This report documents the inputs and methodologies used in the February 2004 version of the VISTAS 2002 onroad and nonroad mobile source emission inventories.

II. ONROAD METHODS AND DATA

A. 2002 VMT DEVELOPMENT

Table II-1 summarizes the type of VMT data submitted by each agency. Depending upon the data submitted by the individual State or agency, up to three different procedures were performed on the data. First, VMT data that were not provided at the annual level were converted from daily VMT to annual VMT. Second, VMT provided for years other than 2002 were grown from the base year provided. Finally, the VMT were allocated by vehicle type, if not already at that level of detail. The section discusses each of these procedures in more detail.

It should be noted that although the format and content of the VMT provided by the VISTAS State and Local agencies varied significantly from agency to agency, this draft 2002 VISTAS inventory is based at a minimum on county/roadway type specific VMT, as provided by the individual agencies. This is a significant improvement over the spatial allocation methods used in the U.S. Environmental Protection Agency's (EPA's) National Emission Inventory (NEI) for onroad vehicles.

1. Conversion to Annual VMT

For use in the emission calculations, Pechan's ultimate goal with the VMT data was to develop an annual 2002 VMT database by county, roadway type, and vehicle type. As indicated in Table II-1, the VMT data were submitted using three different time periods: annual, average annual day, and summer day. No temporal adjustments were applied to VMT data submitted as annual VMT. VMT data submitted as average annual day VMT were multiplied by 365 to convert from an average day to the annual time period. The Jefferson County, Kentucky VMT were submitted as summer day VMT. All annual VMT values were converted to units of millions of miles per year. Therefore, any VMT values submitted as miles were divided by a factor of 1,000,000 and VMT values submitted in units of 1,000 miles were divided by a factor of 1,000.

The Jefferson County, Kentucky VMT submittal included a single factor for converting the summer day VMT to average annual day VMT. Thus, the Jefferson County summer day VMT data were first multiplied by a factor of 0.97752 (the temporal conversion factor provided by Jefferson County) to obtain average annual day VMT. The VMT data were then multiplied by 365 to obtain the annual VMT.

Table II-1. VMT Data Provided by State/Local Agencies

State/Area	Time Period	2002 Actual VMT by County/Road Type/Vehicle Type	2002 Actual VMT by County/Road Type	2002 Projected VMT by County/Road Type	2002 VMT from TDM by County/Road Type/Vehicle Type	1999 Actual VMT by County/Road Type/Vehicle Type
Alabama	AAD		X

South Carolina	ANN		X			
Tennessee	AAD		X			
Virginia	ANN					X
West Virginia	ANN	X				X
Time Period Codes: AAD=Average Annual Day, SD=Summer Day, ANN=Annual						

2. Projection to 2002

As indicated in Table II-1, the Virginia VMT submittal was for a base year of 1999 rather than 2002. Thus, these VMT data needed to be projected to 2002 before calculating emissions. For Virginia, growth factors were developed by roadway type for the period from 1999 to 2001 based on historical VMT data by roadway type from Table VM-2 “Functional System Travel” in DOT’s *Highway Statistics* series (DOT, 1999 and 2001). The growth factors, presented in Table II-2, were calculated by dividing Virginia’s 2001 VMT for each of the 12 roadway types from *Highway Statistics 2001* by the corresponding 1999 VMT from *Highway Statistics 1999*. For the period from 2001 to 2002, the growth factors were developed using data obtained from the U.S. Department of Transportation’s Traffic Volume Trends report (DOT, 2002). This monthly publication provides a comparison of preliminary 2002 VMT estimates with comparable 2001 VMT. For several roadway types, these data are provided only at a national level. However, for the combined rural interstates and arterials, these data are presented by State. The resultant data, used to project the 2001 Virginia VMT to 2002, are shown in Table II-2. The 2001 to 2002 growth factors represent the 2002 VMT divided by the 2001 VMT, based on the data Virginia for the rural interstates and arterials and on the national data for the remaining roadway types. Once the growth factors were developed, the Virginia 1999 VMT data were first multiplied by the appropriate 1999 to 2001 growth factor and then by the appropriate 2001 to 2002 growth factor.

Table II-2. VMT Growth Factors Used for Virginia

Roadway Type	Roadway Type Portion of SCC	Virginia 1999 to 2001 VMT Growth Factor	Virginia 2001 to 2002 VMT Growth Factor
Rural Interstate	110	1.043	1.035
Rural Other Principal Arterial	130	1.050	1.035
Rural Major Arterial	150	1.130	1.035
Rural Major Collector	170	0.982	1.011
Rural Minor Collector	190	1.032	1.011
Rural Local	210	0.923	1.011
Urban Interstate	230	1.050	1.024
Urban Other Freeway & Expressway	250	0.984	1.011
Urban Other Principal Arterial	270	1.061	1.011
Urban Minor Arterial	290	0.991	1.011
Urban Collector	310	0.925	1.013
Urban Local	330	0.690	1.013

3. Splitting VMT by Road Type

The final step in developing a consistent 2002 VMT data base was to allocate VMT from the county and roadway type level of detail to the county/roadway type/vehicle type level of detail. As shown in Table II-1, the Jefferson County, Kentucky; Mississippi; Virginia; and West Virginia VMT data supplied for these jurisdictions already included the vehicle type level of detail, so this final adjustment was not needed for these areas. For the remaining areas, some provided VMT mix by vehicle type fractions while others provided no information on the allocation of VMT by vehicle. In this latter case, default VMT fraction data from EPA's MOBILE6 model were used.

The States for which MOBILE6 default VMT mix data were used are: Alabama, Florida, Georgia, Kentucky (excluding Boone County, Campbell County, Kenton County, and Jefferson County), and South Carolina. It should be noted that Georgia initially provided VMT fractions based on Georgia's HPMS classification count data, but after review of ten years of these data determined that they are not reflecting the trend towards increasing travel by light trucks. Georgia therefore decided it was more conservative to assume MOBILE6 default VMT fractions.

a. Allocation of VMT to Vehicle Type using Default VMT Mix Data

To calculate 2002 VMT at the county/roadway type/vehicle type level using national default data, the VMT totals by county and roadway type need to be allocated among the 28 MOBILE6 vehicle types. This was done based on the distribution of the 2001 rural and urban VMT among the six Highway Performance Monitoring Systems (HPMS) vehicle types found in Table VM-1 ("Annual Vehicle Distance Traveled in Miles and Related Data - 1999 - by Highway Category and Vehicle Type") of the Federal Highway Administration's (FHWA's) *Highway Statistics*

2001 (http://www.fhwa.dot.gov/ohim/ hs01/index.htm) and a mapping of these HPMS vehicle categories to the 28 MOBILE6 vehicle types. This mapping of the MOBILE6 vehicle types to the HPMS vehicle types was developed by EPA's Office of Transportation and Air Quality (OTAQ) and is used in the development of the NEI. The data first needed to be expanded to the 28 vehicle type level of detail to obtain the proper cross reference between the HPMS and MOBILE6 vehicle types since the eight vehicle types used in the final VISTAS VMT data base cannot be directly mapped to the HPMS vehicle categories. First, the VMT totals for each of the six HPMS vehicle categories were calculated as a fraction of the total VMT. This calculation was performed separately for the rural VMT and the urban VMT. The resulting 2001 VMT fractions for rural VMT and urban VMT are shown in Table II-3. Note that 2002 VMT are not yet available at this level of detail. Using the default MOBILE6 VMT fractions for 2001 (since the HPMS data represents 2001), taken from a MOBILE6 output file for 2001, the MOBILE6 VMT fractions were renormalized among all MOBILE6 vehicle types mapped to a given HPMS vehicle category. This renormalization is shown in the final column of Table II-3.

Table II-3. Allocation of VMT from HPMS Vehicle Categories to MOBILE6 Vehicle Types for 2001

HPMS Vehicle Category	HPMS 2001 Rural VMT Fractions	HPMS 2001 Urban VMT Fractions	MOBILE6 Vehicle Category	MOBILE6 2001 VMT Fractions by HPMS Category
Passenger Cars	0.5454	0.6065	LDGV	0.9980
			LDDV	0.0020
Motorcycles	0.0039	0.0031	MC	1.0000
Other 2-Axle 4-Tire Vehicles	0.3368	0.3375	LDGT1	0.1565
			LDGT2	0.5211
			LDGT3	0.1585
			LDGT4	0.0729
			LDDT12	0.0005
			LDDT34	0.0032
			HDGV2B	0.0658
			HDDV2B	0.0216
Single-Unit 2-Axle 6-Tire or More Trucks	0.0332	0.0212	HDGV3	0.0376
			HDGV4	0.0206
			HDGV5	0.0436
			HDGV6	0.0934
			HDGV7	0.0437
			HDDV3	0.1023
			HDDV4	0.0867
			HDDV5	0.0380
			HDDV6	0.2138
			HDDV7	0.3205
Combination Trucks	0.0770	0.0300	HDGV8A	0.0001
			HDGV8B	0.0000
			HDDV8A	0.2191
			HDDV8B	0.7808
Buses	0.0037	0.0017	HDGB	0.1920
			HDDBT	0.3258
			HDDBS	0.4822
Total	1.0000	1.0000		

To calculate VMT by vehicle type, each VMT value representing a given county and road type was multiplied by the product of the HPMS VMT fraction (selected depending upon whether the road type represent VMT on rural or urban roads) and the corresponding MOBILE6 VMT fraction by HPMS category. This process resulted in 28 VMT values at the county/roadway type/vehicle type level of detail for each county/roadway type VMT value in the original VMT file.

As an example, Table II-3 shows that the HPMS Passenger Car vehicle category accounts for 54.54 percent of the total VMT on rural road types and that the MOBILE6 LDGV category accounts for 99.8 percent of the VMT in the HPMS Passenger Car category. Therefore, a VMT value representing rural interstates would be multiplied by 0.5454 times 0.9980 (0.5443), to obtain the VMT total on rural interstates from LDGVs. Once all county/roadway type VMT values were expanded to the corresponding set of values of VMT at the county/roadway type/28 MOBILE6 vehicle type level of detail, the VMT data base was then totaled at the eight vehicle type level of detail (LDGV, LDGT1, LDGT2, HDGV, LDDV, LDDT, HDDV, MC).

b. Allocation of VMT to Vehicle Type using State-Provided VMT Mix Data

Both North Carolina and Tennessee provided VMT mix data at the eight vehicle type level of detail. The Tennessee data was provided for ten different county groupings, with a VMT mix provided for six aggregated roadway type categories. North Carolina provided statewide VMT mix fractions for each of the 12 roadway types. Since the VMT mix data for these two States were already at the eight vehicle type level, the procedure for allocating VMT by vehicle type was simpler than the procedure described above using the default data. Each county/roadway type VMT value was matched to the corresponding VMT mix for that county and roadway type and then separately multiplied by each of the eight VMT mix fractions to create eight VMT values by county/roadway type/vehicle type that would sum to the original VMT value at the county/roadway type level of detail.

c. Allocation of VMT by Month

The resulting annual county-level, vehicle, and roadway type-specific VMT data were temporally allocated to months during the emission calculations. National Acid Precipitation Assessment Program (NAPAP) temporal allocation factors were used to apportion the VMT to the four seasons. Monthly VMT data were obtained using a ratio between the number of days in a month and the number of days in the corresponding season. These temporal factors are shown in Table II-4. Several States provided some level of information on temporal adjustment factors for their VMT. These data were not used in this draft version of the 2002 VISTAS emission inventory due to time constraints. However, any State or locally supplied temporal adjustment factors will be included in the final version of the 2002 VISTAS onroad emission inventory.

Table II-4. Default VMT Seasonal and Monthly Temporal Allocation Factors

Roadway Seasonal VMT Factors

Vehicle Type	Roadway Type	Winter	Spring	Summer	Fall
LDV,LDT,MC	Rural	0.2160	0.2390	0.2890	0.2560
LDV,LDT,MC	Urban	0.2340	0.2550	0.2650	0.2450
HDV	All	0.2500	0.2500	0.2500	0.2500

Monthly VMT Factors

Vehicle Type	Roadway Type	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec

B. 2002 ONROAD EMISSION FACTOR DEVELOPMENT USING MOBILE6.2

The onroad emission factors used in the calculation of the VISTAS 2002 onroad emission inventory were generated using EPA's MOBILE6.2 emission factor model. In the development of the MOBILE6.2 input files, Pechan attempted to include as much of the relevant data supplied by the State and local agencies as possible, while at the same time, maintaining a generally similar overall structure to the MOBILE6.2 input files, such that the output emission factors could easily be matched to the appropriate VMT values. This section first discusses the overall general structure of the MOBILE6.2 input files. This is followed by details explaining how this general structure was adapted to include the State and local agency data and summaries of the types of data provided by each agency.

1. General MOBILE6.2 File Structure

Each MOBILE6.2 input file is divided into three sections: the header section, the run data section, and the scenario section. Information contained in the header section is primarily related to defining the output format and content desired by the user. For the processing of the VISTAS emission calculations, the database output format, aggregated to the daily level, was the desired output format. In addition, for proper modeling of the VOC emissions, it was desired to calculate the exhaust VOC emissions separately from the evaporative VOC emissions. However, within the constraints of MOBILE6.2 in the daily aggregated database output format, it is not possible to obtain evaporative and exhaust VOC emission factors broken out separately within each scenario. It is also not possible to obtain emission factors for both PM_{10} and $PM_{2.5}$ within a single MOBILE6.2 scenario. Therefore, two sets of MOBILE6.2 input files were created—one set to model VOC exhaust, NO_x, CO, SO_2, PM_{10}, and NH_3 emission factors and a second set to model VOC evaporative and $PM_{2.5}$ emission factors. Figure II-1 illustrates the header section of a sample VISTAS MOBILE6.2 input file used to generate the VOC exhaust, NO_x, CO, SO_2, PM_{10}, and NH_3 emission factors. Similarly, Figure II-2 illustrates the header section of a sample VISTAS MOBILE6.2 input file used to generate the VOC evaporative and $PM_{2.5}$ emission factors. The primary difference between these two header sections is in the selection of the emission types included, using the DATABASE EMISSIONS command and in the selection of the pollutants to be included in the output. In Figure II-1, having the first two flags set to "2" following the DATABASE EMISSIONS command indicates that the startup and running exhaust emission factor components will be included in the output emission factor table. In Figure II-2, the last six flags of the DATABASE EMISSIONS command line are set to "2" to obtain the evaporative emission factor components in the emission factor output file. In Figure II-2, the pollutants SO_2 and NH_3 are eliminated from the PARTICULATES command line, as the emission factors for these pollutants will be reported in the output file resulting from the file shown in Figure II-1.

The next section of the MOBILE6 input files is the run data section. This section includes data that applies to all scenarios in the input file. Figure II-3 shows an example of this section for a county using default data. The only commands included in this example tell MOBILE6 that the HC emission factors should be expressed in terms of VOC and that refueling emission factors should be excluded from the output. It should be noted that refueling emissions were calculated using a separate set of input files, but were excluded from the onroad input files here since refueling emissions are included in the area source inventory rather than the onroad inventory. Chapter IV discusses the onroad refueling MOBILE6 input files and emission calculations. Comments in Figure II-3 indicate that this input file is using default registration distributions and diesel sales fractions. For any input files that represent counties for which registration distribution, diesel sales fractions, or trip length distributions have been provided or that have an inspection and maintenance (I/M) program, anti-tampering program (ATP), or low emission vehicle program in place in 2002, additional inputs are required in the run data section of the MOBILE6.2 input file. Figure II-4 shows an example of an input file including all of these data. Some of these data inputs are included directly in the MOBILE6.2 input file, while other data are contained in external text files that are named by the commands in the run data section. For questions regarding the specifics of any of the MOBILE6 input commands listed, the MOBILE6 User's Guide should be consulted.

The third and final section of the MOBILE6.2 input files contains the scenario data. For this VISTAS inventory, each speed and road type combination or speed distribution were modeled in twelve consecutive scenarios representing the temperature and fuel properties applicable in each month. Thus, if a State agency supplied an average speed/road type combination for each of the 12 HPMS road categories, the corresponding MOBILE6.2 input file would have 144 scenarios. The first scenario would represent January temperature and fuel conditions at the speed and MOBILE6 roadway type for the first speed/roadway type provided (typically rural interstates). This would be followed by the February scenario modeled for the same speed and roadway type, and so on through the twelfth scenario representing December conditions for the same speed and roadway type combination.

Figure II-5 illustrates a sample scenario from one of the VISTAS MOBILE6.2 input files. This is the first scenario in the file—therefore, it represents January temperature and fuel conditions. The month of a given scenario in the VISTAS MOBILE6.2 input files can be determined by the last two digits of the SCENARIO RECORD command line. In this case, the last two digits are “01” indicating January. It should be noted that the only options for the EVALUATION MONTH command are “1” indicating January or “7” indicating July. For the VISTAS input files, the EVALUATION MONTH was set to “1” for all months from January through June and to 7 for months from July through December. When this flag is set to “1”, it indicates that MOBILE6 will use a January registration distribution. When the flag is set to “7”, MOBILE6 ages the registration by a half year, applying a half year of fleet turnover to the distribution. The EVALUATION MONTH setting can also affect the reductions from reformulated gas programs. However, by including the SEASON command, as shown in Figure II-5, the EVALUATION MONTH flag setting will not affect reformulated gasoline reductions. With the SEASON flag set to “2”, winter reformulated gasoline rules will be applied in areas with a reformulated gas program modeled (using the FUEL PROGRAM command). Summer reformulated gas rules and reductions will be applied when the SEASON flag is set to “1” if reformulated gas has been modeled. In all of the VISTAS input files, the SEASON flag was included for all areas, whether or not a reformulated gasoline program was modeled. This flag has no effect when the FUEL PROGRAM command is not used. The SEASON flag was set to “1” for the months of May through September and to “2” for the remaining months.

```

Local speed data were provided by the agencies in Georgia, Kentucky, North Carolina, Tennessee, and Virginia. A set of 12 monthly scenarios was developed for each speed input for these States, with one exception. The Northern Kentucky (Boone County, Campbell County, and Kenton County) and Jefferson County, Kentucky inputs were speed distribution files, rather than average speeds by individual roadway types (one for Northern Kentucky and one for Jefferson County, Kentucky). In this case, only 12 scenarios were modeled in total in the Jefferson County and Northern Kentucky input files, with the Jefferson County or Northern Kentucky speed distribution referenced in each scenario, respectively. No speed information was provided for Alabama, Florida, Mississippi, South Carolina, or West Virginia. The average speeds modeled in these files were the default speeds used in the NEI. These speeds are shown in Table II-5 and vary by both roadway type and vehicle category. It should be noted that several agencies provided speed information for ramps. Since the VMT data file is organized by SCC and no SCC currently exists for ramp VMT, the ramp speed information could not be used directly. In some cases, the fraction of VMT occurring on ramps was provided. In these cases, this information was combined with the freeway speeds, following the guidance in the MOBILE6 user's guide to determine the overall freeway speed including the ramp speed, at 34.6 mph (the assumed value for ramp speeds in MOBILE6), and the fraction of VMT occurring on the ramps.

Table II-5. Default Speeds Modeled by Road Type and Vehicle Type (mph)

	Speed (mph) and MOBILE6 Road Type		
HPMS Road Type	**Light Duty Vehicles**	**Light Duty Trucks**	**Heavy Duty Trucks**
Rural Interstate	60 Freeway	55 Freeway	40 Freeway
Rural Principal Arterial	45 Arterial	45 Arterial	35 Arterial
Rural Minor Arterial	40 Arterial	40 Arterial	30 Arterial
Rural Major Collector	35 Arterial	35 Arterial	25 Arterial
Rural Minor Collector	30 Arterial	30 Arterial	25 Arterial
Rural Local	30 Arterial	30 Arterial	25 Arterial
Urban Interstate	45 Freeway	45 Freeway	35 Freeway
Urban Other Freeway and Expressway	45 Freeway	45 Freeway	35 Freeway
Urban Principal Arterial	20 Arterial	20 Arterial	15 Arterial
Urban Minor Arterial	20 Arterial	20 Arterial	15 Arterial
Urban Collector	20 Arterial	20 Arterial	15 Arterial
Urban Local	Local	Local	Local

Another optional input included in the scenario section of the MOBILE6 input files is the VMT mix by 16 MOBILE6 vehicle categories. These vehicle categories are based on the 28 MOBILE6 vehicle categories, but with gasoline and diesel vehicles of the same weight class combined together. When no information was provided on VMT mix, the MOBILE6 defaults were used. Local VMT mix information provided by Tennessee, Virginia, and Jefferson County, Kentucky were included in the MOBILE6.2 input files. In some cases, the same VMT mix was applied to all scenarios. In other cases, the VMT mixes were specific to roadway type, so the VMT mix would vary according to the roadway type being represented in the scenario.

C. 2002 ONROAD EMISSION INVENTORY CALCULATIONS

Once the MOBILE6.2 input files were set up and run through the MOBILE6.2 model, onroad emissions were calculated by multiplying the monthly VMT for a given county, roadway type, and vehicle type by the emission factor modeled for the same month, county, vehicle type and roadway type. Because the MOBILE6.2 input files were set up to create output files in the form of database tables, the output is provided by each of the 28 MOBILE6 vehicle types. Thus, the emission factors first were aggregated to the eight vehicle categories included in the VMT files. This was done using the VMT Fraction data provided in each of the MOBILE6 output files. For each of the MOBILE6 vehicle types included in one of the eight vehicle types needed, the VMT fractions were renormalized within that category. These eight vehicle categories are sometimes referred to as the MOBILE5 vehicle categories. For example, the LDGT1 and LDGT2 MOBILE6 vehicle categories are both included in the MOBILE5 LDGT1 category. In this case, the MOBILE6 LDGT1 VMT fraction was divided by the sum of the MOBILE6 LDGT1 and LDGT2 VMT fractions. The same was done with the MOBILE6 LDGT2 VMT fraction, so that the renormalized MOBILE6 LDGT1 and LDGT2 VMT fractions should now sum to 1. Next, these normalized VMT fractions were multiplied by the corresponding MOBILE6 emission factor and all of these weighted emission factors for a given scenario, within a MOBILE5 vehicle category were summed to obtain the weighted emission factors at the MOBILE5 vehicle category level. The VMT fractions included in the MOBILE6 output files are affected by the registration distribution, diesel sales fractions, and VMT mixes supplied in the MOBILE6.2 input files. Areas that used the MOBILE6 defaults for each of these inputs should all have the same VMT fractions, although even in these cases, there are two sets of VMT fractions—one for the months from January through June and another for the months July through December. This occurs due to the aging of the registration distribution caused by the use of the EVALUATION MONTH flag, as discussed above. These emission factors, now at the MOBILE5 vehicle category level, were multiplied by the corresponding VMT values to obtain monthly emissions by county, roadway type, and vehicle category.

D. DATA PROVIDED BY STATE AND LOCAL AGENCIES

The sections above describe some of the data that was supplied by the VISTAS State and local agencies for use in the development of the 2002 onroad emission inventory. Tables II-6 through II-15 summarize the data supplied by each agency in a consistent fashion. These tables primarily list the data that were actually used in this analysis. This section provides additional information on the data supplied by these agencies as well discussing why some of the data supplied could not be used.

Table II-6. Summary of Onroad Data Provided by Alabama

Data Element	Data Supplied by Responsible Agency
VMT Data	2002 actual daily VMT by county/road type
MOBILE6 Input Files	
MOBILE5 Input Files	
VMT Mix Information	
Counties by Temperature Region	
Monthly Temperatures	Monthly 2002 temperatures by county
RVP Data	March-September RVP values
Speed Data	
Registration Data	
Fuel Information	
I/M Program Information	N/A

I/M Program Information	N/A
Other	

Table II-8. Summary of Onroad Data Provided by Georgia

Data Element	Data Supplied by Responsible Agency
VMT Data	2002 actual average annual daily VMT by county and functional classification prepared by Georgia DOT
MOBILE6 Input Files	Provided MOBILE6 sample input files
MOBILE5 Input Files	
VMT Mix Information	
Counties by Temperature Region	
Monthly Temperatures	
RVP Data	Provided summer RVP values
Speed Data	Provided 2002 statewide speeds by road type (speeds based on VMT-weighted average speeds, from a 2002 loaded highway network for the 13-county Atlanta area)
Registration Data	Provided one MOBILE6 registration distribution for 13-county Atlanta area and one MOBILE6 registration distribution for rest-of-state
Fuel Information	Provided information on Georgia gasoline program, applied to 25 counties
I/M Program Information	Provided I/M inputs for 13-county Atlanta area in MOBILE6 format
Other	Provided VMT temporal adjustment factors by month and day of week for each road type (not used in the 01/04 inventory)

Table II-9. Summary of Onroad Data Provided by Kentucky

Data Element	Data Supplied by Responsible Agency
VMT Data	2002 actual daily VMT by county/road type
MOBILE6 Input Files	Provided sample MOBILE6 input files for several counties
MOBILE5 Input Files	
VMT Mix Information	
Counties by Temperature Region	Provided temperature stations to be used for several counties
Monthly Temperatures	
RVP Data	Provided summer RVP for several counties
Speed Data	Provided average speed by road type for several county groupings
Registration Data	
Fuel Information	Verified counties in reformulated gasoline program
I/M Program Information	I/M program information provided
Other	
Jefferson County, Kentucky	
Data Element	**Data Supplied by Responsible Agency**
VMT Data	2002 summer day VMT from TDM by county/road type/vehicle type
MOBILE6 Input Files	Provided MOBILE6 input files representing the four different vehicle control combinations found in Jefferson County
MOBILE5 Input Files	
VMT Mix Information	Provided Jefferson County VMT mix in MOBILE6 format
Counties by Temperature Region	
Monthly Temperatures	Provided 2002 actual monthly temperature data for Louisville area
RVP Data	Provided summer and winter RVP values
Speed Data	Provided speed distribution file for Jefferson County
Registration Data	Provided registration distribution for Jefferson County in MOBILE6 format
Fuel Information	Reformulated gasoline modeled
I/M Program Information	I/M program information provided
Other	Provided absolute humidity data
Boone County, Campbell County, and Kenton County, Kentucky	
Data Element	**Data Supplied by Responsible Agency**
VMT Data	2002 actual daily VMT by county/road type
MOBILE6 Input Files	
MOBILE5 Input Files	Provided MOBILE5 input file for Northern Kentucky counties
VMT Mix Information	
Counties by Temperature Region	
Monthly Temperatures	
RVP Data	Provided summer and winter RVP values
Speed Data	Provided speed distribution file for Northern Kentucky
Registration Data	Provided registration distribution for Northern Kentucky in MOBILE6 format—LDGVs and LDGT1s only
Fuel Information	Reformulated gasoline modeled
I/M Program Information	I/M program information extracted from MOBILE5 input file
Other	Provided Northern Kentucky VMT distributions by facility type and by hour in MOBILE6 format

Table II-10. Summary of Onroad Data Provided by Mississippi

Data Element	Data Supplied by Responsible Agency
VMT Data	1999 actual annual VMT by county/road type/vehicle type
MOBILE6 Input Files	Provided MOBILE6 input files for representative counties
MOBILE5 Input Files	
VMT Mix Information	
Counties by Temperature Region	Provided listing of counties within each of several temperature regions
Monthly Temperatures	
RVP Data	Provided summer RVP data
Speed Data	Speed data provided for each VMT record
Registration Data	2002 county-level registration data provided for nonattainment counties
Fuel Information	Verified counties in reformulated gasoline program
I/M Program Information	I/M and ATP inputs provided in MOBILE6 formats; verified counties that implement I/M
Other	LEV progam modeled statewide; provided diesel sales fractions

Table II-15. Summary of Onroad Data Provided by West Virginia

Data Element	Data Supplied by Responsible Agency
VMT Data	2002 actual annual VMT by county/road type/vehicle type
MOBILE6 Input Files	Supplied several sample MOBILE6 input files
MOBILE5 Input Files	
VMT Mix Information	VMT data included vehicle type splits
Counties by Temperature Region	Supplied counties in each of 4 temperature regions
Monthly Temperatures	
RVP Data	Supplied summer RVP value statewide
Speed Data	Supplied speed data in MOBILE6 input files--speed data determined to be inappropriate for this analysis
Registration Data	
Fuel Information	
I/M Program Information	N/A
Other	

1. Temperature

The default average daily maximum and minimum temperature data for each month used in this analysis was obtained from the National Climatic Data Center. This temperature data was actual 2002 data. It should be noted that a number of agencies provided information on ozone season or summer temperatures. This information could not be used in this analysis, as the ozone season temperature data are based on several years of temperature data and do not represent the average daily minimum and maximum monthly temperatures that were needed for this analysis. Information was provided by Alabama, Kentucky, North Carolina, South Carolina, Virginia, and West Virginia related to monthly temperature. In some cases, this data divided the counties within the State into several temperature regions and listing a city that should be used for obtaining the temperature data. In these cases, a temperature station from the National Climatic Data Center database was selected from the desired city, and this corresponding temperature set was applied to the counties listed by the States. Several of the States provided their own full set of 2002 temperature data either Statewide or by county. These data were included in the analysis, replacing the default temperature data for those States.

2. I/M and ATP Programs

Several agencies provided I/M and ATP inputs in the form of MOBILE5 input files. Pechan converted these inputs to MOBILE6 inputs, following the guidance in the MOBILE6 user's guide. Agencies that provided the data in MOBILE5 format should review the MOBILE6 I/M and ATP inputs carefully to make sure that the conversions fully capture the actual programs as they were implemented in 2002. In addition, from information provided by North Carolina, Tennessee, and Jefferson County, Kentucky, the I/M and ATP programs should only be applied to a portion of the VMT in the corresponding counties. For the North Carolina and Tennessee I/M counties, duplicate MOBILE6.2 input files were created that eliminate the I/M and ATP programs. The VMT from these counties was divided according to the fraction of the VMT subject to I/M and the fraction of the VMT not subject to I/M. These fractions were provided by the corresponding agencies in North Carolina and Tennessee. The VMT data for each I/M county was then divided according to these VMT fractions to obtain one set of VMT for the portion of vehicles subject to I/M and another set for those not subject to I/M. The emission factors from the I/M files were multiplied by the portion of the VMT subject to I/M while the emission factors from the files without the I/M were multiplied by the remaining portion of the VMT. In Jefferson County, Kentucky, a similar procedure was followed. However, in this case, the county also has a significant portion of VMT from vehicles registered in Indiana that are not subject to I/M or that do not have reformulated gasoline. Thus, the Jefferson County VMT was divided into four subsets and four MOBILE6 input files were developed representing the four groups of vehicle types traveling in the county.

3. RVP and Fuel Programs

Default RVP by county and month were obtained from the data used in the 2002 NEI. The NEI fuel data are based on year 2000 fuel survey data for January and July, with data for intermediate months calculated by interpolation. RVP data for July were applied from May through September, the months when Phase II RVP regulations are in effect. For States that supplied

July, summer, or ozone season RVP values, these values were also applied from May through September. If winter RVP values were supplied, these values were applied directly in each of the remaining months. As mentioned above, reformulated gasoline programs were modeled where appropriate. Georgia provided additional fuel inputs to capture the RVP and sulfur content values of its low sulfur gasoline program.

III. NONROAD METHODS AND DATA

A. NONROAD MODEL CATEGORIES

Pechan used EPA's draft NONROAD2002a model to generate 2002 annual emissions for the majority of nonroad engines. To improve the accuracy of these model runs, we asked State/ Local/Tribal (S/L/T) contacts to provide seasonal or monthly gasoline Reid Vapor Pressure (RVP) and temperature; appropriate data on reformulated gasoline (RFG), oxygenated fuel and Stage II programs, and diesel fuel sulfur levels. In addition, to improve the activity data inputs, we asked whether S/L/T agencies had collected information on equipment populations or activity (e.g., hours of use or load factors) to use in place of default populations in the NONROAD model. No S/L/T agencies provided activity data to replace the model defaults.

Seasonal average RVP and average, maximum and minimum temperature values were calculated based on the county-level, monthly RVP and temperature data set prepared for onroad mobile sources. Information on RFG programs and oxygenated fuels programs obtained for the onroad mobile sector was also used. In July 2003, Pechan distributed the input values (RVP, percent O2, temperature, and Stage II control efficiency) to be used for the draft NONROAD model 2002 inventory for review and comment by the VISTAS S/L/T agencies. Pechan obtained comments from the S/L/T agencies listed in Table III-1.

Table III-1. Summary of Comments by S/L/T Agencies on NONROAD Model Input Values Distributed in July 2003

State	Comment
Alabama	Provided region specific data to replace the statewide default values for RVP and ambient temperature
Georgia	Changed oxygen weight percent to zero for all counties
Kentucky	No Stage II programs in Bullitt and Oldham Counties
Tennessee	Revised RVP value for Davidson County
Mississippi	Revised statewide RVP by season
Virginia	No Stage II program in Charles City County

Additional comments on the August 2003 NONROAD model temperature and RVP inputs were incorporated for consistency with data submitted for the onroad mobile modeling (e.g., North Carolina). In addition, the State of West Virginia provided revised geographic allocation files for certain nonroad categories to improve upon the NONROAD model's default county allocation.

Using the inputs shown in the file "VISTAS NONROAD County Inputs.xls," Pechan prepared seasonal option files for each of four seasons (winter, spring, summer, and autumn), and ran the

NONROAD model at the county level. Model default values were used for all other inputs, with the exception of diesel fuel sulfur. A value of 2,500 parts per million volume (ppmv) was used instead of the default 2,318 ppm, since the default represented a national average including California's lower diesel fuel sulfur level. Pechan summed the seasonal results, and then processed the model output to develop a county-level, SCC-level annual emissions inventory for all pollutants except NH_3.

The NH_3 emissions for NONROAD model categories were developed using the following procedures. OTAQ recently reviewed the basis of NH_3 data summarized in a report entitled, "A Study of the Potential Impact of Some Unregulated Motor Vehicle Emissions" (Harvey, 1983). In conducting this review, OTAQ performed an analysis of the available light-duty noncatalyst engine data to develop defensible gasoline nonroad emission factors on a mg/gallon basis (Harvey, 2003). For both gasoline noncatalyst and diesel engines, fuel based emission factors were developed from emission factors expressed on a gram/mile basis by accounting for the reported fuel economy of each tested engine. For gasoline non-catalyst engines, this resulted in a value of 115.8 mg/gallon, which is applied to county-level fuel consumption estimates for 2-stroke gasoline, 4-stroke gasoline and liquified petroleum gas (LPG) equipment. From the diesel engine test data, a value of 83.3 mg/gallon was derived, which is applied to diesel fuel consumption estimates. County-level fuel consumption for these engines, expressed in gallons, is an output from EPA's NONROAD model.

B. AIRCRAFT, COMMERCIAL MARINE VESSELS AND LOCOMOTIVES

For 2002 aircraft, commercial marine vessels (CMVs), and locomotives, Pechan used 1999 emission estimates developed for EPA's 1999 NEI Version 2 as base year estimates for the VISTAS region. These categories are not included in the NONROAD model, and are hereafter referred to as "other nonroad." Pechan then incorporated revised S/L/T estimates summarized in Table III-2, using the replacement procedures summarized in Tables III-3a through III-3d. Pechan tracked changes by labeling the default 1999 NEI records as Version 2 (V2) and the revised S/L/T records as Version 3 (V3). In cases where PM2.5 estimates were not provided, they were developed using the following category-specific fractions applied to the available PM_{10} emission estimates: 1) Aircraft: 0.69; 2) Locomotive: 0.90; and 3) CMV: 0.92 (EPA, 2002). Commercial marine adjustments are described in detail in the following section.

Table III-2. Summary of S/L/T Agency Data Incorporated into the Draft VISTAS 2002 Other Nonroad Inventory

State	Description of Inventory	Pollutants
Alabama	1999 Locomotive emissions for Pickens and Tuscaloosa counties	VOC, NO_x, and CO
Florida	2001 Aircraft, Locomotive and Commercial Marine Vessel emissions for Palm Beach County	VOC, NO_x, CO, PM10, and SO_x
Tennessee	1999 Aircraft and Locomotive emissions for Davidson County	VOC, NO_x, CO, SO_x, and primary PM_{10}
Virginia	1999 Statewide Inventory for Aircraft, Locomotive and Commercial Marine Vessels	VOC, NO_x, CO

[1] Other counties may also have emissions for SCCs 2285002008 and 2285002009. In these cases, sum up SO2, PM10-PRI, and PM2.5-PRI emissions for SCCs 2285002006, 2285002007, 2285002008, and 2285002009 and add to SCC 2285002005. After that, delete all records for SCC 2285002006, 2285002007, 2285002008, and 2285002009.

2. CMV Improvements

This section describes procedures for improving the spatial distribution of CMV emission estimates for the VISTAS region. States that share borders with non-VISTAS States along the Mississippi and Ohio Rivers have expressed concern about the representativeness of port emission estimates at a county-level. Revising the county-level emissions estimates would allow more accurate modeling of emissions in the VISTAS States.

Ideally, CMV emission estimates would be developed using local activity data that account for vessel type, engine type and mode of operation (cruise, maneuvering, and hotelling). Creating this type of "bottom-up" emission inventory requires a large amount of effort. Therefore, Pechan utilized port-specific emission estimates developed for the 1999 NEI, distributed using a revised allocation methodology, which incorporates information on the number of port facilities in each county.

a. Current Allocation Method

The current 2002 VISTAS commercial marine inventory is based on EPA's 1999 NEI Version 2.0, projected to 2002 using appropriate growth factors. State-supplied data were incorporated by EPA or by Pechan for some VISTAS States for this category, including Alabama, Virginia, West Virginia, and Palm Beach County, Florida.

The 1999 NEI estimated emissions for these categories according to the following SCCs:

SCC	Descriptor 1	Descriptor 3	Descriptor 6	Descriptor 8
2280002100	Mobile Sources	Marine Vessels, Commercial	Diesel	Port emissions
2280002200	Mobile Sources	Marine Vessels, Commercial	Diesel	Underway emissions
2280003100	Mobile Sources	Marine Vessels, Commercial	Residual	Port emissions
2280003200	Mobile Sources	Marine Vessels, Commercial	Residual	Underway emissions

For the 1999 NEI, commercial marine diesel emissions were developed by obtaining 2000 emission estimates for all pollutants except SO_2 from OTAQ's marine diesel regulatory background documentation (*Draft Regulatory Impact Analysis - Control of Emissions from Compression-Ignition Marine Engines*). To estimate emissions for 1999, 2000 estimates were backcast using growth factors obtained from the draft RIA cited above. Steam-powered residual CMV emission estimates were developed by obtaining fuel usage data from OTAQ and applying fuel-based emission factors (EPA, 1989). A similar method was used for diesel SO_2 emissions. National diesel usage was estimated assuming a sulfur content of 0.25 percent and EPA emission factors (EPA, 2002).

National diesel emissions were disaggregated into port and underway emissions estimates based on the assumption that 75 percent of distillate fuel is consumed within the port, while the remaining fuel is consumed while underway, consistent with EPA guidance. National residual emissions were disaggregated into port and underway emissions estimates based on the assumption that 25 percent of residual fuel is consumed within the port, while the remaining fuel is consumed while underway (EPA, 1989).

To allocate to counties, port emissions were assigned to the 150 largest U.S. ports based on activity obtained from the U.S. Army Corps of Engineers (USACE). The percentage of total traffic for each port was calculated by dividing the port-level traffic by the total traffic. Emissions for each port were then assigned to a single county.

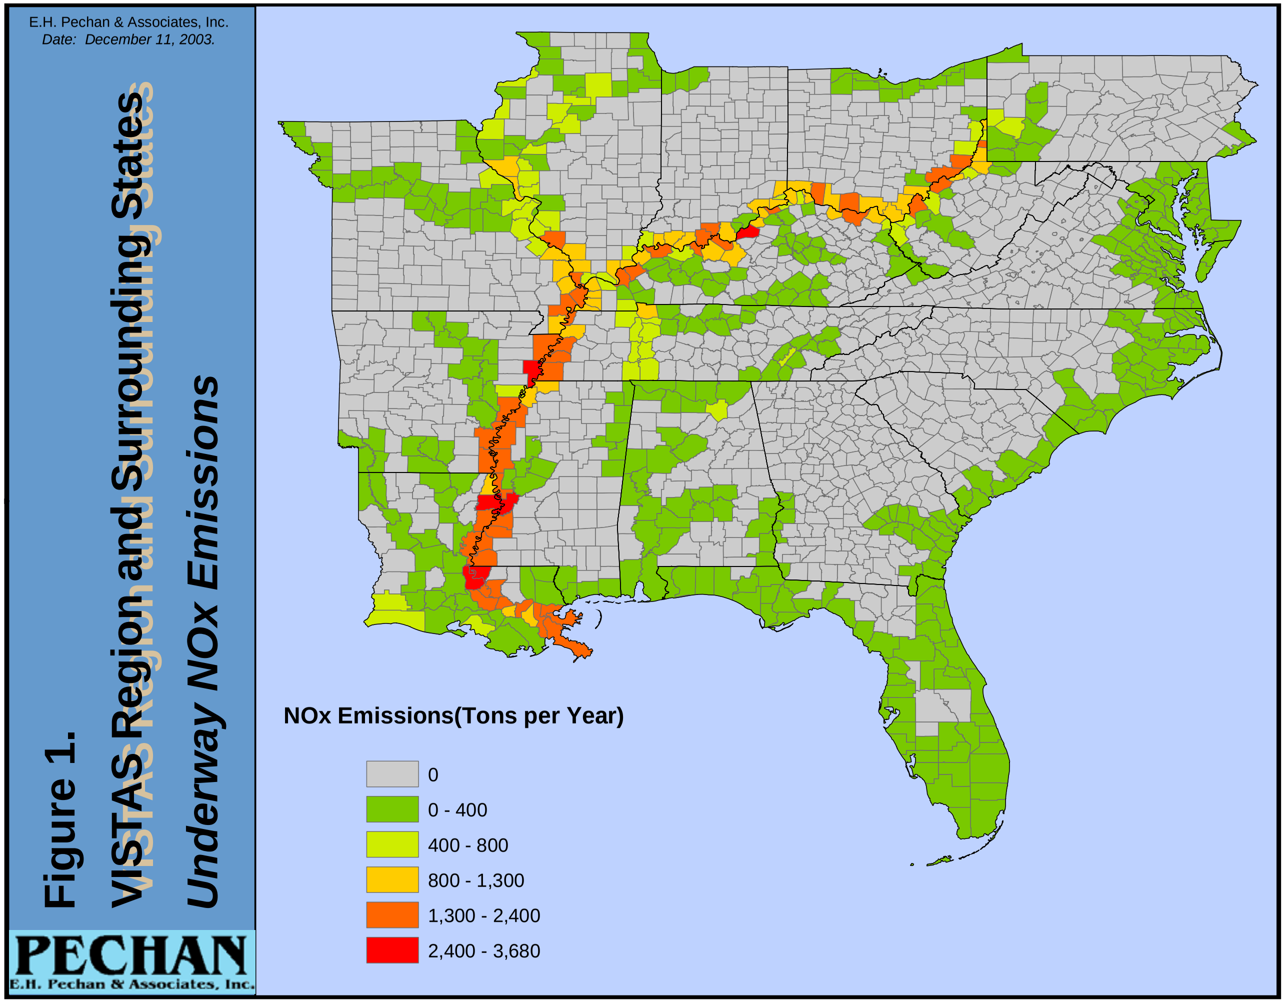
Underway emissions are assigned to counties based on a county=s shipping lane traffic. The Bureau of Transportation Statistics' (BTS=) *National Transportation Atlas Databases-1999* contains data on the thousand tons per mile traveled for each shipping lane link in the United States (BTS-CD26). Where navigable rivers form a county or State boundary, the shipping lane traffic is proportioned to individual counties based on the length of shoreline that is shared. For example, if two counties share a navigable river, and both counties have the same length of shoreline, the shipping traffic is split evenly between the two counties. Shipping lanes that are not within counties, for example in the ocean, are associated to States based on BTS assignments. These waterway weights are then evenly distributed among the counties within these States that have navigable waterways. All shipping activity is summed at the county-level and compared with national shipping activity to determine what portion of activity can be attributed to individual counties. These proportions were used in disaggregating the national CMV emission estimates to the county level.

b. Revised Port Allocation Method

Figures III-1 and III-2 present emission maps for CMV port and underway NO_x emissions created from the 1999 NEI Version 2.0 data. For underway emissions, Pechan believes that the allocation procedure results in a reasonable distribution of county-level emissions. However, the methodology to allocate port emissions results in all the emissions being assigned to a single county. For example, Cabell County in West Virginia is assigned all emissions for Huntington Port, but no emissions are allocated to Lawrence County in Ohio, the county on the opposite river bank.

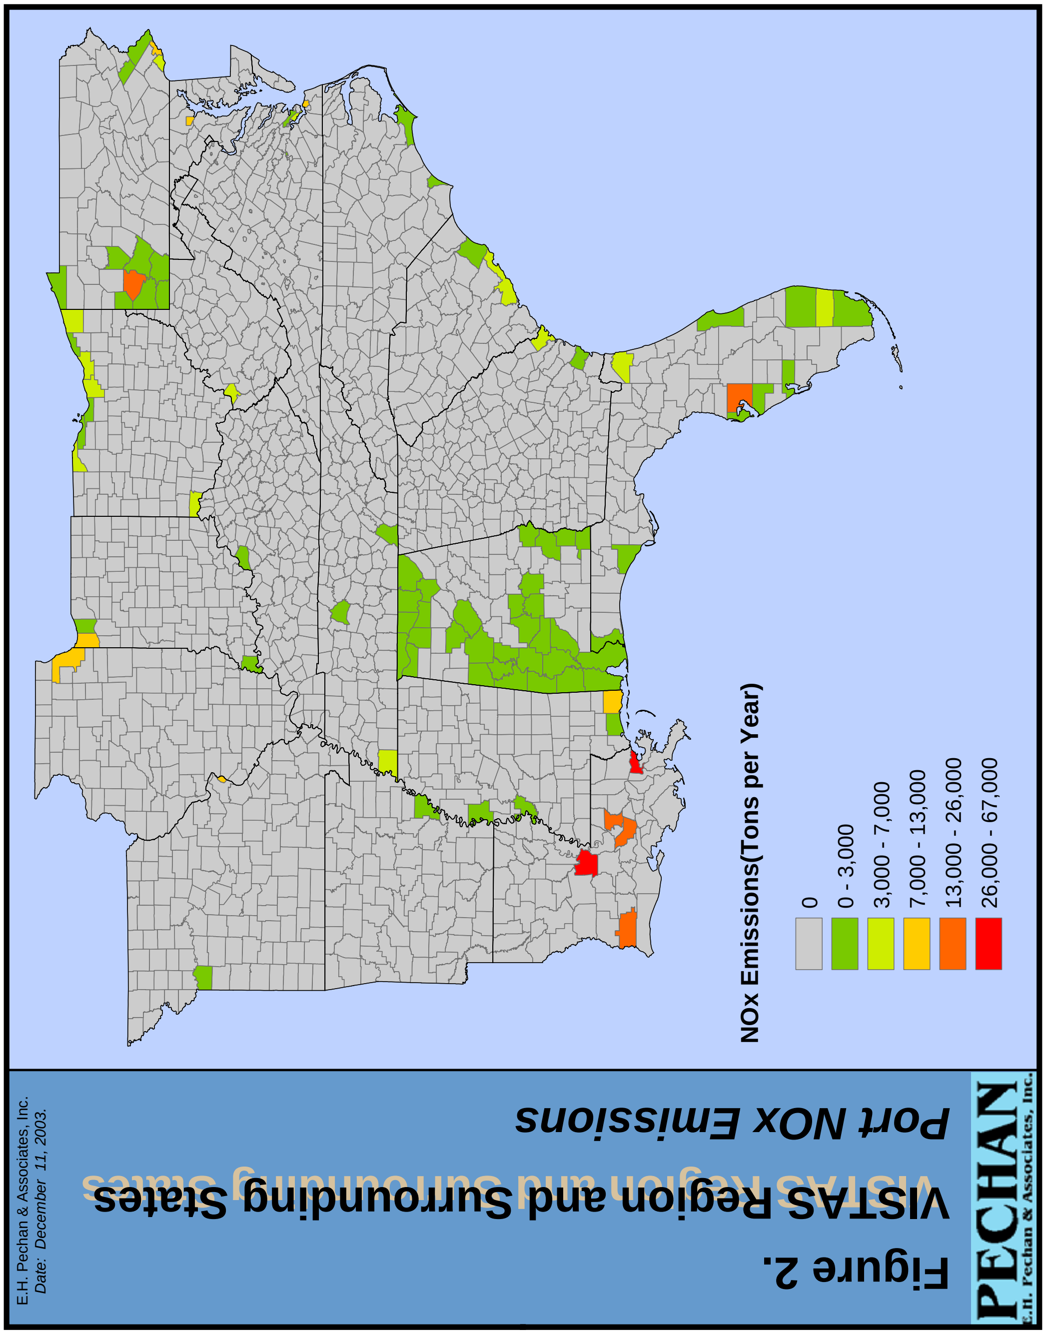
Port areas encompass multiple States and counties and in some cases, multiple waterways. Therefore, the emissions allocation process must incorporate all counties in the vicinity of the port where activity is occurring. This is especially true for inland rivers where activity takes place on both riverbanks and for 10 river miles or more outside the port city. The revised methodology allocates port emissions based on a surrogate for port-related activity in each county, rather than using a single county to define the port.

Figure III-1. VISTAS Region and Surrounding States, *Underway NO_x Emissions*



30

Figure III-2. VISTAS Region and Surrounding States, *Port NO_x Emissions*



31

The report, *Waterborne Commerce of the United States, Calendar Year 1999* (USACE, 2000), hereafter referred to as *Waterborne Commerce*, presents the cargo tonnage and number of vessel trips in major waterways of the United States. The report defines port areas, which USACE uses to develop the Top 150 Ports in the United States by amount of cargo tonnage. As discussed in the previous section, the 1999 NEI allocates all the port emissions to these 150 ports based on the cargo tonnage handled by the port.

Pechan uses this allocation of emissions to each port area as the starting point of its revised allocation process. Table III-4 presents the ports that are located in VISTAS and adjoining States, which are part of the Top 150 Ports.

New Orleans	LA	Huntington	WV
Baton Rouge	LA		

The next step was to develop a list of counties that make up the port area. Port area definitions were obtained from *Waterborne Commerce*. Table III-6 presents the port definitions for the VISTAS States and adjoining States. Using the port definitions by river mile, Pechan established which counties are included in each port area. In many cases, these port areas encompass multiple counties. For example, Pittsburgh is defined in *Waterborne Commerce* as:

> Ohio River from Pittsburgh, PA to mile 40 (Pennsylvania/Ohio State Line);
> Allegheny River from Pittsburgh, PA to mile 72 (to head of project);
> Monongahela River from Pittsburgh, PA to mile 91 (to head of project).

Therefore, the Port of Pittsburgh includes the following counties in Pennsylvania; Allegheny, Westmoreland, Armstrong, Washington, Fayette, Greene, Beaver. This process was repeated for all the port areas listed in Table III-4.

The next step in allocating emissions is to develop a surrogate for the amount of CMV activity in each county of the port area. Pechan assumed that the activity of vessels in each county is related to the number of port facilities operating in a given county. Port facilities include terminals, piers, wharves, and docks that are involved in all types of commercial activity and support services. Pechan obtained the number of port facilities in each county from *The Port Series Reports* (USACE, 2003). The USACE periodically surveys the commercial marine industry to obtain information on port facilities and publishes it in *The Port Series Reports*. The reports give the name, location, operations, and describe the physical and inter-modal characteristics of the facilities. The data includes the location of the facility by river mile, State, and county.

For each port area, Pechan calculated the ratio between the number of port facilities in each county to the total number of facilities in all counties that make up the port area. This ratio was used to allocate emissions for each port area to the county-level. Table III-5 presents the allocation ratios for each county in the port areas. Some port areas were still encompassed by one county using the definition of the port from *Waterborne Commerce*. However, a number of port areas include multiple counties. Note that New Orleans and Pittsburgh do not include any counties in VISTAS States.

Table III-5. List of VISTAS Ports and Ports of Adjoining States

Port	State	County	Ratio	Port	State	County	Ratio	Port	State	County	Ratio

Pechan was directed to perform the reallocation for all VISTAS ports. Figure III-3 presents the reallocation of port emissions in all States except Alabama. Alabama's CMV data were provided to EPA and already incorporated into the 1999 NEI Version 2, and Pechan did not have access to the default 1999 NEI estimates for this State and category. Since State data take precedence, the inventory prepared by Pechan reflects the incorporation of State data for those areas that developed independent CMV emission estimates, including Virginia and Palm Beach County, Florida. In addition, West Virginia provided their own county fractions to allocate emissions for the Port of Huntington, using District-level data from the Army Corps of Engineers on tonnage of freight shipped and received. West Virginia also requested that residual-fueled CMV activity/emissions be zeroed out for their State. States providing their own data are encouraged to review the allocations Pechan developed for their port areas, and to provide further comment or direction as needed.

Table III-6. Definition of Port Areas Obtained from Waterborne Commerce (USACE, 2000)

VISTAS PORTS
MOBILE, AL Entrance. bay and river channels, and channels into Chickasaw and Three Mile Creeks; Branch Channels; Theodore Ship Channel.
GUNTERSVILLE, AL Both banks of the Tennessee River at mile 358 to mile 363.
JACKSONVILLE HARBOR, FL Atlantic Ocean to the Florida East Coast Railway Bridge at Jacksonville, 26.8 miles.
TAMPA, FL Gulf of Mexico to and including the channels of upper Tampa Harbor, 49.8 miles; Channel to Port Tampa and thence to Courtney Campbell Parkway, 17.5 miles; Natural channel leading from Port Tampa Channel toward St. Petersburg, 1.8 miles; Alafia River Channel, 3.6 miles; Hillsborough River to City Waterworks Dam, 10 miles; Channels in "Little Manatee River, Fl; Port Manatee, Fl Harbor."
MIAMI HARBOR, FL Atlantic Ocean to inner end of turning basin at Miami, 6 miles; Meloy Channel and thence natural channels along the easterly side of Biscayne Bay to Bakers Haulover Inlet, FL, about 11 miles; channel from turning basin to mouth of Miami River, 1.1 miles; existing Florida East Coast Railway Channel, Fishermans Channel from mouth of Miami River to Government Cut, 3.8 miles; and the channels reported under "Miami River, FL."
EVERGLADES HARBOR, COLLIER COUNTY, FL - No definition given
CANAVERAL HARBOR, FL Entrance Channel (Atlantic Ocean) to Barrier Beach inner channel and Turning Basins, thence a Barge canal through a lock in the perimeter dike and continuing to the Intracoastal Waterway, Jacksonville to Miami.
CHARLOTTE HARBOR, FL Gulf of Mexico to Municipal Terminal at Punta Gorda, about 29.5 miles; waterfront on Gasparilla Island from Port Boca Grande to Boca Grande, 4.5 miles; and Myakka River to El Jobean, 4 miles.
PALM BEACH HARBOR, FL Atlantic Ocean to Port of Palm Beach Terminals, 1.7 miles; Lake Worth from Riviera Bridge to Southern Boulevard Bridge at West Palm Beach, 7.5 miles; and "Palm Beach, FL side channel and basin."
PORT MANATEE, FL 40 feet deep by 400 feet wide entrance channel and basin. The entrance channel extends approximately 3 miles in length from the turning basin to its intersection with Tampa Harbor main channel. Controlling Depth: 40 feet in entrance channel and turning basin.
PANAMA CITY HARBOR, FL Entrance channel, inside bay and Watson Bayou. Project Depth: Approach channel, 34 feet; across Lands End, 32 feet; Watson Bayou, 10 feet.

Table III-6. Definition of Port Areas Obtained from Waterborne Commerce (USACE, 2000)

PENSACOLA HARBOR, FL Entrance channel and entire harbor, including Bayou Chico. Project Depth: entrance, 35 feet; Inner Harbor, 33 feet; Bayou Chico, 15 and 14 feet.
WEEDON ISLAND, FL – no definition
BRUNSWICK HARBOR, GA From 32-foot contour in the ocean across the Barthrough St. Simon Sound, Brunswick River, and Turtle River to the upper end of the Allied Chemical Company's Wharf, formerly Atlantic Refining Company Wharf, 20.4 miles; from Brunswick River through East River, to the upper end of the project in Academy Creek, 2.7 miles; from St. Simon Sound through Back River to Mill Creek, the upper end of Back River improvement, 2.9 miles; from Back River through Terry Creek to the Glynn Canning Company's Wharf, 1.8 miles; a total distance of 27.8 miles.
SAVANNAH HARBOR, GA From the 40-foot contour in the ocean to the Continental Can Company Plant, 32.15 miles.
LOUISVILLE, KY Both banks of the Ohio River from mile 606 to mile 616 Controlling Depth: 9 feet. Project Depth: 9 feet at low water stages.
BILOXI HARBOR, MS Mississippi Sound, Biloxi Bay, Back Bay, and land cut to Gulfport Lake. Project Depth: East entrance channel, Mississippi Sound to Gulfport Lake, 12 feet: West entrance channel, Mississippi Sound to Biloxi Harbor, 10 feet; Ott Bayou, 12 feet.
GREENVILLE, MS From Mississippi River mile 537 AHP left descending bank in an easterly direction, an entrance channel, 8,000 feet long and 250 feet wide transitioning into the harbor and port area 10,000 feet long and 500 feet wide, then transitioning into Lake Ferguson, a channel 5,700 feet long and 250 feet wide.
GULFPORT HARBOR, MS Mississippi Sound Channel, Ship Island Pass Channel, and Small Craft Harbor about 4,300 feet long west of the anchorage basin. Project Depth: Mississippi Sound, 30 feet; Ship Island Pass, 32 feet; Small Craft Harbor, 8 feet.
PASCAGOULA HARBOR, MS Lower 4 miles of Dog River and lower 6.8 miles of Pascagoula River, Mississippi Sound, Bayou Casotte, and Horn Island Pass Channels.
VICKSBURG, MS From Mississippi River mile 437 AHP on left descending bank in a northerly direction, a channel 14,500 feet long by 150 feet wide in the Yazoo Diversion Canal, thence a dredged entrance channel 4,800 feet long and 150 feet wide, transitioning into a 300-foot wide dredged slack water harbor and turning basin 10,700 feet long.
MOREHEAD CITY HARBOR, NC Morehead City Harbor, NC.

Table III-6. Definition of Port Areas Obtained from Waterborne Commerce (USACE, 2000)

PORT OF WILMINGTON, NC (see also Wilmington Harbor NC for waterway data) Both banks of the Cape Fear River extending from a point about 18 miles below the foot of Castle St. in Wilmington to a point about 2 miles above the Railroad Bridge at Navassa, and both banks of Northeast (Cape Fear) River from its mouth to a point about 1.67 miles above the Hilton Railroad Bridge.
CHARLESTON HARBOR, SC (Including Ashley River, Cooper River, Shem Creek And Shipyard River, SC) Ocean to Goose Creek via Cooper River and Town Creek; to the Standard Wharf on Ashley River; to the Mount Pleasant Memorial Highway Bridge on Shem Creek; to the Airco Alloys Wharf on Shipyard River; Wando River to Cainhoy.
GEORGETOWN HARBOR, SC (Winyah Bay) Atlantic Ocean Entrance to Winyah Bay, SC, to and including turning basin in Sampit River at the City of Georgetown, SC.
MEMPHIS, TN Section Inlcuded: From mile 715.5 to mile 741.0 on Lower Mississippi River and includes Memphis Harbor (McKellar Lake) and Wolf River Harbor, Tennessee. Controlling Depth: 9 feet. Project Depth: 9 feet at low water stages.
PORT OF NASHVILLE, TN (included in traffic of Cumberland River, TN and KY) Both banks of Cumberland River, mile 182 to mile 194 Controlling Depth: 9 feet. Project Depth: 9 feet at low water stages.
CHATTANOOGA, TN Section Included: Both banks of the Tennessee River at mile 454 to 471. Controlling Depth: 9 feet. Project Depth: 9 feet at low water stages.
PORT OF RICHMOND, VA (Included in James River, VA Consolidated Report)
PORT OF NEWPORT NEWS, VA (Including Newport News Creek, VA) Lower east shore of James River from mouth to 1.8 miles, and portion of north shore of Hampton Roads covering approximately 15,000 linear feet of waterfront at Newport News; and Newport News Creek.
PORT OF HOPEWELL, VA (Included In James River VA Consolidated Report) South side of James River, from City Point, at mouth of Appomattox River, 2 miles downstream to the mouth of Baileys Creek. Controlling Depth: 25 feet at mean low water. Project Depth: 35 feet, maintained to 25 feet.
NORFOLK HARBOR, VA From 55-foot contour in Hampton Roads to Norfolk & Western (formerly Virginia) Railway Bridge Crossing Southern Branch of Elizabeth River, 14.78 miles; thence upstream in Southern Branch, 4.61 miles. In Eastern Branch, 2.54 miles upstream from the mouth of that branch; in Western Branch, 1.78 miles upstream from the mouth of that branch; and 0.73 miles in Scotts Creek.
HUNTINGTON, WV Both banks of the Ohio River from mile 303 to mile 317 Controlling Depth: 9 feet. Project Depth: 9 feet at low water stages.

Table III-6. Definition of Port Areas Obtained from Waterborne Commerce (USACE, 2000)

NON-VISTAS PORTS
HELENA, AR Mile 659 through mile 663 on the Lower Mississippi River. The project provides for maintenance of an off-river harbor with dimensions of 9 feet deep and 450 feet wide for a length of 3,200 feet.
MOUNT VERNON, IN Section Included: Right Bank of Ohio River from mile 151 to mile 154. Controlling Depth: 9 feet. Project Depth: 9 feet at low water stages.
CINCINNATI, OH Both banks of the Ohio River from mile 465 to mile 491. Controlling Depth: 9 feet. Project Depth: 9 feet at low water stages.
PORT OF PITTSBURGH, PA Ohio River from Pittsburgh, PA to mile 40 (Pennsylvania/Ohio State Line); Allegheny River from Pittsburgh, PA to mile 72(to head of project); Monongahela River from Pittsburgh, PA to mile 91(to head of project). Includes Aliquippa-Rochester, Pittsburgh, Clairton-Elizabeth. Controlling Depth: 9 feet. Project Depth: 9 feet.
PORT OF PLAQUEMINES, LA Both banks of Mississippi River from mile 0 A.H.P. through mile 81.2 A.H.P Controlling and Project Depths: 45 feet.
PORT OF BATON ROUGE, LA Both banks of Mississippi River from mile 168.5 A.H.P. through mile 253 A.H.P; including the Baton Rouge Barge Canal from a point on the east bank of the Mississippi River at mile 234.5 A.H.P., for a distance of 5 miles.
PORT OF NEW ORLEANS, LA Both banks of the Mississippi River from mile 81.2 A.H.P. through mile 114.9 A.H.P.; Innerharbor Navigation Canal, 5.5 miles; Mississippi River-Gulf Outlet from its junction with the Innerharbor Navigation Canal to Bayou Bienvenue, 7 miles; and Harvey Canal, 5.5 miles.
PORT OF SOUTH LOUISIANA (LA) Both banks of Mississippi River from mile 114.9 A.H.P. through mile 168.5 A.H.P. Controlling and Project Depths: 45 feet.

3. Projection Methods

Pechan then projected the revised 1999 inventory to 2002 using surrogate growth indicators. For the aircraft category, 1999 and 2002 approach operations by airport and aircraft type were compiled from the Federal Aviation Administration's Air Traffic Activity Data System (ATADS). The airport-level landing and takeoffs (LTOs) were assigned to counties and summed for the county. For counties with aircraft emissions without a county match in ATADS, State-average growth factors were calculated and applied. The county-level growth factors are not presented in this report, but could be provided to VISTAS S/L/Ts if requested.

For locomotives, projected emissions were developed in two steps as described below. For 1999 to 2001, State-level vessel bunkering and rail fuel consumption was obtained from the Energy Information Administration's (EIA's) *Fuel Oil and Kerosene Sales.* For 2001 to 2002, Pechan applied national growth factors developed from fuel consumption projections in EIA's *Annual Energy Outlook.* Table III-7a lists the growth factors for locomotives that were applied to the 1999 emissions to first develop 2001 emissions. Table III-7b lists the growth factors used to generate 2002 emissions. Locomotive emissions were not revised from the August 2003 draft VISTAS 2002 inventory.

Table III-7a. Growth Factors for Railroad Distillate Fuel Oil Use

FIPSST	State	Rail Distillate Fuel Oil Sales (Thousand Gallons)		Growth Factor (GF)
		1999	2001	
01	Alabama	42,137	55,777	**1.3**
12	Florida	127,269	107,084	**0.8**

Since the CMV emissions were revised for the 1999 base year, these emissions were projected using 2002 *Fuel Oil and Kerosene Sales* data, which became available in November 2003. Table III-8 lists the growth factors for CMVs that were applied to 1999 emissions to generate 2002 emissions. The same regional growth factor that accounts for an average regional growth rate was applied to CMV emissions for all VISTAS States. Because the State-level data represents sales and not use, and CMV activity spans State borders, a regional growth factor was deemed more appropriate. Pechan could make a similar adjustment for the locomotive growth factors, which are also based on fuel sales for 1999 to 2001, if requested by VISTAS.

Table III-8. Growth Factors for Commercial Marine Vessel Distillate and Residual Fuel Oil Use

IV. ONROAD REFUELING METHODS

Emissions were separately calculated from onroad refueling, also known as Stage II emissions. Since refueling is a category of evaporative rather than exhaust emissions, VOC is the only criteria pollutant of concern for this category. This chapter discusses the controls modeled for this emission category and the methods used to calculate these emissions. Refueling emissions for onroad sources were updated in February 2004 to account for the VMT updates provided by several States.

A. CONTROLS

Based on default information from the NEI as well as some information provided by VISTAS agencies, portions of five of the VISTAS States have onroad Stage II refueling controls in place. These States, along with the specific counties with onroad Stage II controls, are listed in Table IV-1. This table also shows information about the Stage II control program in each State including the year a Stage II program began, the number of years that the program was phased-in over, and the control efficiency of the program in reducing VOC emissions from Stage II refueling for the LDGV, LDGT, and HDGV vehicle categories. These are the inputs required for modeling a Stage II control program using MOBILE6. States with Stage II programs should review this information and provide any corrections for the next round of emissions modeling.

Table IV-1. Onroad Stage II Control Programs

State	Start Year	Phase-In Years	Control Efficiency	Counties
Florida	1993	2	95%	Broward, Miami-Dade, Palm Beach
Georgia	1992	3	81%	Cherokee, Clayton, Cobb, Coweta, DeKalb, Douglas, Fayette, Forsyth, Fulton, Gwinnett, Henry, Paulding, Rockdale
Kentucky	1999	2	86%	Boone, Campbell, Kenton
Kentucky	1992	2	95%	Jefferson
Tennessee	1993	3	95%	Davidson, Rutherford, Sumner, Williamson, Wilson
Virginia	1993	2	95%	Counties: Arlington, Chesterfield, Fairfax, Hanover, Henrico, Loudoun, Prince William, Stafford Independent Cities: Alexandria, Colonial Heights, Fairfax, Falls Church, Hopewell, Manassas, Manassas Park, Richmond

B. METHODS

A simplified set of MOBILE6.2 input files was created to simulate the onroad refueling emission factors. These input files were simplified because several of the inputs used for calculating the onroad exhaust and evaporative emission factors do not affect the refueling emission factors. For example, the refueling emission factors are unaffected by vehicle speed or I/M program. Thus, for each group of counties in a State with the same fuel parameters, temperature parameters, fleet characteristics (registration distribution, diesel sales fractions), and Stage II control program parameters, a MOBILE6.2 input file was created to model the onroad refueling emission factors. As mentioned above, speed does not affect the refueling emission factors, so each input file contained only 12 scenarios—one for each month of the year. Within each scenario, the temperature and fuel parameters were varied, using the same temperature and fuel data modeled in the onroad exhaust and evaporative MOBILE6.2 input files. Other fleet characteristics, such as registration distributions and diesel sales fractions, were included in the input files where applicable. The inputs shown in Table IV-1 were included for the input files representing counties with Stage II control programs. The header section of the MOBILE6.2 input files was set up so that only refueling emission factors would be included in the tabular output file.

After the MOBILE6.2 input files were generated, they were run through the MOBILE6.2 model to obtain refueling VOC emission factors in the database table format. These emission factors are produced for the 28 MOBILE6 vehicle types. The emission factors were then weighted using the VMT fraction information included in the MOBILE6 output tables to obtain VOC refueling emission factors for the 8 vehicle types included in the VISTAS VMT database. The VMT fraction information contained in the MOBILE6 input files is based on the default MOBILE6 registration distributions, diesel sales fractions, and VMT fractions, or, when this information is provided in the input files, based on area-specific fleet parameters. A database of emission factors by month, county, and 8 vehicle types was then prepared. In calculating monthly onroad refueling emissions, the VISTAS annual VMT data were temporally allocated by month in the same manner as described in Chapter II for the onroad exhaust and evaporative emission calculations. These VMT were then multiplied by the corresponding monthly emission factor (in terms of grams per mile) to obtain refueling emissions from onroad vehicles. The monthly emissions for each county were then summed to obtain annual refueling emissions. Also, since refueling emissions are included in the area source inventory and are not distinguished by vehicle type, all refueling emissions from onroad vehicles were summed for each county in the VISTAS region. Summaries of the refueling emissions from onroad vehicles are presented in Chapter VI.

V. NONROAD REFUELING METHODS

The NONROAD model accounts for refueling emissions from nonroad equipment under two separate components, vapor displacement and spillage. Vapor displacement emissions result when new liquid fuel being added to a fuel tank displaces fuel vapors already present in the tank. Spillage emissions result when fuel is spilled during the refueling process.

Nonroad equipment may be fueled from a gasoline pump or a portable container. Refueling nonroad equipment from a portable container results in different emissions for both spillage and vapor displacement compared to refueling from a gasoline pump. In addition, the use of portable containers also results in extra refueling events. Both spillage and displacement emissions will also occur when the container is filled from a gasoline pump. However, due to lack of data, the NONROAD2002 model does not attempt to quantify this set of refueling emissions. As such, the NONROAD model refueling emissions associated with nonroad equipment being filled directly at the gasoline pumps will be used to represent the nonroad Stage II emission component. Stage II control factors listed in Table IV-1 were input in the county-specific NONROAD model option files. Once the model runs were performed, Pechan extracted the refueling and spillage emissions corresponding only to those engines (typically the larger horsepower engines) within each SCC assumed to be refueled at the pump. The list of SCC and horsepower ranges associated with pump versus container refueling is specified in the model since different emission rates are assumed for these two types of refueling.

Table V-1 presents draft annual Stage II VOC emission estimates by State. These emissions were combined with the onroad vehicle Stage II estimates described in Section IV of this report.

Table V-1. 2002 Draft Stage II Refueling Emissions by State

FIPSST	NAME	VOC Emissions, tpy
01	Alabama	167.25
12	Florida	842.60
13	Georgia	209.01
21	Kentucky	112.65
28	Mississippi	147.18
37	North Carolina	298.49
45	Tennessee	197.81
47	South Carolina	155.33
51	Virginia	174.70
54	West Virginia	39.33

VI. SUMMARY OF RESULTS

This chapter presents the emission results from the February 2004 draft version of the 2002 mobile source emissions inventory for the VISTAS region. These emissions result from the data and procedures described in the preceding chapters of this report.

A. ONROAD RESULTS

Table VI-1 summarizes the latest 2002 VISTAS onroad emissions inventory by State. This table also summarizes the total VMT for each State. Tables VI-2 and VI-3 are provided here for the purpose of comparing this inventory with another existing onroad inventory. The emissions shown in Table VI-2 are taken from Version 2 of EPA's 1999 NEI. Table VI-3 then shows the percentage change from the 1999 NEI to the 2002 draft VISTAS inventory. If the two inventories had been developed using comparable data, one would generally expect to see reductions in the onroad emissions from 1999 to 2002 due to fleet turnover resulting in the replacement of older, dirtier vehicles with vehicles meeting more stringent emission standards. However, this reduction in per-vehicle emissions also needs to overcome increases in VMT for the overall emissions to decrease. All of the VISTAS States show increases in VMT from 1999 to 2002, except North Carolina. This decrease in VMT needs to be further investigated by the State agency. States that were modeled with significant State or locally supplied inputs in the VISTAS modeling, such as Virginia and Georgia, would be expected to have more significant differences from the NEI data than States with no State-supplied information other than VMT. Some of the State inputs that cause significant deviations from the NEI estimates are registration distributions, VMT mixes by vehicle type, and speeds by road type. In addition, some of the pollutants are more affected by these inputs, while others (such as NH_3) are minimally affected by these inputs. The 2002 VISTAS onroad emissions will continue to undergo review. Any comments or questions on these emissions by the State or local agencies will be investigated as part of this review.

Table VI-1. 2002 VISTAS Onroad Emissions and VMT by State (February 2004 Version)

State	2002 Annual Emissions (tons per year)							2002 Annual VMT

B. NONROAD RESULTS

Table VI-5 provides a summary of draft 2002 nonroad sector annual emissions by State, including Stage II refueling emission estimates. Table VI-6 provides a summary of the draft 2002 NONROAD model emission estimates by State, and compares the values to 2001 NONROAD model NEI Version 2 estimates by showing the percent difference. A similar comparison is shown in Table VI-7 for other nonroad emission estimates compared to the 1999 NEI Version 2.

For the NONROAD model categories, SO_2, PM_{10}, $PM_{2.5}$, and NH_3 decrease consistently across all States. SO_2 emissions decrease due in part to a lower diesel fuel sulfur content input for the NONROAD model runs, which also contributes to decreases in particulate emissions. The decrease in NH_3 is due primarily to corrections made to compresses natural gas (CNG) engine NH_3 emissions, which involved zeroing out the estimates. The 1999 NEI erroneously applied emission factors on a grams per gallon basis to CNG fuel consumption. Although reported as uncompressed gallons in the NONROAD model, the CNG fuel consumption estimates represent a gaseous, not liquid, volume. Based on OTAQ's recommendations, CNG NH_3 emissions are now reported as zero. CO and NO_x show little change for all States, and changes in VOC vary by State and are dependent on the contribution of specific equipment categories (detail not shown).

For other nonroad categories, the increase in PM_{10} and $PM_{2.5}$ is due to the addition of commercial aircraft PM emissions. Commercial aircraft PM_{10} and $PM_{2.5}$ emissions were zero in the 1999 NEI; hence, the large percent increase. To gap fill this portion of the inventory, Pechan calculated and applied an average air taxi PM/NO_x emission ratio to commercial aircraft NO_x emissions. States with a higher proportion of commercial aircraft show significant PM increases (e.g., FL, TN, VA). In addition, NO_x emissions decrease due to new State data for other nonroad from AL and VA.

VII. OBSERVATIONS AND RECOMMENDATIONS FOR IMPROVEMENT

This chapter lists several areas where the onroad and nonroad emission inventories could be improved. Some of these improvements require a long lead-time for the States and would not likely be available for the final 2002 VISTAS modeling, but could improve future State and regional inventory efforts.

A. ONROAD SECTOR IMPROVEMENTS

In the onroad sector, significant improvements have been made to the inventory due to the State and local agencies providing 2002 VMT data by county and roadway type. For this February 2004 version of the VISTAS onroad inventory, only the Virginia VMT were projected by Pechan. It is anticipated that this States will be able to provide 2002 VMT data for use in the next revision of the inventory.

Local registration distribution data were provided by fewer than half of the VISTAS States. In many cases, registration data can be obtained from State Departments of Motor Vehicles. States that do not already do so should request a download of the data summarizing registrations by model year and vehicle class from their appropriate motor vehicle agency. Although it is probably too late in many cases to obtain 2002 data, 2003 registration data could be used with some adjustments in developing the 2002 emission inventories. Registration data will become even more important as VISTAS prepares to project a 2018 onroad emission inventory, since the 2018 projections will be affected by the number of vehicles that are subject to the Tier 2 emission standards and the new heavy duty vehicle standards. The registration distributions directly determine the proportion of vehicles subject to these new emission standards.

A relatively small amount of data was obtained regarding the distribution of VMT by season or month. Many State Departments of Transportation collect data that could be used to better distribute VMT by season or month. States should check to see what is available. These distributions will affect the episodic modeling that will be conducted by VISTAS. Pechan is currently performing a VMT scoping study for VISTAS to determine what data are available for better allocating VMT and emissions by month, day, and hour. These temporal improvements are expected to be incorporated into the next update of the VISTAS onroad emission inventory.

Due to the direct relationship between the VMT mix by vehicle type and the overall emissions, States should investigate potential sources of information for this data to replace the default data used here in most States.

EPA is currently in the process of preparing guidance on estimating emissions from heavy duty vehicles during long-term idling (sometimes referred to as hotelling). While these emissions are theoretically included in the MOBILE6 HDDV emission factors, they are not currently accounted for in the appropriate locations. For example, these emissions would typically occur at rest stops, trucking centers, and warehouse and distribution centers. With the current modeling, these emissions are spread over all counties, based on the VMT traveled by HDDVs in each county. If significant sources of truck idling emissions occur in or near Class I areas, the current modeling may be underestimating the effect of these emissions. If States are able to obtain data on the locations and utilization of truck rest stops, some of this emissions effect could be more appropriately accounted for in future versions of VISTAS modeling.

B. NONROAD SECTOR IMPROVEMENTS

NH_3 emissions for aircraft, commercial marine and locomotives are still reported as zero. As a result of recent communications with OTAQ, Pechan would suggest applying the updated nonroad diesel NH_3 emission factors used for the NONROAD model categories to activity data for commercial marine vessels and locomotives. To develop ammonia from commercial marine vessels and locomotives, Pechan would need to obtain or compile the county-level fuel consumption estimates used as the basis for 1999 emissions for these categories to use as the activity data for calculating updated NH_3 emissions. The presence of State or local data in the 1999 NEI does not allow for this to be determined easily by backing out the reported emission factors, and in some cases (e.g., diesel commercial marine), actual emissions (instead of activity) were obtained at a national level and allocated to counties (EPA, 2002). Alternatively, Pechan could use county level fuel consumption estimates developed for these categories for 2000 or 2001. These activity data were used by Pechan to estimate dioxin/furan emission estimates for the 2000 and 2001 NEI. Pechan could normalize the 2000 or 2001 county distribution to national level fuel consumption estimates for 1999. Due to the characteristics of aircraft jet and piston engines, Pechan does not recommend estimating aircraft NH_3 emissions using the available NH_3 emission factors.

Documentation of the Base G2 and Best & Final 2002 Base Year, 2009 and 2018, Emission Inventories for VISTAS

Introduction

Base G2 document was delivered final in Aug (?) 2007. In fall 2007 states updated specific point source EGU and non-EGU facility record in Best and Final (B&F) inventories for 2009 and 2018 to account for BART controls, consent decrees, corrections to Base G2, and source specific controls. Only EGU and non-EGU point source records were changed. Area, non-road, on-road remained the same as Base G2. In this report all records for area, non-road, and on-road were used in B&F modeling the same as Base G2. This report has been updated from the Base G2 report submitted in July 2007 just for B&F changes to EGU and non-EGU sources. A history of the development of the VISTAS inventory follows. Specific sections of the document detail the modifications made as the inventory progressed from Base F through B&F.

The Base G2 inventory included changes in 2018 controls on specific electric generating units in GA, FL, NC, and WV. There were no changes in 2009 controls for EGU and no changes between the Base G and Base G2 inventories for non-EGU point, on-road, non-road, or area sources in 2009 or 2018. The Base G2 modeling run included changes for 2018 EGU controls plus corrections in 2002 typical, 2009, and 2018 for errors in emissions processing in Base G. These corrections in emissions processing are not seen when comparing the Base G and G2 inventory files.

Base G and Base G2 inventories represent two separate model runs, as does the B&F. Since Base G2 supersedes Base G, VISTAS will maintain only the Base G2 and B&F model files since both were used in State Implementation Plan submittals.

History of VISTAS Base and Projection Year Emission Inventory Development

This section is provided to supply the history behind the development of the base and projection year inventories provided to the Visibility Improvement State and Tribal Association of the Southeast (VISTAS) and the Association for Southeast Integrated Planning (ASIP). Through the various iterations, the inventories that have been developed have typically had version numbers provided by the contractors who developed the inventories and to a certain extent these were also based on their purpose. Different components of the 2002 base year inventories have been supplied by E.H. Pechan and Associates, Inc. (Pechan), MACTEC Engineering and Consulting, Inc.

(MACTEC), and by Alpine Geophysics, Inc. (AG). The projection year inventories were developed by MACTEC and AG.

The initial 2002 base year inventory was jointly developed by Pechan and MACTEC. Pechan developed the on-road and non-road mobile source components of the inventory while MACTEC developed the point and area source component of the inventory. This version of the inventory included updates to on-road mobile that incorporated information from the 1999 NEI Version 2 final along with updated information on VMT, fuel programs, and other inputs to the MOBILE6 model to produce a draft version of the 2002 inventory. For non-road sources, a similar approach was used. Updated State information on temperatures and fuel characteristics were obtained from VISTAS States and used with the NONROAD 2002 model to calculate 2002 emissions for NONROAD model sources. These estimates were coupled with data for commercial marine vessels, locomotives and airplanes projected to 2002 using appropriate growth surrogates. A draft version of these inventories was prepared in late 2003, with a final version in early 2004. An overview of the development of the on-road component can be found at: http://www.vistas-sesarm.org/documents/Pechan_drafton-roadinventory_082803.ppt while an overview of the non-road component can be found at: http://www.vistas-sesarm.org/documents/Pechan_Non-roadInventory_082803.ppt.

Similarly, draft versions of the 2002 point and area source base year inventories were prepared by MACTEC in the same timeframe (late 2003 for the draft, final in early 2004). The point source component was based on data submitted by the VISTAS States or on the 1999 NEI. The data submitted by the States ranged from 1999 to 2001 and was all projected to 2002 using appropriate growth surrogates from Economic Growth Analysis System (EGAS) version 4. Toxic Release Inventory (TRI) data were used to augment the inventory for NH_3. Continuous Emissions Monitor (CEM) data from the U.S. EPA's Clean Air Markets Division was used to supply emissions for electric generating utilities (EGUs). Particulate matter emissions were augmented (when missing) by using emission factor ratios. Details on all these calculations are discussed in Section 1.1.1.3 of this document.

The area source component of the 2002 draft base year emissions was prepared similarly to the point sources, using State submittals and the 1999 NEI Version 2 final as the basis for projecting emissions to 2002 using EGAS growth factors. For ammonia area sources the Carnegie Mellon University (CMU) ammonia model was used to calculate emissions. Finally, data on acreage burned on a fire by fire basis was solicited from State forestry agencies in order to calculate fire emissions on a fire by fire basis. Virtually all VISTAS State forestry agencies provided data for these calculations at least for wild and

prescribed fires. An overview of the point and area source development methods can be found at:
http://www.vistas-sesarm.org/documents/MACTEC_draftpointareainventory_82803.ppt.

Three interim versions of the 2002 base year inventory were developed. The first was delivered in August of 2003, the second in April of 2004 and the final one in October of 2004. The August 2003 and April 2004 inventories were prepared by MACTEC and Pechan. A draft version of the revised 2002 base year inventory was released in June of 2004, with a final version released in October 2004. That 2002 base year inventory was solely prepared by MACTEC. The October 2004 inventory incorporated 2002 Consolidated Emissions Reporting Rule (CERR) data into the inventory along with some updated data from the VISTAS States. This inventory is typically referred to as version 3.1 of the VISTAS inventory.

Closely following the version 3.1 2002 base year inventory, a "preliminary" 2018 projection inventory was developed. This "preliminary" 2018 inventory was developed in late 2004 (Oct/Nov) and was designed solely for use in modeling sensitivity runs to provide a quick and dirty assessment of what "on the books" and "on the way" controls could be expected to provide in terms of improvements to visibility and regional haze impairment. A brief overview of the history of the three versions of the 2002 base year and the 2018 preliminary inventory use can be found at: http://www.vistas-sesarm.org/documents/STAD1204/2002and2018Emissions14Dec2004.ppt.

Following preparation of the final 3.1 version of the 2002 base year inventory, States were asked to review and provide comments on that inventory to MACTEC for update and revision. At the same time MACTEC prepared a revised draft version of the 2018 projection inventory (January 2005) and a draft version of a 2009 projection inventory (April 2005). All of these were known as version 3.1 and were provided to the VISTAS States for review and comment. Comments were received and updates to the inventories based on these comments were prepared. The revised inventories were provided to the VISTAS States. At that time to be consistent with the modeling nomenclature being used by AG in performing their modeling runs, the inventory became the Base F VISTAS inventory. The Base F inventory was delivered for review and comment in August of 2005. In addition, MACTEC delivered a report entitled *Documentation of the Revised 2002 Base Year, Revised 2018, and Initial 2009 Emission Inventories for VISTAS* on August 2, 2005 that described the methods used to develop the Base F inventories. For the Electric Generating Utilities (EGU) different versions of the Integrated Planning Model were used between Base D and Base F, resulting in different projections of future EGU emissions.

Over the period from August 2005 until June/July 2006 MACTEC received comments and updates to some categories from VISTAS States, particularly EGU. In addition, a new NONROAD model (NONROAD05) was released. Thus additional updates to the inventory were prepared based on the comments received along with revised NONROAD emission estimates from NONROAD05. The resultant inventory became the Base G inventory.

Following release of the Base G inventory in early 2007, four States specified additional changes to reflect their best estimates of EGU emission levels and controls in 2018. The resulting 2018 EGU emission inventory is referred to as Base G2, which was released in July 2007.

The current version of the VISTAS inventory is referred to as the “Best and Final (B&F)” inventory. States specified additional changes to the point source inventory to reflect improved knowledge of EGU emission levels and controls in 2009 and 2018. States also specified changes to nonEGU sources reflecting new information on anticipated controls and shutdowns. No changes to any other source sector (e.g., area, fire, nonroad, onroad) were made for the B&F inventory. The 2018 B&F inventory was released in October 2007, and the 2009 B&F inventory was released in December 2007.

This document details the development of the Base G/G2/B&F inventories for 2002, 2009 and 2018. The information that follows describes the development of the VISTAS inventory by sector from Base F forward. Unless specific updates were made to an inventory sector, the methods used for Base F were retained. Table I-1 through Table I-3 indicate roughly which version of the inventory is in use for each sector of the inventory as of the B&F inventory.

Under a separate contract, AG was asked to obtain and convert emission inventory data for the five states that make up the Midwest Regional Planning Organization (MRPO) for use by VISTAS/ASIP modelers. Details of this effort are documented in an Appendix to this report.

1.0 2002 Base Year Inventory Development

1.1 Point Sources

This section details the development of the 2002 base year inventory for point sources. There were two major components to the development of the point source sector of the inventory. The first component was the incorporation of data submitted by the Visibility Improvement State and Tribal Association of he Southeast (VISTAS) States and local (S/L) agencies to the United States Environmental Protection Agency (EPA) as part of the Consolidated Emissions Reporting Rule (CERR) requirements Work on incorporating the CERR data into the revised base year involved: 1) obtaining the data from EPA or the S/L agency, 2) evaluating the emissions and pollutants reported in the CERR submittals, 3) augmenting CERR data with annual emission estimates for PM_{10}-PRI and $PM_{2.5}$-PRI; 4) evaluating the emissions from electric generating units, 5) completing quality assurance reviews for each component of the point source inventory, and 6) updating the database with corrections or new information from S/L agencies based on their review of the 2002 inventory. The processes used to perform those operations are described in the first portion of this section.

The second component was the development of a "typical" year inventory for electric generating units (EGUs). VISTAS determined that a typical year electric generating units (EGU) inventory was necessary to smooth out any anomalies in emissions from the EGU sector due to meteorology, economic, and outage factors in 2002. The typical year EGU inventory is intended to represent the five year (2000-2004) period that will be used to determine the regional haze reasonable progress goals. The second part of this section discusses the development of the typical year EGU inventory.

1.1.1 Development of 2002 Point Source Inventory

MACTEC developed a draft 2002 emission inventory in June 2004 (*Development of the Draft 2002 VISTAS Emission Inventory for Regional Haze Modeling – Point Sources*, MACTEC, June 18, 2004). The starting point for the draft 2002 emission inventory was EPA's 1999 National Emission Inventory (NEI), Version 2 Final (NEI99V2). For several states, we replaced the NEI99V2 data with more recent inventories for either calendar year 1999, 2000, or 2001 as submitted by the S/L agencies. We also performed several other updates, including updating emission estimates for selected large source of ammonia, incorporating 2002 Continuous Emissions Monitoring-(CEM)-based SO_2 and NO_x emissions for electric utilities, adding PM_{10} and $PM_{2.5}$ emissions when they were missing from an S/L submittal, and performing a variety of additional Quality assurance/Quality control (QA/QC) checks.

The next version of the 2002 inventory (referred to as Base F) was released in August 2005 (*Documentation of the Revised 2002 Base Year, Revised 2018, and Initial 2009 Emission Inventories for VISTAS*, MACTEC, August 2, 2005). The primary task in preparing the Base F 2002 base year inventory was the replacement of NEI99V2 data with data submitted by the VISTAS S/L agencies as part of the CERR submittal and included in EPA's 2002 NEI.

The next version of the 2002 inventory (referred to as Base G) was released in August 2006 and is documented in this report. The primary task in preparing the Base G 2002 base year inventory was the incorporation of corrections and new information as submitted by the S/L agencies based on their review of the Base F inventory. Note that no changes to the Base G 2002 point source inventory were made during the Base G2 and B&F update cycles (in other words, for the 2002 actual and typical inventories, Base G = Base G2 = B&F).

The following subsections document the data sources for the Base G/B&F inventory, the checks made on the CERR submittals, the process for augmenting the inventory with PM_{10} and $PM_{2.5}$ emissions, the evaluation of EGU emissions, other QA/QC checks, and other Base G updates. The final subsection summarizes the Base G/B&F 2002 inventory by state, pollutant, and sector (EGU and non-EGU).

1.1.1.1 Data Sources

Several data sources were used to compile the Base F point source inventory: 1) the inventories that the S/L submitted to EPA from May through July 2004 as required by the CERR; 2) supplemental data supplied by the S/L agencies that may have been revised or finalized after the CERR submittal to EPA, and 3) the draft VISTAS 2002 inventory in cases where S/L CERR data were not available. For the Base G inventory, we replaced data from Hamilton County, Tennessee, using data from Hamilton County's CERR submittal as contained in EPA's 2002 NEI inventory (in Base F, the inventory for Hamilton County was based on the draft VISTAS 2002 inventory, which in turn was based on the 1999 NEI).

Table 1.1-1 summarizes the data used as the starting point for the Base F 2002 inventory. Once all of the files were obtained, MACTEC ran the files through the EPA National Emission Inventory Format (NIF) Basic Format and Content checking tool to ensure that the files were submitted in standard NIF format and that there were no referential integrity issues with those files. In a couple of cases small errors were found. For example, in one case non-standard pollutant designations were used for particulate matter (PM) and ammonia emissions. MACTEC contacted each VISTAS State point source contact person to resolve the issues with the files and corrections were made. Once all corrections to the native files were made, MACTEC continued with the incorporation of the data into the VISTAS point source files. S/L agencies completed a detailed review of the Base F inventory. Additional updates and corrections to the Base F inventory were requested by S/L agencies and incorporated into the Base G inventory. The Base G changes are documented in more detail in Section 1.1.1.6. No additional changes to the Base G inventory were made as part of the Base G2/B&F round of updates.

Table 1.1-1 State Data Submittals Used for the Base F 2002 Point Source Inventory.

State / Local Program	Point Source Emissions Data Source
AL	C

Knox County, TN	B
Jefferson County, AL	B
Jefferson County, KY	B
Buncombe County, NC	B
Forsyth County, NC	B
Mecklenburg County, NC	B

Key
A = Draft VISTAS 2002
B = CERR Submittal from EPA's file transfer protocol (FTP) site
C = Other (CERR or other submittal sent directly from S/L agency to MACTEC)
D = CERR Submittal from EPA's NEI 2002 Final Inventory

1.1.1.2 Initial Data Evaluation

For the Base F inventory, we conducted an initial review of the 2002 point source CERR data in accordance with the QA procedures specified in the Quality Assurance Project Plan (QAPP) for this project. The following evaluations were completed to identify potential data quality issues associated with the CERR data:

- Compared the number of sites in the CERR submittal to the number of sites in the VISTAS draft 2002 inventory; for all States, the number of sites in the CERR submittal was less than in the VISTAS draft 2002 inventory, since the CERR data was limited to major sources, while the VISTAS draft 2002 inventory contained data for both major and minor sources; verified with S/L contacts that minor sources not included in the CERR point source inventory were included in the CERR area source inventory.

- Checked for correct pollutant codes and corrected to make them NIF-compliant; for example, some S/L agencies reported ammonia emissions using the CAS Number or as "ammonia", rather than the NIF-compliant "NH_3" code.
- Checked for types of particulate matter codes reported (i.e., PM-FIL, PM-CON, PM-PRI, PM_{10}-PRI, PM10-FIL, $PM_{2.5}$-PRI, $PM_{2.5}$-FIL); corrected codes with obvious errors (i.e., changed PMPRI to PM-PRI). (The PM augmentation process for filling in missing PM pollutants is discussed later in Section 1.1.1.3)
- Converted all emission values that weren't in tons to tons to allow for preparation of emission summaries using consistent units.
- Checked start and end dates in the PE and EM tables to confirm consistency with the 2002 base year.
- Compared annual and daily emissions when daily emissions were reported; in some cases, the daily value was non-zero (but very small) but the annual value was zero. This was generally the result of rounding in an S/L agency's submittal.
- Compared ammonia emissions as reported in the CERR submittals and the 2002 Toxics Release Inventory; worked with S/L agencies to resolve any outstanding discrepancies.
- Compared SO_2 and NO_x emissions for EGUs to EPA's Clean Air Markets Division CEM database to identify any outstanding discrepancies. (A full discussion of the EGU emissions analysis is discussed later in Section 1.1.1.4)
- Prepared State-level emission summaries by pollutant for both the EGU and non-EGU sectors to allow S/L agencies to compare emissions as reported in the 1999 NEI Version 2, the VISTAS draft 2002 inventory, and the CERR submittals.
- Prepared facility-level emission summaries by pollutant to allow S/L agencies to review facility level emissions for reasonableness and accuracy.

We communicated the results of these analyses through email/telephone exchanges with the S/L point source contacts as well as through Excel summary spreadsheets. S/L agencies submitted corrections and updates as necessary to resolve any QA/QC issues from these checks.

1.1.1.3 PM Augmentation

Particulate matter emissions can be reported in many different forms, as follows:

PM Category	Description
PM-PRI	Primary PM (includes filterable and condensable)

PM-CON	Primary PM, condensable portion only (all less than 1 micron)
PM-FIL	Primary PM, filterable portion only
PM_{10}-PRI	Primary PM_{10} (includes filterable and condensable)
PM_{10}-FIL	Primary PM_{10} filterable portion only
$PM_{2.5}$ -PRI	Primary $PM_{2.5}$ (includes filterable and condensable)
$PM_{2.5}$ -FIL	Primary $PM_{2.5}$ filterable portion only

S/L agencies did not report PM emissions in a consistent manner. The State/local inventories submitted for VISTAS included emissions data for either PM-FIL, PM-PRI, PM_{10}-FIL, PM_{10}-PRI, $PM_{2.5}$ -FIL, $PM_{2.5}$ -PRI, and/or PM-CON. From any one of these pollutants, EPA has developed augmentation procedures to estimate PM_{10}-PRI, PM_{10}-FIL, $PM_{2.5}$ -PRI, $PM_{2.5}$ -FIL, and PM-CON. If not included in a State/local inventory, PM_{10}-PRI and $PM_{2.5}$ -PRI were calculated by adding PM_{10}-FIL and PM-CON or $PM_{2.5}$ -FIL and PM-CON, respectively.

The procedures for augmenting point source PM emissions are documented in detail in Appendix C of *Documentation for the Final 1999 National Emissions Inventory {Version 3} for Criteria Air Pollutants and Ammonia – Point Sources*, January 31, 2004). Briefly, the PM data augmentation procedure includes the following five steps:

- Step 1: Prepare S/L/T PM and PM_{10} Emissions for Input to the PM Calculator
- Step 2: Develop and Apply Source-Specific Conversion Factors
- Step 3: Prepare Factors from PM Calculator
- Step 4: Develop and Apply Algorithms to Estimate Emissions from S/L/T Inventory Data
- Step 5: Review Results and Update the NEI with Emission Estimates and Control Information.

Please refer to the EPA documentation for a complete description of the PM augmentation procedures.

Table 1.1-2 compares the original PM emission estimates from the S/L CERR submittals and the revised 2002 VISTAS emissions estimates calculated using the above methodology. This table is intended to show that we took whatever States provided in the way of PM and filled in gaps to add in PM-CON where emissions were missing in order to calculate PM_{10}-PRI and $PM_{2.5}$ -PRI for all processes to get a complete set of particulate data. We did not compare any other pollutants besides PM, since for other pollutants CERR emissions equal VISTAS emissions. As noted in Table 1.1-2, we made significant revisions to the PM emissions for Kentucky in the Base F inventory and for South Carolina in the Base G inventory.

Table 1.1-2 Comparison of Particulate Matter Emissions from the S/L Data Submittals and the Base G 2002 VISTAS Point Source Inventory

State	Database	PM-PRI	PM-FIL	PM-CON	PM_{10}-PRI	PM_{10}-FIL	$PM_{2.5}$ -PRI	$PM_{2.5}$ -FIL
AL	CERR	28,803	9,174	0	16,522	6,548	8,895	4,765

	VISTAS	23,928	17,632	6,296	21,089	14,793	11,044	5,739
NC	CERR	48,110	0	0	36,222	0	24,159	0
	VISTAS	48,114	41,407	6,708	36,992	30,284	27,512	21,113
SC	CERR	0	43,837	0	0	32,656	0	21,852
	VISTAS	43,844	38,633	5,210	34,799	29,588	26,418	21,207
TN	CERR	1,660	25,500	21,482	43,413	22,164	34,167	12,140
	VISTAS	56,797	32,085	24,715	50,937	26,269	41,442	16,774
VA	CERR	0	0	0	17,065	0	12,000	0
	VISTAS	40,856	36,414	4,442	17,065	12,623	12,771	8,607
WV	CERR	0	29,277	0	0	14,778	0	8445
	VISTAS	36,188	29,392	6,795	22,053	15,258	15,523	8,733

Note 1: CERR refers to data as submitted by S/L agencies; VISTAS refers to data calculated by MACTEC using the PM augmentation methodologies described in this document.

Note 2: KY DEP's initial CERR submittal reported particulate matter emissions using only PM-PRI pollutant code. MACTEC used this pollutant code during the initial PM augmentation routine. In February 2005, KY DEP indicated that data reported using the PM-PRI code should actually have been reported using the PM_{10}-PRI code. MACTEC performed a subsequent PM augmentation in April 2005 using the PM_{10}-PRI code. These changes were reflected in the Base F emission inventory.

Note 3: South Carolina Department of Health and Environmental Control (SC DHEC) initial CERR submittal reported particulate matter emissions using the PM-FIL, PM_{10}-FIL, and $PM_{2.5}$ -FIL pollutant codes. MACTEC used these pollutant codes during the initial PM augmentation routine. In August 2005, SC DHEC indicated that data reported using the PM-FIL, PM_{10}-FIL, and $PM_{2.5}$ -FIL pollutant codes should actually have been reported using the PM-PRI, PM_{10}-PRI, and $PM_{2.5}$ _PRI codes. MACTEC performed a subsequent PM augmentation in April 2006 using the revised pollutant codes. These changes were reflected in the Base G emission inventory.

Note 4: The emission values in the VISTAS emission rows above differ slightly from the final values in the Base G inventory. This is due to several corrections and updates to the 2002 inventory submitted by S/L agencies after the PM augmentation was performed as discussed in Section 1.1.1.6.

After the PM augmentation process was performed, we executed a series of checks to identify potential inconsistencies in the PM inventory. These checks included:

- PM-PRI less than PM_{10}-PRI, $PM_{2.5}$ -PRI, PM_{10}-FIL, $PM_{2.5}$ -FIL, or PM-CON;
- PM-FIL less than PM_{10}-FIL, $PM_{2.5}$ -FIL;
- PM_{10}-PRI less than $PM_{2.5}$ -PRI, PM_{10}-FIL, $PM_{2.5}$ -FIL or PM-CON;
- PM_{10}-FIL less than $PM_{2.5}$ -FIL;
- PM25-PRI less than $PM_{2.5}$ -FIL or PM-CON;
- The sum of PM_{10}-FIL and PM-CON not equal to PM_{10}-PRI; and
- The sum of $PM_{2.5}$ -FIL and PM-CON not equal to $PM_{2.5}$ -PRI.

S/L agencies were asked to review this information and provide corrections where the inconsistencies were significant. In general, corrections (or general directions) were provided in the case of the potential inconsistency issues. In other cases, the agency provided specific process level pollutant corrections.

Note that for the Base G inventory, only the PM_{10}-PRI and $PM_{2.5}$ -PRI emission estimates were retained since they are the only two PM species that are included in the air quality modeling. Other PM species were removed from the Base G inventory to facilitate emissions modeling.

1.1.1.4 EGU Analysis

We made a comparison of the annual SO_2 and NO_x emissions for EGUs as reported in the S/L agencies CERR submittals and EPA's Clean Air Markets Division (CAMD) CEM database to identify any outstanding discrepancies. Facilities report hourly CEM data to EPA for units that are subject to CEM reporting requirements of the NO_x State Implementation Plan (SIP) Call rule and Title IV of the Clean Air Act (CAA). EPA sums the hourly CEM emissions to the annual level, and we compared these annual CEM emissions to those in the S/L inventories. The 2002 CEM inventory containing NO_x and SO_2 emissions and heat input data were downloaded from the EPA CAMD web site (www.epa.gov/airmarkets).

The first step in the EGU analysis involved preparing a crosswalk file to match facilities and units in the CAMD inventory to facilities and units in the S/L inventories. In the CAMD inventory, the Office of Regulatory Information Systems (ORIS) identification (ID) code identifies unique facilities and the unit ID identifies unique boilers and internal combustion engines (i.e., turbines and reciprocating engines). In the S/L inventories, the State and county FIPS and State facility ID together identify unique facilities and the emission unit ID identifies unique boilers or internal combustion engines. In most cases, there is a one-to-one correspondence between the CAMD identifiers and the S/L identifiers. However, in some of the S/L inventories, the emissions for multiple emission units are summed and reported under one emission unit ID. We created an Excel spreadsheet that contained an initial crosswalk with the ORIS ID and unit ID in the CEM inventory matched to the State and county Federal

Implementation Plan (FIPS), State facility ID, and emission unit ID in the S/L inventory. The initial crosswalk contained both the annual emissions summed from the CAMD database as well as the S/L emission estimate. It should be noted that the initial matching of the IDs in both inventories was based on previous crosswalks that had been developed for the preliminary VISTAS 2002 inventory and in-house information compiled by MACTEC and Alpine Geophysics. The matching at the facility level was nearly complete. In some cases, however, S/L agency or stakeholder assistance was needed to match some of the CEM units to emission units in the S/L inventories.

The second step in the EGU analysis was to prepare an Excel spreadsheet that compared the annual emissions from the hourly CAMD inventory to the annual emissions reported in the S/L inventory. The facility-level comparison of CEM to emission inventory NO_x and SO_2 emissions found that for most facilities, the annual emissions from the S/L inventory equaled the CAMD CEM emissions. Minor differences could be explained because the facility in the S/L inventory contained additional small or emergency units that were not included in the CAMD database.

The final step was to compare the SO_2 and NO_x emissions for select Southern Company units in the VISTAS region. Southern Company is a super-regional company that owns EGUs in four VISTAS States – Alabama, Florida, Georgia, and Mississippi – and participates in VISTAS as an industry stakeholder. Southern Company independently provided emission estimates for 2002 as part of the development of the preliminary VISTAS 2002 inventory. In most cases, these estimates were reviewed by the States and incorporated into the States CERR submittal. The exception to this was a decision made by Georgia's Department of Environmental Protection (GDEP) to utilize CEM-based emissions for the actual 2002 emissions inventory for sources within the State when Southern Company also provided data. There were no major inconsistencies between the Southern Company data, the CAMD data, and the S/L CERR data.

The minor inconsistencies included small differences (<2 percent) in emission estimates, exclusion/inclusion of small gas-fired units in the different databases, and grouping of emission units in S/L CERR submittals where CAMD listed each unit individually. We compared SO_2 and NO_x emissions on a unit by unit basis and did not find any major inconsistencies.

1.1.1.5 QA Review of Base F Inventory

QA checks were run on the Base F point source inventory data set to ensure that all corrections provided by the S/L agencies and stakeholders were correctly incorporated into the S/L inventories and that there were no remaining QA issues. After exporting the inventory to ASCII text files in NIF 3.0, the EPA QA program was run on the ASCII files and the QA output was reviewed to verify that all QA issues that could be addressed were resolved.

Throughout the inventory development process, QA steps were performed to ensure that no double counting of emissions occurred, and to ensure that a full and complete inventory was developed for VISTAS. QA was an important component to the inventory development process and MACTEC performed the following QA steps on the point source component of the VISTAS revised 2002 base year inventory:

1. Facility level emission summaries were prepared and evaluated to ensure that emissions were consistent and that there were no missing sources.
2. State-level EGU and non-EGU comparisons (by pollutant) were developed between the Base F 2002 base year inventory, the draft VISTAS 2002 inventory, and the 1999 NEI Version 2 inventory.
3. Data product summaries and raw NIF 3.0 data files were provided to the VISTAS Emission Inventory Technical Advisor and to the Point Source, EGU, and non-EGU Special Interest Work Group representatives for review and comment. Changes based on these comments were reviewed and approved by the S/L point source contact prior to implementing the changes in the files.
4. Version numbering was used for all inventory files developed. The version numbering process used a decimal system to track major and minor changes. For example, a major change would result in a version going from Base F1 to Base F2.

1.1.1.6 Additional Base G Updates and Corrections

S/L agencies completed a detailed review of the Base F inventory. Table 1.1-3 summarizes the updates and corrections to the Base F inventory that were requested by S/L agencies and incorporated into the Base G inventory.

There was a discrepancy between the base year 2002 and 2009/2018 emissions for PM_{10}-PRI, $PM_{2.5}$-PRI, and NH_3. The 2002 emissions were provided directly by the S/L agencies and were estimated using a variety of techniques (i.e., EPA emission factors, S/L emission factors, site-specific emission factors, and source test data). The 2009/2018 emissions, on the other hand, were estimated by Pechan (see Section 2.1.1.3) using an emission factor file based solely on AP-42 emission factors. An adjustment was made for 2002 EGU PM and NH_3 emissions to reconcile these differences. The post-processed Integrated Planning Model® (IPM®) 2009/2018 output uses a set of PM and NH_3 emission factors that are “the most recent EPA approved uncontrolled emission factors” – these are most likely not the same emission factors used by States and emission inventory preparation contractors for estimating these emissions in 2002 for EGUs in the VISTAS domain. VISTAS performed a set of modifications to replace 2002 base year PM and NH_3 emission estimates with estimates derived from the most recent EPA-approved emission factors. For further details of the methodology used to make this adjustment, see *EGU Emission Factors and Emission Factor Assignment*, memorandum from Greg Stella to VISTAS State Point Source Contacts and VISTAS EGU Special Interest Workgroup, June 13, 2005.

Table 1.1-3 Summary of Updates and Corrections to the Base F 2002 Inventory Incorporated into the 2002 Base G Inventory.

Affected State(s)	Nature of Update/Correction
TN, WV	The latitude and longitude values for TN (except the four local programs) and WV were truncated to two decimal places in the Base F inventory. MACTEC re-exported the NIF ER tables in a manner that so that the latitude and longitude were not truncated in the Base G inventory.
AL	Corrected the latitude and longitude for two facilities: Ergon Terminalling (Site ID: 01-073-010730167) and Southern Power Franklin (Site ID: 01-081-0036).
	Corrections to stack parameters at 10 facilities for stacks with parameters that do not appear to fall into the ranges typically termed "acceptable" for AQ modeling.
FL	Corrected emission values for the Miami Dade RRF facility (Site ID: 12-086-0250348).
GA	Hercules Incorporated (12-051-05100005) had an erroneous process id (#3) within emission unit id SB9 and was deleted. This removes about 6,000 tons of SO_2 from the 2002 inventory.
	Provided a revised file of location coordinates at the stack level that was used to replace the location coordinated in the ER file.
NC	Made several changes to Base F inventory to correct the following errors: 1. Corrected emissions at Hooker Furniture (Site ID: 37-081-08100910), release point G-29, 9211.38 tons volatile organic compounds (VOC's) should be 212.2 tons, 529.58 tons PM_{10} should be 17.02 tons, 529.58 tons PM2.5 should be 15.79 tons in 2002 inventory. 2. Identified many stack parameters in the ER file that were unrealistic. Several have zero for height, diameter, gas velocity, and flow rate. NC used the procedures outlined in Section 8 of the document ""National Emission Inventory QA and Augmentation Report" to correct unrealistic stack parameters. 3. Identified truncated latitude and longitude values in Base F inventory. NC updated all Title V facility latitude and longitude that was submitted to EPA for those facilities in 2004. Smaller facilities with only two decimal places were not corrected. 4. Corrected emissions for International Paper (3709700045) Emission Unit ID, G-12, should be 1.8844 tons VOCs instead of 2819.19 tons in 2002
SC	Corrected PM species emission values. SC DHEC's initial CERR submittal reported particulate matter emissions using the PM-FIL, PM_{10}-FIL, and PM25-FIL pollutant codes. In August 2005, SC DHEC indicated that data reported using the PM-FIL, PM_{10}-FIL, and PM25-FIL pollutant codes should actually have been reported using the PM-PRI, PM_{10}-PRI, and PM25_PRI codes. MACTEC performed a subsequent PM augmentation in April 2006 using the revised pollutant codes. These changes were reflected in the Base G emission inventory.
TN	Identified six facilities that closed in 2000/2001 but had non-zero emissions in the 2002 Base F inventory. MACTEC changed emissions to zero for all pollutants in the Base G 2002 inventory.
	Supplied updated emission inventory for the Bowater facility (47-107-0012) based on the facility's updated 2002 emission inventory update.
	Replaced data from Hamilton County, Tennessee, using data from Hamilton County's CERR submittal as contained in EPA's 2002 NEI (in Base F, the inventory for Hamilton County was based on the draft VISTAS 2002 inventory, which in turn was based on the 1999 NEI).
	Updated emissions for PCS Nitrogen Fertilizer LP (Site ID: 47-157-00146)
WV	Updated emissions for Steel of West Virginia (Site ID: 54-011-0009)
	Made changes to several Site ID names due to changes in ownership
	Made corrections to latitude/longitude and stack parameters at a few facilities for stacks with parameters that do not appear to fall into the ranges typically termed "acceptable" for AQ modeling.

1.1.1.7 Summary of B&F 2002 Inventory

Tables 1.1-4 through 1.1-10 summarize the B&F 2002 base year inventory. All values are in tons. Note that no changes to the Base G 2002 point source inventory were made during the Base G2 and B&F update cycles (in other words, Base G = Base G2 = B&F). Note also that Alabama suggested additional changes to the 2002 inventory resulting from their $PM_{2.5}$ modeling for the Birmingham area; however, these changes were identified too late to be incorporated in the VISTAS B&F inventory and ASIP modeling.

For the purposes of Tables 1.1-4 through 1.1-10, EGU emissions include the emissions from all processes with a Source Classification Code (SCC) of either 1-01-xxx-xx (External Combustion Boilers – Electric Generation) or 2-01-xxx-xx (Internal Combustion Engines – Electric Generation). Emissions for all other SCCs are included in the non-EGU column. Note that aggregating emissions into EGU and non-EGU sectors based on the above SCCs causes a minor inconsistency with the EGU emissions reported in EPA's CAMD database. The EGU emissions summarized in these tables may include emissions from some smaller electric generating units in the VISTAS inventory that are not in CAMD's 2002 CEM database or the IPM forecasted emissions. The minor inconsistencies result in a less than 2 percent difference between the summary tables below and the data from CAMD's CEM database.

Table 1.1-4 Base G / B&F 2002 VISTAS Point Source Inventory for SO_2 (tons/year).

State	All Point Sources	EGUs	Non-EGUs
AL	544,309	447,828	96,481
FL	518,721	453,631	65,090
GA	568,731	514,952	53,778
KY	518,086	484,057	34,029
MS	103,388	67,429	35,960
NC	522,113	477,990	44,123
SC	259,916	206,399	53,518
TN	413,755	334,151	79,604
VA	305,106	241,204	63,903
WV	570,153	516,084	54,070
Total	**4,324,278**	**3,743,725**	**580,556**

Note: EGU emissions include SCCs 1-01-xxx-xx and 2-01-xxx-xx; non-EGU has all other SCCs.

Table 1.1-5 Base G / B&F 2002 VISTAS Point Source Inventory for NO_x (tons/year).

State	All Point Sources	EGUs	Non-EGUs

1.1.2 Development of Typical Year EGU inventory

VISTAS developed a typical year 2002 emission inventory for EGUs to avoid anomalies in emissions due to variability in meteorology, economic, and outage factors in 2002. The typical year inventory represents the five year (2000-2004) period and was used to determine the regional haze reasonable progress goals. Actual 2002 emissions were used when comparing the CMAQ modeling results to the 2002 measurements in the model performance evaluation. A detailed discussion of how the actual and typical year EGU inventories were used for modeling is contained in the *Technical Support Document for VISTAS Emissions and Air Quality Modeling to Support Regional Haze State Implementation Plans* located on the VISTAS web site (http://www.vistas-sesarm.org)

Data from EPA's CAMD were used to develop normalization factors for producing a 2002 typical year inventory for EGUs. We used the ratio of the 2000-2004 average heat input and the 2002 actual heat input to normalize the 2002 actual emissions. MACTEC obtained data from EPA's CAMD for utilities regulated by the Acid Rain program. Annual data for the period 2000 to 2004 were obtained from the CAMD web site (www.epa.gov/airmarkets). The parameters available were the SO_2 and NO_x emission rates, heat input, and operating hours. We used the actual 2002 heat input and the average heat input for the 5-year period from 2000-2004 as the normalization factor, as follows:

$$\text{Normalization Factor:} \quad \frac{\text{2000-2004 average heat input}}{\text{2002 actual heat input}}$$

If the unit did not operate for all five years, then the 2000-2004 average heat input was calculated for the one or two years in which the unit did operate. For example, if the unit operated only during 2002, then the normalization factor would be 1.0. The annual actual emissions were multiplied by the normalization factor to determine the typical emissions for 2002, as follows:

$$\text{Typical Emissions} = \text{2002 actual emissions} \times \text{Normalization Factor}$$

After applying the normalization factor, some adjustments were needed for special circumstances. For example, a unit may not have operated in 2002 and thus have zero emissions. If the unit had been permanently retired prior to 2002, then we used zero emissions for the typical year. If the unit had not been permanently retired and would normally operate in a typical year, then we used the 2001 (or 2000) heat input and emission rate to calculate the typical year emissions.

The Southern Company provided typical year data for their sources. Hourly emissions data for criteria pollutants were provided. MACTEC aggregated the hourly emissions into annual values. Further documentation of how Southern Company created the typical year inventory for their units can be found in *Developing Southern Company Emissions and Flue Gas Characteristics for VISTAS Regional Haze Modeling (April 2005, presented at 14th International Emission Inventory Conference* http://www.epa.gov/ttn/chief/conference/ei14/session9/kandasamy.pdf). Since Southern Company only supplied filterable particulate emissions, we ran the $PM_{10}/PM_{2.5}$ augmentation routine to calculate annual emission estimates for PM_{10}-PRI and $PM_{2.5}$-PRI. The Southern Company typical year data were used for Southern Company sources in Alabama, Florida, and Mississippi. Georgia EPD elected to use the typical year normalization factor derived from the CAMD data instead of the Southern Company typical year data (as was used in the Base F inventory).

The final step was to replace the 2002 actual emissions with the 2002 typical year data described above. MACTEC provided the raw data and results of the typical year calculations in a spreadsheet for S/L agency review and comment. Any comments made were incorporated into the Base G inventory.

Table 1.1-11 summarizes emissions by State and pollutant for the actual 2002 EGU inventory and the typical year EGU inventory. For the entire VISTAS region, actual 2002 SO_2 emissions were about 1.6 percent higher than the typical year emissions. The differences on a state-be-state basis ranged from actual emissions being 2.3 percent lower in Kentucky to 10.9 percent higher in Mississippi. For the entire VISTAS region, actual 2002 NO_x emissions were about 1.7 percent lower than the typical year emissions. The differences on a state-be-state basis ranged from actual emissions being 1.6 percent lower in Kentucky to 6.3 percent higher in Mississippi.

Table 1.1-11 Comparison of SO_2 and NO_x Emissions (tons/year) for EGUs.

	SO_2 Emissions (tons/year)			NO_x Emissions (tons/year)		
State	**Actual 2002**	**Typical 2002**	**Percentage Difference**	**Actual 2002**	**Typical 2002**	**Percentage Difference**
AL	447,828	423,736	5.4	161,038	154,704	3.9
FL	453,631	444,383	2.0	257,677	255,678	0.8
GA	514,952	517,633	-0.5	147,517	148,126	-0.4
KY	484,057	495,153	-2.3	198,817	201,928	-1.6
MS	67,429	60,086	10.9	43,135	40,433	6.3
NC	477,990	478,489	-0.1	151,854	148,812	2.0
SC	206,399	210,272	-1.9	88,241	88,528	-0.3
TN	334,151	320,146	4.2	157,307	152,137	3.3
VA	241,204	233,691	3.1	86,886	85,081	2.1
WV	516,084	500,381	3.0	230,977	222,437	3.7
Total	**3,743,725**	**3,683,968**	**1.6**	**1,523,449**	**1,497,864**	**1.7**

Note: a negative percentage difference indicates actual emissions are less than the typical year emissions.

1.2 Area Sources

This section details the development of the Base G 2002 base year inventory for area sources. There are three major components of the area source sector of the inventory. The first component is the "typical" year fire inventory. Version 3.1 of the VISTAS base year fire inventory provided actual 2002 emissions estimates. Since fire emissions are not easily grown or projected, in order to effectively represent fires in both the base and future year inventories, VISTAS determined that a typical year fire inventory was necessary. Development of the "typical" year fire inventory covered wildfire, prescribed burning, agricultural fires and land clearing fires. The first part of this section of the report discusses the development of the typical year fire inventory. The methodology provided in that section is identical to the documentation provided for Base F since the "typical" year inventory was developed as part of the Base F development effort. The major change in Base G for the fire component of the inventory was the development of projection year inventories that represent alternatives to the "typical" year inventory. These alternative projections incorporated projected changes in the acreage burned for prescribed fires on Federal lands. These projections are an augmentation of the "typical" year inventory.

The second component of the area source inventory was the incorporation of data submitted by the VISTAS States to the United States Environmental Protection Agency (EPA) as part of the CERR. Work on incorporating the CERR data into the revised base year involved: 1) obtaining the data from EPA, 2) evaluating the emissions and pollutants reported in order to avoid double counting and 3) backfilling from the existing VISTAS 2002 base year inventory for missing sources/pollutants. The processes used to perform those operations are described in the second portion of this section. That work was performed as part of the Base F inventory effort. In general no changes to that method were made as part of the Base G inventory updates. The methods used for the Base F inventory development effort using the CERR submittals have been maintained in this document. Where necessary, additional documentation has been added to 1) reflect changes that resulted from VISTAS States review of the Base F inventory and the incorporation of those changes into Base G, 2) changes made to how certain sources were estimated or 3) addition of new sources not found in Base F.

The final component of the area source inventory was related to the development of NH_3 emission estimates for livestock and fertilizers and paved road PM emissions. For the NH_3 emission estimates for livestock and fertilizers we used version 3.6 of the Carnegie Mellon University (CMU) NH_3 model. For the paved road PM emissions, we used the most recent estimates developed by EPA as part of the National Emission Inventory (NEI) development effort. EPA had developed an improved methodology for estimating paved road emissions so those values were substituted directly into the inventory after receiving consensus from all of the VISTAS States to perform the replacement. Details on these methods are provided in the third portion of this section of the document. That section is virtually identical to that from the Base F inventory document as there were only a couple of changes to the ammonia portion of the inventory and some updates to all fugitive dust categories including paved roads on a global basis between Base F and Base G.

Finally, quality assurance steps for each component of the area source inventory are discussed.

1.2.1 Development of a "typical" year fire inventory

Typical year fire emissions were developed starting from the actual fire acreage data and emission calculated for each VISTAS State. The table below shows the data submitted by each State in the VISTAS region indicating what data was received from each State for the purposes of calculating actual fire emissions.

Fire Type	AL	FL	GA	KY	MS	NC	SC	TN	VA	WV
Land Clearing	✓	✓	✓				✓			
Ag Burning	✓	✓	✓				✓			
Wildfires	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓
Prescribed	✓	✓	✓	✓	✓	✓	✓	✓		✓

In order to effectively characterize fire emissions in the VISTAS region, a typical (as opposed to strictly 2002 year based inventory) was required. Development of a typical year fire inventory provided the capability of using a comparable data set for both the base year and future years. Thus fire emissions would remain the same for air quality and visibility modeling in both the base and any future years. MACTEC originally proposed five different methods for developing the typical fire year to the VISTAS Fire Special Interest Work Group (SIWG) and requested their feedback and preference for developing the final typical year inventory. The method that was selected by SIWG members was to use a method similar to that used to develop an early version of a 2018 projection inventory. For that early 2018 inventory, State level ratios of acres over a longer term record (three or more years) developed for each fire type relative to 2002. The 2002 acreage was then scaled up or down based on these ratios to develop a typical year inventory. For Base F and G, the decision of the VISTAS Fire SIWG was to base the ratio on county level data for States that supplied long term fire-by-fire acreage data rather than State-level ratios. Where States did not supply long term fire-by-fire acreage data, MACTEC reverted to using State-level ratios. With one broad exception (wildfires) this method was implemented for all fires. MACTEC solicited long term fire-by-fire acreage data by fire type from each VISTAS State. A minimum of three or more years of data were used to develop the ratios. Those data were then used to develop a ratio for each county based on the number of acres burned in each county for each fire type relative to 2002.

Thus if we had long term county prescribed fire data from a State, we developed a county acreage ratio of:

$$Ratio = \frac{\text{Long term average county level Rx acres}}{\text{2002 actual county level Rx acreage}}$$

This ratio was then multiplied times the actual 2002 acreage to get a typical value (basically the long term average county level acres). Wherever possible this calculation was performed on a fire by fire basis. The acreage calculated using the ratio was then used with the fuel loading and emission factor values that we already had (and had been reviewed by the SIWG) to calculate emissions using the same method used for the 2002 actual values (which were previously documented). The following lists indicate which counties used the State ratios by fire type.

Land Clearing		Agricultural Fires		Prescribed Burning	
FIPS	**COUNTY**	**FIPS**	**COUNTY**	**FIPS**	**COUNTY**
12086	Miami-Dade County	13063	Clayton County	13059	Clarke County
12037	Franklin County	13083	Dade County	13083	Dade County
12043	Glades County	13089	Dekalb County	13089	Dekalb County

12077	Liberty County	13215	Muscogee County	13139	Hall County
12081	Manatee County	13227	Pickens County	13215	Muscogee County
12095	Orange County	13241	Rabun County	13241	Rabun County
12097	Osceola County	13247	Rockdale County	13247	Rockdale County
12103	Pinellas County	13311	White County		
12115	Sarasota County				
13015	Bartow County				
13021	Bibb County				
13045	Carroll County				
13047	Catoosa County				
13057	Cherokee County				
13059	Clarke County				
13063	Clayton County				
13073	Columbia County				
13077	Coweta County				
13083	Dade County				
13089	Dekalb County				
13097	Douglas County				
13117	Forsyth County				
13121	Fulton County				
13129	Gordon County				
13135	Gwinnett County				
13137	Habersham County				
13143	Haralson County				
13147	Hart County				

Land Clearing		Agricultural Fires		Prescribed Burning	
FIPS	COUNTY	FIPS	COUNTY	FIPS	COUNTY
13151	Henry County				
13169	Jones County				
13215	Muscogee County				
13237	Putnam County				
13241	Rabun County				
13291	Union County				
13311	White County				

There were three exceptions to this method.

Exception 1: Use of State Ratios for Wildfires

The first exception was that wildfires estimates were developed using State ratios rather than county ratios. This change was made after initial quality assurance of the draft estimates revealed that some counties were showing unrealistic values created by very short term data records or missing data that created unrealistic ratios. In addition, exceptionally large and small fires were removed from the database since they were felt to be atypical. For example the Blackjack Complex fire in Georgia was removed from the dataset because the number of acres burned was "atypical" in that fire. We also removed all fires less than 0.1 acres from the dataset.

Exception 2: Correction for Blackened Acres on Forest Service Lands

Following discussions with the United States Forest Service (Forest Service) (memo from Cindy Huber and Bill Jackson, dated August 13, 2004), it was determined that the acres submitted by the Forest Service for wildfires and prescribed fires represented perimeter acres rather than "blackened" acres. Thus for wildfires and prescribed fires on Forest Service lands, a further correction was implemented to correct the perimeter acre values to blackened acres. The correction was made based on the size of the fire. For prescribed fires over 100 acres in size the acreage was adjusted to be 80 percent of the initial reported value. For prescribed fires of 100 acres or less the acreage values were maintained as reported. For wildfires, all reported acreage values were adjusted to be 66 percent of their initially reported values. These changes were made to all values reported for Forest Service managed lands.

Exception 3: Missing/Non-reported data

When we did not receive data from a VISTAS State for a particular fire type, a composite average for the entire VISTAS region was used to determine the typical value for that type fire. For example, if no agricultural burning long term acreage data was reported for a particular State, MACTEC determined an overall VISTAS regional average ratio that was used to multiply times the 2002 values to produce the "typical" values. This technique was applied to all fire types when data was missing.

In addition, for wildfires and prescribed burning, ratios were developed for "northern" and "southern" tier States within the VISTAS region and those ratios were applied to each State with missing data depending upon whether they were considered a "northern" or "southern" tier State. Development of "southern" and "northern" tier data was an attempt to account for a change from a predominantly pine/evergreen ecosystem (southern) to a pine/deciduous ecosystem (northern). States classified as "southern" included: AL, FL, GA, MS, and SC. States classified as "northern" included: KY, NC, TN, VA, and WV.

Finally for land clearing and agricultural fires, there are no NH_3 and SO_2 emissions. This is due to the lack of emission factors for these pollutants for these fire types.

Table 1.2-1 shows fire emissions from the original base year emission inventory (VISTAS 3.1), the actual 2002 emissions and the typical year emissions for the entire VISTAS region. The actual 2002 and typical fire emissions represent the Base F and Base G 2002 emissions. The typical emissions also represent the 2009 and 2018 emissions for all fire types with the exception of prescribed burning. Revisions made to the typical year prescribed fire emissions for 2009 and 2018 are detailed in the projection section. Also, State level Base G emissions from fires for all years can be found in the tables in Appendix A. Values for fires in those tables are "typical" year values.

Figures 1.2-1 through 1.2-4 show the State by State changes in emissions between the original 2002 base year fire inventories, the actual 2002 and the typical year inventories for carbon monoxide (CO) by fire type. Due to the relative magnitude of CO emissions compared to other criteria and PM pollutants from fires; this pollutant is normally chosen to represent the distribution of fires in the example plots.

Table 1.2-1 Emissions from Fires in the VISTAS Region – Comparison between Original Base Year 2002 (VISTAS 3.1), 2002 Actual and Typical Year Base G Emissions.

		CO	NH_3	NO_X	PM_{10}-FIL	PM_{10}-PRI	$PM_{2.5}$-FIL	$PM_{2.5}$-PRI	SO_2	VOC

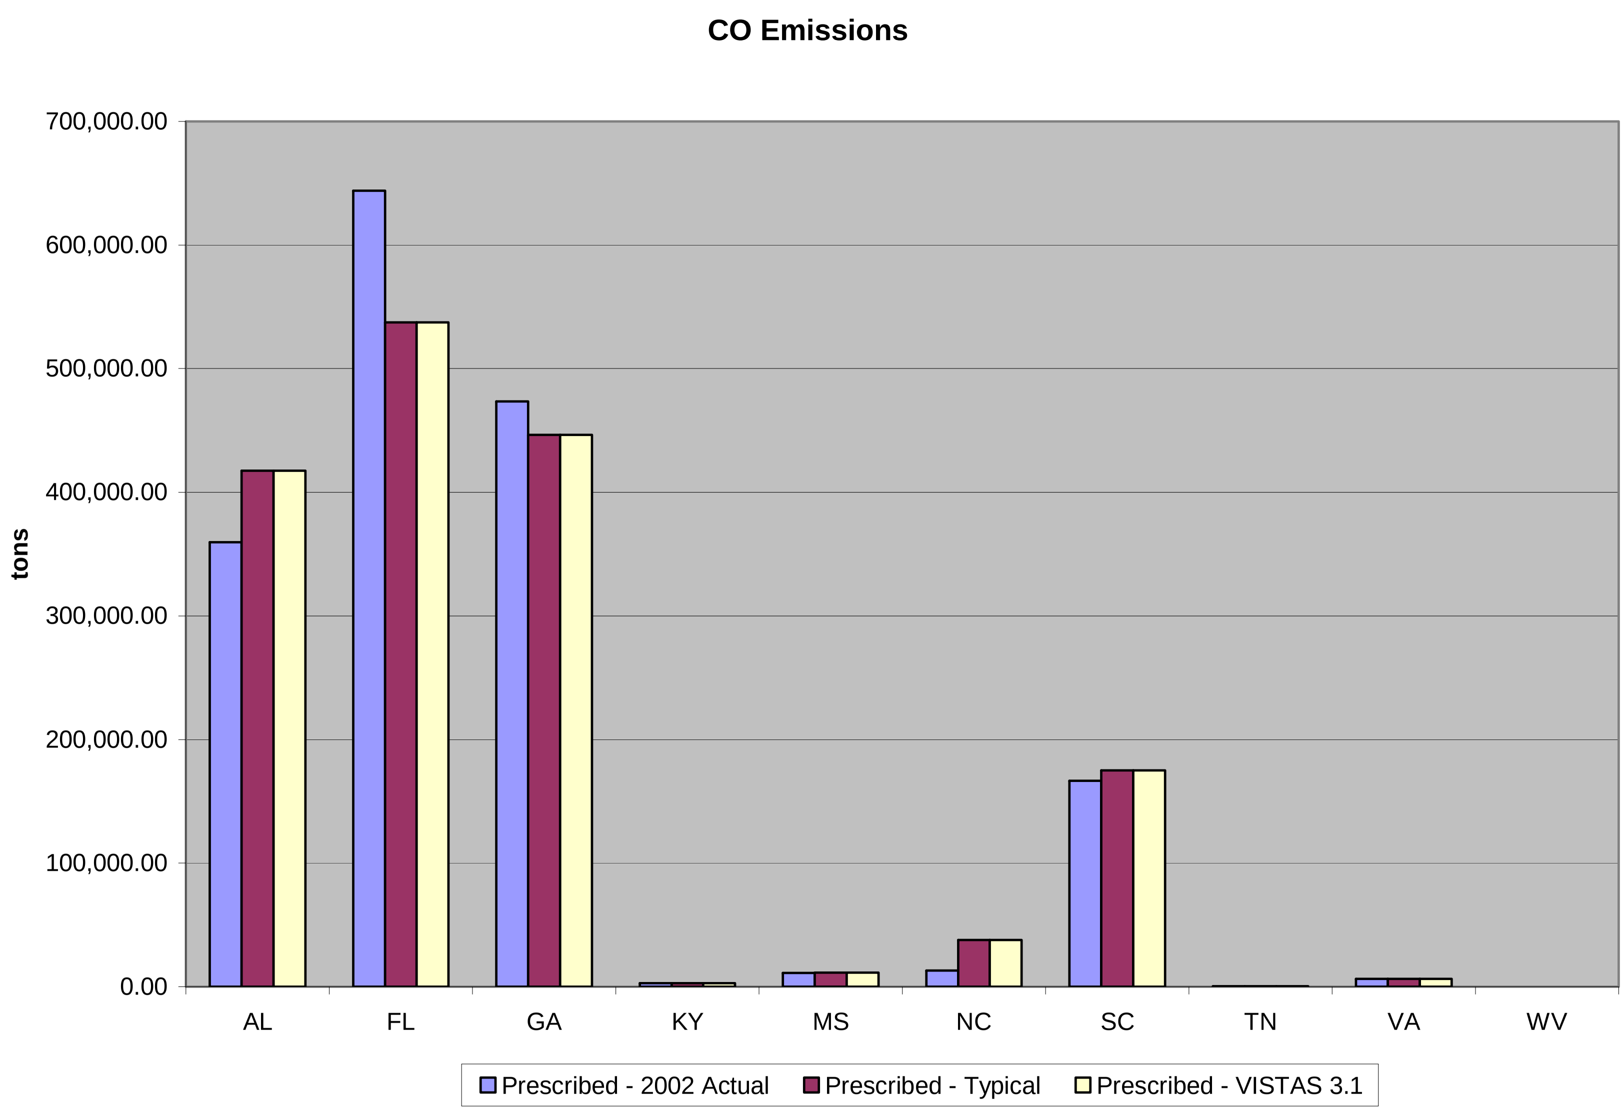

Figure 1.2-4 CO Emissions from Wildfire Burning for the Original Base Year, 2002 Actual Base G and 2002 Typical Base G Inventories.

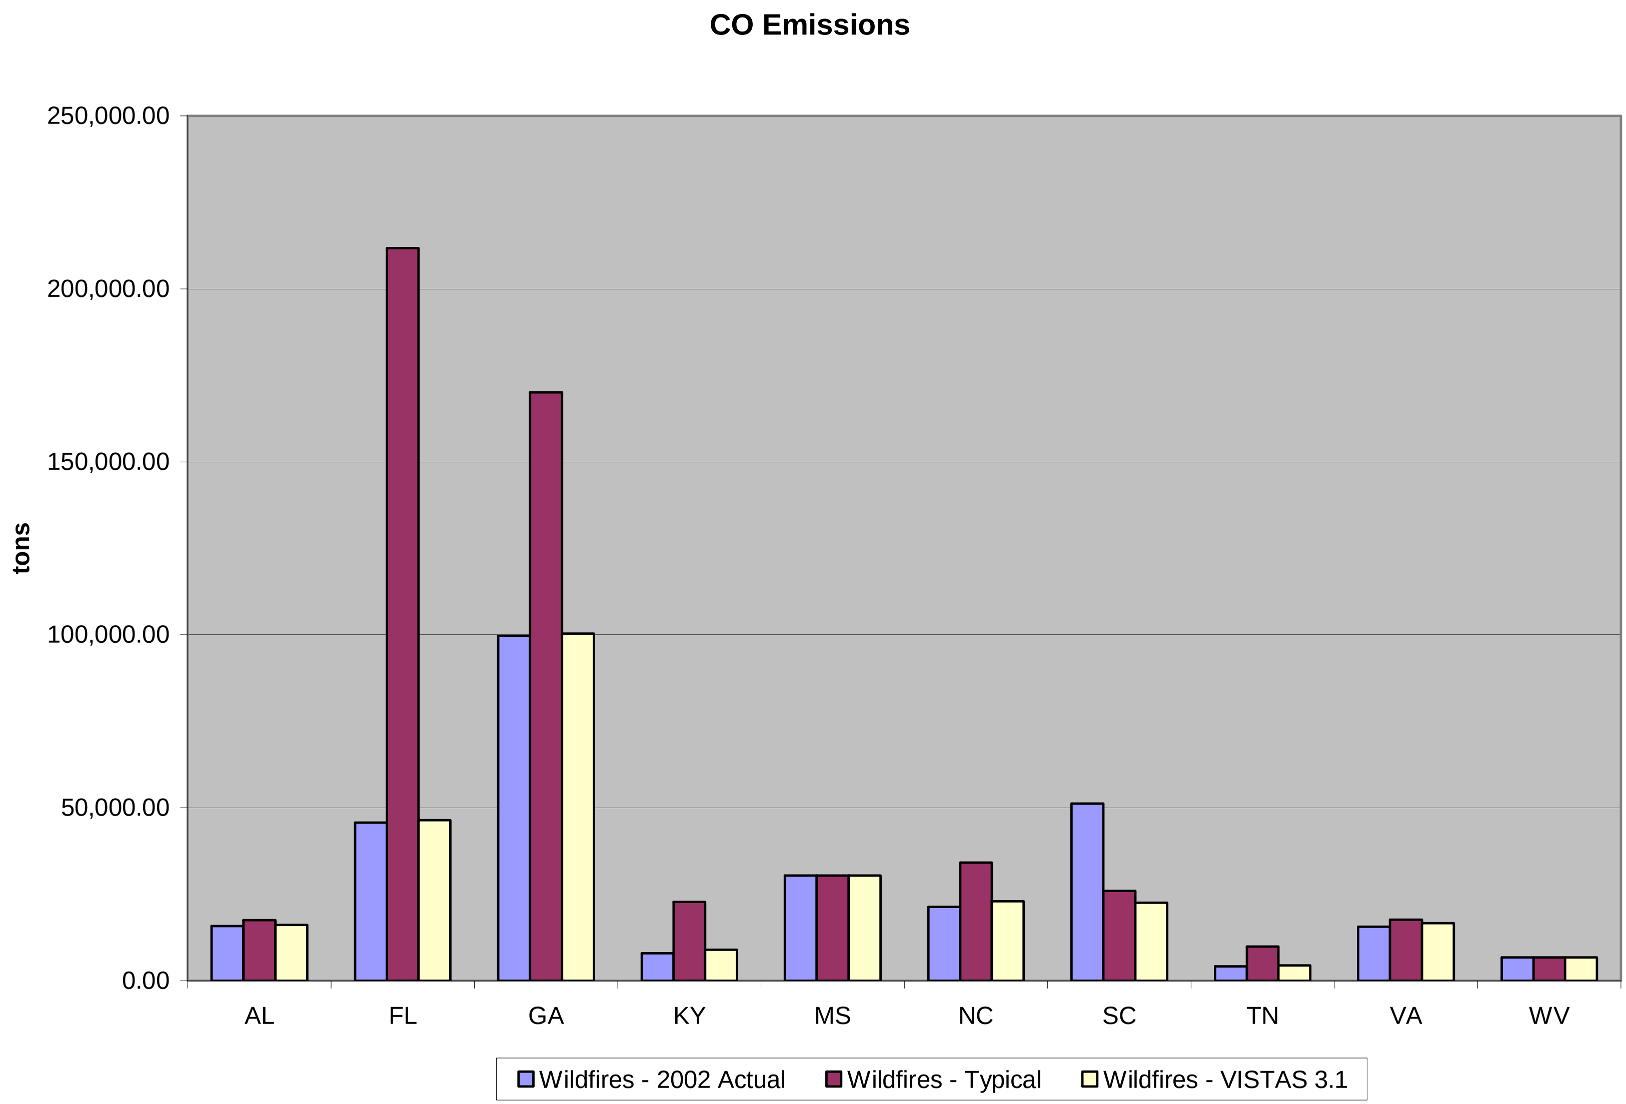

1.2.2 Development of non-fire inventory

The second task in preparing the area source component of the Base F and Base G 2002 base year inventory was the incorporation of data submitted by the VISTAS States to the EPA as part of the CERR. With few exceptions, Base F and Base G inventories for this component of the inventory are identical. Modifications to the Base F methodology (described below) only resulted from modifications from the VISTAS States during review of the Base F inventory. The changes made to the inventory based on these reviews are described in the last portion of this section of the report. The information presented below describes the method used to incorporate CERR data as part of Base F.

Work on incorporating the CERR data into the 2002 Base F inventory involved: 1) obtaining the data from EPA, 2) evaluating the emissions and pollutants reported in order to avoid double counting and 3) backfilling from the earlier version of the VISTAS 2002 base year inventory for missing sources/pollutants. The processes used to perform those operations are described below. This work did not include any of the fire emission estimates described above. In addition it did not include emission estimates for ammonia from agricultural and fertilizer sources. Finally it did not include PM emissions from paved roads. Each of those categories was estimated separately.

Data on the CERR submittals was obtained from EPA’s Draft NEI download file transfer protocol (FTP) site where the data are stored after they’ve been processed for review. The data submitted in National Emission Inventory Format (NIF) was downloaded from that site. Once all of the files were obtained, MACTEC ran the files through the EPA NIF Format and Content checking tool to ensure that the files were submitted in standard NIF format and that there were no issues with those files. In a couple of cases small errors were found. For example, in one case a county FIPs code that was no longer in use was found. MACTEC contacted each VISTAS State area source contact person to resolve the issues with the files and corrections were made. Once all corrections to the native files were completed, MACTEC continued with the incorporation of the data into the VISTAS area source files.

Our general assumption was that unless we determined otherwise, the CERR submittals represented full and complete inventories. Where a State submitted a complete inventory, our plan was to simply delete the previous 2002 base year data and replace it with the CERR submittal. Prior to this replacement however, we stripped out the following emissions:

1. All wildfire, prescribed burning, land clearing and agricultural burning emissions submitted to EPA by the States as part of the CERR process were removed since they were to be replaced with emissions estimated using methods described earlier.
2. All fertilizer and agricultural ammonia emission records submitted to EPA by the States as part of the CERR process were removed. These were replaced with the estimates developed using the CMU Ammonia model.

3. All emissions from paved roads submitted to EPA by the States as part of the CERR process were removed. These emissions were replaced with updated emissions developed by U.S. EPA as part of their 2002 NEI development effort.

This approach was used for most State and Local emission submittals to prepare the Base F inventory. There were a few cases where alternative data were used to prepare the Base F inventory. In general, these alternatives involved submittal of alternative files to the CERR data by S/L agencies. Table 1.2-2 below summarizes the data used to prepare the Base F inventory. In general the data were derived from one of the following sources:

1. CERR submittal obtained from EPA FTP site as directed by VISTAS States;
2. State submitted file (either revised from CERR submittal or separate format);
3. VISTAS original 2002 base year (VISTAS version 3.1 base year file); or
4. EPA's preliminary 2002 NEI.

Table 1.2-2 Summary of State Data Submittals for the 2002 VISTAS Area Source Base F Inventory

State / Local Program	Area Source Emissions Data Source
AL	B
FL	B
GA	C
KY	A
MS	B
NC	C
SC	B
TN	B
VA	B
WV	A/C
Davidson County, TN	B
Hamilton County, TN	C
Memphis/Shelby County, TN	A
Knox County, TN	B
Jefferson County, AL	* so B from State
Jefferson County, KY	B
Buncombe County, NC	* so C from State
Forsyth County, NC	* so C from State
Mecklenburg County, NC	* so C from State

A = VISTAS 2002 (version 3.1)
B = CERR Submittal from EPA's ftp site
C = Other (CERR or other submittal sent directly from State to MACTEC)
* = No response

In order to track the sources of data in the final Base F and Base G NIF files, a field was added to the NIF format files developed for VISTAS to track each data source. A field named Data_Source was added to the EM table. A series of codes were added to this field to mark the source of each emissions value in the Base F and Base G inventories. Values in this field are detailed in Table 1.2-3.

Table 1.2-3 Data Source Codes and Data Sources for VISTAS 2002 Base F Area Source Emissions Inventory.

Data Source Codes	Data Source
Base F Codes	
CMU Model	CMU Ammonia model v 3.6
E-02-X or E-99-F or L-02-X or S-02-X	EPA CERR submittal (from FTP site)
EPA Paved	EPA Paved Road emissions estimates
EPAPRE02NEI	EPA Preliminary 2002 NEI
STATEFILE	State submitted file
VISTBASYR31	VISTAS 2002 Base Year version 3.1
VISTRATIO	Developed from VISTAS Ratios (used only for missing pollutants)
Additional Base G Codes	
ALBASEGFILE	Base G update file provided by AL
NCBASEGFILE	Base G update file provided by NC
OTAQRPT	Portable Fuel Container Emissions from OTAQ Report
STELLA	Revised data provided by VISTAS EI Advisor Greg Stella
VABASEGFILE	Base G update file provided by VA
VAStateFile	Revisions/additions to Base G update file provided by VA

Most States submitted complete inventories for Base F. Virginia's inventory required a two stage update. Virginia's CERR submittal only contained ozone precursor pollutants (including CO). For Virginia, MACTEC's original plan was to maintain the previous 2002 VISTAS base year emissions for non-ozone pollutants and then do a simple replacement for ozone pollutants. However during the QA phase of the work, MACTEC discovered that there were categories that had ozone precursor or CO emissions in the submittal that weren't in the original 2002 VISTAS base year inventory that should have PM or SO_2 emissions. For those records, MACTEC used an emissions ratio to build records for emissions of these pollutants. Data for Virginia PM and SO_2 emissions were generated by developing SCC level ratios to NO_x from the VISTAS 2002 base year inventory (version 3.1) or from emission factors and then calculating the emissions based on that ratio.

1.2.3 2002 Base G inventory updates

After the Base F inventory was submitted and used for modeling, VISTAS States were provided an opportunity for further review and comment on the Base F inventory. As a result of this review and comment period, several VISTAS States provided revisions to the Base F inventory.

In addition to and as an outgrowth of some of the comments provided by the States during the review process, some of the changes made to the inventory were made globally across the entire VISTAS region. This section discusses the specific State changes followed by the global changes made to the area source component of the inventory for all VISTAS States.

1.2.3.1 Changes resulting from State review and comment

Alabama

Alabama suggested several changes and had questions concerning a few categories in the Base F inventory. The changes/questions were:

1. For Source Classification Code (SCC) 2102005000 (Industrial Boilers: Residual Oil) and SCC 2103007000 (Institutional/Commercial Heating: Liquefied Petroleum Gas) the Alabama noted that the Base F VISTAS inventory had values for NO_x, VOC and CO for the State, but no values for SO_2, PM_{10} or $PM_{2.5}$.

MACTEC evaluated this information and found that there were actually emissions for two counties in AL for that SCC that had either SO_2 and/or PM emissions. The data used to develop the 2002 Base F inventory for AL came from the preliminary 2002 CERR submittals (see above) which should have included SO_2 and PM but did not except for two counties. According to MACTEC's protocol for use of these files, the files received from EPA were to be used "as is" unless the States provided comments during the Base F comment period to correct the CERR submittal. No comments were received from AL on the CERR submittal used for Base F. For 2002 Base G, AL provided an updated database file for these SCCs for all counties in the State that provided revised values for emissions and included SO_2 and PM. The revised file was used to update the Base F data for Base G.

2. AL noted that the Base F inventory included SCC 2401002000 (Solvent Utilization, Surface Coating, Architectural Coatings - Solvent-based, Total: All Solvent Types) and 2401003000 (Solvent Utilization, Surface Coating,

Architectural Coatings - Water-based, Total: All Solvent Types) as well as SCC 2401001000 (Solvent Utilization, Surface Coating, Architectural Coatings, Total: All Solvent Types). This resulted in double counting of the emissions for this category. AL suggested removal of the breakdown SCCs and use of the total SCC.

MACTEC deleted records for the breakdown SCCs and retained the total all solvents SCC emissions.

3. AL found the SCCs listed below missing from the Base F VISTAS inventory.

SCC	VOC Emissions	SCC Description
2401025000	1139.91	Surface Coatings: Metal Furniture, all coating types
2401030000	425.27	Surface Coatings: Paper, all coating types
2401065000	344.08	Surface Coatings: Electronic and Other Electrical, all coating types
2430000000	504.29	Solvent Utilization, Rubber/Plastics, All Processes, Total: All Solvent Types
2440020000	3043.78	Solvent Utilization, Miscellaneous Industrial, Adhesive (Industrial) Application, Total: All Solvent Types
Total for AL	5457.32	

MACTEC found that the emissions for these SCCs were included in the Base F inventory, but with slightly different total emissions. AL provided an updated county-level emissions file for use in updating the Base G inventory. That file was used to update the NIF records for AL for those SCCs.

4. AL noted that emissions in the Base F inventory were found for SCC 2465000000 and SCCs 2465100000, 2465200000, 2465400000, 2465600000, and 2465800000. These last five SCCs represent a subset of the emissions in the 246500000 SCC resulting in potential double counting of emissions.

MACTEC deleted all emissions associated with the Total SCC 2465000000 and retained the subset SCCs for the Base G inventory.

Florida

Florida provided comments indicating that they felt that emissions from the following sources and counties were too high, especially for CO and PM and were likely zero:

- motor vehicle fire - Palm Beach County
- woodstoves - Miami Dade, Hillsborough, Orange, Polk, Ft Myers, Pasco and Sarasota Counties
- fireplaces - Miami Dade and Hillsborough Counties

Emissions from these sources in the counties specified were set to zero by MACTEC for the Base G inventory.

North Carolina

North Carolina provided corrected emission files for 2002 Base F. A text file with emission values was provided and used to update the Base F emissions to Base G. The updated emissions were applied directly to the Base F NIF file. The file provided was similar to the "EM" NIF table. An update query was used to update the data supplied in the text file to the Access database NIF file. All changes were implemented.

South Carolina

South Carolina had two issues concerning the Base F inventory. These issues related to 1) additional SCCs that were in BASE F 2009 and 2018, but not in 2002 Base F and 2) SCCs that were in the U.S. EPA 2002 NEI inventory, but not in the VISTAS 2002, 2009, or 2018 Base F inventory.

MACTEC investigated the additional SCCs found in 2009 and 2018 Base F and found that the SCCs actually were not missing in the 2002 Base F inventory but only had emissions for PM. Thus the emissions were maintained as they were provided in Base F.

With respect to the SCCs that were found in the U.S. EPA 2002 NEI, MACTEC investigated and found that they were not included in the Base F inventory because they were not included in the 2002 CERR submittal used to produce the Base F updates. The SCCs were apparently added by EPA later in the NEI development process. In addition, MACTEC also evaluated whether or not the SCCs were found in other VISTAS States Base F inventories. MACTEC found that some States included them and some did not, there was no consistency between the States. MACTEC also found that typically emissions for these SCCs were low in emissions, generally with emissions of only a few tons to tens of tons per year. The decision was made with South Carolina concurrence not to add these SCCs to the Base G inventory. These SCCs were: 210205000, 2102011000, 2103007000, 2103011000, 2104007000, 2104011000, 2302002100, 2302002200, 2302003100, 2302003200, 2610000500, 2810001000, and 281001500.

Virginia

Virginia provided an updated 2002 base year emissions file. The data in that file were used to update the Base F inventory emission values to those for Base G. In addition, Virginia provided information on several source categories that required controls for future year projections since the sources were located in counties/cities in northern Virginia and were subject to future year Ozone Transport Commission (OTC) regulations. MACTEC added in the base year control levels to the Base G inventory file for these categories so that they could be estimated correctly in future years. The controls added were for mobile equipment repair/refinishing sources, architectural and industrial maintenance coating sources, consumer products sources, and solvent metal cleaning sources. Minor errors were found in some entries for the initial file provided and VA provided a revised file with corrections and minor additions.

Jefferson County, KY

In December 2007, KY Division of Air Quality staff identified that Jefferson County, KY was showing zero area source SO_2 emissions. MACTEC was asked to investigate why there were zero emissions. MACTEC's investigation showed that some of the surrounding counties had area source SO_2 emissions, but that Jefferson County's were indeed zero. MACTEC determined that there were emissions in pre-Base F inventories which would have originated from the 1999 NEI grown to 2002. However under our Base F update procedure, we obtained a CERR submittal from Jefferson County. That file contained only emissions for Jefferson County including a limited number of non-ozone pollutant records. Thus under our procedure for processing CERR submittals (see above), the file was considered to be full and complete for purposes of inclusion in the Base F inventory and was processed as if it contained more than just ozone pollutant records (i.e., supplemental pollutant records were not required). The file provided, however did not have any SO_2 records. The lack of area source SO_2 emissions was not discovered during the normal State/local review process or during MACTEC's QA process performed on the initial version of the Base F inventory and was thus carried forward into the Base G2 (and thus the Best and Final) inventory and modeling effort where it remained undiscovered until December 2007.

After discovery of the lack of SO_2 records, MACTEC recovered the SO_2 (and some PM) records from the pre-Base F inventories and prepared updated records for 2002, 2009 and 2018. However, because of the timing of the release of these data (December 2007) and the fact that VISTAS could not rerun 2002 and 2009 in time for the final modeling needs with these data, these changes were not included in the final files (Base G2/Best and Final). Therefore, the summaries provided in this document do not reflect those emissions, nor do the Best and Final inventory files include them.

1.2.4 Ammonia and paved road emissions

The final component of the Base F inventory development was estimation of NH_3 emission estimates for livestock and fertilizers and paved road PM emissions. For the NH_3 emission estimates for livestock and fertilizers we used version 3.6 of the CMU NH_3 model (http://www.cmu.edu/ammonia/). Results from this model were used for all VISTAS States. The CMU model version 3.6 was used in large part because it had been just recently been updated to include the latest (2002) Census of Agriculture animal population statistics. Prior to inclusion of the CMU model estimates, MACTEC removed any ammonia records for agricultural livestock or fertilizer emissions from the VISTAS 2002 initial base year inventory. MACTEC also generated emissions from human perspiration and from wildlife using the CMU model and added those emissions for each State.

For the Base G ammonia inventory, MACTEC removed all wildlife and human perspiration emissions. VISTAS decided to remove these emissions from the inventory. Human perspiration was dropped due to a discrepancy in the units used for the emission factor that was not resolved prior to preparing the estimates and wildlife was dropped because VISTAS felt the activity data was too uncertain. Thus all emissions from these two categories were deleted in the Base G 2002 inventory.

For the paved road PM Base F emissions, we used the most recent estimates developed by EPA as part of the NEI development effort (Roy Huntley, U.S. EPA, email communication, 8/30/2004). EPA had developed an improved methodology for estimating paved road emissions for 2002 and had used that method to calculate emissions for that source category. MACTEC obtained those emissions from EPA and those values were substituted directly into the inventory after receiving consensus from all of the VISTAS States to perform the replacement. These files were obtained in March of 2005 in NIF format from the EPA FTP site.

For the Base G emissions, modifications were made to the emissions estimates based on changes suggested by work of the Western Regional Air Partnership and U.S. EPA. Details of these changes are provided below in the section on global changes made as part of the Base G inventory updates.

1.2.5 Global Changes Made for Base G

There were three global changes made between the Base F and the Base G inventory (beyond the removal of wildlife and human perspiration NH_3 emissions). These changes were:

1. Removal of Stage II emissions from the area source inventory and inclusion in the mobile sector of the inventory,

2. Adjustment of fugitive dust $PM_{2.5}$ emissions, and

3. Addition of emissions from portable fuel containers.

As part of the Base F review process, several VISTAS States had expressed surprise that the Stage II refueling emission estimates were in the area source component of the inventory. This decision had been made with SIWG agreement early on in the inventory development process because 1) some States had included it in their CERR submittals and 2) because the non-road and on-road mobile estimates had differing activity factor units and could not be easily combined. However for Base G, the VISTAS States all agreed, especially in light of the different ways in which the emissions were reported in the CERR, to remove the Stage II refueling emissions from the area source inventory and include them in the non-road and on-road sectors. Thus all records related to Stage II refueling were removed from the area source component of the Base G inventory.

$PM_{2.5}$ emissions from several fugitive dust sources were also updated for Base G. The Western Regional Air Partnership (WRAP) and U.S. EPA had been investigating overestimation of the $PM_{2.5}$ / PM_{10} ratio in several fugitive dust categories and U.S. EPA was in the process of making revisions to AP-42 for several categories during preparation of the Base G inventory. Based on data received from U.S. EPA, VISTAS decided to revise the $PM_{2.5}$ emissions from construction, paved roads and unpaved road sources. $PM_{2.5}$ emissions in Base F were multiplied by 0.67, 0.6, and 0.67 for construction, paved roads and unpaved roads respectively to produce the values found in Base G. No changes were made to PM_{10}, only to $PM_{2.5}$.

Finally, as part of Virginia's comments on the Base F inventory, emissions from portable fuel containers were mentioned as being absent from the inventory. MACTEC was tasked with developing a methodology that could be used to add these emissions to the Base G area source inventory. In investigating options for a method of estimating emissions, MACTEC found that the U.S. EPA had prepared a national inventory of emissions by State for portable fuel containers. Data on emissions from this source prepared by U.S. EPA were presented in, "Estimating Emissions Associated with Portable Fuel Containers (PFCs), Draft Report, Office of Transportation and Air Quality, United States Environmental Protection Agency, Report # EPA420-D-06-003, February 2006".

State-level emission estimates for 2005 derived from Appendix Table B-2 of the PFCs report were used as the starting point for developing 2002 county-level emissions estimates. State emissions were derived from that table by using all of the emission estimates in that table with the exception of values for vapor displacement and spillage from refueling operations. Those components of the State emissions were left out of the State-level emissions to avoid double counting refueling emissions in the non-road sector. For the purposes of 2002 emission estimates for Base G, the 2005 values were assumed equal to 2002 values.

The 2005 State-level estimates minus the refueling component from Appendix Table B-2 of the report were summed for each State and then allocated to the county-level. The county-level allocation was based on the fuel usage information obtained from the NONROAD 2005 model runs conducted as part of the Base G inventory development effort (see the 2002 base year Base G non-road section below). MACTEC used the spillage file from the NONROAD model (normally located in the DATA\EMSFAC directory in a standard installation of NONROAD) to determine the SCCs that used containers for refueling. The spillage file contains information by SCC and horsepower indicating whether or not the refueling occurs using a container or a pump. All SCC and horsepower classes using containers were extracted from the file and cross-referenced with the fuel usage by county for those SCC/horsepower combinations from the appropriate year model runs (2002, 2009 or 2018). Then the fuel usages by county from the NONROAD 2005 runs prepared for VISTAS were summed for those SCCs by county. The county level fuel use was then divided by the State total fuel use for the same SCCs to determine the fraction of total State fuel usage and that fraction was used to allocate the State-level emissions to the county.

1.2.6 Quality Assurance steps

Throughout the inventory development process, quality assurance steps were performed to ensure that no double counting of emissions occurred, and to ensure that a full and complete inventory was developed for VISTAS. Quality assurance was an important component to the inventory development process and MACTEC performed the following QA steps on the area source component of the 2002 Base F inventory:

1. All CERR and NIF format State supplied data submittals were run through EPA's Format and Content checking software.
2. SCC level emission summaries were prepared and evaluated to ensure that emissions were consistent and that there were no missing sources.
3. Tier comparisons (by pollutant) were developed between the revised 2002 base year inventory and the previous (version 3.1) base year inventory.
4. Fields were either added or used within each NIF data table to track the sources of data for each emission record.
5. Data product summaries were provided to both the VISTAS Emission Inventory Technical Advisor and to Area Source and Fires SIWG representatives for review and comment. Changes based on these comments were implemented in the files.
6. Version numbering was used for all inventory files developed. The version numbering process used a decimal system to track major and minor changes. For

example, a major change would result in a version going from 1.0 to 2.0. A minor change would cause a version number to go from 1.0 to 1.1. Minor changes resulting from largely editorial changes would result in a change from 1.00 to 1.01.

In addition, for the fires inventory, data related to fuel loading and fuel consumption was reviewed and approved by the VISTAS Fire SIWG to ensure that values used for each type of fire and each individual fire were appropriate. Members of the VISTAS Fire SIWG included representatives from most State Divisions of Forestry (or equivalent) as well as U.S. Forest Service and National Park Service personnel.

For Base G, similar QA steps to those outlined above for Base F were undertaken. In addition, all final NIF files were checked using the EPA Format and Content checking software and summary information by State and pollutant were prepared comparing the Base F and Base G inventories.

1.3 Mobile Sources

This section describes the revisions made to the initial 2002 VISTAS Base Year emission inventory on-road mobile source input files. For this work actual emission estimates were not made, rather data files consistent with Mobile Emissions Estimation Model Version 6 (MOBILE6) were developed and provided to the VISTAS modeling contractor. These input data files were then run during the VISTAS modeling to generate on-road mobile source emissions using episodic and meteorological specific conditions configured in the sparse matrix operator Kernel Emissions modeling system (SMOKE) emissions processor.

During initial discussions with the VISTAS Mobile Source SIWG, some States indicated a desire to use CERR mobile source emissions data in place of the VISTAS 2002 inventories generated by E.H. Pechan and Associates, Inc. (the initial VISTAS 2002 Base Year inventory files).

However, the CERR emissions data by itself were not sufficient for an inventory process that includes both base and future year inventories. MACTEC needed to be able to replicate the CERR data rather than simply obtain CERR emissions estimates. The reason for this is that only input files were being prepared to provide revised 2002 estimates during the VISTAS modeling process, rather than the actual emission estimates and that the 2002 input data files would be used as a starting point for the projected emission estimates. This meant that the appropriate vehicle miles traveled (VMT), MOBILE6, and/or NONROAD model input data needed to be provided. If these data were provided with the CERR emissions estimates we used it as the starting point for revision of the 2002 Base Year inventory. However MACTEC did not have access to the on-road mobile CERR submissions from EPA, so re-submittal of these data directly to MACTEC was requested in order to begin compiling the appropriate input file data.

In those cases where States did not provide CERR on-road mobile source input data files, our default approach was to maintain the data input files and VMT estimates for the initial 2002 Base Year inventory prepared by Pechan.

1.3.1 Development of on-road mobile source input files and VMT estimates

Development of the 2002 on-road input files and VMT was a multi-step process depending upon what the State mobile source contacts instructed us to use as their data. Information provided below provides incremental revisions made to on-road mobile source inventories or inputs in series from one inventory version to the next. In general the process involved one of three steps from the original 2002 on-road mobile source data.

Base F Revisions

1. The first step was to evaluate the initial 2002 base year files and make any non-substantive changes (i.e., changes only to confirm that the files posted for 2002 by Pechan were executable and that all the necessary external files needed to run MOBILE6 were present). This approach was taken for AL, FL, GA, MS, SC, and WV. For these States the determination was made that the previous files would be okay to use as originally prepared. For SC, the VMT file was updated, but that did not affect the MOBILE6 input files.

2. For other States, modification to the input files was required. The information below indicates what changes were made for other States in the VISTAS region.

KY – For Kentucky, the Inspection and Maintenance (I/M) records in the input files for Jefferson County were updated in order to better reflect the actual I/M program in the Louisville metropolitan area.

NC - Substantial revisions were implemented to these input files based on input from the State. The modifications necessary to reflect the desires of the State led to complete replacement of the previous input files. Among the changes made were:

- The regrouping of counties (including the movement of some counties from one county group to another and the creation of new input files for previously grouped counties). There were originally 32 input files; after the changes there were 49. The pointer file was corrected to reflect these changes.
- Travel speeds were updated in over 3000 scenarios.
- All I/M records were updated.
- All registration distributions were updated.

- I/M VMT fractions were updated (which only affected the pointer file).
- VMT estimates were updated (which has no direct effect on the MOBILE6 input files but does ultimately affect emissions).

3. VA and TN – For these States, new input files were provided due to substantive changes that the State wanted to make relative to the 2002 initial base year input files. In addition, revised VMT data were developed for each State.

Base G Revisions

For the production of the VISTAS 2002 Base G inventory, VISTAS states reviewed the Base F inputs, and provided corrections, updates and supplemental data.

For all states modeled, the Base G updates include:

Adding Stage II refueling emissions calculations to the SMOKE processing.

Revised the HDD compliance for all states. (REBUILD EFFECTS = .1)

In addition to the global changes, individual VISTAS states made the following updates:

KY – updated VMT and M6 input values for selected counties.

NC – revised VMT and registration distributions.

TN - revised VMT and vehicle registration distributions for selected counties.

VA – revised winter RFG calculations in Mobile 6 inputs.

WV – revised VMT input data.

AL, FL, and GA did not provide updates for Base G and therefore the Base F inputs were used for these States.

1.3.1.1 Emissions from on-road mobile sources

The MOBILE6 module of the Sparse Matrix Operator Kernel Emissions (SMOKE) model was used to develop the on-road mobile source emissions estimates for CO, NO_X, NH_3, SO_2, PM, and VOC emissions. The MOBILE6 parameters, vehicle fleet descriptions, and VMT estimates are combined with gridded, episode-specific temperature data to calculate the gridded, temporalized emission estimates. The MOBILE6 emissions factors are based on episode-specific temperatures predicted by the meteorological model. Further, the MOBILE6 emissions factors model accounts for the following:

- Hourly and daily minimum/maximum temperatures;

- Facility speeds;
- Locale-specific inspection/maintenance (I/M) control programs, if any;
- Adjustments for running losses;
- Splitting of evaporative and exhaust emissions into separate source categories;
- VMT, fleet turnover, and changes in fuel composition and Reid vapor pressure (RVP).

The primary input to MOBILE6 is the MOBILE shell file. The MOBILE shell contains the various options (e.g. type of inspection and maintenance program in effect, type of oxygenated fuel program in effect, alternative vehicle mix profiles, RVP of in-use fuel, operating mode) that direct the calculation of the MOBILE6 emissions factors. The shells used in these runs were based on VISTAS Base F modeling inputs as noted in the previous section.

For this analysis, the on-road mobile source emissions were produced using selected weeks (seven days) of each month and using these days as representative of the entire month. This selection criterion allows for the representation of day-of-the-week variability in the on-road motor vehicles, and models a representation of the meteorological variability in each month. The modeled weeks were selected from mid-month, avoiding inclusion of major holidays.

The parameters for the SMOKE runs are as follows:

Episodes:
2002 Initial Base Year, and
2009 and 2018 Future years, using 2009/2018 inventories and modeled using the same meteorology and episode days as 2002.

Episode represented by the following weeks per month:
January 15-21
February 12-18
March 12-18
April16-22
May 14-20
June 11-17
July 16-22
August 13-19
September 17-23
October 15-21
November 12-18
December 17-23

Days modeled as holidays for annual run:

New Year's Day - January 1

Good Friday – March 29

Memorial Day – May 27

July 4th

Labor Day – September 2

Thanksgiving Day – November 28, 29

Christmas Eve – December 24

Christmas Day – December 25

Output time zone:

Greenwich Mean Time (zone 0)

Projection:

Lambert Conformal with Alpha=33, Beta=45, Gamma=-97, and center at (-97, 40).

Domain:

36 Kilometer Grid: Origin at (-2736, -2088) kilometers with 148 rows by 112 columns and 36-km square grid cells.

12 Kilometer Grid: Origin at (108, -1620) kilometers with 168 rows by 177 columns and 12-km square grid cells.

CMAQ model species:

The CMAQ configuration was CB-IV with PM. The model species produced were: CO, NO, NO_2, ALD_2, ETH, FORM, ISOP, NR, OLE, PAR, TERPB, TOL, XYL, NH_3, SO_2, SULF, PEC, PMFINE, PNO_3, POA, PSO_4, and PMC.

Meteorology data:

Daily (25-hour). SMOKE requires the following five types of MCIP outputs: (1) Grid cross 2-d, (2) Grid cross 3-d, (3) Met cross 2-d, (4) Met cross 3-d, and (5), Met dot 3-d.

The reconstructed emissions based on the representative week run were calculated by mapping each day of week (Mon, Tue, Wed, etc.) from the modeled month to the same day of week generated in the representative week run. In the case of holidays, these days were mapped to representative week Sundays. An example of this mapping for the January episode is presented in Table 1.3-1 below. Note that although the emissions were generated for individual calendar years (2002, 2009 and 2018) the meteorology is based on 2002.

* Modeled holiday

1.3.2 Development of non-road emission estimates

Emissions from non-road sources were estimated in two steps. First, emissions for non-road sources that are included in the NONROAD model were developed. Second, emissions from sources not included in the NONROAD model were estimated. The sections below detail the procedures used for each group of sources.

1.3.2.1 Emissions from NONROAD model sources

An initial 2002 base year emissions inventory for non-road engines and equipment covered by the EPA NONROAD model was prepared for VISTAS in early 2004. The methods and assumptions used to develop the inventory are presented in a February 9, 2004 report "*Development of the VISTAS Draft 2002 Mobile Source Emission Inventory (February 2004 Version)*" as prepared by E.H. Pechan & Associates, Inc. Except as otherwise stated below, all aspects of the preparation methodology documented in that report continue to apply to the revised NONROAD modeling discussed in this section.

Revisions to the initial 2002 NONROAD emissions inventory were implemented to ensure that the latest State and local data were considered, as well as to more accurately reflect gasoline sulfur contents for 2002 and correct other State-specific discrepancies. Those revisions comprise the Base F VISTAS non-road inventory. This section details the specific revisions made to the NONROAD model input files for the Base F and Base G VISTAS base year inventories, and provides insight into some key differences between the versions of the NONROAD model employed for the Base F and Base G inventories and the previous version employed for the initial 2002 base year inventory prepared by Pechan.

Revisions to the initial 2002 emissions inventory prepared by Pechan were actually implemented in two stages. An initial set of revisions was implemented in the fall of 2004. Those revisions resulted in the Base F inventory. These were followed by a second set of revisions in the spring of 2006. Those estimates produced the Base G base year inventory. To accurately document the combined effects of both sets of revisions, each set is discussed separately below. Unless otherwise indicated, all revisions implemented in Base F were carried directly into the Base G revision process without change. Thus, the inventories that resulted from the Base F revisions served as the starting point for the Base G revisions.

For Base F, three VISTAS States provided detailed data revisions for consideration in developing revised model inputs. These States were:

1. North Carolina
2. Tennessee (including a separate submission for Davidson County), and
3. Virginia.

The remaining seven VISTAS States indicated that the initial 2002 VISTAS input files prepared by Pechan continued to reflect the most recent data available. These States were:

1. Alabama,
2. Florida,
3. Georgia,
4. Kentucky,
5. Mississippi,
6. South Carolina, and
7. West Virginia.

However, it should be recognized that the NONROAD input files for *all* ten VISTAS States were updated to reflect gasoline sulfur content revisions for the Base F 2002 base year inventory (as discussed below). The original files prepared by Pechan are available on their FTP site in the /pub/VISTAS/MOB_0104/ directory.

Before presenting the specific implemented revisions, it is important to note that the Base F 2002 base year inventory utilized a newer release of the NONROAD model than was used for the initial 2002 base year inventory (prepared by Pechan). The Base F 2002 base year inventory, as developed in spring 2004, was based on the Draft NONROAD2004 model, which was released by the EPA in May of 2004. This model is no longer available on EPA's website. The initial 2002 base year inventory (prepared by Pechan) was based on the Draft NONROAD2002a version of the model (which is also no longer available on EPA's website). Key differences between the models are as follows:

- Draft NONROAD2004 included the effects of the Tier 4 non-road engine and equipment standards (this did not impact the Base F 2002 inventory estimates, but did affect Base F future year forecasts).

- Draft NONROAD2004 included the *exhaust* emission impacts of the large spark-ignition engine standards; the evaporative impacts of these standards are *not* incorporated (this does not impact 2002 inventory estimates, but does affect future year forecasts).
- Draft NONROAD2004 included revised equipment population estimates.
- The $PM_{2.5}$ fraction for *diesel* equipment in Draft NONROAD2004 had been updated from 0.92 to 0.97.
- Draft NONROAD2004 included revisions to recreational marine activity, useful life, and emission rates.

To the extent that these revisions affect 2002 emissions estimates, they will be reflected as differentials between the initial and Base F 2002 VISTAS base year inventories. It is perhaps important to identify that, at the time of the Base F inventory revisions; the EPA recognized the Draft NONROAD2004 model as an appropriate mechanism for SIP development. Although the model was designated as a draft update, it reflected the latest and most accurate NONROAD planning data at that time, as evidenced by the EPA's use of that version for the Tier 4 Final Rulemaking.

Prior to the Base G inventory revisions implemented in 2006, the EPA released another updated version of the NONROAD model, designated as Final NONROAD2005 (which can be downloaded from: http://www.epa.gov/OMSWWW/nonrdmdl.htm#model). This version ostensibly represents the final version of the model, although certain components of it have been updated since its first release in December 2005. For the Base G inventory developed in the first half of 2006, all updates of the Final NONROAD2005 model through March 2006 are included. Key differences between Final NONROAD2005 and Draft NONROAD2004 are as follows:

- Final NONROAD2005 reflects the latest basic emission rate and deterioration data.
- Final NONROAD2005 includes emission estimates for a range of evaporative emissions categories not included in Draft NONROAD2004 (tank and hose permeation, hot soak, and running loss emissions).
- Final NONROAD2005 includes a revised diurnal emissions algorithm.
- Final NONROAD2005 includes a revised equipment scrappage algorithm.
- Final NONROAD2005 includes revised state and county equipment allocation data.
- Final NONROAD2005 allows separate sulfur content inputs for marine and land-based diesel fuel.
- Final NONROAD2005 includes revised conversion factors for hydrocarbon emissions.

- Final NONROAD2005 includes the evaporative emission impacts of the large spark-ignition engine standards (this does not impact 2002 inventory estimates, but does affect future year forecasts).

Unfortunately, due to the extensive revisions associated with Final NONROAD2005, input files created for use with Draft NONROAD2004 (e.g., Base F input files) and earlier versions of the model cannot be used directly with Final NONROAD2005 (used for Base G). This created a rather significant impact in that the VISTAS NONROAD modeling process involves the consideration of over 200 unique sets of input data. To avoid creating new input files for each of these datasets, a conversion process was undertaken wherein each of the Draft NONROAD2004 (Base F) input data files were converted into the proper format required for proper execution in Final NONROAD2005 (Base G).[1] This process consisted of the following steps:

- Revise the Draft NONROAD2004 (Base F) input files to include the following two line EPA-developed comment at the end of the input file header (this is a nonsubstantive change implemented solely for consistency with input files produced directly using Final NONROAD2005):

```
9/2005 epa: Add growth & tech years to OPTIONS packet
 and Counties & Retrofit files to RUNFILES packet.
```

- Revise the Draft NONROAD2004 (Base F) input files to include the following two command lines after the "Weekday or weekend" command in the PERIOD packet:

```
Year of growth calc:
Year of tech sel  :
```

- Revise the Draft NONROAD2004 (Base F) input files to include the following command line after the "Diesel sulfur percent" command in the OPTIONS packet:

```
Marine Dsl sulfur %: 0.2638
```

  Note that the value 0.2638 (2638 parts per million by weight [ppmW]) is applicable only for 2002 modeling and was accordingly revised (as described below) for both the 2009 and 2018 Base G forecast inventories. The 2638 ppmW sulfur value for 2002 marine diesel fuel was taken from the 48-State (excludes Alaska and Hawaii) tabulation presented in the April 27, 2004 EPA document "*Diesel Fuel Sulfur Inputs for the Draft*

[1] The necessary conversions where developed by comparing substantively identical input files created using the graphical user interfaces for both Draft NONROAD2004 and Final NONROAD2005. The differences between the input files indicated the specific revisions necessary to convert existing VISTAS input files into Final NONROAD2005 format.

NONROAD2004 Model used in the 2004 Non-road Diesel Engine Final Rule." It should also be noted that this value differs by about 5 percent from the 2500 ppmW value previously used for the initial 2002 VISTAS modeling (performed by Pechan). Prior to Final NONROAD2005 (used for Base G), the NONROAD model allowed only a single diesel fuel sulfur input that was applied to both land-based and marine equipment. As documented in the February 9, 2004 report "*Development of the VISTAS Draft 2002 Mobile Source Emission Inventory (February 2004 Version)*" as prepared by E.H. Pechan & Associates, Inc., a value of 2500 ppmW sulfur was used for all 2002 VISTAS NONROAD modeling. Given the ability of Final NONROAD2005 to distinguish a separate sulfur content for marine equipment and the existing EPA guidance document suggesting an appropriate marine sulfur value of 2638 ppmW for 2002, the existing modeling value of 2500 ppmW was modified (for marine equipment only).

- Replace the Draft NONROAD2004 (Base F) input files RUNFILES packet command line:

```
TECHNOLOGY     : c:\non-road\data\tech\tech.dat
```

  with the command lines:

```
EXH TECHNOLOGY   : c:\non-road\data\tech\tech-exh.dat
EVP TECHNOLOGY   : c:\non-road\data\tech\tech-evp.dat
```

- Revise the Draft NONROAD2004 (Base F) input files to include the following two command lines after the "EPS2 AMS" command in the RUNFILES packet:

```
US COUNTIES FIPS  : c:\non-road\data\allocate\fips.dat
RETROFIT      :
```

- Revise the Draft NONROAD2004 (Base F) input files to include the following command line after the "Rec marine outbrd" command in the ALLOC FILES packet:

```
Locomotive NOx   : c:\non-road\data\allocate\XX_rail.alo
```

  Where "XX" varies across input files. For any given file, "XX" is the two digit abbreviation of the state associated with the scenario being modeled (e.g., for Alabama modeling, XX=AL).

- Replace the Draft NONROAD2004 (Base F) input files EMFAC FILES packet command line:

```
Diurnal      : c:\non-road\data\emsfac\diurnal.emf
```

with the eight command lines:

```
Diurnal      : c:\non-road\data\emsfac\evdiu.emf
TANK PERM     : c:\non-road\data\emsfac\evtank.emf
NON-RM HOSE PERM  : c:\non-road\data\emsfac\evhose.emf
RM FILL NECK PERM : c:\non-road\data\emsfac\evneck.emf
RM SUPPLY/RETURN  : c:\non-road\data\emsfac\evsupret.emf
RM VENT PERM    : c:\non-road\data\emsfac\evvent.emf
HOT SOAKS     : c:\non-road\data\emsfac\evhotsk.emf
RUNINGLOSS     : c:\non-road\data\emsfac\evrunls.emfEVP
```

- Revise the Draft NONROAD2004 (Base F) input files to include the following command line after the "PM exhaust" command in the DETERIORATE FILES packet:

```
Diurnal      : c:\non-road\data\detfac\evdiu.det
```

Once revised in this format, the VISTAS non-road input files developed for use with Draft NONROAD2004 (Base F) were executable under the Final NONROAD2005 model (Base G).

The only additional revisions implemented to develop a Final NONROAD2005-based inventory (Base G) involved elimination of non-default equipment allocation files for North Carolina and West Virginia. Due to concerns about improper equipment allocation across counties under the Draft NONROAD2004 model (used for Base F), as well as for earlier versions of the NONROAD model, North Carolina had produced alternative allocation data files indicating the number of employees in air transportation by county, the number of wholesale establishments by county, and the number of employees in landscaping services by county. For the same reason, West Virginia had produced alternative equipment allocation files indicating the number of employees in air transportation by county, the tonnage of underground coal production by county, the number of golf courses and country clubs by county, the number of wholesale establishments by county, the number of employees in logging operations by county, the number of employees in landscaping services by county, the number of employees in manufacturing operations by county, the number of employees in oil and gas drilling and extraction operations by county, and the number of recreational vehicle parks and campgrounds by county. These alternative equipment allocation files were used for all VISTAS inventory modeling conducted prior to the release of Final NONROAD2005 (i.e., through Base F). However, both North Carolina and West Virginia determined that the default allocation file revisions associated with the release of Final NONROAD2005 were appropriate to address the concerns that led to the development of the alternative allocation files. As a result, all alternative allocation file commands were removed from VISTAS NONROAD2005 (Base G) input files for North Carolina and West Virginia, so that the entire region under the Base G inventory is now modeled using the default allocation files provided with NONROAD2005.

In addition to the alternative equipment allocation files, North Carolina had previously developed an alternative seasonal adjustment file that was used for the Base F inventory in place of the default file provided with Draft NONROAD2004 (and earlier model versions). The alternative data file implemented a single change, namely reclassifying North Carolina as a southeastern state rather than a mid-Atlantic state (as identified in the default data file). Since Final NONROAD2005 continues to identify North Carolina as a mid-Atlantic state, North Carolina requested that the southeastern reclassification be continued for all NONROAD2005 modeling (Base G). To ensure that any other revisions associated with the seasonal adjustment file released with NONROAD2005 were not overlooked, the previously developed alternative seasonal adjustment file for North Carolina was scrapped and a new alternative file was created from the default seasonal adjustment file provided with Final NONROAD2005 for Base G inventory development. The alternative file, which was used for all North Carolina modeling, reclassifies North Carolina from a mid-Atlantic to a southeastern state. This represents the only non-default data file used for VISTAS NONROAD2005-based (Base G) modeling.

The remainder of this section documents all changes to the originally established VISTAS input file values as documented in the February 9, 2004 report "*Development of the VISTAS Draft 2002 Mobile Source Emission Inventory (February 2004 Version)*" as prepared by E.H. Pechan & Associates, Inc. Unless specifically stated below, all values from that report continue to be used without change in the latest VISTAS modeling.

Base F Revisions:

For the initial 2002 base year inventory (developed by Pechan), all NONROAD modeling runs for VISTAS were performed utilizing a gasoline sulfur content of 339 ppmW and a diesel sulfur content of 2,500 ppmW. Although the EPA-recommended non-road diesel fuel sulfur content for 2002 is 2,283 ppmW, the 2,500 ppmW sulfur content used for the initial 2002 base year VISTAS inventory was designed to remove the effect of lower non-road diesel fuel sulfur limits applicable only in California. (The EPA recommended inputs can be found in "*Diesel Fuel Sulfur Inputs for the Draft NONROAD2004 Model used in the 2004 Non-road Diesel Engine Final Rule*," EPA, April 27, 2004.) This correction is appropriate and was retained for the Base F 2002 inventory. Thus, the Base F inventory continued to assume a diesel fuel sulfur content of 2,500 ppmW across the VISTAS region.

However, 339 ppmW is not the EPA recommended 2002 gasoline sulfur content for either eastern conventional gasoline areas or Federal Reformulated Gasoline (RFG) areas. The recommended sulfur content for eastern conventional gasoline is 279 ppmW year-round, while the recommended sulfur content for RFG areas is 129 ppmW during the summer season and 279 ppmW during the winter season. (Conventional gasoline and RFG sulfur contents for 2002 can be found in "*User's Guide to MOBILE6.1 and MOBILE6.2, Mobile Source Emission Factor*

Model," EPA420-R-03-010, U.S. EPA, August 2003 [pages 149-155] (available at link at http://www.epa.gov/otaq/m6.htm) and in the source code for MOBILE6.2 at Block Data BD05.) Given the differences in the EPA-recommended values and the value used to generate the initial 2002 base year inventory, the input files for Base F for *all* VISTAS areas were updated to reflect revised gasoline sulfur content assumptions.

Since the VISTAS NONROAD modeling is performed on a seasonal basis, and since gasoline sulfur content in RFG areas varies with the RFG season, seasonally-specific gasoline sulfur content values were estimated for use in RFG area modeling. In addition, 25 counties in Georgia are subject to a summertime gasoline sulfur limit of 150 ppmW, so that seasonal sulfur content estimates were also estimated for these counties. The initial 2002 base year NONROAD inventory (prepared by Pechan) for these Georgia counties was based on a year-round 339 ppmW gasoline sulfur content, but that oversight was corrected in the Base F 2002 base year inventory. Based on the seasonal definitions employed in the NONROAD model, monthly sulfur contents were averaged to estimate seasonal gasoline sulfur contents as follows:

Month/Season	RFG Areas	Conventional Gasoline Areas	Georgia Gasoline Control Areas
March	279 ppmW	279 ppmW	279 ppmW
April	279 ppmW	279 ppmW	279 ppmW
May	129 ppmW	279 ppmW	150 ppmW
Spring	229 ppmW	279 ppmW	236 ppmW
June	129 ppmW	279 ppmW	150 ppmW
July	129 ppmW	279 ppmW	150 ppmW
August	129 ppmW	279 ppmW	150 ppmW
Summer	129 ppmW	279 ppmW	150 ppmW
September	129 ppmW	279 ppmW	150 ppmW
October	279 ppmW	279 ppmW	279 ppmW
November	279 ppmW	279 ppmW	279 ppmW
Fall	229 ppmW	279 ppmW	236 ppmW
December	279 ppmW	279 ppmW	279 ppmW
January	279 ppmW	279 ppmW	279 ppmW
February	279 ppmW	279 ppmW	279 ppmW
Winter	279 ppmW	279 ppmW	279 ppmW

Note that the seasonal data are based on simple arithmetic averages and do not consider any monthly variation in activity (and fuel sales), and that the transition between summer and winter seasons is also not considered. Additionally, the summer fuel control season is treated as though it applies from May through September, while the summer RFG season actually ends on September 15 and the Georgia fuel control season does not officially begin until June 1. This treatment is consistent with the treatment of both fuel control programs in the VISTAS on-road vehicle modeling. Each of these influences will result in some error in the estimated sulfur content estimates, but it is expected that this error is small relative to the overall correction from a year-round sulfur content estimate of 339 ppmW.

All NONROAD modeling revisions made as part of the Base F inventory preparation process are presented in Table 1.3-2. Due to more involved updates in several areas, the number of NONROAD input files as well as sequence numbers used to represent these files was also updated in a few instances (as compared to the files used to create the initial 2002 VISTAS non-road inventory, as documented in the February 9, 2004 report "*Development of the VISTAS Draft 2002 Mobile Source Emission Inventory (February 2004 Version)*" as prepared by E.H. Pechan & Associates, Inc. These structural revisions are presented in Table 1.3-3, and are provided solely for the benefit of NONROAD modelers as the indicated revisions have no impact on generated emission estimates.

Table 1.3-2 Summary of Base F NONROAD Modeling Revisions

State	Revisions Implemented
AL	(1) Gasoline sulfur content changed from 339 ppmW to 279 ppmW in all counties and all seasons (all are conventional gasoline areas).
FL	(1) Gasoline sulfur content changed from 339 ppmW to 279 ppmW in all counties and all seasons (all are conventional gasoline areas).
GA	(1) Gasoline sulfur content changed from 339 ppmW to 279 ppmW in all seasons for conventional gasoline counties. (2) Gasoline sulfur content changed from 339 ppmW to 150 ppmW in the summer for all gasoline control counties. (3) Gasoline sulfur content changed from 339 ppmW to 236 ppmW in the spring and fall for all gasoline control counties. (4) Gasoline sulfur content changed from 339 ppmW to 279 ppmW in the winter for all gasoline control counties. *Gasoline control counties: Barrow, Bartow, Butts, Carroll, Cherokee (a), Clayton (a), Cobb (a), Coweta (a), Dawson, De Kalb (a), Douglas (a), Fayette (a), Forsyth (a), Fulton (a), Gwinnett (a), Hall, Haralson, Henry (a), Jackson, Newton, Paulding (a), Pickens, Rockdale (a), Spalding, and Walton*
KY	(1) Gasoline sulfur content changed from 339 ppmW to 279 ppmW in all seasons for conventional gasoline counties. (2) Gasoline sulfur content changed from 339 ppmW to 129 ppmW in the summer for all gasoline control counties. (3) Gasoline sulfur content changed from 339 ppmW to 229 ppmW in the spring and fall for all gasoline control counties. (4) Gasoline sulfur content changed from 339 ppmW to 279 ppmW in the winter for all gasoline control counties. *Gasoline control counties: Boone, Bullitt (b), Campbell, Jefferson, Kenton, and Oldham (b)*
MS	(1) Gasoline sulfur content changed from 339 ppmW to 279 ppmW in all counties and all seasons (all are conventional gasoline areas).
NC	(1) Gasoline sulfur content changed from 339 ppmW to 279 ppmW in all counties and all seasons (all are conventional gasoline areas). (2) Utilize revised (i.e., local) allocation files for three equipment categories. (3) Utilize revised (i.e., local) seasonal activity data.
SC	(1) Gasoline sulfur content changed from 339 ppmW to 279 ppmW in all counties and all seasons (all are conventional gasoline areas).
TN	(1) Gasoline sulfur content changed from 339 ppmW to 279 ppmW in all counties and all seasons (all are conventional gasoline areas). (2) Gasoline Reid Vapor Pressure (RVP) values changed in accordance with local recommendations. (3) Temperature data changed in accordance with local recommendations. (4) Counties regrouped in accordance with local recommendations.

Table 1.3-2. Summary of Base F NONROAD Modeling Revisions (continued)

State	Revisions Implemented
VA	(1) Gasoline sulfur content changed from 339 ppmW to 279 ppmW in all seasons for conventional gasoline counties. (2) Gasoline sulfur content changed from 339 ppmW to 129 ppmW in the summer for all gasoline control counties. (3) Gasoline sulfur content changed from 339 ppmW to 229 ppmW in the spring and fall for all gasoline control counties. (4) Gasoline sulfur content changed from 339 ppmW to 279 ppmW in the winter for all gasoline control counties. (5) Gasoline RVP values changed in accordance with local recommendations. (6) Counties regrouped in accordance with local recommendations. (7) The control effectiveness for counties subject to Stage II controls revised to 77 percent in accordance with local recommendations. *Gasoline control counties: Arlington Co., Fairfax Co., Loudoun Co., Prince William Co., Stafford Co., Alexandria City, Fairfax City, Falls Church City, Manassas City, Manassas Park City, Chesterfield Co., Hanover Co., Henrico Co., Colonial Heights City, Hopewell City, Richmond City, James City, York Co., Chesapeake City, Hampton City, Newport News City, Norfolk City, Poquoson City, Portsmouth City, Suffolk City, Virginia Beach City, and Williamsburg City (c)*
WV	(1) Gasoline sulfur content changed from 339 ppmW to 279 ppmW in all counties and all seasons (all are conventional gasoline areas). (2) Continue to utilize local allocation files for nine equipment categories.

Notes:

(a) County is subject to local control currently, but is scheduled to join the RFG program in January 2005.
(b) Control area is a portion of the county, but modeling is performed as though the control applies countywide.
(c) The EPA also lists Charles City County as an RFG area, but local planners indicate that Charles City County is a conventional gasoline area and it is modeled as such.

Table 1.3-3 Base F NONROAD Input File Sequence and Structural Revisions

State	Initial 2002 Base Year Inventory Input File Sequence Numbers	Revised 2002 Inventory Input File Sequence Numbers	Reason(s) for Change	Number of Revised 2002 Inventory NONROAD Input Files
AL	01-08	01-08	No Structural Changes	32 (at 8 per season)
FL	09-10	09-10	No Structural Changes	8 (at 2 per season)
GA	11-13	11-13	No Structural Changes	12 (at 3 per season)
KY	14-22	14-22	No Structural Changes	36 (at 9 per season)
MS	48	48	No Structural Changes	4 (at 1 per season)
NC	23-25	23-25	No Structural Changes	12 (at 3 per season)
SC	26-32	26-32	No Structural Changes	28 (at 7 per season)
TN	33-34	33-34, 49-52	Counties Regrouped	24 (at 6 per season)
VA	35-43	35-38, 40-43	Counties Regrouped	32 (at 8 per season)
WV	44-47	44-47	No Structural Changes	16 (at 4 per season)
All	**01-48**	**01-38, 40-52**		**204 (at 51 per season)**

Note: (1) All files include internal revisions to reflect the data changes summarized in Table 1.3-3 above. This table is intended to present structural revisions that are of interest in assembling the NONROAD model input files into a complete VISTAS region inventory. The indicated revisions do not (in and of themselves) result in emission estimate changes.

(2) The NONROAD model imposes an eight digit input file name limit, so all input files for the revised 2002 base year inventory follow a modified naming convention to allow each to be distinguished from the input files for the initial 2002 base year inventory. For the initial 2002 base year inventory, the naming convention was:

ss02aaqq, where: ss = the two character State abbreviation,
aa = a two character season indicator as follows: AU = autumn, WI = winter, SP = spring, and SU = summer, and
qq = the two digit sequence number indicated above.

For the revised 2002 inventory, the naming convention was modified to:

ss02aFqq, where: ss = the two character State abbreviation,
a = a one character season indicator as follows: A = autumn, W = winter, S = spring, and X = summer, and
qq = the two digit sequence number indicated above.

Base G Revisions:

As described above, the primary modeling revision implemented for the Base G 2002 inventory was the use of the Final NONROAD2005 model (in place of the Base F use of Draft NONROAD2004). However, there were other minor revisions implemented for 13 Georgia counties and somewhat more significant revisions implemented for Tennessee. In Georgia, Stage II refueling control was assumed for 13 counties that previously were modeled as having no refueling control under Base F. In addition, to accommodate this Stage II change as well as forecast year changes in gasoline vapor pressure, corresponding changes in the structure and sequence of Georgia NONROAD input files were made. With the exception of the minor Stage II impacts, these structural and sequence changes have no impact on 2002 emission estimates, but allow for consistency between 2002 and forecast year input file structure and sequence. In Tennessee, more significant changes were implemented to gasoline vapor pressure assumptions, as well as similar minor changes in Stage II refueling control assumptions.

In accordance with instructions from Georgia regulators, Stage II refueling control was assumed in the following 13 Georgia counties at a control efficiency value of 81 percent for the Base G inventory:

> Cherokee, Clayton, Cobb, Coweta, DeKalb, Douglas, Fayette, Forsyth, Fulton, Gwinnett, Henry, Paulding, and Rockdale.

No Stage II control was assumed in these counties in prior inventories.

Tennessee regulators provided revised monthly values for gasoline vapor pressure. Based on the seasonal definitions employed in the NONROAD model, monthly vapor pressures were averaged to estimate seasonal vapor pressures as follows:

Month/Season	Nashville Area	Memphis Area	Remainder of Tennessee
March	13.5 psi	13.5 psi	13.5 psi
April	13.5 psi	13.5 psi	13.5 psi
May	9.0 psi	9.0 psi	9.0 psi
Spring	12.0 psi	12.0 psi	12.0 psi
June	7.8 psi	7.8 psi	9.0 psi
July	7.8 psi	7.8 psi	9.0 psi
August	7.8 psi	7.8 psi	9.0 psi
Summer	7.8 psi	7.8 psi	9.0 psi
September 1-15	7.8 psi	7.8 psi	9.0 psi
September 16-30	11.5 psi	11.5 psi	11.5 psi
October	13.5 psi	13.5 psi	13.5 psi
November	13.5 psi	13.5 psi	13.5 psi
Fall	12.2 psi	12.2 psi	12.4 psi
December	15.0 psi	15.0 psi	15.0 psi
January	15.0 psi	15.0 psi	15.0 psi
February	13.5 psi	13.5 psi	13.5 psi
Winter	14.5 psi	14.5 psi	14.5 psi

Note: The Nashville area consists of Davidson, Rutherford, Sumner, Williamson and Wilson counties, the Memphis area consists of Shelby County.

As with the Base F revisions, the seasonal data are based on simple arithmetic averages and do not consider any monthly variation in activity (and fuel sales), nor is the transition between summer and winter seasons considered. Additionally, a monthly average of the September 1-15 and September 16-30 data is calculated prior to averaging the September-November data to estimate a fall average vapor pressure, so that the month of September is weighted identically to the months of October and November.

Tennessee regulators also indicated that Stage II vapor recovery was not in effect in Shelby County, so the Base F NONROAD input files for the county (which assumed Stage II was in place) were revised accordingly.

All Base G NONROAD modeling revisions are presented in Table 1.3-4. As indicated above, the differentiation of inputs across previously grouped counties also required revision to the overall number and sequence of VISTAS NONROAD input files (as compared to the files used to create both the initial VISTAS non-road inventory, as documented in the February 9, 2004 report "*Development of the VISTAS Draft 2002 Mobile Source Emission Inventory (February 2004 Version)*" as prepared by E.H. Pechan & Associates, Inc., and the Base F revised inventory as documented above. These structural revisions are presented in Table 1.3-5, and are provided solely for the benefit of NONROAD modelers as the indicated revisions have no impact on generated emission estimates.

Table 1.3-4 Summary of Base G NONROAD Modeling Revisions

State	Revisions Implemented
AL	(1) Marine diesel sulfur content changed from 2500 ppmW to 2638 ppmW in all counties and seasons.
FL	(1) Marine diesel sulfur content changed from 2500 ppmW to 2638 ppmW in all counties and seasons.
GA	(1) Marine diesel sulfur content changed from 2500 ppmW to 2638 ppmW in all counties and seasons. (2) Stage II refueling vapor recovery implemented in 13 counties at an efficiency of 81 percent. (3) Counties regrouped to accommodate base and forecast year data differentiations. *Stage II control counties: Cherokee, Clayton, Cobb, Coweta, De Kalb, Douglas, Fayette, Forsyth, Fulton, Gwinnett, Henry, Paulding, and Rockdale*
KY	(1) Marine diesel sulfur content changed from 2500 ppmW to 2638 ppmW in all counties and seasons.
MS	(1) Marine diesel sulfur content changed from 2500 ppmW to 2638 ppmW in all counties and seasons.
NC	(1) Marine diesel sulfur content changed from 2500 ppmW to 2638 ppmW in all counties and seasons. (2) Revert to default equipment allocation files for all equipment categories. (3) Utilize revised (i.e., local) seasonal activity data.
SC	(1) Marine diesel sulfur content changed from 2500 ppmW to 2638 ppmW in all counties and seasons.
TN	(1) Marine diesel sulfur content changed from 2500 ppmW to 2638 ppmW in all counties and seasons. (2) Gasoline RVP values changed in accordance with local recommendations. (3) Stage II vapor recovery eliminated from Shelby County modeling.
VA	(1) Marine diesel sulfur content changed from 2500 ppmW to 2638 ppmW in all counties and seasons.
WV	(1) Marine diesel sulfur content changed from 2500 ppmW to 2638 ppmW in all counties and seasons. (2) Revert to default equipment allocation files for all equipment categories.

Table 1.3-5 Spring 2006 NONROAD Input File Sequence and Structural Revisions

State	2002 Inventory Input File Sequence Numbers (Fall 2004)	2002 Inventory Input File Sequence Numbers (Spring 2006)	Reason(s) for Change	Number of Final 2002 Inventory NONROAD Input Files
AL	01-08	01-08	No Structural Changes	32 (at 8 per season)
FL	09-10	09-10	No Structural Changes	8 (at 2 per season)
GA	11-13	11-13, 53-54	Counties Regrouped	20 (at 5 per season)
KY	14-22	14-22	No Structural Changes	36 (at 9 per season)
MS	48	48	No Structural Changes	4 (at 1 per season)
NC	23-25	23-25	No Structural Changes	12 (at 3 per season)
SC	26-32	26-32	No Structural Changes	28 (at 7 per season)
TN	33-34, 49-52	33-34, 49-52	No Structural Changes	24 (at 6 per season)
VA	35-38, 40-43	35-38, 40-43	No Structural Changes	32 (at 8 per season)
WV	44-47	44-47	No Structural Changes	16 (at 4 per season)
All	**01-38, 40-52**	**01-38, 40-54**		**212 (at 53 per season)**

Note: (1) All files include internal revisions to reflect the data changes summarized in Table 1.3-5 above. This table is intended to present structural revisions that are of interest in assembling the NONROAD model input files into a complete VISTAS region inventory. The indicated revisions do not (in and of themselves) result in emission estimate changes.

(2) The NONROAD model imposes an eight digit input file name limit, so all input files for the revised 2002 base year inventory follow a modified naming convention to allow each to be distinguished from the input files for the initial 2002 and fall 2004-revised 2002 base year inventory. For the initial 2002 base year inventory, the naming convention was:

ss02aaqq, where: ss = the two character State abbreviation,
aa = a two character season indicator as follows: AU = autumn, WI = winter, SP = spring, and SU = summer, and
qq = the two digit sequence number indicated above.

For the fall 2004-revised 2002 inventory, the naming convention was modified to:

ss02aFqq, where: ss = the two character State abbreviation,
a = a one character season indicator as follows: A = autumn, W = winter, S = spring, and X = summer, and
qq = the two digit sequence number indicated above.

For the spring 2006-revised 2002 inventory, the naming convention was modified to:

ss02aCqq, where: ss = the two character State abbreviation,
a = a one character season indicator as follows: A = autumn, W = winter, S = spring, and X = summer, and
qq = the two digit sequence number indicated above.

1.3.2.2 Emissions from Commercial Marine Vessels, Locomotives, and Airplanes

An initial 2002 base year emissions inventory for aircraft, locomotives, and commercial marine vessels (CMV) was prepared for VISTAS in early 2004. The methods and data used to develop the inventory are presented in a February 9, 2004 report "*Development of the VISTAS Draft 2002 Mobile Source Emission Inventory (February 2004 Version)*" as prepared by E.H. Pechan & Associates, Inc. A summary of the initial 2002 base year emissions inventory is presented in Table 1.3-6. Except as otherwise stated below, all aspects of the preparation methodology continue to apply to the Base F and Base G emission inventories.

Revisions to the initial 2002 emissions inventory (prepared by Pechan) were implemented to ensure that the latest State and local data were incorporated as well as to correct an overestimation of PM emissions from aircraft. Revisions were actually implemented in two stages. An initial set of revisions was implemented in the fall of 2004. Those revisions constitute the Base F inventory. These were followed by a second set of revisions in 2006, which constitute the Base G inventory. To accurately document the combined effects of both sets of revisions, each set is discussed separately below. Unless otherwise indicated, all revisions implemented for Base F were carried directly into the Base G revision process without change. Thus, the inventories that resulted from the Base F revisions served as the starting point for the Base G revisions.

<u>Base F Revisions:</u>

Revisions to the initial 2002 base year emissions inventory were implemented to ensure that the latest State and local data were incorporated as well as to correct an overestimation of PM emissions from aircraft. Seven of the ten VISTAS States provided revised inventory data in the form of emissions reported to the EPA under the CERR. States providing CERR data were Alabama, Georgia, Mississippi, North Carolina, Tennessee (excluding Davidson, Hamilton, Knox, and Shelby Counties), Virginia, and West Virginia.

In many cases, the CERR data were only marginally different than the initial 2002 base year inventory data, but there were several instances where significant updates were evident. The remaining three VISTAS States (Florida, Kentucky, and South Carolina), plus Davidson, Hamilton, Knox, and Shelby counties in Tennessee, indicated that the initial 2002 VISTAS inventory continued to reflect the most recent data available. Florida did provide updated aircraft emissions data for one county (Miami-Dade) and these data were incorporated into the Base F 2002 inventory as described below.

Since several States recommended retaining the initial 2002 base year inventory data for Base F, the initial step toward revising the 2002 inventory consisted of modifying the estimated aircraft PM emissions of the initial inventory. The overestimation of aircraft PM became evident shortly after the release of the initial 2002 base year inventory, when it was determined that VISTAS region airports would constitute the top seven, and 11 of the top 15, PM sources in the nation. Moreover, PM emissions for one airport (Miami International) were a full order of magnitude larger than *all* other modeled elemental carbon PM emission sources. In addition, unexpected relationships across airports were also observed, with emissions for Atlanta's Hartsfield International being substantially less than those of Miami International, even though Atlanta handles over twice as many aircraft operations annually. Given the pervasiveness of this problem, and since the CERR data submitted by States was based on the initial 2002 VISTAS inventory data, aircraft PM emissions for the entire VISTAS region were recalculated.

Table 1.3-6 Initial 2002 Base Year Aircraft, Locomotive, and Non-Recreational Marine Emissions as Reported in February 2004 Pechan Report (annual tons)

Aircraft do emit PM while operating. However, official EPA inventory procedures for aircraft generally do not include PM emission factors and, therefore, aircraft PM is generally erroneously reported as zero. In an effort to overcome this deficiency, the developers of the initial VISTAS 2002 base year aircraft inventory (Pechan) estimated PM emission rates for aircraft using estimated NO_x emissions and an unreported PM-to-NO_x ratio (i.e., PM = NO_x times a PM-to-NO_x ratio). According to the initial 2002 base year inventory documentation, this approach was applied only to commercial aircraft NO_x, but a review of that inventory indicates that the technique was also applied to military, general aviation, and air taxi aircraft in many, but not all, instances. Although there is nothing inherently incorrect with this approach, the accuracy and inconsistent application of the assumed PM-to-NO_x ratio results in grossly overestimated aircraft PM.

Through examination of the initial 2002 base year aircraft inventory (prepared by E.H. Pechan and Associates, Inc.), it is apparent that the commercial aircraft PM-to-NO_x ratio used to generate PM emission estimates was approximately equal to 3.95 (i.e., PM = NO_x times 3.95). While the majority of observed commercial aircraft PM-to-NO_x ratios in that inventory are equal to 3.95, a few range as low as 3.00. If all aircraft estimates are included (i.e., commercial plus military, general aviation, and air taxi), observed PM-to-NO_x ratios range from 0 to 123.0, and average 3.43 as illustrated in Table 1.3-7

Table 1.3-7 PM-to-NO_x Ratios by Aircraft Type In Initial 2002 Base Year Inventory.

Aircraft Type	Average PM-to-NO_x	Range of PM-to-NO_x	Average $PM_{2.5}$ / PM_{10}	Range of $PM_{2.5}$ / PM_{10}
Undefined (1)	0.046	0-0.062	0.690	0.690-0.690
Military	0.073	0-92.3	0.688	0.333-1.000
Commercial	3.953	3.00-3.953	0.690	0.667-0.696
General Aviation	2.059	0-9.00	0.689	0.500-1.000
Air Taxi	2.734	0-123.0	0.690	0.500-1.000
Aggregate	3.427	0-123.0	0.690	0.333-1.000

Note: (1) Two counties report aircraft emissions as SCC 2275000000 “all aircraft.”

As indicated, the aggregate PM-to-NO_x ratio is similar in magnitude to the ratio for commercial aircraft. This results from the dominant nature of commercial aircraft NO_x emissions relative to NO_x from other aircraft types. It is surmised that ratios that deviate from 3.95 are based on PM emission estimates generated by local planners, which were retained without change in the PM estimation process (although a considerable number of unexplained “zero PM” records also exist in the initial 2002 base year inventory dataset). Regardless, based on previous statistical analyses performed in support of aircraft emissions inventory development outside the VISTAS region, a PM-to-NO_x ratio of 3.95 is too large by over an order of magnitude.

In analyses performed for the Tucson, Arizona planning area, PM-to-NO_x ratios for aircraft over a standard aircraft landing and takeoff (LTO) cycle are shown in Table 1.3-8. Data for this table is taken from "Emissions Inventories for the Tucson Air Planning Area, Volume I., Study Description and Results," prepared for the Pima Association of Governments, Tucson, AZ, November 2001. Pages 4-40 through 4-42 of that report, which document the statistical derivation of these ratios, are included in this report as Appendix E.

Table 1.3-8 Tucson, AZ PM-to-NO_x Ratios by Aircraft Type.

Aircraft Type	PM-to-NO_x
Commercial Aircraft	0.26
Military Aircraft	0.88
Air Taxi Aircraft	0.50
General Aviation Aircraft	1.90

Note:

The PM and NO_x emission estimates presented in the Tucson study are for local aircraft operating mode times. For this work, emission estimates for Tucson were recalculated for a standard LTO cycle, so that the ratios presented are applicable to the standard LTO cycle and not a Tucson-specific cycle. Thus, the ratios presented herein vary somewhat from those associated with the emission estimates presented in the Tucson study report.

In reviewing these data, it should be considered that they apply to a standard (i.e., EPA-defined) commercial aircraft LTO cycle.[2] Aircraft PM-to-NO_x ratios vary with operating mode, so that aircraft at airports with mode times that differ from the standard cycle will exhibit varying ratios. However, conducting an airport-specific analysis for all airports in the VISTAS region was beyond the scope of this work. While local PM-to-NO_x ratios could vary somewhat from the indicated standard cycle ratios, any error due to this variation will be significantly less than the order of magnitude error associated with the 3.95 commercial aircraft ratio used for the initial 2002 base year inventory.

It should be recognized that while the Tucson area is far removed from the VISTAS region, the data analyzed to generate the PM-to-NO_x ratios is standard aircraft emission factor data routinely employed for inventory purposes throughout the United States (as encoded in models such as the

[2] As defined in *AP-42, Compilation of Air Pollutant Emission Factors, Volume II, Mobile Sources, a standard commercial aircraft LTO cycle consists of 4 minutes of approach time, 26 minutes of taxi (7 minutes in plus 19 minutes out), 0.7 minutes of takeoff, and 2.2 minutes of climbout time (approach and climbout times being based on a 3000 foot mixing height).*

Federal Aviation Administration's Emissions Data Management Systems [EDMS]). With the exception of aircraft operating conditions, there are no inherent geographic implications associated with the use of data from the Tucson study. As indicated above, issues associated with local operating conditions have been eliminated by recalculating the Tucson study ratios for a standard LTO cycle.

To implement the revised PM-to-NO_x ratios in the Base F inventory, *all* aircraft PM records were removed from the initial 2002 base year inventory (prepared by Pechan). This includes records for which local planners may have estimated PM emissions. This approach was taken for two reasons. First, there is no way to distinguish which records may have been generated by local planners. Second, the data available to local planners may be no better than that used to generate the presented PM-to-NO_x ratio data, so the consistent application of these data to the entire VISTAS region was determined to be the most appropriate approach to generating consistent inventories throughout the region. In undertaking this removal, it became apparent that there was an imbalance in the aircraft NO_x and PM records in the initial 2002 base year inventory. Whereas there were 1,531 NO_x records in the NIF emission data sets for this source category, there were only 1,212 PM records. The imbalance was distributed between three States, South Carolina, Tennessee, and Virginia as follows:

Table 1.3-9 Non-Corresponding Aircraft Emissions Records

Aircraft NO_x records with no corresponding PM record:

Aircraft Type	South Carolina	Virginia	Total
Military Aircraft	8	100	108
General Aviation Aircraft	14	94	108
Air Taxi Aircraft	5	99	104
Aggregate	27	293	320

Aircraft PM records with no corresponding NO_x record:

Aircraft Type	Tennessee	Total
Air Taxi Aircraft	1	1
Aggregate	1	1

The unmatched PM record was for Hamilton County (Chattanooga), Tennessee and when removed, was not replaced since there was no corresponding NO_x record with which to estimate revised PM emissions. It is unclear how this orphaned record originated, but clearly there can be no air taxi PM emissions without other combustion-related emissions. Thus, the removal of the PM_{10} and $PM_{2.5}$ records for Hamilton County permanently reduced the overall size of the 2002 initial base year inventory database used as a starting point for Base F by two records.

Of the 320 unmatched NO_x records, 269 were records for which the reported emission rate was zero. Therefore, even though associated PM records were missing, the overall inventory was not affected. However, the 51 missing records for which NO_x emissions were non-zero, did impact PM estimates for the overall inventory.

Replacement PM_{10} records were calculated for all aircraft NO_x records using the PM-to-NO_x ratios presented above. Aircraft type-specific ratios were utilized in all cases, except for two counties where aircraft emissions were reported under the generic aircraft SCC 2275000000. For these counties (Palm Beach County, Florida and Davidson County, Tennessee), the commercial aircraft PM-to-NO_x ratio was applied since both contain commercial airports (Palm Beach International and Nashville International).

Replacement aircraft $PM_{2.5}$ records were also developed. The initial 2002 base year inventory assumed that aircraft $PM_{2.5}$ was 69 percent of aircraft PM_{10}. The origin of this fraction is not clear, but it is very low for combustion related PM. The majority of internal combustion engine related PM is typically 1 micron or smaller ($PM_{1.0}$), so that typical internal combustion engine $PM_{2.5}$ fractions approach 100 percent. For example, the EPA NONROAD model assumes 92 percent for gasoline engine particulate and 97 percent for diesel engine particulate. Based on recent correspondence from the EPA, it appears that the agency is preparing to recommend a $PM_{2.5}$ fraction of 98 percent for aircraft. (August 12, 2004 e-mail correspondence from U.S. EPA to Gregory Stella of Alpine Geophysics.) This is substantially more consistent with expectations based on emissions test data for other internal combustion engine sources and was used as the basis for the recalculated aircraft $PM_{2.5}$ emission estimates in the Base F inventory.

Although a substantial portion of the initial 2002 base year inventory was ultimately replaced with data prepared by State and local planners under CERR requirements in developing the Base F inventory, it was necessary to first revise the initial 2002 base year aircraft inventory as described so that records extracted from the inventory for areas not supplying CERR data for the Base F update would be accurate. Therefore, in *no case* is the aggregated State data reported for the Base F inventory identical to that of the initial 2002 base year inventory. Even areas relying on the initial 2002 base year inventory will reflect updates in Base F due to changes in emissions of PM_{10} and $PM_{2.5}$ from aircraft.

Table 1.3-10 presents the updated initial 2002 base year inventory estimates. These estimates do not reflect any changes related to modifications made to incorporate the CERR data, but instead indicate the impacts associated solely with the recalculation of aircraft PM emissions alone to apply the more appropriate PM to NO_x ratios. Table 1.3-11 presents a summary of the net impacts of these changes, where an over 90 percent reduction in aircraft PM is observed for all VISTAS areas except South Carolina and Virginia. The reasons for the lesser changes in these two States is that the overall aircraft NO_x inventories for both include a large share of military aircraft NO_x to which no (or very low) particulate estimates were assigned in the initial 2002 base year inventory. Since these operations are assigned non-zero PM emissions under the revised approach, the increase in military aircraft PM offsets a portion of the reduction in commercial aircraft PM. In Virginia, zero (or near zero) PM military operations were responsible for about 35 percent of total aircraft NO_x, while the corresponding fraction in South Carolina was almost 70 percent. As indicated, aggregate aircraft, locomotive, and commercial marine vessel PM is 70-75 percent lower in the updated 2002 base year inventory.

Table 1.3-10 Initial 2002 Base Year Aircraft, Locomotive, and Non-Recreational Marine Emissions with Modified Aircraft PM Emission Rates (annual tons)

Source	State	CO	NO_x	PM_{10}	$PM_{2.5}$	SO_2	VOC

As indicated above, for the Base F 2002 base year inventory, data for all or portions of seven VISTAS States were replaced with corresponding data from recent (as of the fall of 2004) CERR submissions for 2002. Before replacing these data, however, an analysis of the CERR data was performed to ensure consistency with VISTAS inventory methods. It should perhaps also be noted that three of the CERR datasets provided for the Base F 2002 base year inventory (specifically those for Tennessee, Virginia, and West Virginia) included both annual and daily emissions data. Only the annual data were used. Daily values were removed.

Several important observations resulted from this analysis. First, it was clear that all of the CERR data continued to rely on the inaccurate aircraft PM estimation approach employed for the initial 2002 base year inventory. Therefore, an identical aircraft PM replacement procedure as described above for updating the initial 2002 base year inventory was undertaken for CERR supplied data. As a result, the CERR data for *all* VISTAS States has been modified for inclusion in the Base F 2002 VISTAS base year inventory due to PM replacement procedures.

As was the case with the initial VISTAS 2002 base year inventory, there were a substantial number of aircraft NO_x records without corresponding PM records, so that the number of recalculated PM records added to the CERR dataset is greater than the number of PM records removed. The aggregated CERR inventory data, reflecting data for all or parts of seven States, consisted of 13,656 records, of which 1,211 were aircraft NO_x records. However, the number of corresponding aircraft PM records was 662 (662 PM_{10} records and 662 $PM_{2.5}$ records). This imbalance was distributed as follows:

Table 1.3-12 CERR Aircraft NO_x Records with No Corresponding PM Record.

Aircraft Type	Georgia	Tennessee	Virginia	Total
Military Aircraft			136	136
Commercial Aircraft		4	136	140
General Aviation Aircraft	1		136	137
Air Taxi Aircraft			136	136
Aggregate	**1**	**4**	**544**	**549**

From this tabulation, it is clear that virtually the entire imbalance is associated with the Virginia CERR submission, with minor imbalances in Georgia and Tennessee. Of the 549 unmatched NO_x records, 461 were records for which the reported emission rate was zero. Therefore, even though the associated PM records were missing, the overall inventory was not affected. However, the 88 missing records for which NO_x emissions were non-zero do impact PM emission estimates for the overall inventory.

Replacement aircraft PM records (both PM_{10} and $PM_{2.5}$) were generated for the CERR dataset using procedures identical to those described above for the updated initial 2002 base year inventory.

Further analysis revealed that the CERR data for Virginia included only VOC, CO, and NO_x emissions for all aircraft, locomotives, and non-recreational marine vessels. Since SO_2, PM_{10}, and $PM_{2.5}$ records are included in the 2002 VISTAS inventory, an estimation method was developed for these emission species and applied to the Virginia CERR data. For PM, the developed methodology was only employed for locomotive and marine vessel data since aircraft PM was estimated using the PM-to-NO_x ratio methodology described above.

Consideration was given to simply adding the Virginia SO_2 and non-aircraft PM records from the initial 2002 VISTAS inventory dataset, but it is very unlikely that either the source distribution or associated emission rates are identical across the CERR and initial VISTAS inventories. This was confirmed through a comparative analysis of dataset CO records. Therefore, an estimation methodology was developed using Virginia source-specific SO_2/CO, PM_{10}/CO, and $PM_{2.5}$/PM_{10} ratios from the initial 2002 base year VISTAS inventory. The calculated ratios were then applied to the source-specific CERR CO emission estimates to derive associated source-specific SO_2, PM_{10}, and $PM_{2.5}$ emissions for the Base F inventory.

Initially, the development of the emissions ratios from the initial 2002 base year inventory was performed at the State (i.e., Virginia), county, and SCC level of detail. However, it readily became clear that there were substantial inconsistencies in ratios for identical SCCs across counties. For example, in one county, the SO_2/CO ratio might be 0.2, while in the next county it would be 2.0. Since the sources in question are virtually identical (e.g., diesel locomotives) and since the fueling infrastructure for these large non-road equipment sources is regional as opposed to local in nature, such variations in emission rates are not realistic. Therefore, a more aggregated approach was employed in which SCC-specific emission ratios were developed for the State as a whole. Through this approach county-to-county variation in emission ratios is eliminated, but the underlying variation in CO emissions does continue to influence the resulting aggregate emission estimates. The applied emission ratios are as follows:

Table 1.3-13 Calculated Emission Ratios for VA.

Source	SCC	SO_2/CO	PM_{10}/CO	$PM_{2.5}$/CO	$PM_{2.5}$/PM_{10}
Military Aircraft	2275001000	0.0215	*Emissions estimated using PM-to-NO_x ratios as described previously.*		
Commercial Aircraft	2275020000	0.3292			
General Aviation Aircraft	2275050000	0.0002			
Air Taxi Aircraft	2275060000	0.0015			
Aircraft Refueling	2275900000	0.0000	0.0000	0.0000	
Diesel Commercial Marine	2280002000	0.3697	0.3434	0.3157	0.92
Residual Commercial Marine	2280003000	0.3697	0.3434	0.3157	0.92
Diesel Military Marine	2283002000	0.2422	0.2248	0.2068	0.92
Line Haul Locomotives	2285002005	3.2757	1.2999	1.1696	0.90
Yard Locomotives	2285002010	2.2908	1.2461	1.1205	0.90

It is important to recognize that the inconsistency of emissions ratios across Virginia counties for sources of virtually identical design, which utilize a regional rather than local fueling infrastructure, has potential implications for other VISTAS States. There is no immediately obvious reason to believe that such inconsistencies would be isolated to Virginia.

One final revision to the CERR dataset was undertaken as part of the Base F effort, and that was the removal of two records for unpaved airstrip particulate (SCC 2275085000) in Alabama. Otherwise identical records for these emissions were reported both in terms of filterable and primary particulate. The filterable particulate records were removed as all other particulate emissions in the VISTAS inventories are in terms of primary particulate. It is also perhaps worth noting that a series of aircraft refueling records (SCC 2275900000) for Virginia were left in place, even through typically such emissions would be reported under SCC 2501080XXX in the area source inventory. If additional VISTAS aircraft refueling emissions are reported under SCC 2501080XXX, then it may be desirable to recode these records.

Finally, data for areas of the VISTAS region not represented in the CERR dataset were added to the CERR data by extracting the appropriate records from the initial 2002 base year inventory (with revisions for aircraft PM to NO_x ratios). Specifically, records applicable to the States of Florida, Kentucky, South Carolina, and the Tennessee counties of Davidson, Hamilton, Knox, and Shelby were extracted from the revised initial 2002 inventory and added to the CERR dataset to establish the 2002 Base F inventory.

Following this aggregation, one last dataset revision was implemented to complete the development of the 2002 Base F inventory. As indicated in the introduction of this section, the initial 2002 base year emission estimates for Miami International Airport were determined to be excessive. Although the reason for this inaccuracy was not apparent, revised estimates for aircraft emissions in Miami-Dade County were obtained from Florida planners and used to overwrite the erroneous estimates. (Aircraft emission estimates were provided in an August 10, 2004 e-mail transmittal from Bruce Coward of Miami-Dade County to Martin Costello of the Florida Department of Environmental Protection.)

Table 1.3-14 presents a summary of the resulting Base F VISTAS 2002 base year inventory estimates for aircraft, locomotives, and non-recreational marine vessels. Table 1.3-15 provides a comparison of the Base F 2002 base year inventory estimates to those of the initial 2002 base year inventory. As indicated, total emissions for VOC, CO, NO_x, and SO_2 are generally within 10 percent, but final PM emissions are reduced by 70-80 percent due to the approximate 90 percent reductions in aircraft PM estimates. In addition, the significant changes in Georgia aircraft emissions are due to the CERR correction of Atlanta Hartsfield International Airport emissions, which were significantly underestimated in the initial 2002 base year inventory. The reduction in Florida aircraft emissions due to the correction of Miami International estimates is also apparent.

Lastly, Table 1.3-16 provides a direct comparison of emission estimates from the initial and Base F 2002 base year inventories for all 16 VISTAS region airports with estimated annual aircraft NO_x emissions of 200 tons or greater (as identified at the conclusion of the Base F revisions).[3] The table entries are sorted in order of decreasing NO_x and once again, the dramatic reduction in PM emissions is evident. However, in addition, the appropriate reversal of the relationship between Atlanta's Hartsfield and Miami International Airport is also depicted. As a rough method of quality assurance, Table 1.3-15 also includes a *gross* estimate of expected airport NO_x emissions using detailed NO_x estimates developed for Tucson International Airport in conjunction with the ratio of local to Tucson LTOs. (The Tucson NO_x estimates are revised to reflect a standard LTO cycle rather than the Tucson-specific LTO cycle. This should provide for a more realistic comparison to VISTAS estimates.) This is not meant to serve as anything other than a crude indicator of the propriety of the developed VISTAS estimates, and it is clear that the range of estimated-to-expected NO_x emissions has been substantially narrowed in the Base F 2002 base year inventory. Whereas estimated-to-expected ratios varied from about 0.2 to over 3.5 in the initial 2002 base year inventory, the range of variation is tightened on both ends, from about 0.5 to 1.75 for the Base F 2002 base year inventory. In effect, all estimates are now within a factor of two of the expected estimates, which is quite reasonable given likely variation in local and standard LTO cycles and variations in aircraft fleet mix across airports.

It is perhaps important to note that some shifting in county emissions assignments is evident between the initial and Base F 2002 base year aircraft inventories. For example, for the initial 2002 base year inventory, Atlanta Hartsfield estimates were assigned to Fulton County (FIP 13121), while they are assigned to Clayton County (FIP 13063) for the Base F 2002 base year inventory. Similarly, Dulles International Airport emissions were assigned solely to Fairfax County, Virginia (FIP 51059) in the initial 2002 base year inventory, but are split between Fairfax and Loudoun County (FIP 51107) for Base F. Such shifts reflect local planner decision-making and are not an artifact of the revisions described above.

[3] Subsequent revisions performed for Base G result in the addition of the Cincinnati/Northern Kentucky International Airport to the group of airports with aircraft operations generating at least 200 tons of NO_x. These revisions are discussed below, including the addition of an appropriately modified version of the aircraft emissions table.

Note: For the Base F inventory, Dulles International Airport emissions are split between two Virginia counties.
Predicted NO_x is based on the ratio of airport LTOs to test airport (Tucson International Airport) LTOs and NO_x.
This is not a rigorous comparison, but rather an approximate indicator of expected magnitude.

Base G Revisions:

Further revisions to the 2002 base year emissions inventory were implemented in response to additional state data submittals in the spring of 2006. The inventories developed through the Base F revision process (as described above) served as the starting point for the 2006 revisions. Thus, unless otherwise indicated below, all documented Base F revisions continue to apply to the Base G-revised 2002 base year inventory.

As part of the Base G review and update process, Virginia regulators provided 443 updated emission records for aircraft. These records reflected revisions to aircraft VOC, CO, and NO_x, and in a few cases SO_2, emissions records that were already in the Base F VISTAS 2002 inventory (as opposed to the addition of previously unreported data). The specific revisions broke down as follows:

Table 1.3-17 Base G VA Aircraft Records Updates

Aircraft Type	VOC	CO	NO_x	SO_2	Total
Military Aircraft	9	9	9	1	28
Commercial Aircraft	12	12	12	17	53
General Aviation Aircraft	65	66	66	0	197
Air Taxi Aircraft	56	56	53	0	165
Aggregate	142	143	140	18	443

Emissions values for each of the 443 records in the Base F 2002 VISTAS inventory were updated for Base G to reflect the revised data. However, as described above for the Base F revisions, all aircraft SO_2, PM_{10}, and $PM_{2.5}$ emissions in Virginia are estimated on the basis of CO (in the case of SO_2) and NO_x emissions (in the cases of PM_{10} and $PM_{2.5}$). Therefore, since Virginia regulators did not provide updated SO_2 emissions for all updated CO emissions records, or updated PM_{10} or $PM_{2.5}$ emissions for all updated NO_x emissions records, it was necessary to re-estimate aircraft SO_2, PM_{10}, and $PM_{2.5}$ emissions in all cases where updated CO or NO_x emissions were provided for Base G (and explicit SO_2 and/or PM_{10} and $PM_{2.5}$ emissions were not).

The procedure used to estimate the SO_2, PM_{10}, and $PM_{2.5}$ emissions revisions was identical to that described above for the Base F inventory revisions, except that revised SO_2-to-CO emissions ratios were calculated for commercial aircraft, where 12 pairs of revised CO and SO_2 emissions estimates were available. Although a single pair of revised CO and SO_2 emissions records was available for military aircraft, this was deemed an insufficient sample with which to replace the military aircraft SO_2-to-CO emissions ratios previously calculated in Base F. However, it is worth noting that the SO_2-to-CO emissions ratio for the revised military aircraft emissions pair was within 16 percent of the previously calculated ratio, so any error associated with retention of the Base F ratio will be minor. Table 1.3-18 presents the emissions ratios.

Table 1.3-18 Calculated Base G Emission Ratios for VA.

Source	SCC	SO_2/CO (fall 2004)	SO_2/CO (spring 2006)	SO_2/CO (used in 2006)	PM_{10}/NO_x	$PM_{2.5}/PM_{10}$
Military Aircraft	2275001000	0.0215	0.0180	0.0215	0.88	0.98
Commercial Aircraft	2275020000	0.3292	0.0696	0.0696	0.26	0.98
General Aviation Aircraft	2275050000	0.00016	n/a	0.00016	1.9	0.98
Air Taxi Aircraft	2275060000	0.0015	n/a	0.0015	0.5	0.98

Application of the SO_2-to-CO emissions ratios to the 130 revised aircraft CO records, for which no corresponding SO_2 emission revisions were provided, resulted in an additional 130 aircraft SO_2 emission records updates for Virginia. Similarly, application of the PM_{10}-to-NO_x emissions ratios to the 140 revised aircraft NO_x records for which no corresponding PM_{10} emission revisions were provided, resulted in an additional 140 aircraft PM_{10} emission records updates for Virginia. Application of the $PM_{2.5}$-to-PM_{10} emissions ratios to the 140 revised aircraft PM_{10} records resulted in an additional 140 aircraft $PM_{2.5}$ emission records updates for Virginia. Thus, in total, 853 (443+130+140+140) Virginia aircraft emissions records were updated for Base G.

Also as part of the Base G review and update process, Alabama regulators provided 178 updated PM emission records for aircraft (89 records for PM_{10} and 89 records for $PM_{2.5}$), 42 additional emissions records for locomotives (14 records for VOC, 14 records for CO, and 14 records for NO_x), and 179 additional emission records for aircraft (30 records for VOC, 30 records for CO, 30 records for NO_x, 29 records for SO_2, 30 records for PM_{10}, and 30 records for $PM_{2.5}$). After review, it was determined that the 178 updated PM emission records for aircraft actually reflected the original (overestimated) aircraft PM data that was replaced universally throughout the VISTAS region for Base F. Implementing these latest revisions would, in effect, “undo” the Base F aircraft PM revisions. Following discussions with Alabama regulators, it was determined that the 178 aircraft PM records would not be updated for the Base G revisions.

The 42 additional emissions records for locomotives were determined to correspond exactly to existing SO_2, PM_{10}, and $PM_{2.5}$ emissions records already in the Base F VISTAS 2002 inventory. It is not clear why these existing records contained no corresponding data for VOC, CO, and NO_x, but those data are now reflected through the additional 42 records that have now been added to the Base G 2002 VISTAS inventory for Alabama.

After examining the 179 additional aircraft emissions records in conjunction with Alabama regulators, it was determined that 17 of the records (commercial aircraft records in Dale, Limestone, and Talladega counties) were erroneous and should be excluded from the update. The remaining 162 records reflected additional general aviation, air taxi, and military aircraft activity in 20 counties and were specifically comprised of 27 records each for VOC, CO, NO_x, SO_2, PM_{10}, and $PM_{2.5}$. There were no further issues with the VOC, CO, NO_x, and SO_2 records and these were added to the Base G 2002 VISTAS inventory without change. It was, however, apparent that the PM_{10} and $PM_{2.5}$ records reflected an overestimation of aircraft PM similar to that which was previously corrected throughout the VISTAS region for Base F (as documented above). To overcome this overestimation, the additional aircraft PM_{10} and $PM_{2.5}$ records provided by Alabama regulators were replaced with revised emission estimates developed on the basis of the PM_{10}-to-NO_x and $PM_{2.5}$-to-PM_{10} ratios documented under the Base F revisions above. So although 27 aircraft PM_{10} records and 27 aircraft $PM_{2.5}$ records were added to the 2002 Alabama inventory, they reflected different emissions values than those provided directly by Alabama regulators.

In total, 204 additional emissions records (42 for locomotives and 162 for aircraft) were added to the Base G 2002 Alabama inventory.

Finally, as part of the Base G review and update process, Kentucky regulators provided 12 updated aircraft emission records for Boone County, to correct previously underestimated aircraft emissions associated with the Cincinnati/Northern Kentucky International Airport. VOC, CO, and NO_x emissions data were provided for military, commercial, general aviation, and air taxi aircraft. No associated updates for SO_2, PM_{10}, or $PM_{2.5}$ emissions were provided. Corresponding PM_{10} emission estimates were developed by applying the PM_{10}-to-NO_x ratios presented in Table 1.3-17 above to the updated NO_x emission estimates. $PM_{2.5}$ emission estimates were developed by applying the $PM_{2.5}$-to-PM_{10} ratios from that same table to the estimated PM_{10} emissions. SO_2 emission estimates were developed by applying the SO_2-to-PM_{10} ratios developed from the older data (i.e., the data being replaced) for Boone County aircraft to the updated PM_{10} emissions. Thus, a total of 24 inventory records for Kentucky were updated (VOC, CO, NO_x, SO_2, PM_{10}, and $PM_{2.5}$ for four aircraft types).

Upon implementation of the universe of updates, 877 existing emission records were revised (853 in Virginia and 24 in Kentucky) and 204 additional emission records (all in Alabama) were added to the 2002 VISTAS inventory. The total number of aircraft, locomotive, and commercial marine inventory records thus changed from 22,838 records in Base F to 23,042 records in Base G.

Table 1.3-19 presents a summary of the resulting Base G VISTAS 2002 base year inventory estimates for aircraft, locomotives, and non-recreational marine vessels. Table 1.3-20 provides a comparison of the Base G 2002 base year inventory estimates to those of the Base F 2002 base year inventory. As indicated, total emissions for VOC, CO, NO_x, and SO_2 are generally within about 5 percent, with changes restricted to the states of Alabama, Kentucky, and Virginia.

Lastly, Table 1.3-21 provides an updated comparison of emission estimates from the Base F and Base G 2002 base year inventories for all 17 VISTAS region airports with estimated annual aircraft NO_x emissions of 200 tons or greater. As compared to Table 1.3-16, the table reflects the Base G addition of the Cincinnati/Northern Kentucky International Airport. Aircraft emission estimates for the other 16 airports are unchanged from their Base F values.

Note: For the revised inventory, Dulles International Airport emissions are split between two Virginia counties.
Predicted NO_x is based on the ratio of airport LTOs to test airport (Tucson International Airport) LTOs and NO_x.
This is not a rigorous comparison, but rather an approximate indicator of expected magnitude.

1.3.2.3 Emissions from NONROAD Model Sources in Illinois, Indiana, and Ohio

As part of the Base G update process, VISTAS requested that emissions estimates for 2002 be produced for the states of Illinois, Indiana, and Ohio. These estimates were to be produced at the same spatial (i.e., county level by SCC) and temporal resolution as estimates for the VISTAS region.

The requested estimates were produced by extracting a complete set of county-level input data applicable to each of the three states from the latest version of the EPA's NMIM (National Mobile Inventory Model) model. This included appropriate consideration of all non-default NMIM input files generated by the Midwest Regional Planning Organization (MRPO), as described below. These input data were then assembled into appropriate input files for the Final NONROAD2005 model and emission estimates were produced using the same procedure employed for the VISTAS region as part of the Base G updates.

A complete set of monthly input data was developed for each county in Illinois, Indiana, and Ohio by extracting data from the following NMIM database files (using the NMIM MySQL query browser):

> county, countrynrfile, countyyear, countyyearmonth, countyyearmonthhour, gasoline, diesel, and natural gas

The database files:

> countrynrfile, countyyear, countyyearmonth, and gasoline

were non-default database files provided to VISTAS by the MRPO, and are intended to reflect the latest planning data being used by MRPO modelers.

From these files, monthly data for gasoline vapor pressure, gasoline oxygen content, gasoline sulfur content, diesel sulfur content for land-based equipment, diesel sulfur content for marine-based equipment, natural gas sulfur content, minimum daily temperature, maximum daily temperature, and average daily temperature were developed. In addition, the altitude and Stage II refueling control status of each county, as well as the identity of the associated equipment population, activity, growth, allocation, and seasonal distribution files, was determined. These data were then assembled into Final NONROAD2005 input files on a seasonal basis, with monthly data being arithmetically averaged to produce seasonal equivalents as follows:

Winter	=	Average of December, January, and February
Spring	=	Average of March, April, and May
Summer	=	Average of June, July, and August,
Fall	=	Average of September, October, and November

Unlike the VISTAS Base G approach, this approach results in the use of the following non-default data files during the Final NONROAD2005 modeling process:

Table 1.3-22 Non-Default Files Used for MRPO Modeling

Data File	Illinois	Indiana	Ohio
Activity File	1700002.act	1800002.act	3900002.act
Growth File	17000.grw	18000.grw	39000.grw
Population File	17000.pop	18000.pop	39000.pop
Season File	17000.sea	18000.sea	39000.sea
Inboard Marine Allocation File	17000wib.alo	18000wib.alo	39000wib.alo
Outboard Marine Allocation File	17000wob.alo	18000wob.alo	39000wob.alo
Specific Fuel Consumption	MRPO-specific file provided by MRPO modelers (arbitrarily named “mrpoBSFC.emf” for this work)		

One compromise was made relative to the level of resolution that is available through the basic approach described above, that being the treatment of ambient temperature data. Because NMIM offers a unique temperature profile for every U.S. county -- developed by aggregating temperature data from included and surrounding weather stations on the basis of their distances from the county population centroid -- it is not possible to explicitly group counties with otherwise identical input streams. Ungrouped however, there would be 1,128 distinct input streams to be processed (102 Illinois counties plus 92 Indiana counties plus 88 Ohio counties at four seasons each), or over five times the number of files processed for the entire VISTAS region.

To surmount this problem and allow counties with similar temperature profiles to be grouped an approach was employed wherein counties were considered groupable if *all* temperature inputs[4] are within ± 2 ºF of the corresponding group average. This criterion is quite stringent in that it results in less tolerant grouping than that employed for VISTAS modeling, which uses temperature data from the nearest meteorological station as opposed to "unique" meteorological

4 Non-road temperature inputs used for county grouping are: winter minimum, spring minimum, summer minimum, fall minimum, winter maximum, spring maximum, summer maximum, fall maximum, winter average, spring average, summer average, and fall average.

data for each county. Under this approach, the actual deviation for grouped counties is *much* less that ± 2º F for the overwhelming majority of the 12 grouped temperature inputs.

In addition to the required temperature consistency, all other input data for counties to be grouped had to be identical for all four seasons. Using this criterion, Illinois emissions were modeled using 12 county groups, Indiana emissions were modeled using 9 county groups, and Ohio emissions were modeled using 10 county groups. Thus, 31 iterations of NONROAD2002 were required per season, as compared to the 53 iterations per season required for the VISTAS region.

It should be noted that a potential quality assurance issue was noted in assembling the NONROAD2005 input data for a number of Indiana counties. Specifically, the gasoline vapor pressure for most Indiana counties reflects a value of 9.0 psi in *all* spring, summer, fall, and winter months. This is likely to indicate a problem with the accuracy of the NMIM databases for these counties, but these data were used as defined for this work.

1.3.3 Quality Assurance steps

Throughout the inventory development process, quality assurance steps were performed to ensure that no double counting of emissions occurred, and to ensure that a full and complete inventory was developed for VISTAS. Quality assurance was an important component to the inventory development process and MACTEC performed the following QA steps on the area source component of the 2002 base year revised:

1. All CERR and NIF format State supplied data submittals were run through EPA's Format and Content checking software.
2. SCC level emission summaries were prepared and evaluated to ensure that emissions were consistent and that there were no missing sources.
3. Tier comparisons (by pollutant) were developed between the revised 2002 base year inventory and the initial base year inventory.
4. Data product summaries were provided to both the VISTAS Emission Inventory Technical Advisor and to Mobile Source SIWG representatives for review and comment. Changes based on these comments were implemented in the files.
5. Version numbering was used for all inventory files developed. The version numbering process used a decimal system to track major and minor changes. For example, a major change would result in a version going from 1.0 to 2.0. A minor change would cause a version number to go from 1.0 to 1.1. Minor changes resulting from largely editorial changes would result in a change from 1.00 to 1.01.

2.0 Projection Inventory Development

2.1 Point Sources

We used different approaches for different sectors of the point source inventory:

- For the EGUs, VISTAS relied primarily on the Integrated Planning Model® (IPM®) to project future generation as well as to calculate the impact of future emission control programs. The IPM results were adjusted based on S/L agency knowledge of planned emission controls at specific EGUs.
- For non-EGUs, we used recently updated growth and control data consistent with the data used in EPA's CAIR analyses, and supplemented these data with available S/L agency knowledge of planned emission controls or other changes at specific non-EGUs and updated fuel use forecast data for the U.S. Department of Energy.

For both sectors, we generated 2009 and 2018 inventories for a combined on-the-books (OTB) and on-the-way (OTW) control scenario. The OTB/OTW control scenario accounts for post-2002 emission reductions from promulgated and proposed non-EGU federal control programs as of July 1, 2004; the final Clean Air Interstate Rule (CAIR); and State, local, and site-specific control programs as of October 1, 2007. Section 2.1.1 discusses the EGU projection inventory development, while Section 2.1.2 discusses the non-EGU projection inventory development.

2.1.1 EGU Emission Projections

The following subsections discuss the following specific aspects of the development of the EGU projections. First, we present a chronology of the EGU development process and discuss key decisions in selecting the final methods for performing the emissions projections. Next, we describe the development of the final set of IPM runs that are included in the VISTAS Base G inventory. Next, we describe the process of transforming the IPM parsed files into NIF format. Fourth, we discuss the process for ensuring that units accounted for in IPM were not double-counted in the non-EGU inventory. Fifth, we describe the QA/QC checks that were made to ensure that the IPM results were properly incorporated into the VISTAS inventory. Sixth, we document the changes to the IPM results that S/L agencies specified they wanted included in the VISTAS inventory based on new information that were not accounted for in the IPM runs. Finally, we present summaries of the B&F projected EGU emissions by year, state, and pollutant.

2.1.1.1 Chronology of the Development of EGU Projections

At the beginning of the EGU inventory development process, VISTAS considered three options for developing the VISTAS 2009 and 2018 projection inventories for EGUs:

- Option 1 – Use the results of IPM modeling conducted in support of the proposed Clean Air Interstate Rule (CAIR) base and control case analyses as the starting point and refine the projections with readily available inputs from stakeholders; these IPM runs were conducted for 2010 and 2015, which VISTAS would use to represent projected emissions in 2009 and 2018 respectively.
- Option 2 – Use the VISTAS 2002 typical year as the starting point, apply growth factors from the Energy Information Administration, and refine future emission rates with stakeholder input regarding utilization rates, capacity, retirements, and new unit information.
- Option 3 – Use the results of a new round of IPM modeling sponsored by VISTAS and the Midwest Regional Planning Organization (MRPO). These runs incorporated VISTAS specific unit and regulation modified parameters, and generate results for 2009 and 2018 explicitly.

An additional consideration for each of the three options was the inclusion of emission projections developed by the Southern Company specifically for their units. Southern Company is a super-regional company which owns EGUs in Alabama, Florida, Georgia, and Mississippi and participates in VISTAS as an industry stakeholder. Southern Company used their energy budget forecast to project net generation and heat input for every existing and future Southern Company EGU for the years 2009 and 2018. Further documentation of how Southern Company generated the 2009/2018 inventory for their units can be found in *Developing Southern Company Emissions and Flue Gas Characteristics for VISTAS Regional Haze Modeling (April 2005, presented at 14th International Emission Inventory Conference).*

Each of these three options and the Southern Company projections were discussed in a series of conference calls with the VISTAS EGU Special Interest Work Group (SIWG) during the fall of 2004. During a conference call on December 6, 2004, the VISTAS EGU SIWG approved the use of the latest VISTAS/MRPO sponsored IPM runs (Option 3) to represent the 2009 and 2018 EGU forecasts of emissions for the OTB and OTW cases. During the call, Alabama and Georgia specified that they did not wish to use Southern Company provided emissions forecasts of 2009 and 2018 to represent the sources in their States. Mississippi decided to utilize the Southern Company projections to represent activity at Southern Company facilities in Mississippi. After the call, Florida decided against using Southern Company provided emissions forecasts of 2009 and 2018 to represent the sources in their State. Thus, Southern Company data was used only for Southern Company units in Mississippi for both the Base F and Base G projections.

The Option 3 IPM modeling resulted from a joint agreement by VISTAS and MRPO to work together to develop future year utility emissions based on IPM modeling. The decision to use

IPM modeling was based in part on a study of utility forecast methods by E.H. Pechan and Associates, Inc. (Pechan) for MRPO, which recommended IPM as a viable methodology (see *Electricity Generating Unit {EGU} Growth Modeling Method Task 2 Evaluation*, February 11, 2004). Although IPM results were available from EPA's modeling to support their rulemaking for the Clean Air Interstate Rule (CAIR), VISTAS stakeholders felt that certain model inputs needed to be improved. Thus, VISTAS and MRPO decided to hire contractors to conduct new IPM modeling and to post-process the IPM results. Southern Company projections in 2009 were roughly comparable with IPM. For 2018, Southern Company projections were generally less than IPM because of assumptions made by Southern Company on which units would be economical to control and incorrect data in the NEEDS database which feeds IPM.

In August 2004, VISTAS contracted with ICF International, Inc., to run IPM to provide utility forecasts for 2009 and 2018 under two future scenarios – Base Case and CAIR Case. The Base Case represents the current operation of the power system under currently known laws and regulations (as known at the time the run was made), including those that come into force in the study horizon. The CAIR Case is the Base Case with the proposed CAIR rule superimposed. The run results were parsed at the unit level for the 2009 and 2018 run years. Also in August 2004, MRPO contracted with E.H. Pechan to post-process the IPM outputs generated by ICF to provide model-ready emission files. The IPM output files were delivered by ICF to VISTAS in November (*Future Year Electricity Generating Sector Emission Inventory Development Using the Integrated Planning Model (IPM®) in Support of Fine Particulate Mass and Visibility Modeling in the VISTAS and Midwest RPO Regions*, January 2005), and the post-processed data files were delivered by Pechan to the MRPO in December 2004 (*LADCO IPM Model Parsed File Post-Processing Methodology and File Preparation*, February 8, 2005).

On March 10, 2005, EPA issued the final Clean Air Interstate Rule. VISTAS and MRPO, in conjunction with other RPOs, conducted another round of IPM modeling which reflected changes to control assumptions based on the final CAIR as well as additional changes to model inputs based on S/L agency and stakeholder comments. Several conference calls were conducted in the spring of 2005 to discuss and provide comments on IPM assumptions related to six main topics: power system operation, generating resources, emission control technologies, set-up parameters and rule, financial assumptions, and fuel assumptions. Based on these discussions, VISTAS sponsored a new set of IPM runs to reflect the final CAIR requirements as well as certain changes to IPM assumptions that were agreed to by the VISTAS states. This set of IPM runs is documented in *Future Year Electricity Generating Sector Emission Inventory Development Using the Integrated Planning Model (IPM®) in Support of Fine Particulate Mass and Visibility Modeling in the VISTAS and Midwest RPO Regions*, April 2005 (these runs are referred to as the VISTAS Phase I analysis).

Further refinements to the IPM inputs and assumptions were made by the RPOs, and ICF performed the following four runs using IPM during the summer of 2005 (these runs are referred to as the VISTAS/CENRAP Phase II analysis):

- Base Case with EPA 2.1.9 coal, gas and oil price assumptions.
- Base Case with EPA 2.1.9 coal and gas supply curves adjusted for AEO 2005 reference case price and volume relationships.
- Strategy Case with EPA 2.1.9 coal, gas and oil price assumptions.
- Strategy Case with EPA 2.1.9 coal and gas supply curves adjusted for AEO 2005 reference case price and volume relationships.

The above runs were parsed for 2009 and 2018 run years. The above four runs were based on VISTAS Phase I and the EPA 2.1.9 assumptions. The changes that were implemented in the above four runs are summarized below:

- Unadjusted AEO 2005 electricity demand projections were incorporated in the above four runs.
- The gas supply curves were adjusted for AEO 2005 reference case price and volume relationships. The EPA 2.1.9 gas supply curves were scaled such that IPM will solve for AEO 2005 gas prices when the power sector gas demand in IPM is consistent with AEO 2005 power sector gas demand projections.
- The coal supply curves used in EPA 2.1.9 were scaled in such a manner that the average mine mouth coal prices that the IPM is solving in aggregated coal supply regions are comparable to AEO 2005. Due to the fact that the coal grades and supply regions between AEO 2005 and the EPA 2.1.9 are not directly comparable, this was an approximate approach and had to be performed in an iterative fashion. The coal transportation matrix was not updated with EIA assumptions due to significant differences between the EPA 2.1.9 and EIA AEO 2005 coal supply and coal demand region configurations.
- The cost and performance of new units were updated to AEO 2005 reference case levels in all of the above four funs.
- The run years 2008, 2009, 2012, 2015, 2018, 2020 and 2026 were modeled.
- The AEO 2005 life extension costs for fossil and nuclear units were incorporated in the above runs.

- The extensive NEEDS comments provided by VISTAS, MRPO, CENRAP and MANE-VU were incorporated into the VISTAS Phase I NEEDS.
- MANE-VU's comments in regards to the state regulations in the northeast were incorporated.
- Renewable Portfolio Standards (RPS) in the northeast was modeled based on the Regional Greenhouse Gas Initiative analysis. A single RPS cap was modeled for MA, RI, NY, NJ, MD and CT. These states could buy credits from NY, PJM and New England model regions.
- The investments required under the Illinois power, Mirant and First Energy NSR settlements were incorporated in the above runs.

For the VISTAS/CENRAP Phase II set of IPM runs, ICF generated two different parsed files. One file includes all fuel burning units (fossil, biomass, landfill gas) as well as non-fuel burning units (hydro, wind, etc.). The second file contains just the fossil-fuel burning units (e.g., emissions from biomass and landfill gas are omitted). The RPOs decided to use the fossil-only file for modeling to be consistent with EPA, since EPA used the fossil only results for CAIR analyses. For the 10 VISTAS states, non-fossil fuels accounted for only 0.13 percent of the NOx emissions and 0.04 percent of the SO_2 emissions in the 2009 IPM runs.

S/L agencies reviewed the results of the VISTAS/CENRAP Phase II set of IPM runs, which were incorporated into the VISTAS Base F inventory. S/L agencies primarily reviewed and commented on the IPM results with respect to IPM decisions on NO_x post-combustion controls and SO_2 scrubbers. S/L agencies provided the latest information on when and where new SO_2 and NO_x controls are planned to come online. S/L agencies also reviewed the IPM results to verify that existing controls and emission rates were properly reflected in the IPM runs. As directed by the S/L agencies, adjustments to the IPM results were made to specific units with any new information they had as part of the permitting process or other contact with the industry that indicates which units will install controls as a result of CAIR and when these new controls will come on-line. Mississippi decided to continue to use the Southern Company projections instead of the IPM projections to represent emissions at Southern Company facilities in Mississippi. The initial set of state-specified changes to the VISTAS/CENRAP Phase II set of IPM runs were used to create the Base G projection inventory (and are documented later in Section 2.1.1.6). The second set of state specified changes were made only for the 2018 inventory, resulting in the Base G2 2018 inventory (documented later in Section 2.1.1.7). The final set of state specified changes applied to both the 2009 and 2018 inventories and were used to create the B&F 2009 and 2018 inventories (documented later in Section 2.1.1.8).

2.1.1.2 VISTAS IPM runs for EGU sources

The following general summary of the VISTAS IPM® modeling is based on ICF's documentation *Future Year Electricity Generating Sector Emission Inventory Development Using the IPM® in Support of Fine Particulate Mass and Visibility Modeling in the VISTAS and Midwest RPO Regions*, April 2005. The ICF documentation is to be used as an extension to EPA's proposed CAIR modeling runs documented in *Documentation Supplement for EPA Modeling Applications (V.2.1.6) Using the IPM*, EPA 430/R-03-007, July 2003.

IPM provides "forecasts of least-cost capacity expansion, electricity dispatch, and emission control strategies for meeting energy demand and environmental, transmission, dispatch, and reliability constraints." The underlying database in this modeling is U.S. EPA's National Electric Energy Data System (NEEDS) released with the CAIR Notice of Data Availability (NODA). The NEEDS database contains the existing and planned/committed unit data in EPA modeling applications of IPM. NEEDS includes basic geographic, operating, air emissions, and other data on these generating units. VISTAS States and stakeholders provided changes for:

- NO_x post-combustion control on existing units
- SO_2 scrubbers on existing units
- SO_2 emission limitations
- PM controls on existing units
- Summer net dependable capacity
- Heat rate for existing units
- SO_2 and NO_x control plans based on State rules or enforcement settlements

The years 2009 and 2018 were explicitly modeled.

2.1.1.3 Post-Processing of IPM Parsed Files

The following summary of the VISTAS/Midwest Regional Planning Organization (MRPO) IPM modeling is based on Pechan's documentation *LADCO IPM Model Parsed File Post-Processing Methodology and File Preparation*, February 8, 2005. The essence of the IPM model post-processing methodology is to take an initial IPM model output file and transform it into air quality model input files. ICF via VISTAS/MRPO provides an initial spreadsheet file containing unit-level records of both

(1) "existing" units and

(2) committed or new generic aggregates.

All records have unit and fuel type data; existing, retrofit (for SO_2 and NO_x), and separate NO_x control information; annual SO_2 and NO_x emissions and heat input; summer season (May-September) NO_x and heat input; July day NO_x and heat input; coal heat input by coal type;

nameplate capacity megawatt (MW), and State FIPS code. Existing units also have county FIPS code, a unique plant identifier (ORISPL) and unit ID (also called boiler ID) (BLRID); generic units do not have these data. The processing includes estimating various types of emissions and adding in control efficiencies, stack parameters, latitude-longitude coordinates, and State identifiers (plant ID, point ID, stack ID, process ID). Additionally, the generic units are sited in a county and given appropriate IDs. This processing is described in more detail below.

The data are prepared by transforming the generic aggregates into units similar to the existing units in terms of the available data. The generic aggregates are split into smaller generic units based on their unit types and capacity, are provided a dummy ORIS unique plant and boiler ID, and are given a county FIPS code based on an algorithm that sites each generic by assigning a sister plant that is in a county based on its attainment/nonattainment status. Within a State, plants (in county then ORIS plant code order) in attainment counties are used first as sister sites to generic units, followed by plants in PM nonattainment counties, followed by plants in 8-hour ozone nonattainment counties. Note that no LADCO or VISTAS States provided blackout counties that would not be considered when siting generics, so this process is identical to the one used for EPA IPM post-processing.

SCCs were assigned for all units; unit/fuel/firing/bottom type data were used for existing units' assignments, while only unit and fuel type were used for generic units' assignments. Latitude-longitude coordinates were assigned, first using the EPA-provided data files, secondly using the September 17, 2004 Pechan in-house latitude-longitude file, and lastly using county centroids. These data were only used when the data were not provided in the 2002 NIF files. Stack parameters were attached, first using the EPA-provided data files, secondly using a March 9, 2004 Pechan in-house stack parameter file based on previous EIA-767 data, and lastly using an EPA June 2003 SCC-based default stack parameter file. These data were only used when the data were not provided in the 2002 NIF files.

Additional data were required for estimating VOC, CO, filterable primary PM_{10} and PM2.5, PM condensable, and NH_3 emissions for all units. Thus, ash and sulfur contents were assigned by first using 2002 EIA-767 values for existing units or SCC-based defaults; filterable PM10 and PM2.5 efficiencies were obtained from the 2002 EGU NEI that were based on 2002 EIA-767 control data and the PM Calculator program (a default of 99.2 percent is used for coal units if necessary); fuel use was back calculated from the given heat input and a default SCC-based heat content; and emission factors were obtained from an EPA-approved October 7, 2004 Pechan emission factor file based on AP-42 emission factors. Note that this updated file is not the one used for estimating emissions for previous EPA post-processed IPM files. Emissions for 28 temporal-pollutant combinations were estimated since there are seven pollutants (VOC, CO, primary PM_{10} and $PM_{2.5}$, NH_3, SO_2 and NO_x) and four temporal periods (annual, summer season, winter season, July day).

The next step was to match the IPM unit IDs with the identifiers in VISTAS 2002 inventory. A crosswalk file was used to obtain FIPS State and county, plant ID (within State and county), and point ID. If the FIPS State and county, plant ID and point ID are in the 2002 VISTAS NIF tables, then the process ID and stack ID are obtained from the NIF; otherwise, defaults, described above, were used.

Pechan provided the post-processed files in NIF 3.0 format. Two sets of tables were developed : “NIF files” for IPM units that have a crosswalk match and are in the 2002 VISTAS inventory, and “NoNIF files” for IPM units that are not in the 2002 VISTAS inventory (which includes existing units with or without a crosswalk match as well as generic units).

For Base F and Base G projections, VISTAS reviewed the PM and NH_3 emissions from EGUs as provided by Pechan and identified significantly higher emissions in 2009/2018 than in 2002. VISTAS determined that Pechan used a set of PM and NH_3 emission factors that are “the most recent EPA approved uncontrolled emission factors” for estimating 2009/2018 emissions. These factors are most likely not the same emission factors used by States for estimating these emissions in 2002 for EGUs in the VISTAS domain. Thus, the emission increase from 2002 to 2009/2018 was simply an artifact of the change in emission factor, not anything to do with changes in activity or control technology application. Also, VISTAS identified an inconsistent use of SCCs for determining emission factors between the base and future years.

VISTAS resolution of the PM and NH_3 problem is fully documented in *EGU Emission Factors and Emission Factor Assignment*, memorandum from Greg Stella to VISTAS State Point Source Contacts and VISTAS EGU Special Interest Workgroup, June 13, 2005. The first step was the adjustment of the 2002 base year emissions inventory. Using the latest “EPA-approved” uncontrolled emission factors by SCC, Alpine Geophysics utilized CERR or VISTAS reported annual heat input, fuel throughput, heat, ash and sulfur content to estimate annual uncontrolled emissions for units identified as output by IPM. This step was conducted for non-CEM pollutants (CO, VOC, PM, and NH_3) only. For PM emissions, the condensable component of emissions was calculated and added to the resulting PM primary estimations. The resulting emissions were then adjusted by any control efficiency factors reported in the CERR or VISTAS data collection effort. The second adjustment was to the future year inventories. Alpine Geophysics updated the SCCs in the future year inventory to assign the same base year SCC. Using the same methods as described for the 2002 revisions, those non-IPM generated pollutants were estimated using IPM predicted fuel characteristics and base year 2002 SCC assignments.

2.1.1.4 Eliminating Double Counting of EGU Units

The following procedures were used to avoid double counting of EGU emissions in the 2009/2018 point source inventory. The 2002 VISTAS point source emission inventory contains both EGUs and non-EGUs. Since this file contains both EGUs and non-EGU point sources, and

EGU emissions are projected using the IPM, it was necessary to split the 2002 point source file into two components. The first component contains those emission units accounted for in the IPM forecasts. The second component contains all other point sources not accounted for in IPM.

As described in the previous section, Pechan developed 2009/2018 NIF files for EGUs from the IPM parsed files. All IPM matched units were initially removed from the 2009/2018 point source inventory to create the non-EGU inventory (which was projected to 2009/2018 using the non-EGU growth and control factors described in Section 2.1.2). This was done on a unit-by-unit basis based on a cross-reference table that matches IPM emission unit identifiers (ORISPL plant code and BLRID emission unit code) to VISTAS NIF emission unit identifiers (FIPSST state code, FIPSCNTY county code, State Plant ID, State Point ID). When there was a match between the IPM ORISPL/BLRID and the VISTAS emission unit ID, the unit was assigned to the EGU inventory; all other emission units were assigned to the non-EGU inventory.

If an emission unit was contained in the NIF files created by Pechan from the IPM output, the corresponding unit was removed from the initial 2009/2018 point source inventory. The NIF 2009/2018 EGU files from the IPM parsed files were then merged with the non-EGU 2009/2018 files to create the 2009/2018 Base F point source files.

Next, we prepared several ad-hoc QA/QC queries to verify that there was no double-counting of emissions in the EGU and non-EGU inventories:

- We reviewed the IPM parsed files {VISTASII_PC_1f_AllUnits_2009 (To Client).xls and VISTASII_PC_1f_AllUnits_2018 (To Client).xls} to identify EGUs accounted for in IPM. We compared this list of emission units to the non-EGU inventory derived from the VISTAS cross-reference table to verify that units accounted for in IPM were not double-counted in the non-EGU inventory. As a result of this comparison, we made a few adjustments in the cross-reference table to add emission units for four plants to ensure these units accounted for in IPM were moved to the EGU inventory.
- We reviewed the non-EGU inventory to identify remaining emission units with an Standard Industrial Classification (SIC) code of "4911 Electrical Services" or Source Classification Code of "1-01-xxx-xx External Combustion Boiler, Electric Generation". We compared the list of sources meeting these selection criteria to the IPM parsed file to ensure that these units were not double-counted.

S/L agencies also reviewed the 2009/2018 point source inventory to verify whether there was any double counting of EGU emissions. In two instances, S/L agencies provided corrections where an emission unit was double counted.

2.1.1.5 Quality Assurance Steps

Quality assurance was an important component to the inventory development process. The following QA steps on the EGU component of the VISTAS revised 2009/2018 EGU inventory:

1. Provided parsed files (i.e., Excel spreadsheets that provide unit-level results derived from the model plant projections obtained by the IPM) to the VISTAS EGU SIWG for review.
2. Provided facility level emission summaries for 2009/2018 for both the base case and CAIR case to the VISTAS EGU SIWG to ensure that emissions were consistent and that there were no missing sources.
3. Compared, at the State-level, emissions from the IPM parsed files and the post-processed NIF files to verify that the post-processed NIF files were consistent with the IPM parsed file results.

VISTAS requested S/L review of these files – the changes specified by states as a result of this review are documented in the following subsection.

2.1.1.6 S/L Adjustments to IPM Modeling Results for Base G Projections

After S/L agency review of the final set of IPM runs (as incorporated into the Base F inventory), S/L agencies specified a number of changes to the IPM results to better reflect current information on when and where future controls would occur. These changes to the IPM results primarily involved S/L agency addition or subtraction future emission controls based on the best available data from state rules, enforcement agreements, compliance plans, permits, and discussions/commitments from individual companies.

For example, Dominion Virginia Power released their company-wide plan to reduce emission to meet the requirements of CAIR and other programs. This plan varies substantially from the IPM results both in terms current and future controls and timing of these controls. As a result, VA DEQ developed their best estimates of future controls on EGUs in Virginia. Also, Duke Energy and Progress Energy have updated their plans for complying with North Carolina's Clean Smokestack Act. These plans vary substantially from the IPM results both in terms current and future controls and timing of these controls. As a result, NC DENR replaced the IPM emission projections for 2009 with projections from the Duke Energy and Progress Energy compliance plan. NC DENR elected to use the IPM results for 2018.

Some S/L agencies specified changes to the controls assigned by IPM to reflect their best estimates of emission controls. These changes involved either 1) adding selective catalytic reduction (SCR) or scrubber controls to units where IPM did not predict SCR or scrubber controls, or 2) removing IPM-assigned SCR or scrubber controls at units where the S/L agency indicated their were no firm plans for controls at those units. We generally used a control efficiency of 90 percent when adding or removing SO_2 scrubber controls (unless a different control efficiency was provided by the State). We generally used a control efficiency of 90 percent when adding or removing NO_x SCR controls at coal-fired plants, 80 percent when adding or removing NO_x SCR controls at gas-fired plants, and 35 percent when adding or removing NO_x SNCR controls (unless a different control efficiency was provided by the State). The changes specified by the S/L agencies are summarized in Table 2.1-1. A comparison of the IPM and VISTAS control assumptions for all coal-fired EGUs in the Base G/G2 inventories are summarized in Appendix H. In addition to the changes to the IPM-assigned controls, the S/L agencies also specified other types of changes to the IPM results. These other specific changes to the IPM results are summarized in Table 2.1-2.

S/L agencies provided information and/or comment on changes in stack parameters from the 2002 inventory for 2009/2018 inventory. Changes to stack parameters were also made in cases where new controls are scheduled to be installed. In cases where an emission unit projected to have a SO_2 scrubber in either 2009 or 2018, some states were able to provide revised stack parameters for some units based on design features for the new control system. Other units projected to install scrubbers by 2009 or 2018 are not far enough along in the design process to have specific design details. For those units, the VISTAS EGU SIWG made the following assumptions: 1) the scrubber is a wet scrubber; 2) keep the current stack height the same; 3) keep the current flow rate the same, and 4) change the stack exit temperature to 169 degrees F (this is the virtual temperature derived from a wet temperature of 130 degrees F). VISTAS determined that exit temperature (wet) of 130 degrees F +/- 5 degrees F is representative of different size units and wet scrubber technology.

2.1.1.7 S/L Adjustments to IPM Modeling Results for Base G2 2018 Projections

Following release of the Base G inventory, four States specified additional changes to reflect their best estimates of emission controls in 2018. These additional changes are marked with an "*" in Tables 2.1-1 and 2.1-2. The following changes were requested and implemented in the VISTAS 2018 Base G2 EGU emissions and modeling inventories:

- **Florida -** Removed scrubbers from Smith units 1 & 2. Added scrubbers to Crist units 4, 5, & 6. Forecast emissions (from 2002 base) using growth factors for Northside units 1A and 2A. These units were estimated to be non operational in the IPM base case run.
- **Georgia -** Added scrubbers to Plant Scherer (Units 1-4) and Plant Yates (Units 6 & 7).
- **North Carolina -** Remove scrubber from F Lee unit 3.
- **West Virginia -** Pleasants Units 1 and 2 had SO2 emissions reduced to account for the facility's inclusion of previously bypassed 15% effluent stream to the scrubber and the control efficiency and emissions will reflect a change from 79.9% to 95% control.

Table 2.1-1 Adjustments to IPM Control Determinations Specified by S/L Agencies for the Base G/G2 2009/2018 EGU Inventories.

Table 2.1-2 Other Adjustments to IPM Results Specified by S/L Agencies for the Base G/G2 2009/2018 EGU Inventories.

State	Plant Name and ID	Unit	Nature of Update/Correction
FL	Central Power and Lime ORISID= 10333	GEN1	Central Power and Lime (ORIS10333) is a duplicate entry. This is point 18 in Florida Crushed Stone (12-053-0530021). Removed IPM emissions for Central Power and Lime.
	Cedar Bay Generating ORISID=10672	GEN1	FLDEP disagrees with IPM projections - no knowledge of expansion of this facility and the cogeneration facility should not grow faster than the underlying industry. Cedar Bay is connected to Stone Container (12-031-0310067). Replaced IPM emissions with 2002 emissions for Cedar Bay (12-031-0310337) times the growth factors for Stone Container.
	Indiantown Cogeneration ORISID=50976	GEN1	FLDEP disagrees with IPM projections - no knowledge of expansion of this facility and the cogeneration facility should not grow faster than the underlying industry. Indiantown is connected to Louis Dreyfus Citrus (12-085-0850002). Replaced IPM emissions with 2002 emissions for Indiantown (12-085-0850102) times the growth factors for Louis Drefus Citrus.
GA	Bowen ORISID=703	1BLR 2BLR 3BLR 4BLR	IPM indicated retrofit scrubbers on all 4 units in 2009, but the IPM emissions showed little reductions from 2002 levels. Changed emissions to reflect scrubbers on 3BLR and 4BLR by 2009.
	Wansley ORISID=6052	1, 2	IPM indicated retrofit scrubbers on both units in 2009, but the IPM emissions showed little reductions from 2002 levels. Changed emissions to reflect one scrubber on Unit 1 by 2009.
	Riverside ORISID=734	4	All of plant Riverside was retired from service June 1, 2005; emissions set to zero in 2009 and 2018.
	McIntosh ORISID=727	CT10A CT10B CT11A CT11B	The McIntosh Combined Cycle facility became commercial June 1, 2005. Added 346 tons of NO_x and 121 tons of SO_2 per unit to the 2009 and 2018 inventories.
	Longleaf Energy Station	1, 2	Longleaf Energy Station is being proposed by LS Power Development, Inc. GA specified that the emissions from this proposed plant be included in the 2018 projections. Boilers 1 and 2 added 1,882 tons of NO_x and 3,227 tons of SO_2 per unit to the 2018 inventory.
	Duke Murray (55382)	1	Corrected coordinates to 34.7189 and -84.9353
MS	R D Morrow ORISID=6061	1, 2	Revised the 2018 emissions to reflect controls not indicated by IPM. The SO_2 emissions are much lower than IPM, but their expected NO_x emissions are actually higher than IPM. The controls will be coming online 2009 or 2010, so the 2009 inventory did not change.
	Jack Watson (2049) Victor J Daniel (6073) Chevron Oil (2047)	All	MS DEQ specified that the emission projections provided by the Southern Company for their units in Mississippi were to be used instead of the IPM results.

Table 2.1-2 (continued)

State	Plant Name and ID	Unit	Nature of Update/Correction
NC	G G Allen (2718) Belews Creek (8042)1 Buck (2720) Cliffside (2721) Dan River (2723) Marshall (2727) Riverbend (2732)	All	Replaced all IPM 2009 results with emission projections from Duke Power's NC Clean Air Compliance Plan for 2006. Used IPM results for 2018
	Asheville (2706) Cape Fear (2708) Lee (2709) Mayo (6250) Roxboro (2712) Sutton (2713) Weatherspoon (2716)	All	Replaced all IPM 2009 results with emission projections from Progress Energy's NC Clean Smokestacks Act Calendar Year 2005 Progress Report. Used IPM results for 2018, except for Lee #3* where IPM projected a retrofit scrubber but NC specified that no scrubber was to be applied.
	Dwayne Collier Battle Cogeneration Facility ORISID=10384	GEN1 GEN2	Dwayne Collier Battle is a duplicate entry. This is Cogentrix of Rocky Mount (37-065-3706500146, stacks G-26 and G-27). Duplicate entries were removed both the 2009 and 2018 inventories.
	Kannapolis Energy Partners ORISID=10626	GEN2 GEN3	Kannapolis Energy emissions are being used as credits for another facility. IPM emissions from this facility (37-025-ORIS10626) were removed from the EGU inventory for 2009 and 2018. Emissions from Kannapolis Energy (37-025-3702500113) were carried forward in the 2009/2018 inventory.
SC	Cross ORISID=130	1, 2	Unit 1: upgrade scrubber from 82 percent to 95 percent removal efficiency by June 30, 2006. Recalculate emissions based on upgrade in control efficiency. Unit 2: upgrade scrubber from 70 percent to 87 percent removal efficiency by June 30, 2006. Recalculate emissions based on upgrade in control efficiency.
	Winyah ORISID=6249	1 – 4	Unit 1: Install scrubber that meets 95 percent removal efficiency by Dec. 31, 2008; Upgrade ESP from 0.38 to 0.03 lb/mmBTU by Dec. 31, 2008 Unit 2: Replace scrubber with one that meets 95 percent removal efficiency from 45 percent by Dec. 31, 2008; Upgrade ESP from 0.10 to 0.03 lb/mmBTU by Dec. 31, 2008 Unit 3: Upgrade scrubber from 70 percent to 90 percent removal efficiency by Dec. 31, 2012; Upgrade ESP from 0.10 to 0.03 lb/mmBTU by Dec. 31, 2012 Unit 4: Upgrade scrubber from 70 percent to 90 percent removal efficiency by Dec. 31, 2007; Upgrade ESP from 0.10 to 0.03 lb/mmBTU by Dec. 31, 2007 Recalculated SO_2 and PM emissions based on upgrade in control efficiencies.

Table 2.1-2 (continued)

State	Plant Name and ID	Unit	Nature of Update/Correction
SC	Dolphus Grainger ORISID=3317	1, 2	Unit 1: Upgrade ESP from 0.60 to 0.03 lb/mmBTU by Dec. 31, 2012. Reduced PM_{10} and PM25 emissions in 2018 by 95 percent based on change in allowable emission rate Unit 2: Install low NO_x burners that meet 0.46 lb/mmBTU from 0.9 by May 1, 2004. Recalculated NO_x emissions using 0.46/lbs/mmBtu and IPM heat input Unit 2: Upgrade ESP from 0.60 to 0.03 lb/mmBTU by Dec. 31, 2012. Reduced PM_{10} and PM25 emissions in 2018 by 95 percent based on change in allowable emission rate
	Jeffries ORISID=3319	3, 4	Unit 3: Upgrade ESP from 0.54 to 0.03 lb/mmBTU by Dec. 31, 2012. Reduced PM_{10} and PM25 emissions in 2018 by 94.44 percent based on change in allowable emission rate Unit 4: Upgrade ESP from 0.54 to 0.03 lb/mmBTU by Dec. 31, 2012. Reduced PM_{10} and PM25 emissions in 2018 by 94.44 percent based on change in allowable emission rate
	W S Lee ORISID=3264	1, 2	IPM does not indicate that these units are installing SOFA NO_x control technology by April 30, 2006 to meet 0.27 lb/mmBTU, down from 0.45 lb/mmBtu. Calculated NO_x emissions using IPM heat input and 0.27 lbs/mmBtu
	Generic Unit ORISID=900545	All	All predictions for generic units appear reasonable with the exception of Plant ID ORIS900545 Point ID GSC45 which was modeled in Georgetown County. It will be very difficult to add new generation this close to the Cape Romain Class I area. Santee Cooper has no plans for future generation in Georgetown County, but does have plans for new future generation in Florence County. This unit was moved to coordinates specified in Florence County.
VA	AEP Clinch River ORISID=3775	1, 2, 3	Used IPM results for 2009; replaced all 2018 IPM results with VADEQ's growth and control estimates (no SCR or scrubbers).
	AEP Glen Lyn ORISID=3776	51, 52, 6	Used 2009/2018 IPM results for units 51 and 52; used 2009 IPM for unit 6; replaced 2018 IPM for unit 6 with VADEQ's growth and control estimates (nor SCR or scrubber).
	Dominion Clover ORISID=7213	1, 2	Used 2009/2018 IPM results.
	Dominion Bremo ORISID=3796	3, 4	Used 2009/2018 IPM results.
	Dominion Chesterfield ORISID=3797	3, 4, 5, 6	Replaced all 2009/2018 IPM results using VADEQ's growth and control estimates.
	Dominion Yorktown ORISID=3809	1, 2, 3	Units 1, 2: Used 2009/2018 IPM results for NOx and used VADEQ's growth and control estimates for SO2. Unit 3: IPM predicts zero heat input for this 880 MW #6 oil fired unit. Dominion plans to continue to operate Unit 3. Replaced all 2009/2018 IPM results using VADEQ's growth and control estimates.

Table 2.1-2 (continued)

State	Plant Name and ID	Unit	Nature of Update/Correction
VA	Dominion Chesapeake ORISID=3803	1 – 4	Unit 1: Used 2009/2018 IPM for NOx; used 2009 IPM for SO2; used VADEQ's growth and control estimates for SO2 (added scrubber that IPM did not have) Unit 2: Used 2009/2018 IPM for NOx; used 2009 IPM for SO2; used VADEQ's growth and control estimates for SO2 (added scrubber that IPM did not have) Unit 3: Used VA DEQ's growth and control estimates for 2009 NOx (added SCR that IPM did not have); used IPM result for 2018 NOx; Used 2009/2018 IPM for SO2. Unit 4: Used VA DEQ's growth and control estimates for 2009 NOx (added SCR that IPM did not have); used IPM result for 2018 NOx; Used 2009/2018 IPM for SO2.
	Dominion Possum Point ORISID=3804	3 & 4 5 6	Unit 3&4: IPM had 137 tons of NO_x for these units in 2009 and 111 tons in 2018. VA DEQ specified that the permitted emission rates should be used, which equates to 3,066 tons in 2009 and 2018. Unit 5: IPM had zero heat input. Replaced all 2009/2018 IPM results using VADEQ's growth and control estimates. Unit 6: Replaced all 2009/2018 IPM results using VADEQ's growth and control estimates.
	Potomac River ORISID=3788	1 - 5	Units 1&2: IPM retired these units. Mirant has no plans at this time to retire any units. Replaced all 2009/2018 IPM results using VADEQ's growth and control estimates. Units 3, 4, 5: Replaced all 2009/2018 IPM results using VADEQ's growth and control estimates.
WV	Albright ORISID=3942	1, 2	IPM predicted early retirement for these units. AEP indicated there are no plans for early retirement. For 2009, used 2002 actual emissions as these units are not likely to retire by 2009. For 2018, used IPM prediction of retirement.
	Rivesville ORISID=3945	7, 8	IPM predicted early retirement for these units. AEP indicated there are no plans for early retirement. For 2009, used 2002 actual emissions as these units are not likely to retire by 2009. For 2018, used IPM prediction of retirement.
	Willow Island ORISID=3946	1, 2	Unit 1: IPM predicted early retirement for these units. AEP indicated there are no plans for early retirement. For 2009, used 2002 emissions as these units are not likely to retire by 2009. For 2018, used IPM prediction of retirement. Unit 2: IPM predicted SCR and scrubber for 2009. These controls will not be in place by 2009.
	North Branch ORISID=7537	1A, 1B	SO_2 Permit Rate was corrected from 2.7 to 0.678 lb/MMBtu. Used SO_2 Permit Rate and IPM predicted total fuel used to calculate SO_2 emissions in 2009 and 2018
	Mt. Storm ORISID=3954	1, 2, 3	SO_2 Permit Rate was corrected from 2.7 to 0.15 lb/MMBtu. Used SO_2 Permit Rate of 0.15 lb/MMBtu and IPM predicted total fuel used to calculate SO_2 emissions in 2009 and 2018
	Pleasants Power Station ORISID=6004	1, 2	IPM applied a scrubber with a 79.9% control efficiency; WV indicated that the control efficiency should be 95%.

2.1.1.8 S/L Adjustments to IPM Modeling Results for B&F Projections

For the B&F inventory, the S/L agencies were asked to review the Base G2 inventory with respect to the following items:

- Identify any updates needed to better reflect current information on when and where future controls would occur based on the best available data from state rules, enforcement agreements, compliance plans, permits, and discussions/commitments from individual companies;
- Identify any updates needed to change the IPM determination that most oil/gas steam units would either retire early or have no operation in 2009 or 2018; and
- Identify any updates needed to change the IPM assignment and VISTAS post-processing of generic units with specific information on new capacity.

The changes specified by the S/L agencies are summarized in Table 2.1-3. A comparison of the IPM and VISTAS control assumptions for all coal-fired EGUs in the B&F inventories are summarized in Appendix I.

Table 2.1-3 Additional Adjustments to IPM Results Specified by S/L Agencies for the B&F 2009/2018 EGU Inventories.

State	Plant Name and ID	Unit	Nature of Update/Correction
AL	Multiple	---	Alabama suggest additional changes to the 2009 inventory resulting from their $PM_{2.5}$ modeling for the Birmingham area; however, these changes were identified too late to be incorporated in the VISTAS B&F inventory and ASIP modeling.
FL	Cape Canaveral Indian River Port Everglades Turkey Point Manatee Martin Riviera Anclote CD McIntosh Northside B Suwannee River	1, 2 1, 2, 3 1 – 4 1, 2 1, 2 1, 2 3, 4 1, 2 1 3 3	The IPM 2009/2018 solution has either shut-down these oil-fired units or converted them to natural gas only. FLDEP has reason to believe that these units may continue to operate using oil. For some of these units, the owner or operator of the units have provided (and FLDEP approved) an estimate of how the units will be operated in 2009/2018. For others, to be conservative, FLDEP assumed that the oil-fired units will operate in 2009/2018 exactly as they operated in 2002.
	Gulf Power Schultz ORISID=643	1 - 4	Plant is expected to shut down and was taken out of the 2018 projection.
	Northside ORISID=667	1A, 1B	These units were estimated to be non operational by IPM in 2009 and 2018. FLDEP believes these units will continue to operate. Emissions were estimated using the 2002 base case emissions and growth factors for Northside units 1A and 2A. The changes for 2009 were made in the B&F inventory; the changes for 2018 were made in the Base G2 inventory.

	Crist ORISID=641	4, 5 6, 7	IPM did not assign scrubbers to these units. Scrubbers are currently being installed and should be operational in 2009. SO2 emissions reduced by 90%.
GA	Mitchell ORISID=727	SG03	GADNR provided new emission projections for 2018.

Table 2.1-3 (continued)

State	Plant Name and ID	Unit	Nature of Update/Correction
GA	Kraft ORISID=733	SG03	GADNR provided new emission projections for 2018.
	McIntosh ORISID=6124	SG01	GADNR provided new emission projections for 2018.
	Bowen ORISID=703	SG03 SG04	GADNR provided new SO2 emission projections for 2009 and 2018 based on a 95% control efficiency instead of 90%.
	Hammond ORISID=708	SG01 to SG04	GADNR provided new SO2 emission projections for 2009 and 2018 based on a 95% control efficiency instead of 90%.
	Wansley ORISID=6052	SG01	GADNR provided new SO2 emission projections for 2009 and 2018 based on a 95% control efficiency instead of 90%.
KY	John Sherman Cooper ORISID=1384	1	IPM did not assign a scrubber to this unit in 2018. KDAQ believes that a scrubber should be assigned for 2018.
	John Sherman Cooper ORISID=1384	2	IPM assigned SCR in 2009. KDAQ does not expect SCR by then; emissions changed to reflect low-NOx burner.
	Spurlock Station ORISID=6041	1, 2	IPM did not assign scrubbers to these units in 2009. Per a consent decree and for BART, KDAQ specified a 90% reduction in SO2 emissions from SO2 controls.
	Big Sandy ORISID=1353	BSU1	IPM assigned a scrubber and SCR in 2009. KDAQ does not expect scrubber or SCR controls to be operational in 2009.
MS	Entergy Delta Entergy Rex Brown Entergy Baxter Wilson Entergy Gerald Andrus	1, 2 3, 4 1, 2 1	The IPM 2009/2018 solution has either shut-down these oil-fired units or converted them to natural gas only. MSDEQ has reason to believe that these units may continue to operate using oil. To be conservative, MSDEQ assumed that the oil-fired units will operate in 2009/2018 exactly as they operated in 2002.
NC	Cliffside ORISID=2721	7	Removed Unit 7 from the 2018 inventory since the NC Utilities Commission disapproved the permit application.
	Cape Fear ORISID=2798	1, 2	IPM assigned scrubbers to both units in 2018; NCDENR indicated that the facility projected Furnace Sorbent Injection. Increased SO2 emissions to reflect change in control efficiency.
SC	99 Oil-fired Units		The IPM 2009/2018 solution has either shut-down 99 oil-fired units or converted them to natural gas only. SCDHEC has reason to believe that these units may continue to operate using oil. To be conservative, SCDHEC assumed that the oil-fired units will operate in 2009/2018 exactly as they operated in 2002.
SC	Santee Cooper Cross ORISID=130	4	For both 2009 and 2018, added in a new 660 MW Unit 4 (not in IPM) that is identical to the new Unit 3 (which was in IPM). Used the new Unit 4 to replace the IPM-generated 500 MW coal-fired Generic Unit (ORIS900545) located in the adjacent county.

Table 2.1-3 (continued)

State	Plant Name and ID	Unit	Nature of Update/Correction
SC	New Santee Cooper Units Planned for Florence County	1, 2	Santee Cooper is planning two new coal burning units in Florence County, each at 660 MW. These units were not explicitly identified in IPM. Used these new units to replace three IPM-generated 500 MW coal-fired Generic Units (ORIS900145, ORIS900245, ORIS900345) in Darlington and Colleton Counties.
	USDOE SRS Area D ORISID=7652	1	Facility is replacing coal-fired boilers with three biomass boilers. Recalculated emissions for 2018 using emission factors for biomass combustion and IPM heat inputs.
VA	Dominion Chesapeake ORISID=3803	1 - 4	Changed SO2 emissions in 2009 and 2018 to reflect information from the facility on project SO2 controls.
	Dominion Southwest Virginia Project	1	For 2018, replace the IPM generated Generic Unit located in Russell county (ORISID=900251) to Wise County to reflect the planned Dominion facility going into Wise County. Used the potential to emit for the Dominion facility.
	Clinch River ORISID=3775	1, 2, 3	Changed emissions in 2018 to reflect requirements of Consent Order. The CO requires SNCR by 12/31/2009; IPM assigned SCR in 2018. The CO caps SO2 emissions at 16,300 tpy starting Jan 1, 2015.
WV	Pleasants Power Station ORISID=6004	1, 2	For both 2009 and 2018, Units 1 and 2 had SO2 emissions reduced to account for the facility's inclusion of previously bypassed 15% effluent stream to the scrubber. The control efficiency and emissions changed from 79.9% to 95% control.
	Nine Generic Units Generated by IPM		IPM placed 746 MW of new fossil fuel-fired generation in West Virginia - 173 MW coal-fired, 24 MW IGCC, and the remainder gas-fired. A 600 MW pulverized coal-fired EGU is under construction, scheduled to be online in 2010 [Longview]; a 98 MW CFB co-generation unit is permitted and expected to be built [Western Greenbrier]; and a 600 MW IGCC plant is currently in the permitting process [Mountaineer IGCC]. WVDEP decided to replace the IPM generic units in WV with the 3 units mentioned above.
	Longview Site ID: 54- 061-0134	1	For 2018 inventory, added Longview which is permitted, under construction, and scheduled to be online in 2010. The unit is a 600 MW pulverized coal-fired unit with baghouse, LNB, SCR, and wet FGD as required controls. Used permitted emission rates for 2018.
WV	Western Greenbriar Site ID: 54-025-0066	1	For 2018 inventory, added Western Greenbrier, which is permitted but not under construction. The unit is a 98 MW coal-fired CFB burning waste coal. Used permitted emission rates for 2018.
	Mountaineer IGCC Site ID: 54-053-00063	1	For 2018 inventory, added Mountaineer IGCC, which has applied for a permit to construct a nominal 600 MW IGCC. Used emission rates from the permit application for 2018.

2.1.1.9 Conversion of MRPO BaseM 2009 EGU Data to SMOKE Input Format

To support ASIP $PM_{2.5}$ CAMx modeling of the future year 2009, Alpine Geophysics obtained and processed an emission inventory for the 5 MRPO states (Illinois, Indiana, Michigan, Wisconsin, and Ohio). Appendix x details the technical steps that were made as part of the conversion of the MRPO BaseM EGU files into IDA format for ASIP PM-2.5 CAMx modeling of the future year 2009.

2.1.1.10 Summary of 2009/2018 EGU Point Source Inventories

Tables 2.1-4 through 2.1-10 compare the Base G 2002 base year inventory to the Base F, Base G/G2 and B&F 2009/2018 projection inventories. The Base F projections rely primarily on the results of the IPM, while the Base G and B&F projections include the adjustments to the IPM results specified by the S/L agencies in the previous section.

2.1.2 Non-EGU Emission Projections

The general approach for assembling future year data was to use growth and control data consistent with the data used in EPA's Clean Air Interstate Rule analyses, supplement these data with available stakeholder input, and provide the results for stakeholder review to ensure credibility. We used the revised 2002 VISTAS base year inventory, based on the 2002 CERR submittals as the starting point for the non-EGU projection inventories. As described in Section 2.1.1.4, we split the point source inventory into EGU and non-EGU components. MACTEC performed the following activities to apply growth and control factors to the 2002 inventory to generate the 2009 and 2018 projection inventories:

- Obtained, reviewed, and applied the most current growth factors developed by EPA, based on forecasts from an updated Regional Economic Models, Inc. (REMI) model (version 5.5) and the latest *Annual Energy Outlook* published by the Department of Energy (DOE);
- Obtained, reviewed, and applied any State-specific or sector-specific growth factors submitted by stakeholders;
- Obtained and incorporated information regarding sources that have shut down after 2002 and set the emissions to zero in the projection inventories;
- Obtained, reviewed, and applied control assumptions for programs "on-the-books" and "on-the-way";
- Provided data files in NIF3.0 format and emission summaries in EXCEL format for review and comment; and
- Updated the database with corrections or new information from S/L agencies based on their review of the Base F 2009/2018 inventories.

The following sections discuss each of these steps.

2.1.2.1 Growth assumptions for non-EGU sources

This section describes the growth factor data used in developing the Base F inventory for 2009 and 2018, as well as the changes to the growth factor data made for the Base G inventory.

The growth factor data used in developing the Base F inventory were consistent with EPA's analyses for the CAIR rulemaking. These growth factors are fully documented in the reports entitled *Development of Growth Factors for Future Year Modeling Inventories* (dated April 30, 2004) and *CAIR Emission Inventory Overview* (dated July 23, 2004). Three sources of data were used in developing the growth factors for the Base F inventory:

- State-specific growth rates from the Regional Economic Model, Inc. (REMI) Policy Insight® model, Version 5.5 (being used in the development of the EGAS Version 5.0). The REMI socioeconomic data (output by industry sector, population, farm sector value added, and gasoline and oil expenditures) are available by 4-digit SIC code at the State level.

- Energy consumption data from the DOE's Energy Information Administration's (EIA) *Annual Energy Outlook 2004, with Projections through 2025* for use in generating growth factors for non-EGU fuel combustion sources. These data include regional or national fuel-use forecast data that were mapped to specific SCCs for the non-EGU fuel use sectors (e.g., commercial coal, industrial natural gas). Growth factors for the residential natural gas combustion category, for example, are based on residential natural gas consumption forecasts that are reported at the Census division level. These Census divisions represent a group of States (e.g., the South Atlantic division includes eight southeastern States and the District of Columbia). Although one would expect different growth rates in each of these States due to unique demographic and socioeconomic trends, EIA's projects all States within each division using the same growth rate.
- Specific changes for sectors (e.g., plastics, synthetic rubber, carbon black, cement manufacturing, primary metals, fabricated metals, motor vehicles and equipment) where the REMI-based rates were unrealistic or highly uncertain. Growth projections for these sectors were based on industry group forecasts, Bureau of Labor Statistics (BLS) projections and Bureau of Economic Analysis (BEA) historical growth from 1987-2002.

In addition to the growth data described above, we received two sets of growth projections from VISTAS stakeholders.

The American Forest and Paper Association (AF&PA) supplied growth projections for the pulp and paper sector, which were applied to SIC 26xx Paper and Allied Products. The AF&PA projection factors are for the U.S. industry and apply to all States equally. The numbers come from the 15-year forecast for world pulp and recovered paper prepared by Resource Information Systems Inc. (RISI).

SIC Code	Sector	AF&PA Growth Factor	
		2002 to 2009	2002 to 2018
2611	Pulp Mills	1.067	1.169
2621	Paper Mills	1.067	1.169
2631	Paperboard Mills	1.067	1.169

For both the Base F and Base G inventories, we used the above AF&PA growth factors by SIC instead of the factors obtained from EPA's CAIR analysis.

For the Base F inventory, the NCDENR supplied recent projections for three key sectors in North Carolina where declining production was anticipated – SIC 22xx Textile Mill Products, 23xx Apparel and Other Fabrics, and 25xx Furniture and Fixtures. For the Base G inventory, NCDENR decided to use a growth factor of 1.0 for these SIC codes for both 2009 and 2018. Although NCDENR has data that shows a steady decline in these industries in NC, NCDENR wanted to maintain the emission levels at 2002 levels so the future emission reduction credits were available in the event that they are needed for nonattainment areas. The specific growth factors for these industrial sectors in North Carolina were:

NCDENR Growth Factors for Specific Industrial Sectors					
SIC Code	Industrial Sector	2009		2018	
		Base F	Base G	Base F	Base G
22xx	Textile Mill Products	0.6239	1.00	0.2792	1.00
23xx	Apparel and Other Fabrics	0.5867	1.00	0.2247	1.00
25xx	Furniture and Fixtures	0.8970	1.00	0.7647	1.00

For the Base G inventory, we made one additional change to the growth factors. The Base F inventory relied on DOE's AEO2004 forecasts for projecting emissions for fuel-burning SCCs (applies mainly to ICI boilers 1-02-xxx-xx and 1-03-xxx-xx, as well as in-process fuel use). We replaced the AEO2004 data with the more recent AEO2006 forecasts (released in February 2006) to reflect changes in the energy market and to improve the emissions growth factors produced. We obtained the corresponding AEO2006 projection tables from DOE's web site located at http://www.eia.doe.gov/oiaf/aeo/supplement/supref.html. We developed tables comparing the growth factors based on AEO2004 and AEO2006. These comparison tables were reviewed by the S/L agencies. Based on this review, VISTAS decided to use the AEO2006 growth factors for fuel burning SCCs.

We used the EPA's EGAS model and updated the corresponding AEO2006 projection tables to create growth factors by SCC. We applied the updated growth factors to 2002 actual emissions and replaced the 2009 and 2018 emissions in NIF EM tables for the affected SCCs.

2.1.2.2 Source Shutdowns

A few states indicated that significant source shutdowns have occurred since 2002 and that emissions from these sources should not be included in the future year inventories. These sources are identified in Table 2.1-11.

Table 2.1-11 Summary of Source Shutdowns Incorporated in Base G Inventory.

State	Description of Source Shutdowns
AL	None specified.
FL	The following facilities are shutdown and projected emissions were set to zero in 2009/2018. 0570075 CORONET INDUSTRIES, INC. 1050050 U S AGRI-CHEMICALS CORP. 1050051 U.S. AGRI-CHEMICALS CORPORATION These facilities emitted 2,417 tons of SO_2 and 113 tons of NO_x in 2002.
GA	Georgia indicated that the former Blue Circle (now LaFarge) facility in downtown Atlanta will likely shut down before 2009. The facility has two cement kilns, one of which is already shut down. The second kiln will continue to operate until the new facility in Alabama has enough milling capacity, after which the entire Atlanta facility will be completely closed down. This facility emitted 1,617 tons of SO_2 and 587 tons of NO_x in 2002.
KY	None specified.
MS	AF&PA indicated that the International Paper Natchez Mill (28-001-2800100010) has shut down. This facility emitted 1,398 tons of SO_2 and 1,773 tons of NO_x in 2002.
	The Magnolia Resources - Pachuta Harmony Gas Plant (28-023-00031) is out of business and no longer holds an air permit. This facility emitted 2,257 tons of $SO_2$and 134 tons of NO_x in 2002.
NC	In Base F, two paper mills were identified as being shut down in the 2018 inventory. NCDENR indicated that these mills are not expected to close. The two facilities are Ecusta Business Development (37-175-3717500056) and International Paper (37-083-00007). Their emissions were added back into the Base G 2018 inventory.
	BASF Corporation (37-021-724) in Buncombe County is currently operating but has plans to shut down in 2007. This facility emitted 461 tons of SO_2 and 266 tons of NO_x in 2002.
SC	South Carolina provided a list of facilities that were identified as closing down on or after Jan. 1, 2003. The emissions for these facilities were set to zero in the 2009 and 2018 projection inventories. Emissions from these plants in 2002 were: 6,195 tons of SO_2, 2,994 tons of NO_x, and 2,836 tons of VOC. Most of the emissions were from one facility – Celanese Acetate (45-091-2440-0010) in York County.
TN	Davidson County (Nashville) indicated that significant source shutdowns have occurred since data were submitted for the 2002 CERR. Source number 47-037-00002 (Dupont) shut down a portion of their facility, which was permanently taken out of service. Source 47-037-00050 (Nashville Thermal Transfer Corp.) shut down their municipal waste combustors and replaced them with natural gas fired boilers with propane stand by.
	Weyerhaeuser (AKA Willamette) Power Boiler 7 (47-163-0022, EU ID = 017) is being shut down. This emission unit emitted 4,297 tons of SO_2 and 1,443 tons of NO_x in 2002.
	Liberty Fibers (47-063-0197) in Hamblen County has recently shut down. This facility emitted 5,377 tons of SO_2; 2,057 tons of NO_x; and 9,059 tons of VOC in 2002.
VA	Rock-Tenn (51-680-00097) received a permit dated 9/13/2003 which required the shutdown of units 1 and 2 by 2/27/2004. This permit was part of a netting exercise that allowed the installation of a new NG/DO boiler. These two units emitted 507 tons of SO_2 and 276 tons of NO_x in 2002.
WV	None specified.

2.1.2.3 Control Programs applied to non-EGU sources

We used the same control programs for both the 2009 and 2018 non-EGU point inventory. Two control scenarios were developed: on-the-books (OTB) controls and on-the-way (OTW) controls. The OTB control scenario accounts for post-2002 emission reductions from promulgated federal, State, local, and site-specific control programs. The OTW control scenario accounts for proposed (but not final) control programs that are reasonably anticipated to result in post-2002 emission reductions. The methodologies used to account for the emission reductions associated with these emission control programs are discussed in the following sections.

Table 2.1-12 Non-EGU Point Source Control Programs Included in 2009/2018 Projection Inventories.

On-the-Books (Cut-off of July 1, 2004 for Base 1 adoption)

- Atlanta / Northern Kentucky / Birmingham 1-hr SIPs
- Industrial Boiler/Process Heater/RICE MACT (see Section 2.1.2.3.2)
- NO_x RACT in 1-hr NAA SIPs
- NO_x SIP Call (Phase I- except where States have adopted II already e.g. NC)
- Petroleum Refinery Initiative (October 1, 2003 notice; MS & WV)
- RFP 3 percent Plans where in place for one hour plans
- VOC 2-, 4-, 7-, and 10-year maximum achievable control technology (MACT0 Standards
- Combustion Turbine MACT

On-the-Way

- NO_x SIP Call (Phase II – remaining States & IC engines)

2.1.2.3.1 OTB - NO_x SIP Call (Phase I)

Phase I of the NO_x SIP call applies to certain large non-EGUs, including large industrial boilers and turbines, and cement kilns. States in the VISTAS region affected by the NO_x SIP call have developed rules for the control of NO_x emissions that have been approved by EPA. We reviewed the available State rules and guidance documents to determine the affected sources and ozone season allowances. We also obtained and reviewed information in the EPA's CAMD NO_x Allowance Tracking System – Allowances Held Report. Since these controls are to be in effect by the year 2007, we capped the emissions for NO_x SIP call affected sources at 2007 levels and carried forward the capped levels for the 2009/2018 future year inventories. Since the NO_x SIP call allowances are given in terms of tons per ozone season (5 month period from May to

September), we calculated annual emissions by multiplying the 5-month allowances by a factor of 12 divided by 5.

2.1.2.3.2 OTB - Industrial Boiler/Process Heater MACT

EPA anticipates reductions in PM and SO_2 as a result of the Industrial Boiler/Process Heater MACT standard. The methods used to account for these reductions are the same as those used for the CAIR analysis. Reductions were included for existing units firing solid fuel (coal, wood, waste, biomass) which had a design capacity greater than 10 mmBtu/hr. EPA prepared a list of SCCs for solid fuel industrial and commercial/ institutional boilers and process heaters. We identified boilers greater than 10 mmBtu/hr using either the boiler capacity from the VISTAS 2002 inventory, or if the boiler capacity was missing, a default capacity based on a methodology developed by EPA for assigning default capacities based on SCC. The applied MACT control efficiencies were 4 percent for SO_2 and 40 for percent for PM_{10} and PM2.5 to account for the co-benefit from installation of acid gas scrubbers and other control equipment to reduce HAPs. On June 8, 2007, the U.S. Court of Appeals for the District of Columbia Circuit vacated and remanded the NESHAP for Industrial, Commercial and Institutional Boilers and Process Heaters. VISTAS States decided to leave the emission reductions in place since they envision using a 112(j) strategy (e.g., the “MACT hammer”) to obtain similar levels of control)

2.1.2.3.3 OTB - 2, 4, 7, and 10-year MACT Standards

Maximum achievable control technology (MACT) requirements were also applied, as documented in the report entitled *Control Packet Development and Data Sources,* dated July 14, 2004. The point source MACTs and associated emission reductions were designed from Federal Register (FR) notices and discussions with EPA’s Emission Standards Division (ESD) staff. We did not apply reductions for MACT standards with an initial compliance date of 2001 or earlier, assuming that the effects of these controls are already accounted for in the 2002 inventories supplied by the States. Emission reductions were applied only for MACT standards with an initial compliance date of 2002 or greater.

2.1.2.3.4 OTB Combustion Turbine MACT

The projection inventories do not include the NO_x co-benefit effects of the MACT regulations for Gas Turbines or stationary Reciprocating Internal Combustion Engines, which EPA estimates to be small compared to the overall inventory.

2.1.2.3.5 OTB - Petroleum Refinery Initiative (MS and WV)

Three refineries in the VISTAS region are affected by two October 2003 Clean Air Act settlements under the EPA Petroleum Refinery Initiative. The refineries are: (1) the Chevron refinery in Pascagoula, MS; (2) the Ergon refinery in Vicksburg, MS; and (3) the Ergon refinery in Newell, WV.

The first consent decree pertained to Chevron refineries in Richmond and El Segundo, CA; Pascagoula, MS; Salt Lake City, UT; and Kapolei, HI. Actions required under the Consent Decree will reduce annual emissions of NO_x by 3,300 tons and SO_2 by 6,300 tons. The consent decree requires a program to reduce NO_x emissions from refinery heaters and boilers through the installation of NO_x controls that meet at least an SNCR level of control. The refineries are to eliminate fuel oil burning in any combustion unit. The consent decree also requires reductions of NO_x and SO_2 from the fluid catalytic cracking unit and control of acid gas flaring incidents. The consent decree does not provide sufficient information to calculate emission reductions for the FCCU or flaring at the Pascagoula refinery. Therefore, we calculated a general percent reduction for NO_x and SO_2 by dividing the expected emission reductions at the five Chevron refineries by the total emissions from these five refineries (as reported in the 1999 NEI). This resulted in applying percent reductions of 45 percent for SO_2 and 28 percent for NO_x to FCCU and flaring emissions at the Chevron Pascagoula refinery.

The second consent decree pertained to the Ergon-West Virginia refinery in Newell, WV; and the Ergon Refining facility in Vicksburg, MS. The consent decree requires the two facilities to implement a 6-year program to reduce NO_x emission from all heaters and boilers greater than 40 mmBtu/hr, and to eliminate fuel oil burning in any combustion unit (except during periods of natural gas curtailment). Specifically, ultra low NO_x burners are required on Boilers A and B at Newell, a low NO_x-equivalent level of control for heater H-101 at Newell and heaters H-1 and H-3 at Vicksburg, and an ultra low NO_x burner level of control for heater H-451 at Vicksburg.

2.1.2.3.6 OTW - NO_x SIP Call (Phase II)

The final Phase II NO_x SIP call rule was finalized on April 21, 2004. States had until April 21, 2005, to submit SIPs meeting the Phase II NO_x budget requirements. The Phase II rule applies to large IC engines, which are primarily used in pipeline transmission service at compressor stations. We identified affected units using the same methodology as was used by EPA in the proposed Phase II rule (i.e., a large IC engine is one that emitted, on average, more than 1 ton per day during 2002). The final rule reflects a control level of 82 percent for natural gas-fired IC engines and 90 percent for diesel or dual fuel categories. As shown later in Table 2.1-12, several S/L agencies provided move specific information on the anticipated controls at the compressor stations. This information was used in the Base G inventory instead of the default approach used by EPA in the proposed Phase II rule.

2.1.2.3.7 Clean Air Interstate Rule

CAIR does not require or assume additional emission reductions from non-EGU boilers and turbines.

2.1.2.4 Quality Assurance steps

Final QA checks were run on the revised projection inventory data set to ensure that all corrections provided by the S/L agencies and stakeholders were correctly incorporated into the S/L inventories and that there were no remaining QA issues that could be addressed during the duration of the project. After exporting the inventory to ASCII text files in NIF 3.0, the EPA QA program was run on the ASCII files and the QA output was reviewed to verify that all QA issues that could be addressed were resolved

Throughout the inventory development process, quality assurance steps were performed to ensure that no double counting of emissions occurred, and to ensure that a full and complete inventory was developed for VISTAS. Quality assurance was an important component to the inventory development process and MACTEC performed the following QA steps on the point source component of the VISTAS revised 2002 base year inventory:

Facility level emission summaries were prepared and evaluated to ensure that emissions were consistent and reasonable. The summaries included base year 2002 emissions, 2009/2018 projected emissions accounting only for growth, 2009/2018 projected emissions accounting for both growth and emission reductions from OTB and OTW controls.

State-level non-EGU comparisons (by pollutant) were developed for the base year 2002 emissions, 2009/2018 projected emissions accounting only for growth, 2009/2018 projected emissions accounting for both growth and emission reductions from OTB and OTW controls.

Data product summaries and raw NIF 3.0 data files were provided to the VISTAS Emission Inventory Technical Advisor and to the Point Source, EGU, and non-EGU Special Interest Work Group representatives for review and comment. Changes based on these comments were reviewed and approved by the S/L point source contact prior to implementing the changes in the files.

Version numbering was used for all inventory files developed. The version numbering process used a decimal system to track major and minor changes. For example, a major change would result in a version going from Base F1 to Base F2.

2.1.2.5 Additional Base G Updates and Corrections

Table 2.1-13 summarizes the updates and corrections to the Base F inventory that were requested by S/L agencies and incorporated into the Base G 2009/2018 inventories.

Table 2.1-13 Summary of Updates and Corrections Incorporated into the Base G 2009/2018 Non-EGU Inventories.

State	Nature of Update/Correction
AL	Corrected the latitude and longitude for two facilities: Ergon Terminalling (Site ID: 01-073-010730167) and Southern Power Franklin (Site ID: 01-081-0036).
	Corrections to stack parameters at 10 facilities for stacks with parameters that do not appear to fall into the ranges typically termed "acceptable" for AQ modeling.
FL	Corrected 2009/2018 emission values for the Miami Dade RRF facility (Site ID: 12-086-0250348) based on revised 2002 emissions and application of growth control factors for 2009/2018.
GA	Hercules Incorporated (12-051-05100005) had an erroneous process id (#3) within emission unit id SB9 and was deleted. This removes about 6,000 tons of SO_2 from the 2009/2018 inventories.
	Provided a revised file of location coordinates at the stack level that was used to replace the location coordinated in the ER file.
	There are several sources that have updated their emissions from their BART eligible units. most of these changes were for fairly small (<50 tpy) sources.
NC	Made several changes to Base F inventory to correct the following errors: 1. Corrected emissions at Hooker Furniture (Site ID: 37-081-3708100910), release point G-29, to use the corrected values in 2002 and carry those same numbers through to 2009 and 2018 since NCDENR assumes zero growth for furniture industry. 2. Identified many stack parameters in the ER file that were unrealistic. Several have zero for height, diameter, gas velocity, and flow rate. NC used the procedures outlined in Section 8 of the document ""National Emission Inventory QA and Augmentation Report" to correct unrealistic stack parameters. 3. Identified truncated latitude and longitude values in Base F inventory. NC updated all Title V facility latitude and longitude that was submitted to EPA for those facilities in 2004. Smaller facilities with only two decimal places were not corrected. 4. Corrected 2018 VOC emissions for International Paper (3709700045) Emission Unit ID, G-12, to reflect changes to the 2002 inventory.
	There are three Transcontinental Natural Gas Pipeline facilities in NC that are subject to the NO_x SIP call. NCDENR took 2004 emissions and grew them to 2009 & 2018 and capped those units that are subject to the NO_x SIP Call Rule. These facility IDs are 37-057-3705700300, 37-097-3709700225, and 37-157-3715700131.
	NCDENR applied NO_x RACT to a two facilities located in the Charlotte nonattainment area. NCDENR provided 2009 & 2018 emissions for Philip Morris USA (37-025-3702500048) and Norandal USA (37-159-3715900057).
SC	Corrected PM species emission values. SC DHEC's initial CERR submittal reported particulate matter emissions using the PM-FIL, PM_{10}-FIL, and $PM_{2.5}$ -FIL pollutant codes. In August 2005, SC DHEC indicated that data reported using the PM-FIL, PM_{10}-FIL, and $PM_{2.5}$ -FIL pollutant codes should actually have been reported using the PM-PRI, PM_{10}-PRI, and $PM_{2.5}$ _PRI codes. MACTEC performed a subsequent PM augmentation in April 2006 using the revised pollutant codes. These changes were reflected in the Base G 2009/2018 emission inventory.
	Specified that the Bowater Inc. facility (45-091-2440-0005) in York County conducted an expansion in 2003/2004 and plans a future expansion. SC provided updated emissions for 2009 and 2018 for this facility.

Table 2.1-13. Continued.

State	Nature of Update/Correction
TN	Updated 2009/2018 emissions for Eastman Chemical (47-163-0003) based on final (Feb. 2005) BART rule.
	Updated 2009/2018 emission inventory for the Bowater facility (47-107-0012) based on the facility's updated 2002 emission inventory update.
	Replaced 2009/2018 data from Hamilton County, Tennessee, using data from Hamilton County's CERR submittal as contained in EPA's 2002 NEI (in Base F, the inventory for Hamilton County was based on the draft VISTAS 2002 inventory, which in turn was based on the 1999 NEI); applied growth and control factors to revised 2002 inventory to generate emission projections for 2009/2018.
	Updated 2009/2018 emissions for PCS Nitrogen Fertilizer LP (Site ID: 47-157-00146) based on the facility's updated 2002 emission inventory update.
	The 2002 NEI correctly reports the actual emissions for CEMEX (47-093-0008) after the NO_x SIP call. There is no reason to suspect that that rate would change in 2008, 2009, or 2018. Emissions for 2009/2018 were set equal to 2002 emissions.
	In the Base F 2009/2018 inventories, NO_x controls were applied for two units at Columbia Gulf Transmission (47-111-0004). There are no plans for controls at these units, EO3 and EO4. The assumed control efficiency of 82 percent was backed out in the 2009/2018 inventories.
VA	VADEQ provided 2009/2018 NO_x emission estimates for NO_x Phase II gas transmission sources at three Transco facilities (51-011-00011, 51-137-00027, 51-143-00120) which were used to replace the default NO_x Phase II control assumptions for these facilities.
	VADEQ provided updated 2009/2018 NO_x and SO_2 emissions based on new controls required by a November 2005 permit modification and netting exercise. The entire power plant facility is limited to 213 tons of NO_x and 107 tons of SO_2 per year. The permit also allowed the installation of 3 new boilers, also under the 213 tons of NO_x /year cap.
WV	Updated 2009/2018 emissions for Steel of West Virginia (Site ID: 54-011-0009) based on the facility's updated 2002 emission inventory update.
	Made changes to several Site ID names due to changes in ownership
	Base F emissions were much too high for Weirton Steel (54-021-0029). WV believes that the source is very unlikely to emit the NO_x SIP Call budgeted amounts in 2009 or 2018. WV provided revised emission estimates based on EGAS for 2009/2018.
	Made corrections to latitude/longitude and stack parameters at a few facilities for stacks with parameters that do not appear to fall into the ranges typically termed "acceptable" for AQ modeling.

2.1.2.6 Additional B&F Updates and Corrections

Table 2.1-14 summarizes the updates and corrections to the Base G non-EGU inventory that were requested by S/L agencies and incorporated into the B&F 2009/2018 non-EGU inventories. The changes were primarily related to better information on anticipated BART controls for specific facilities and emission units.

Table 2.1-14 Summary of Updates and Corrections Incorporated into the B&F 2009/2018 Non-EGU Inventories.

State	Nature of Update/Correction
AL	Alabama suggest additional changes to the 2009 inventory resulting from their $PM_{2.5}$ modeling for the Birmingham area; however, these changes were identified too late to be incorporated in the VISTAS B&F inventory and ASIP modeling.
	For 2018, incorporated emission changes due to BART controls at Exxon Mobil (Site ID: 01-053-0007), International Paper (Site ID: 01-079-0001), and Solutia (Site ID: 01-103-0010). International Paper (Site ID: 01-079-0001) Unit 004 to be shutdown in the 2018 inventory.
FL	For both 2009 and 2018, incorporated emission changes due to BART controls at Georgia Pacific (Site ID: 12-107-1070005) Unit 15.
MS	For 2018 only, changed SO2 emission estimate for Pursue Energy (Site ID: 28-121-00036) based on the facility's estimates of the gas reserve at the site.
	For 2018 only, changed emission estimates for all pollutants at several emission units at the Chevron Pascagoula Refinery (Site ID: 28-059-00058) to reflect BART source reductions.
SC	For both 2009 and 2018, identified 15 facilities that have permanently closed. Emissions from these facilities set to zero for all pollutants.
TN	For both 2009 and 2018, identified seven facilities that have permanently closed. Emissions from these facilities were set to zero for all pollutants.
	For both 2009 and 2018, identified three emission units that have permanently closed. Emissions from these units were set to zero for all pollutants. 47-009-0130-002 (APAC – TN, Inc.-Harrison Construction – Asphalt plant), 47-009-0130-003 (APAC – TN, Inc.-Harrison Construction – Asphalt crusher), and 47-139-0004-001 (Intertrade - Number 6 acid plant)
	The following individual source will be shut down in 2010: 47-001-0020-002 (DOE, Y-12 – Boilers 1-4). For the 2018 inventory only, emissions from this unit were set to zero for all pollutants.
	A portion of 47-163-0003-020101 (Eastman, B-83-1 Stoker Boilers). This source previously consisted of 14 boilers (Boilers 11-24). Boilers 11-17 have been removed from service. Emissions for both 2009 and 2018 were reduced by 26.64%, based on the portion of the heat input capacity that is being removed from service.
	SO2 emissions in 2018 from 47-163-0003-021520 (Eastman, B-253-1 Tangential PC Boilers) were reduced by 90% to reflect anticipated BART controls.
	Reduced SO2 emissions at 47-157-00475 (Lucite International) in Shelby County as a result of a consent decree with U.S. EPA.
VA	Changed SO2 emissions in 2009 and 2018 for thirteen facilities to reflect updated information from VADEQ regarding projected SO2 controls.
WV	Weirton Steel (54-029-00001) and Wheeling Pittsburgh Steel (54-009-00002) have undergone significant, permanent process changes since 2002. WV DEP staff have consulted with facility staff and determined that calendar year 2004 emissions represent a better basis for future year emissions estimates. Therefore, WVDEP compiled emissions data from the 2004 inventory for these sources and applied the most current VISTAS growth factors to estimate emissions in 2009 and 2018.

2.1.2.7 Conversion of MRPO BaseM 2009 non-EGU Data to SMOKE Input Format

To support ASIP $PM_{2.5}$ CAMx modeling of the future year 2009, Alpine Geophysics obtained and processed an emission inventory for the 5 MRPO states (Illinois, Indiana, Michigan, Wisconsin, and Ohio). Appendix x details the technical steps that were made as part of the conversion of the MRPO BaseM non-EGU files into IDA format for ASIP PM-2.5 CAMx modeling of the future year 2009.

2.1.2.8 Summary of the 2009/2018 non-EGU Point Source Inventories

Tables 2.1-15 through 2.1-21 summarize the revised 2009/2018 non-EGU point source inventories. The "growth only" column does not include the shutdowns (section 2.1.2.2) or control factors (section 2.1.2.3), only the growth factors described in section 2.1.2.1.

2.2 Area Sources

This section describes the methodology used to develop the 2009 and 2018 projection Base F and Base G projection inventories. This section describes two approaches to these projections. Separate methods for projecting emissions were used for non-agricultural (stationary area) and agricultural area sources (predominantly NH_3 emissions). The two methods used for these sectors are described in the sections that follow.

2.2.1 Stationary area sources

The general approach used to calculate Base F projected emissions for stationary area sources was as follows:

1. Use the VISTAS Base F 2002 base year inventory as the starting point for projections.
2. MACTEC then worked with the VISTAS States (via the Stationary Area Source SIWG) to obtain any State specific growth factors and/or future controls from the States to use in developing the projections.
3. MACTEC then back calculated uncontrolled emissions from the Base F 2002 base year inventory based on existing controls reported in the 2002 Base F base year inventory.
4. Controls (including control efficiency, rule effectiveness and rule penetration) provided by the States or originally developed for use in estimating projected emissions for U.S. EPA's Heavy Duty Diesel (HDD) rulemaking emission projections and used in the Clean Air Interstate Rule (CAIR) projections were then used to calculate controlled emissions. State submitted controls had precedence over the U.S. EPA developed controls.
5. Growth factors supplied from the States or the U.S. EPA's CAIR emission projections were then applied to project the controlled emissions to the appropriate year. In some cases EGAS Version 5 growth factors were used if no growth factor was available from either the States or the CAIR growth factor files. The use of EGAS Version 5 growth factors was on a case-by-case basis wherever State-supplied or CAIR factors were not available for SCCs found in the 2002 Base F inventory. Use of the EGAS factors was necessitated due to the CERR submittals used in constructing the Base F 2002 inventory. Use of the CERR data resulted in SCCs that were not found in the CAIR inventory and if no State-supplied growth factor was provided required the use of an EGAS growth factor.
6. MACTEC then provided the final draft Base F projection inventory for review and comment by the VISTAS States.

For Base F stationary area sources, no State-supplied growth or control factors were provided. Thus for all of the sources in this sector of the inventory, growth and controls for Base F were applied based on controls initially identified for the CAIR and growth factors identified for the CAIR projections.

For the Base G projections, the Base G 2002 base year inventory (see section 1.2.3) was used as a starting point. States provided some updated future controls but growth factors used were identical to those used for Base F. The revised controls for Base G were largely for new sources added as part of the 2002 Base F comments. The calculation of Base G projections was identical to the six steps outlined above with the exception of revisions made to prescribed fire for 2009 and 2018 and for the State of North Carolina. North Carolina provided 2009 and 2018 updated emission files used to update the emissions for each year for several source categories. However not all sources in the inventory were included in these NC updates. As a consequence, the final Base G 2009 and 2018 inventory for NC included emissions updated using the NC supplied files and emissions developed using growth and control factors as outlined above.

In a few cases, additional growth factors had to be added for source categories that had not initially been included in the Base F inventory. These growth factors were obtained from EGAS 5.0. Finally updates to growth factors from EGAS 5.0 were made for fuel fired emission sources. The updated growth factors reflected the most recent data from the Department of Energy's Annual Energy Outlook (AEO). These data were used to reflect changes in energy efficiency resulting from new or updated fuel firing technologies.

2.2.1.1 Stationary area source controls

The controls obtained by MACTEC for the HDD rulemaking were controls for the years 2007, 2020, and 2030. Since MACTEC was preparing 2009 and 2018 projections, control values for intermediate years were prepared using a straight line interpolation of control level between 2007 and 2020. The equation used to calculate the control level was as follows:

CE = (((2020 CE – 2007 CE)/13)*YRS) + 2007 CE

Where:

CE	=	Control Efficiency for either 2009 or 2018
2020 CE	=	HDD Control Efficiency value for 2020
2007 CE	=	HDD Control Efficiency value for 2007
13	=	Number of years between 2020 and 2007
YRS	=	Number of years beyond 2007 to VISTAS Projection year

For 2009 the value of YRS would be two (2) and for 2018 the value would be eleven (11). Control efficiency values were determined for VOC, CO and PM. Rule penetration values for each year in the HDD controls tables obtained by MACTEC were always 100 percent so those values were maintained for the VISTAS projections.

Prior to performing the linear interpolation of the controls, MACTEC evaluated controls from the CAIR projections (NOTE: Initially the controls came from the IAQTR projections, however the controls used in CAIR were virtually identical to those in IAQTR). Those controls appeared to be identical to those used for the HDD rulemaking. In addition, MACTEC received some additional information on some controls for area source solvents (email from Jim Wilson, E.H. Pechan and Associates, Inc. to Gregory Stella, VISTAS Emission Inventory Technical Advisor, 3/5/04) that were used to check against the controls in the HDD rulemaking files. Where those controls proved to be more stringent than the HDD values, MACTEC updated the control file with those values (which were then used in the interpolation to develop 2009 and 2018 values). Finally, for VOC the HDD controls were initially provided at the State-county-SCC level. However, upon direction from the VISTAS Emission Inventory Technical advisor, the VOC controls were consolidated at the SCC level and applied across all counties within the VISTAS region (email from Gregory Stella, Alpine Geophysics, 3/3/2004) to ensure that no controls were missed due to changes in county FIPS codes and/or SCC designations between the time the HDD controls were developed and 2002.

The equation below indicates how VOC emissions were projected for stationary area sources.

$$VOC_{2018} = VOC_{2002}\ x \left(1 - \left(\frac{VOC\_CE_{2018}}{100}\right)\left(\frac{VOC\_RE_{2018}}{100}\right)\left(\frac{VOC\_RP_{2018}}{100}\right)\right)$$

Where:

VOC_{2018} = VOC emissions for 2018

VOC_{2002} = Uncontrolled VOC emissions for 2002

VOC_CE_{2018} = Control Efficiency for VOC (in this example for 2018)

VOC_RE_{2018} = Rule Effectiveness for VOC (in this example for 2018)

VOC_RP_{2018} = Rule Penetration for VOC (in this example for 2018)

A similar equation could be constructed for either PM or CO. It should be noted that the control efficiencies calculated based on the HDD rulemaking were only applied if they were greater than any existing 2002 base year controls. No controls were found for SO_2 or NO_x area sources.

In the pre-Base F 2018 emission estimates, an energy efficiency factor was applied to energy related stationary area sources. The energy efficiency factor was applied along with the growth factor to account for both growth and changes in energy efficiency. That factor was not applied to the Base F projections since information supplied by U.S. EPA related to the CAIR growth factors indicated that growth values for those categories were derived from U.S. Department of Energy (DOE) and were felt to account for changes in growth and projected energy efficiency. For the Base G inventory, these energy efficiency factors were re-instituted and used in conjunction with EGAS 5.0 growth factors in a manner identical to that used for the pre-Base F inventories. The energy efficiency factors were derived from U.S. DOE's Annual Energy Outlook report.

One significant difference between the Base F and Base G control factors was for counties and independent cities in northern Virginia. Several counties and independent cities in northern Virginia are subject to Ozone Transport Commission rules. For these counties and independent cities, controls for portable fuel containers, mobile equipment repair/refinishing, consumer products, solvent metal cleaning, and the architectural and industrial maintenance rules were added. The counties/independent cities (FIPS code) included in the changes for Base G were: Alexandria City (51510), Arlington (51013), Fairfax City (51600), Fairfax (51059), Falls Church City (51610), Fredericksburg City (51630), Loudoun (51107), Manassas City (51683), Manassas Park City (51685), Prince William County (51153), Spotsylvania (51177), and Stafford (51179). Not all OTC rules applied to all counties/cities.

2.2.1.2 Stationary area source growth

As indicated above, growth factors for the Base F and Base G 2009 and 2018 inventories were obtained from the U.S. EPA and are linear interpolations of the growth factors used for the Clean Air Interstate Rule (CAIR) projections. The growth factors for the CAIR obtained by MACTEC were developed using a base year of 2001 and provided growth factors for 2010 and 2015. MACTEC used the TREND function in Microsoft Excel™ to calculate 2002, 2009 and 2018 values from the 2001, 2010 and 2015 values. The TREND function provides a linear interpolation of intermediate values from a known series of data points (in this case the 2001, 2010 and 2015 values) based on the equation for a straight line. These values were calculated at the State and SCC level with the exception of paved road emissions (SCC = 2294000000). The growth factors for paved roads were available in the CAIR data set at the State, county and SCC level so they were applied at that level.

Prior to utilizing the growth factors from the CAIR projections, MACTEC confirmed that all SCCs found in the VISTAS 2002 base year inventory were in the CAIR file (for Base F the starting point was the version 3.1 2002 base year inventory, for Base G the starting point was the Base F 2002 base year inventory). Some SCCs were not found in the CAIR file. For those SCCs, the growth factors used were derived in one of five ways. First where possible, they were taken from a beta version of EGAS 5.0. In other cases, the growth factor was set to one (i.e., no growth). In other cases, a similar SCC that had a CAIR growth factor was used. In a few cases a growth factor based on an average CAIR growth at the 6 digit SCC level was calculated. Finally a number of records used population as the growth surrogate. For the Base G inventory, CAIR growth factors for fuel fired area sources were replaced with EGAS 5.0 growth factors (used in conjunction with AEO fuel efficiency factors). A comment field in the growth factor file was used to mark those records that were not taken directly from the CAIR projection growth factors.

2.2.1.3 Differences between 2009/2018

Methodologically, there was no difference in the way that 2009 and 2018 emissions were calculated for stationary area sources. The individual control and growth factors were different (due to the linear interpolation used to calculate the values) but the calculation methods were identical. This applies to both Base F and Base G.

The only exception to this is for the State of North Carolina for Base G. North Carolina provided an emissions update file used to override calculated projections for a number of area source categories. The values in these files (provided for both 2009 and 2018) were used to overwrite the calculated projected emissions in the final NIF file.

2.2.2 Agricultural area sources

The general approach used to calculate projected emissions for agricultural area sources (predominantly NH_3 emission sources) was as follows:

1. MACTEC used the version 3.1 2002 base year inventory data (which was based on the CMU ammonia model version 3.6).

2. MACTEC worked with the VISTAS States (via the Agricultural Sources SIWG) to obtain any State specific growth and/or future controls from the States for agricultural sources.

3. Since the base year emissions were uncontrolled, and no future controls for these sources were identified, MACTEC projected the agricultural emissions using State-specific growth if available, otherwise the U.S. EPA's Interstate Air Quality Transport Rule (IAQTR)/Ammonia inventory was used to develop the growth factors used to project the revised 2002 base year inventory to 2009 or 2018. Since the IAQTR inventory was only used to construct growth factors rather than using the emissions directly, no updated growth factors were prepared from the CAIR inventory values.

4. MACTEC then provided the final draft inventory for review and comment by the VISTAS States.

No change in the agricultural area source emission projections were made between Base F and Base G other than the removal of wild animal and human perspiration as a result of their removal from the 2002 base year file for Base G.

2.2.2.1 Control assumptions for agricultural area sources

No controls were identified either by the individual VISTAS States or in the information provided in the EPA's IAQTR or CAIR Ammonia inventory documents. Thus all projected emissions for agricultural area sources represent simple growth with no controls.

2.2.2.2 Growth assumptions for agricultural area sources

Growth for several agricultural area source livestock categories was developed using the actual emission estimates developed by the EPA as part of the NEI. That work included projections for the years 2002, 2010, 2015, 2020, and 2030. The actual emissions themselves were not used other than to develop growth factors since the 2002 NEI upon which the growth projections were based was prepared prior to the release of the 2002 Census of Agriculture data which was included in the CMU model (version 3.6) used to develop the Base F 2002 VISTAS base year inventory. Thus VISTAS Agricultural Sources SIWG decided to use the NEI ammonia inventory projected emissions to develop the 2009 and revised 2018 growth factors used to project emission for VISTAS. Details on the NEI inventory and projections can be found at:

http://www.epa.gov/ttn/chief/ap42/ch09/related/nh3inventorydraft_jan2004.pdf. The actual data files for the projected emissions can be found at:

http://www.epa.gov/ttn/chief/ap42/ch09/related/nh3output01_23_04.zip.

In order to use the NEI projected emissions as growth factors, several steps were required. These steps were as follows:

1. NEI projected emissions were only available for the years 2002, 2010, 2015, 2020, and 2030, thus the first task was to calculate intermediate year emissions for 2009 and 2018. These values were calculated based on linear interpolation of the existing data.

2. Once the intermediate emissions were calculated, MACTEC developed emission ratios to provide growth factors for 2009 and 2018. Ratios of emissions were established relative to the 2002 NEI emissions.

3. Once the growth factors were established, MACTEC then evaluated whether or not all agricultural SCCs within the revised 2002 base year inventory had corresponding

growth factors. MACTEC established that not all SCCs within the base year inventory had growth factors. These SCCs fell into one of two categories:

b. SCCs that had multiple entries in the NEI but only a single SCC in the 2002 VISTAS base year inventory. The NEI was established using a process model and for some categories of animals, emissions were calculated for several aspects of the process. The CMU model version 3.6 which was the basis for the VISTAS 2002 Base F inventory did not use a process model. As a consequence a mapping of SCCs in the NEI projections and corresponding SCCs in the CMU inventory was made and for those SCCs an average growth factor was calculated from the NEI projections for use with the corresponding SCC in the CMU based 2002 Base F inventory.

c. There were also State, county, SCC trios in the 2002 VISTAS Base F inventory which had no corresponding emissions in the NEI files. For these instances, MACTEC first developed State level average growth factors from the NEI projections for use in growing these records. Even after developing State level average growth factors there were still some State/SCC pairs that did not have matching growth. For these records, MACTEC developed VISTAS regional average growth factors at the SCC level from the NEI data.

1. Once all of the growth factors were developed, they were used to project the emissions to 2009 and 2018. Growth factors were first applied at the State, county and SCC level. Then remaining records were grown with the State/SCC specific growth factors. Finally, any remaining ungrown records were projected at the SCC level using the VISTAS regional growth factor.

For the livestock categories, the NEI emission projections only had data for beef and dairy cattle, poultry and swine. Thus for other livestock categories and for fertilizers alternative growth factors were required.

The growth factors for other livestock categories and fertilizers were obtained from growth factors used for the IAQTR projections made by the U.S. EPA. The methodology for these categories was identical to that used for dairy, beef, poultry and swine with the exception that State/SCC and VISTAS/SCC growth factors were not required for these categories since the IAQTR data contained State, county and SCC level growth factors. The IAQTR data provided growth factors for 1996, 2007, 2010, 2015 and 2020. Linear interpolation was used to develop the growth factors for the intermediate years 2009 and 2018 required for the VISTAS projections.

There were a few exceptions to the methods used for projecting agricultural sources for the VISTAS projections. These exceptions were:

1. All swine emissions for North Carolina were maintained at 2002 levels for each projection year to capture a moratorium on swine production in that State.
2. Ammonia growth factors for a few categories (mainly feedlots) were assigned to be the same as growth factors for PM emissions from the NEI projections. This assignment was made because the CMU model showed emissions from these categories but the NEI projections did not show ammonia emissions but did show PM emissions.
3. No growth factors were found for horse and pony emissions. These emissions were held constant at 2002 levels.

There was no change in this method between Base F and Base G. Thus Base F and Base G agricultural emissions are the same in each inventory. Future efforts on the agricultural emissions category should look at any changes made to the CMU model to reflect the model farm approach used by EPA in their inventory plus any updated growth factors that may be more recent than the EPA inventory used to develop growth estimates for Base F/G.

2.2.2.2.1 Differences between 2009/2018

Methodologically, there was no difference in the way that 2009 and 2018 emissions were calculated for agricultural area sources. The growth factors were different (due to the linear interpolation used to calculate the values) but the calculation methods were identical. In addition there was no difference between Base F and Base G for this category. Thus Base F and Base G agricultural emissions are the same in each inventory.

Tables 2.2-1 show the differences between Base F and Base G emissions for all area sources (including agricultural sources but excluding fires) for the 2002 base year and 2009 and 2018 by State and pollutant.

Table 2.2-1 2002 Base Year Emissions and Percentage Difference for Base F and Base G (based on actual emissions).

2.2.3 Changes to Prescribed Fire for 2009/2018 Base G

Just prior to release of version 3.1 of the VISTAS inventory several Federal agencies indicated that they had plans for increased prescribed fire burning in future years and that the “typical” fire inventory would likely not adequately capture those increases (memo from Bill Jackson and Cindy Huber, August 13, 2004). However data were not readily available to incorporate those changes up through the Base F inventory. As a consequence MACTEC worked with Federal Land Managers to acquire the data necessary to provide 2009 and 2018 specific projections for the prescribed fire component of the Base G fire inventory. The 2009 and 2018 projections developed using the method described below are being used by VISTAS as the 2009 and 2018 base case inventories for all States except FL. For FL the supplied data from the FLMs is not being used as FL felt that their data adequately reflected current and future prescribed burning practices. The "typical" fire projection is the 2002 base prescribed fire projection.

One of the biggest issues in preparing the projection was how best to incorporate the data. Two agencies submitted data: Fish and Wildlife Service (FWS) and Forest Service (FS). FWS submitted annual acreage data by National Wildlife Refuge (NWR) and county with estimates of acres burned per day for each NWR. FS provided fire-by-fire acreage estimates based on mapping projected burning acreage to current 2002 modeling days. However, FWS did not submit data for VISTAS original base year preparation process, thus there was no known FWS data in the 2002 actual or typical inventories. Thus MACTEC had to develop a method that could use the county level data submitted by FWS.

In addition, despite the fact that the FS submitted fire-by-fire data for the 2002 actual inventory and had mapped the projections to current burn days in the 2002 actual inventory, MACTEC could not do a simple replacement of those records with the 2009/2018 projections. This situation was created because several VISTAS States run a prescribed fire permitting program. To avoid double counting, only State data was used in those States for the 2002 actual inventory. Thus there were no Federal data in those States since the Federal data could have potentially duplicated State-supplied prescribed fire data. In VISTAS States without permit programs, the FS supplied data for 2002 was used and those records were marked in database. Thus for those States, the FS supplied 2009/2018 data could be directly substituted for the 2002 data.

The method used by MACTEC to include the FS data applied a county level data approach for FS data where a State had a prescribed fire permitting program and a fire-by-fire replacement for FS data in States without permit programs. MACTEC used a county level approach for all of the FWS data. The approach used for each data set is discussed below.

For the FWS data MACTEC summed the annual acres burned supplied by the FWS across all NWRs in a county. We then subtracted out 2002 acreage for that county from the FWS projected acreage annual total to avoid double counting. The remaining acreage was then multiplied by 0.8 to account for blackened acres instead of the total perimeter acres that were reported. The revised total additional FWS acreage was then added to the total county "typical" acreage to determine future acreage burned for either 2009 or 2018. MACTEC then allocated the increased acreage to current modeling days. The average daily acres burned data provided by FWS per NWR/county was used to allocate the acreage to the correct number of days required to burn all of the acres. Guidance supplied by FWS indicated that up to three times the average daily acres burned could potentially be allocated to any one day. Thus if the estimated acreage per day were 100 acres then up to 300 acres could actually be allocated to a particular day. This approach (use of up to three times the average daily acres burned) was used if there were an insufficient number of 2002 modeling days available to account for all of the acreage increase. MACTEC used an incremental approach to using the increase above the base average daily acres. First we used twice the average daily acreage if that was sufficient to completely allocate the increased acreage over the total number of days available. If that wasn't sufficient then we used three times the average daily acres burned to allocate the acreage. We applied the highest increases to days in the database that already had the highest acreage burned since we felt those days were most likely to represent days with representative conditions for conducting prescribed burns.

The approach used by MACTEC for the FS was slightly different. For States that had permit programs, we used similar approach to the FWS county level approach. First we summed the FS data at county level, we then added that value to the typical acreage and then we allocated the acres to current modeling days. The mapping to current modeling days was performed by Bill Jackson of the USFS and provided to MACTEC. For States that do not have a prescribed fire permit program, MACTEC simply replaced the current fire-by-fire records in the database with fire-by-fire records from the FS and recalculated emissions based on fuel model and fuel loading. We also applied the same 0.8 correction for blackened acres applied to all FS supplied acreage as the supplied values represented perimeter acres.

An additional problem with developing year-specific prescribed fire projections was how to adequately capture the temporal profile for those fires. In the 2002 actual fire inventory, fires occur on same days as state/FLM records. In the 2002 "typical" year inventory, fire acreage increased or decreased from acreage on the same fire days as were in the 2002 actual inventory, since the acres were simply increased for each day based on a multiplier used to convert from actual to typical.

When prescribed fires acreage was added to a future year, MACTEC added acreage to individual fire days proportional to the annual increase (if acreage on a day is 10 percent of annual, add 10 percent of projected increase to that same day).

The table below shows how the FWS data for Okefenokee NWR were allocated for 2009 for Clinch County (Okefenokee NWR is located in four different counties). You can see that the total additional acres for the Clinch County portion of Okefenokee NWR was 1,956 acres. Two hundred eighty (280) acres were the estimated average daily acres burned for that NWR/county combination. Thus to allocate the entire 1,956 acres would require almost 7 burn days (1,956 divided by 280). However only 5 burn days were found for Clinch County in the 2002 actual fire database. Thus we allocated twice the average acreage to the burn day with the most acres burned in the 2002 actual fire database (since our method allowed us to increase the average daily acres burned up to three times the recommended level). Thus the first burn day received 560 acres and all others received 280 except the final day which received 276 to make the total equal to the required 1,956 acres. The table also indicates that the increased acres burned provided increases of from 10-48 percent in the acres burned on the individual burn days and an average of approximately 14 percent for the year as a whole.

CLINCH COUNTY	3/1/2002	4/1/2002	2/1/2002	1/1/2002	11/1/2002	12/1/2002	Total Annual
Acres (typical)	3,757	2,612	1,996	1,801	616	472	11,764
Add on FWS Projection	560	280	280	280	280	276	1,956
Total	4,316	2,891	2,276	2,080	895	747	13,720
Percent Increase	14.9%	10.7%	14.0%	15.6%	45.5%	58.5%	14.3%

The figure below shows the increases for prescribed burning in the four counties that comprise the Okefenokee NWR area (which also includes FS land). In this figure you can see the additional acreage added for the burn days from FWS and the individual day increases caused by projected increases in prescribed burning based on FS data. It should be noted that while the emissions represent 2009, all fire event dates listed are for 2002 to match up with the base year meteorology used in modeling exercises.

Table 2.2-4 shows the percentage difference between the 2009 and 2018 projections developed for Base F and Base G. Base G includes the revised prescribed burning estimates described above. Values are calculated using Base F as the basis for change, thus negative values imply an increase in emissions for Base G.

2.2.4 Quality Assurance steps

Throughout the inventory development process, quality assurance steps were performed to ensure that no double counting of emissions occurred, to ensure that a full and complete inventory was developed for VISTAS, and to make sure that projection calculations were working correctly. Quality assurance was an important component to the inventory development process and MACTEC performed the following QA steps on the stationary and agricultural area source components of the 2009 and revised 2018 projection inventories:

1. All final files were run through EPA's Format and Content checking software.
2. SCC level emission summaries were prepared and evaluated to ensure that emissions were consistent and that there were no missing sources.
3. Tier comparisons (by pollutant) were developed between the 2002 base year inventory and the 2009 and 2018 projection inventories. In addition, total VISTAS pollutant summaries were prepared to compare total emissions by pollutant between versions of the inventory (e.g., between Base F and Base G).
4. Data product summaries were provided to both the VISTAS Emission Inventory Technical Advisor and to the SIWG representatives for review and comment. Changes based on these comments were implemented in the files.
5. Version numbering was used for all inventory files developed. The version numbering process used a decimal system to track major and minor changes. For example, a major change would result in a version going from 1.0 to 2.0. A minor change would cause a version number to go from 1.0 to 1.1. Minor changes resulting from largely editorial changes would result in a change from 1.00 to 1.01.

2.3 Mobile Sources

Our general approach for assembling data was to use as much existing data from the pre-Base F preliminary projections as possible for these inventories, supplement these data with easily available stakeholder input, and provide the results for stakeholder review to ensure credibility. To develop the "base case" projections, MACTEC originally assembled data to develop two 2009 and 2018 base case inventories: 1) an inventory that included all "on-the-books" control programs and 2) an "on-the-way" inventory that included controls that were likely to be "on-the-way". For the Base F and Base G emission forecasts to the mobile source sector, "on-the-books" and "on-the-way" are defined with the same strategies and therefore only a single projection scenario was developed for each forecast year.

To ensure consistency across evaluation years, the 2009 and 2018 base case inventories were developed, to the maximum extent practical, using methodologies identical to those employed in developing the 2002 on-road portion of the revised 2002 VISTAS base year inventory. All modifications to the 2002 inventory methods were developed in consultation with the Mobile Source Special Interest Workgroup (MSSIWG). Generally, modifications were only made to properly account for actual changes expected in the intervening period (i.e., between 2002 and 2009 and between 2002 and 2018), but the underlying inventory development methodology was identical, except to the extent requested by VISTAS or the MSSIWG.

MACTEC developed a preliminary 2018 inventory in early 2004. That inventory was designed to 1) be used for modeling sensitivity evaluations and 2) help establish the methods that would be used for the final 2018 inventory and the initial 2009 inventory. Since that work took place prior to the revision of the 2002 base year inventory data files, MACTEC provided a review of the data and methods used to develop on-road mobile source input files for the initial 2002 base year inventory prior to developing the preliminary 2018 inventory. Through this review, MACTEC determined the following:

- On-road VMT. Most States provided local data for 2002 (or a neighboring year that was converted to 2002 using appropriate VMT growth surrogates such as population). Since these data were not applicable to 2018 due to intervening growth, input for 2018 was solicited from the MSSIWG. At the same time we researched county-specific growth rate data utilized for recent national rulemakings as a backstop approach to State supplied VMT projections.
- Modeling Temperatures. Actual 2002 temperatures were used for the initial 2002 base year inventory.
- Vehicle Registration Mix (age fractions by type of vehicle). A mix of State, local, and MOBILE6 default data were used for the 2002 initial base year inventory. Forecast data were solicited from the States, with a fallback position that we hold the fractions constant at their 2002 values.
- Vehicle Speed by Roadway Type. For the 2002 initial base year inventory, speeds varying by vehicle and road type were used.
- VMT Mixes (fraction of VMT by vehicle type). A mix of State, local, and quasi MOBILE6 default (i.e., MOBILE6 defaults normalized to better reflect local conditions) data were used for the 2002 initial base year inventory. Forecast data were solicited from the States.
- Diesel Sales Fractions. As with the VMT mix data, the diesel sales fraction data employed for the 2002 initial base year inventory represents a mix of State, local, and quasi MOBILE6 default data. The issues related to updating these data to 2018 are also

similar, but are complicated by the fact that MOBILE6 treats diesel sales fraction on a model year, rather than age specific basis. Therefore, diesel sales fractions generally cannot be held constant across time. Once again, we solicited any local projections, with a fallback position that we would keep the data for 2002 and earlier model years constant for the forecast inventory, supplemented with MOBILE6 default data for 2003 and newer model years.

- State/Local Fuel Standards. For the 2002 initial base year inventory, these data were based on appropriate local requirements and updated data for 2018 was only required if changes were expected between 2002 and 2018. There are some national changes in required fuel quality for both on-road and non-road fuels that are expected to occur between 2002 and 2018 and these would be reflected in the 2018 inventory in the absence of more stringent local fuel controls. Expected changes in local fuel control programs were solicited.

- Vehicle Standards. The 2002 initial base year inventory assumed NLEV applicability. This was altered to reflect Tier 2 for 2018, unless a State indicated a specific plan to adopt the California LEV II program. If so, we made the required changes to implement those plans for the preliminary 2018 inventory.

- Other Local Controls. This includes vehicle emissions inspection (i.e., I/M) programs, Stage II vapor recovery programs, anti tampering programs, etc. By nature, the assumptions used for the 2002 initial base year inventory vary across the VISTAS region, but our presumption is that these data accurately reflected each State's situation as it existed in 2002. If a State had no plans to change program requirements between 2002 and 2018, we proposed to maintain the 2002 program descriptions without change. However, if a State planned changes, we requested information on those plans. In the final implementation of the Base F and earlier inventories, Stage II controls were exercised in the area source component of the inventory, since the units used to develop Stage II refueling estimates are different between MOBILE6 and the NONROAD models. However, in the Base G inventories, Stage II refueling was moved to the on-road and non-road sectors.

Once the preliminary 2018 (pre-Base F) base case projection inventory data were compiled, MACTEC applied the data and methods selected and proceeded to develop the preliminary (pre-base F) base case 2018 projection inventories. The resulting inventories were provided to the MSSIWG in a user-friendly format for review. After stakeholder review and comment, the final preliminary 2018 base case inventories and input files were provided to VISTAS in formats identified by the VISTAS Technical Advisor (in this case, MOBILE input files and VMT, NONROAD input files and annual inventory files for NONROAD in NIF 3.0 format). Annual inventory files for MOBILE were not developed as part of this work, only input files and VMT forecasts. MOBILE emissions were calculated by VISTAS air quality modeling contractor using the provided files.

2.3.1 Development of on-road mobile source input files

As indicated above, MACTEC prepared a preliminary version of the 2018 base case mobile inventory input data files. These files were then updated to provide a final set of 2018 base case inventory input data files as well as a set of input files for 2009. The information below describes the updates performed on the preliminary 2018 files and the development of the 2009 input data files for Base F emission estimation.

Our default approach to preparing the revised 2018 and initial 2009 projection inventories for on-road mobile sources was to estimate the emissions by using either:

1. the revised 2002 data provided by each State coupled with the projection methods employed for the preliminary 2018 inventory, or
2. the same data and methods used to generate the preliminary 2018 inventory.

We also investigated whether or not there was more recent VMT forecasting data available (e.g., from the CAIR and if appropriate revised the default VMT growth rates accordingly. This did not affect any State that provided local VMT forecasting data, but would alter the VMT estimates used for other areas.

Since no preliminary 2009 inventory was developed there did not exist an option (2) above for 2009. As a consequence, MACTEC crafted the 2009 initial inventory for on-road mobile sources using methods identical to those employed for the 2018 preliminary inventories coupled with any changes/revisions provided by the States during the review of the revised 2002 base year and the 2018 preliminary inventories. Therefore, as was the case for 2018, we obtained from the States any input data revisions, methodological revisions, and local control program specifications (to the extent that they differed from 2002/2018).

2.3.1.1 Preparation of revised 2018 input data files

Preparation of the revised 2018 inventories required the following updates:

1. The evaluation year was updated to 2018 in all files.
2. The diesel fuel sulfur content was revised from 500 ppm to 11 ppm, consistent with EPA data for 2018 in all files.
3. Since the input data is model year, rather than age, specific for diesel sales fractions (with data for the newest 25 model years required), we updated all files that included

diesel sales fractions. In the revised 2002 base year files, the data included applied to model years 1978-2002. For 2018, the data included would reflect model years 1994-2018. To forecast the 2002 data, MACTEC took the data for 1994-2002 from the 2002 files and added data for 2003-2018. To estimate the data for these years, we employed the assumption employed by "default" in MOBILE6 -- namely that diesel sales fractions for 1996 and later are constant. Therefore, we set the diesel sales fractions for 2003-2018 at the same value as 2002.

4. VMT mix fractions must be updated to reflect expected changes in sales patterns between 2002 and 2018. If explicit VMT mix fractions are not provided, these changes are handled internally by MOBILE6 or externally through absolute VMT distributions. However, files that include explicit VMT mix fractions override the default MOBILE6 update and may or may not be consistent with external VMT distributions. MACTEC updated the VMT mix in such files as follows:

   First, we calculated the VMT fractions for LDV, LDT1, LDT2, HDV, and MC from the external VMT files for 2018. This calculation was performed in accordance with section 5.3.2 of the MOBILE6 Users Guide which indicates:

   LDV = LDGV + LDDV

   LDT1 = LDGT1 + LDDT

   LDT2 = LDGT2

   HDV = HDGV + HDDV

   MC = MC

   The resulting five VMT fractions were then split into the 16 fractions required by MOBILE6 using the distributions for 2018 provided in Appendix D of the MOBILE6 Users Guide. This approach ensures that explicit input file VMT fractions are consistent with the absolute VMT distributions prepared by MACTEC. These changes were made to all files that included VMT mixes.

5. All other input data were retained at 2002 values, except as otherwise instructed by the States. This includes all control program descriptions (I/M, Anti-Tampering Program [ATP], Stage II, etc.), all other fuel qualities (RVP, oxy content, etc.), all other vehicle descriptive data (registrations age distributions, etc.), and all scenario descriptive data. The State-specific updates performed are described below.

<u>Kentucky:</u>

MACTEC revised the 2018 input files for the Louisville, Kentucky area (Louisville Air Pollution Control District [APCD]) based on comments received relative to several components of

MOBILE input data. Based on these comments, the input files for Jefferson County, Kentucky were updated accordingly as follows:

a) I/M and tampering program definitions were removed since the program was discontinued at the end of 2003.

b) The "Speed VMT", "Facility VMT" and "Registration Age Distribution" file pointers were updated to reflect revised 2002 files provided by the Louisville APCD.

c) The "VMT Mix" data, which was previously based on the default approach of "growing" 2002 data, was replaced by 2018-specific data provided by the Louisville APCD.

North Carolina:

North Carolina provided a wide range of revised input data, including complete MOBILE6 input files for July modeling. MACTEC did not use the provided input files directly as they did not match the 2002 NC input files for critical elements such as temperature distributions and gasoline RVP (while they were close, they were slightly different). To maintain continuity between 2002 and 2018 modeling, MACTEC instead elected to revise the 2002 input files to reflect all control program and vehicle-related changes implied by the new 2018 files, while retaining the basic temperature and gasoline RVP assumptions at their 2002 values. Under this approach, the following changes were made:

a) NC provided a county cross reference file specific to 2018 that differed from that used for 2002. We removed files that were referenced in the 2002 input data and replaced those files with those referenced in the 2018 data. In addition, since NC only provided 2018 input files for July, we estimated the basic data for these new files for the other months by cross referencing the target files for 2002 by county against the target files for 2018 by county.

b) We then revised the 2002 version of each input file to reflect the 2018 "header" data included in the NC-provided 2018 files. These data are exclusively limited to I/M and ATP program descriptions, so that the 2002 I/M and ATP data were replaced with 2018 I/M and ATP data.

c) We retained the registration age fractions at their 2002 "values" (external file pointers) as per NC instructions.

d) We retained all scenario-specific data (i.e., temperatures, RVP, etc.) at 2002 values, which (as indicated above), were slightly different in most cases from data included in the 2018 files provided by NC. We believe these differences were due to small deviations between the data assembled to support VISTAS 2002 and the process used to generate the 2018 files provided by NC, and that revising the VISTAS 2002 data to reflect these variations was not appropriate given the resulting inconsistencies that would be reflected between VISTAS 2002 and VISTAS 2018.

e) NC also provided non-I/M versions of the 2018 input files that would generally be used to model the non-I/M portion of VMT. While these files were retained they were not used for the 2018 input data preparation.

Finally, NC also provided a speed profile file and a speed profile cross reference file for 2018. We did not use these in our updates as they have no bearing on the MOBILE6 input files, but they were maintained in case they needed to be included in SMOKE control files for a future year control strategy scenario.

Virginia:

In accordance with instructions from VA, the input files that referenced an external I/M descriptive program file (VAIM02.IM) were revised to reference an alternative external file (VAIM05.IM). This change was to make the I/M program more relevant to the year 2018.

One additional important difference was made with respect to the revised 2018 and initial 2009 on-road mobile source input data files for all States. MACTEC developed updated SMOKE ready input files rather than MOBILE6 files so that the input data could be used directly by the VISTAS modeling contractor to estimate on-road mobile source emissions during modeling runs.

2.3.1.2 Preparation of initial 2009 input data files

The methodology used to develop the 2009 on-road input files was based on forecasting the previously developed revised 2002 base year input files and is identical to that previously described for the revised 2018 methodology except as follows:

1. The evaluation year was updated to 2009.
2. Diesel fuel sulfur content was revised from 500 ppm to 29 ppm. The 29 ppm value was derived from an EPA report entitled "Summary and Analysis of the Highway Diesel Fuel 2003 Pre-compliance Reports" (EPA420-R-03-013, October 2003), which includes the Agency's estimates for the year-to-year fuel volumes associated with the transition from 500 ppm to 15 ppm diesel fuel. According to Table 2 of the report, there will be 2,922,284 barrels per day of 15 ppm diesel distributed in 2009 along with 110,488 barrels per day of 500 ppm diesel. Treating the 15 ppm diesel as 11 ppm on average (consistent with EPA assumptions and assumptions employed for the 2018 input files) and sales weighting the two sulfur content fuels results in an average 2009 diesel fuel sulfur content estimate of 29 ppm.

3. Diesel sales fractions were updated identically to 2018 except that the diesel sales fractions for 2003-2009 were set at the same value as those for 2002 (rather than 2003-2018).
4. VMT mix fractions were updated to 2009 using an identical method to that described for 2018.
5. All other input data were retained at 2002 values, except as otherwise instructed by individual States (see below). This includes all control program descriptions (I/M, ATP, Stage II, etc.), all other fuel qualities (RVP, oxy content, etc.), all other vehicle descriptive data (registration age distributions, etc.), and all scenario descriptive data.

In addition to the updates described above that were applied to all VISTAS-region inputs, the following additional State-specific updates were performed:

KY – Identical changes to those made for 2018 (but specific to 2009) were made for the 2009 input files.

NC – Identical changes to those made for 2018 (but specific to 2009) were made for the 2009 input files.

VA – Identical changes to those made for 2018 were made for 2009.

2.3.2 VMT Data

The basic methodology used to generate the 2009 and 2018 VMT for use in estimating on-road mobile source emissions was as follows:

1. All estimates start from the final VMT estimates used for the 2002 revised base year inventory.
2. Initial 2009 and 2018 VMT estimates were based on linear growth rates for each State, county, and vehicle type as derived from the VMT data assembled by the U.S. EPA for their most recent HDD (heavy duty diesel) rulemaking. The methodology used to derive the growth factors is identical to that employed for the preliminary 2018 VMT estimates (which is described in the next section).
3. For States that provided no independent forecast data, the estimates derived in step 2 are also the final estimates. These States are: Alabama, Florida, Georgia, Kentucky, Mississippi, and West Virginia. For States that provided forecast data, the provided data were used to either replace or augment the forecast data based on the HDD rule. These States, and the specific approaches employed, are detailed following the growth method description.

The steps involved in performing the growth estimates for VMT were as follows:

1. Linear growth estimates were used (although MACTEC investigated the potential use of nonlinear factors and presented that information to the MSSIWG, the decision was made to use linear growth factors instead of nonlinear).
2. Estimates were developed at the vehicle class (i.e., LDGV, LDGT1, LDGT2, etc.) level of detail since the base year 2002 estimates were presented at that level of resolution. In effect, the county and vehicle class specific growth factors were applied to the 2002 VMT estimates for each vehicle and road class.
3. Overall county-specific VMT estimates for each year (developed by summing the vehicle and road class specific forecasts) were then compared to overall county-specific growth. Since overall county growth is a more appropriate controlling factor as it includes the combined impacts of all vehicle classes, the initial year-specific vehicle and road class VMT forecasts were normalized so that they matched the overall county VMT growth. Mathematically, this process is as follows:

(Est_rv_f) = (Est_rv_i) * (C_20XX / Sum(Est_rv_i))

where:

Est_rv_f = the final road/vehicle class-specific estimates,

Est_rv_i = the initial road/vehicle class-specific estimates, and

C_20XX = the county-specific growth target for year 20XX.

Table 2.3-1 presents a basic summary of the forecasts for the preliminary 2018 inventory for illustrative purposes:

Table 2.3-1 2002 versus 2018 VMT (million miles per year)

State	2002	2018	Growth Factor
Alabama	55,723	72,966	1.309
Florida	178,681	258,191	1.445
Georgia	106,785	148,269	1.388
Kentucky	51,020	66,300	1.299
Mississippi	36,278	46,996	1.295
North Carolina	80,166	110,365	1.377
South Carolina	47,074	63,880	1.357
Tennessee	68,316	91,647	1.342
Virginia	76,566	102,971	1.345
West Virginia	19,544	24,891	1.274

The following States provided some types of forecast data for VMT. The information presented below indicates how those data were processed by MACTEC for use in the VISTAS projection inventories.

Kentucky:

Revised 2009 and 2018 VMT mix data were provided by the Louisville APCD. Therefore, the distribution of Jefferson County VMT by vehicle type within the KY VMT file was revised to reflect the provided mix. This did not affect the total forecasted VMT for either Jefferson County or the State, but does alter the fraction of that VMT accumulated by each of the eight vehicle types reflected in the VMT file. The following procedure was employed to make the VMT estimates consistent with the provided 2009/2018 VMT mix:

a) The 16 MOBILE6 VMT mix fractions were aggregated into the following five vehicle types: LDV, LDT1, LDT2, HDV, and MC.

b) The 8 VMT mileage classes were aggregated into the same five vehicle types (across all roadway types) and converted to fractions by normalizing against the total Jefferson County VMT.

c) The ratio of the "desired" VMT fraction (i.e., that provided in the Louisville APCD VMT mix) to the "forecasted" VMT fraction (i.e., that calculated on the basis of the forecasted VMT data) was calculated for each of the five vehicle classes.

d) All forecasted VMT data for Jefferson County were multiplied by the applicable ratio from step c as follows:

new LDGV = old LDGV * LDV ratio
new LDGT1 = old LDGT1 * LDT1 ratio
new LDGT2 = old LDGT2 * LDT2 ratio
new HDGV = old HDGV * HDV ratio
new LDDV = old LDDV * LDV ratio
new LDDT = old LDDT * LDT1 ratio
new HDDV = old HDDV * HDV ratio
new MC = old MC * MC ratio

The total forecasted VMT for Jefferson County was then checked to ensure that it was unchanged.

North Carolina:

North Carolina provided both VMT and VMT mix data by county and roadway type for 2018. Therefore, these data replaced the data developed for North Carolina using HDD rule growth rates in their entirety. Similar data were submitted for 2009. Table 2.3-2 presents the resulting VMT estimates which differ from the "default" HDD rule estimates as follows:

Table 2.3-2 VMT and HDD Rule Estimates for North Carolina (million miles per year)

North Carolina		
2002	106,795	
	State Data	**HDD Data**
2009	123,396	124,626
2018	129,552	146,989

As indicated, there are substantial reductions in the State-provided forecast data relative to that derived from the HDD rule. The growth rates for both 2009 and 2018 are only about half that implied by the HDD data (1.15 versus 1.17 for 2009 and 1.21 versus 1.38 for 2018). The resulting growth rates are the lowest in the VISTAS region.

NC did not provide VMT mix data for 2009. Therefore, the VMT mix fractions estimated using the "default" HDD rule growth rates were applied to the State-provided VMT estimates to generate vehicle-specific VMT. Essentially, the default HDD methodology produces VMT estimates at the county-road type-vehicle type level of detail, and these data can be converted into VMT fractions at that same level of detail. Note that these are not HDD VMT fractions, but VMT fractions developed from 2002 NC data using HDD vehicle-specific growth rates. In effect, they are 2002 NC VMT fractions "grown" to 2009.

The default VMT mix fraction was applied to the State-provided VMT data at the county and road type level of detail to generate VMT data at the county-road type-vehicle type level of detail. The one exception was for county 063, road 110, for which no VMT data were included in the HDD rule. For this single county/road combination, State-aggregate VMT mix fractions (using the HDD growth methodology) were applied to the county/road VMT data. The difference between road 110 VMT fractions across all NC counties is minimal, so there is no effective difference in utilizing this more aggregate approach vis-à-vis the more resolved county/road approach.

South Carolina:

South Carolina provided county and roadway type-specific VMT data for several future years. Data for 2018 was included and was used directly. Data for 2009 was not included, but was linearly interpolated from data provided for 2007 and 2010. The data were disaggregated into vehicle type-specific VMT using the VMT mixes developed for South Carolina using the HDD rule VMT growth rates. Table 2.3-3 presents the resulting VMT estimates which differ from the "default" HDD rule estimates as follows:

Table 2.3-3 VMT and HDD Rule Estimates for South Carolina (million miles per year)

South Carolina		
2002	**47,074**	
	State Data	**HDD Data**
2009	55,147	54,543
2018	65,133	63,880

Tennessee:

In general, Tennessee estimates are based on the HDD rule growth rate as described in step two. However, Knox County provided independent VMT estimates for 2018 and these were used in place of the HDD rule-derived estimates. The Knox County estimates were total county VMT data only, so these were disaggregated into roadway and vehicle-type VMT using the distributions developed for Knox County in step two using the HDD rule VMT growth rates. No data for Knox County were provided for 2009, so the estimates derived using the HDD rule growth factors were adjusted by the ratio of "Knox County provided 2018 VMT" to "Knox County HDD Rule-derived 2018 VMT." Table 2.3-4 presents the resulting VMT estimates which differ from the "default" HDD rule estimates as follows:

Table 2.3-4 VMT and HDD Rule Estimates for Tennessee (million miles per year)

Tennessee		
2002	68,316	
	State Data	**HDD Data**
2009	78,615	78,813
2018	91,417	91,647

Virginia:

Virginia provided county and roadway type-specific annual VMT growth rates and these data were applied to Virginia -provided VMT data for 2002 to estimate VMT in both 2009 and 2018. Virginia provided VMT mix data for 2002, but not 2009 or 2018. Therefore, the estimated VMT data for both 2009 and 2018 were disaggregated into vehicle type-specific VMT using the VMT mixes developed for VA using the HDD rule VMT growth rates. Table 2.3-5 presents the resulting VMT estimates which differ from the "default" HDD rule estimates as follows:

Table 2.3-5 VMT and HDD Rule Estimates for Virginia (million miles per year)

Virginia		
2002	77,472	
	State Data	**HDD Data**
2009	88,419	89,196
2018	104,944	104,164

2.3.3 Base G Revisions

For the development of the VISTAS 2009 and 2018 Base G inventories and input files, VISTAS states reviewed the Base F inputs, and provided corrections, updates and supplemental data as noted below.

For all states modeled, the Base G updates include:

- Adding Stage II refueling emissions calculations to the SMOKE processing.
- Revised the HDD compliance. (REBUILD EFFECTS = .1)
- Revised Diesel sulfur values in 2009 to 43 ppm and 2018 to 11 ppm

In addition to the global changes, individual VISTAS states made the following updates:

KY – updated VMT and M6 input values for selected counties

NC – revised VMT estimates, speeds and vehicle distributions and updated registration distributions for Mobile 6.

TN - revised VMT and vehicle registration distributions for selected counties.

WV – revised VMT input data

AL, FL, and GA and VA did not provide updates for 2009/2018 Base G, and the Base F inputs were used for these States.

2.3.4 Development of non-road emission estimates

The sections that follow describe the projection process used to develop 2009 and 2018 non-road projection estimates, as revised through the spring of 2006, for sources found in the NONROAD model and those sources estimated outside of the model (locomotives, airplanes and commercial marine vessels).

2.3.4.1 NONROAD model sources

NONROAD model input files were prepared in both the fall of 2004 (Base F) and the spring of 2006 (Base G) based on the corresponding 2002 base year inventory input files available at the time the forecasts were developed, with appropriate updates for the projection years. Generally, this means that the Base F 2002 base year input files (as updated through the fall of 2004) were used as the basis for Base F projection year input file development and Base G 2002 base year input files as updated through the spring of 2006 were used as the basis for Base G projection year input file development. Thus, all base year revisions are inherently incorporated into the associated projection year revisions. Other specific updates for the projection years for NONROAD model sources consist of:

1. Revise the emission inventory year in the model (as well as various output file naming commands) to be reflective of the projection year.
2. Revise the fuel sulfur content for gasoline and diesel powered equipment.
3. Implement a limited number of local control program charges (national control program changes are handled internally within the NONROAD model, so explicit input file changes are not required).

All equipment population growth and fleet turnover impacts are also handled internally within the NONROAD model, so that explicit changes input file changes are not required.

Base F Input File Changes:

To correctly account for diesel fuel sulfur content differences between the base and projection years, two sets of input and output files were prepared for each forecast year, one set for land-based equipment and one set for marine equipment. This two-step projection process was required for Base F, because diesel fuel sulfur contents varied between land-based and marine-based non-road equipment and the Draft NONROAD2004 used for Base F allowed only a single diesel fuel sulfur input. Thus, the model was executed separately for land-based and marine-based equipment for Base F, and the associated outputs subsequently combined. The specific diesel fuel sulfur contents modeled were as follows:

Diesel S (ppm)	2002	2009	2018
Land-Based	2500	348	11
Marine-Based	2500	408	56

As indicated, the Draft NONROAD2004 model was run with both sets of input files and the output file results were then combined to produce a single NONROAD output set.

To correctly account for the national reduction in gasoline sulfur content (a national control not explicitly handled by the NONROAD model), all NONROAD input files for both 2009 and 2018 were revised to reflect a gasoline fuel sulfur content of 30 ppmW.

Base G Input File Changes:

With the release of Final NONROAD2005 that was used for the Base G projection year inventory development, the NONROAD model is capable of handling separate diesel fuel sulfur inputs for land-based and marine-based non-road equipment in a single model execution. Therefore, the two step modeling process described above for Base F updates was no longer required. Instead, the differential diesel fuel sulfur values are assembled into a single NONROAD input file as follows:

Diesel S (ppm)	2002	2009	2018
Land-Based	2500	348	11
Marine-Based	2638	408	56

Additionally, revised gasoline vapor pressure data were provided by Georgia regulators for 20 counties[5] where reduced volatility requirements were established in 2003. Since this requirement began after the 2002 base year, the vapor pressure values in the base year input files for these counties are not correct for either the 2009 or 2018 forecast years. Therefore, to correctly forecast emissions in these counties, the forecast year gasoline vapor pressure inputs were revised to:

Gasoline RVP (psi)	2002	2009	2018
Spring	9.87	9.2	9.2
Summer	9.0	7.0	7.0
Fall	9.87	9.2	9.2
Winter	12.5	12.5	12.5

The summer vapor pressure was simply set equal to the 2003 control value, while the spring and fall vapor pressures were adjusted to reflect a single month of the reduced volatility limit. The winter volatility was assumed to be unaffected by the summertime control requirement.

2.3.4.1.1 Differences between 2009/2018

Other than diesel fuel sulfur content and the year of the projections, there are no differences in the methodology used to estimate emissions from NONROAD model sources. As indicated above, however the Base F 2009/2018 projections were developed using Draft NONROAD2004, while the Base G 2009/2018 projections were made using Final NONROAD2005.

5 The specific counties are: Banks, Chattooga, Clarke, Floyd, Gordon, Heard, Jasper, Jones, Lamar, Lumpkin, Madison, Meriwether, Monroe, Morgan, Oconee, Pike, Polk, Putnam, Troup, and Upson.

2.3.4.2 Non-NONROAD model sources

Using the 2002 base year emissions inventory for aircraft, locomotives, and commercial marine vessels (CMV) prepared as described earlier in this document, corresponding emission projections for 2009 and 2018 were developed in both the fall of 2004 (Base F) and the spring of 2006 (Base G). This section describes the procedures employed in developing those inventories. The information presented is intended to build off of that presented in the section describing the 2002 Base F base year inventory. It should be recognized that for both the Base F and Base G inventories, the base year inventory used to develop the emission forecasts was the latest available at the time of forecast development. Generally, this means that the 2002 base year inventory as updated through the fall of 2004 was used as the basis for the Base F projection year inventory development, and the Base F 2002 base year inventory was used as the basis for Base G projection year inventory development. Thus, all base year revisions (as described earlier in this document) are inherently incorporated into the associated projection year revisions.

Base F Revisions:

Table 2.3-6 shows the 2002 base year emissions for each State in the VISTAS region for aircraft, locomotives and CMV (as they existed prior to Base F development).

Table 2.3-6 Pre-Base F 2002 Aircraft, Locomotive, and Non-Recreational Marine Emissions (annual tons, as of the fall of 2004)

Source	State	CO	NO_x	PM_{10}	$PM_{2.5}$	SO_2	VOC
Aircraft (2275)	AL	3,787	175	226	87	17	196

Grand Total		**118,739**	**420,228**	**22,823**	**21,170**	**52,931**	**24,881**

Although some of the data utilized was updated, the methodology used to develop the Base F 2009 and 2018 emissions forecasts for aircraft, locomotives, and CMV is identical to that used earlier to develop preliminary 2018 Base 1 ("On the Books") and 2018 Base 2 ("On the Way") inventories. Briefly, the methodology relies on growth and control factors developed from inventories used in support of recent EPA rulemakings, and consists of the following steps:

(a) Begin with the 2002 base year emission estimates for aircraft, locomotive, and CMV as described above (at the State-county-SCC-pollutant level of detail).

(b) Detailed inventory data (both before and after controls) for these same emission sources for 1996, 2010, 2015, and 2020 were obtained from the EPA's Clean Air Interstate Rule (CAIR) Technical Support Document (which can be found at http://www.epa.gov/cair/pdfs/finaltech01.pdf). Using these data, combined growth and control factors for the period 2002-2009 and 2002-2018 were estimated using straight line interpolation between 1996 and 2010 (for 2009) and 2015 and 2020 (for 2018). This is done at the State-county-SCC-pollutant level of detail.

(c) The EPA growth and control data are matched against the 2002 VISTAS base year data using State-county-SCC-pollutant as the match key. Ideally, there would be a one-to-one match and the process would end at this point. Unfortunately, actual match results were not always ideal, so additional matching criteria were required. For subsequent reference, this initial (highest resolution) matching criterion is denoted as the "CAIR-Primary" criterion.

(d) A second matching criterion is applied that utilizes a similar, but higher-level SCC (lower resolution) matching approach. For example, SCC 2275020000 (commercial aircraft) in the 2002 base year inventory data would be matched with SCC 2275000000 (all aircraft) in the CAIR data. This criterion is applied to records in the 2002 base year emissions file that are not matched using the "CAIR-Primary" criterion, and is also performed at the State-county-SCC-pollutant level of detail. For subsequent reference, this is denoted as the "CAIR-Secondary" criterion. At the end of this process, a number of unmatched records remained, so a third level matching criterion was required.

(e) In the third matching step, the most frequently used SCC in the EPA CAIR files for each of the aircraft, locomotive, and commercial marine sectors was averaged at the State level to produce a "default" State and pollutant-specific growth and control factor for the sector. The resulting factor is used as a "default" growth factor for all unmatched county-SCC-pollutant level data in each State. In effect, State-specific growth data are applied to county level data for which an explicit match between the VISTAS 2002 base year data and EPA CAIR data could not be developed. The default growth and control

SCCs are 2275020000 (commercial aircraft) for the aircraft sector, 2280002000 (commercial marine diesel total) for the CMV sector, and 2285002000 (railroad equipment diesel total) for the locomotive sector. Matches made using this criterion are denoted as “CAIR-Tertiary” matches.

(f) According to EPA documentation, the CAIR baseline emissions include the impacts of the (then proposed) Tier 4 (T4) non-road diesel rulemaking, which implements a low sulfur fuel requirement that affects both future CMV and locomotive emissions. However, the impacts of this rule were originally intended to be excluded from the initial VISTAS 2018 forecast, which was to include only “on-the-books” controls. (The T4 rule was finalized subsequent to the development of the preliminary 2018 inventory in March of 2004.) Given its final status, T4 impacts were moved into the “on the books” inventory for non-road equipment. In addition, since there are no other proposed rules affecting the non-road sector between 2002 and 2018, there is no difference between the 2018 “on the books” and 2018 “on the way” inventories for the sector; so that only a single forecast inventory (for each evaluation year) was developed. Nevertheless, since the algorithms developed to produce the VISTAS forecasts were developed when there was a distinction between the “on the books” and “on the way” inventories, the distinct algorithms used to produce the two inventories have been maintained even though the conceptual distinctions have been lost. This approach was taken for two reasons. First, it allowed the previously developed algorithms to be utilized without change. Second, it allowed for separate treatment of the T4 emissions impact which was important as those impacts changed between the proposed and final T4 rules. Thus, previous EPA inventories that include the proposed T4 impacts would not be accurate. Therefore, the procedural discussion continues to reflect the distinctions between non-T4 and T4 emissions, as these distinctions continue to be intrinsically important to the forecasting process. Therefore, a second set of EPA CAIR files that excluded the Tier 4 diesel impacts was obtained and the same matching exercise described above in steps (b) through (e) was performed using these “No T4” files. It is important to note that the matching exercise described in steps (b) through (e) cannot simply be replaced because the “No T4” files obtained from the EPA include only those SCCs specifically affected by the T4 rule (i.e., diesel CMV and locomotives). So in effect, the matching exercise was augmented (rather than replaced) with an additional three criteria analogous to those described in steps (c) through (e), and these are denoted as the “No T4-Primary,” “No T4-Secondary,” and “No T4-Tertiary” criteria. Because they exclude the impacts of the proposed T4 rule, matches using the “No T4” criteria supersede matches made using the basic CAIR criteria (as described in steps (c) through (e) above).

(g) The CAIR matching criteria were overridden for any record for which States provided local growth data. Only North Carolina provided these forecasts, as that State has provided specific growth factors for airport emissions in four counties. Because the provided data were based on forecasted changes in landings and takeoffs at major North Carolina airports, the factors were applied only to commercial (SCC 2275020000) and air taxi (SCC 2275060000) emissions. Emissions forecasts for military and general aviation aircraft operations, as well as all aircraft operations in counties other than the four identified in the North Carolina growth factor submission, continued to utilize the growth factors developed according to steps (b) through (f) above. Table 2.3-7 presents the locally generated growth factors applied in North Carolina.

Table 2.3-7 Locally Generated Growth Factors for North Carolina

FIP	2009 Factor	2018 Factor
37067	0.71	0.84
37081	0.97	0.89
37119	1.15	1.01
37183	0.88	0.81

Note:

Growth factor = Year Emissions/2002 Emissions.
Under CAIR approach, 2009 = 1.16 to 1.17 for all 4 counties.
Under CAIR approach, 2018 = 1.36 to 1.37 for all 4 counties.

(h) Using this approach, each State-county-SCC-pollutant was assigned a combined growth and control factor using the EPA CAIR forecast or locally provided data. The 22,838 data records for aircraft, locomotives, and CMV in the 2002 revised base year emissions file were assigned growth factors in accordance with the following breakdown:

48 records matched State-provided growth factors,
4,179 records matched using the CAIR-Primary criterion,
240 records matched using the CAIR-Secondary criterion,
7,463 records matched using the CAIR-Tertiary criterion,
720 records matched using the No T4-Primary criterion,
3,858 records matched using the No T4-Secondary criterion, and
6,330 records matched using the No T4-Tertiary criterion.

(i) Finally, the impacts of the T4 rule as adopted were applied to the grown "non T4" emission estimates. The actual T4 emission standards do not affect aircraft, locomotive, or CMV directly, but associated diesel fuel sulfur requirements do affect locomotives and CMV. Lower fuel sulfur content affects both SO_2 and PM emissions. Expected fuel sulfur contents were obtained for each evaluation year from the EPA technical support document for the final T4 rule (*Final Regulatory Analysis: Control of Emissions from Non-road Diesel Engines,* EPA420-R-04-007, May 2004). According to that document, the average diesel fuel sulfur content for locomotives and CMV is expected to be 408 ppmW in 2009 and 56 ppmW in 2018. These compare to expected non-T4 fuel sulfur levels of 2599 ppmW in 2009 and 2336 ppmW in 2018. Table 2.3-8 uses calculated emissions estimates for base and T4 control scenarios to estimate emission reduction impacts.

Table 2.3-8 Estimated Emission Reduction Impacts based on T-4 Rule

				2009	2018
CMV SO_2	=	Non-T4 SO_2	×	0.1569	0.0241
Locomotive SO_2	=	Non-T4 SO_2	×	0.1569	0.0241
CMV PM	=	Non-T4 PM	×	0.8962	0.8762
Locomotive PM	=	Non-T4 PM	×	0.8117	0.7734

However, since the diesel fuel sulfur content assumed for the 2002 VISTAS base year inventory, upon which both the 2009 and 2018 inventories were based, is 2500 ppmW, a small adjustment to the emission reduction multipliers calculated from the T4 rule is appropriate since they are measured relative to modestly different sulfur contents (2599 ppmW for 2009 and 2336 ppmW for 2018). Correcting for these modest differences produces the emission reduction impact estimates relative to forecasts based on the VISTAS 2002 inventory shown in Table 2.3-9.

Table 2.3-9 Estimated Emission Reduction Impacts Relative to VISTAS 2002 Base Year Values

				2009	2018
CMV SO_2	=	Non-T4 SO_2	×	0.1632	0.0225
Locomotive SO_2	=	Non-T4 SO_2	×	0.1632	0.0225
CMV PM	=	Non-T4 PM	×	0.9004	0.8685
Locomotive PM	=	Non-T4 PM	×	0.8187	0.7610

These factors were applied directly to the non-T4 emission forecasts to produce the final VISTAS 2009 and 2018 emissions inventories for aircraft, locomotive, and CMV.

The only exception is for Palm Beach County, Florida, where CMV emissions are reported as “all fuels” rather than separately by residual and diesel fuel components. To estimate T4 impacts in Palm Beach County, the ratio of diesel CMV emissions to total

CMV emissions in the remainder of Florida was calculated and the T4 impact estimates for Palm Beach County were adjusted to reflect that ratio. Table 2.3-10 shows the calculated diesel CMV ratios.

Table 2.3-10 Diesel CMV Adjustment Ratios for Palm Beach County, FL

GROWTH BASIS	SO_2	PM
2009 (1996, 2020 Growth Basis)	0.2410	0.7861
2009 (1996, 2010, 2015, and 2020 Growth Basis)	0.1279	0.7875
2018 (1996, 2020 Growth Basis)	0.2432	0.7925
2018 (1996, 2010, 2015, and 2020 Growth Basis)	0.2624	0.7918

The differences between the growth bases are discussed in detail below.

Combining these ratios with the T4 impact estimates for diesel engines, as presented above, yields the following impact adjustment factors for Palm Beach County:

Table 2.3-11 Overall Adjustment Factors for Palm Beach County, FL

GROWTH BASIS		
2009 SO_2 (19, 20 Growth Basis)	0.7894	[0.1632×0.2410+(1-0.2410)]
2009 SO_2 (96, 10, 15, and 20 Growth Basis)	0.8930	[0.1632×0.1279+(1-0.1279)]
2018 SO_2 (96, 20 Growth Basis)	0.7623	[0.0225×0.2432+(1-0.2432)]
2018 SO_2 (96, 10, 15, and 20 Growth Basis)	0.7436	[0.0225×0.2624+(1-0.2624)]
2009 PM (19, 20 Growth Basis)	0.9217	[0.9004×0.7861+(1-0.7861)]
2009 PM (96, 10, 15, and 20 Growth Basis)	0.9216	[0.9004×0.7875+(1-0.7875)]
2018 PM (96, 20 Growth Basis)	0.8958	[0.8685×0.7925+(1-0.7925)]
2018 PM (96, 10, 15, and 20 Growth Basis)	0.8959	[0.8685×0.7918+(1-0.7918)]

The differences between the growth bases are discussed in detail below.

Utilizing this approach, emission inventory forecasts for both 2009 and 2018 were developed. As indicated in step (b) above, basic growth factors were developed using EPA CAIR inventory data for 1996, 2010, 2015, and 2020. From these data, equivalent EPA CAIR inventories for 2002 and 2009 were developed through linear interpolation of the 1996 and 2010 inventories, while an equivalent CAIR inventory for 2018 was developed through linear interpolation of the 2015 and 2020 inventories. Growth factors for 2009 and 2018 were then estimated as the ratios of the CAIR 2009 and 2018 inventories to the CAIR 2002 inventory.

During the development of the preliminary 2018 VISTAS inventory in March 2004, this process yielded reasonable results and exhibited no particular systematic concerns. However, when the 2009 Base F inventory was developed, significant concerns related to SO_2 and PM were encountered. Essentially, what was revealed by the Base F 2009 forecast was a series of apparent inconsistencies in the CAIR 2010 and 2015 emission inventories (as compared to the 1996 and 2020 CAIR inventories) that were masked during the construction of the “longer-term” 2018 inventory.

The apparent inconsistencies are best illustrated by looking at the actual data extracted from the CAIR inventory files. Note that although a limited example is being presented, the same general issue applies throughout the CAIR files. For FIP 01001 (Autauga County, Alabama) and SCC 2285002000 (Diesel Rail), the CAIR inventories indicate SO_2 emission estimates as shown in Table 2.3-12.

Table 2.3-12 SO_2 Emissions for Diesel Rail in Autauga County, AL from the CAIR Projections

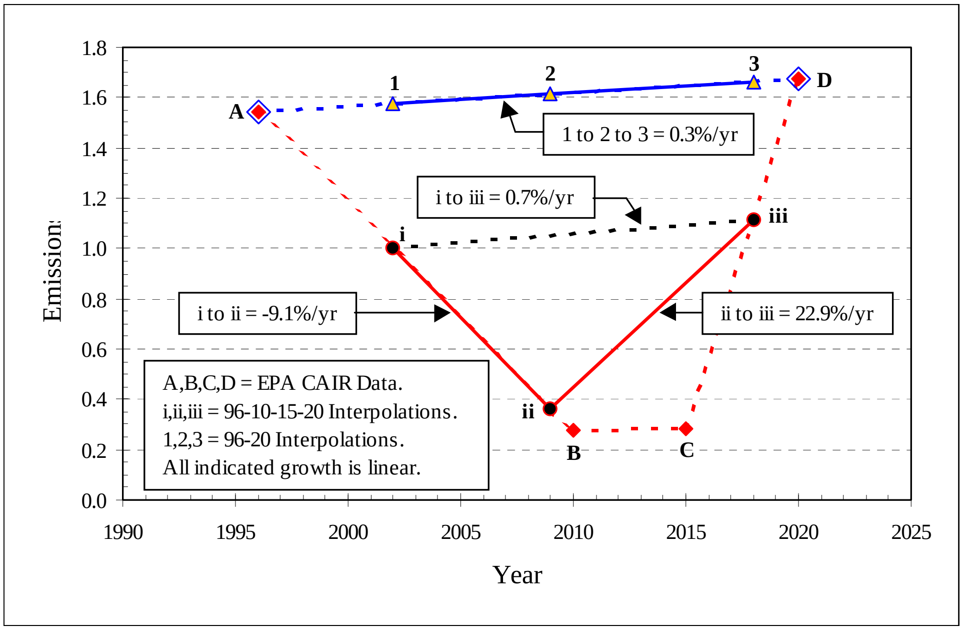
YEAR	TONS
1996:	15.3445
2010:	2.7271
2015:	2.8178
2020:	16.6232

Clearly, there is a major drop in emissions between 1996 and 2010, followed by a major increase in emissions between 2015 and 2020. Several observations regarding these changes are important. First, the CAIR data were reported to exclude the T4 rule, so that the drop in emissions should be related to something other than simply a change in diesel fuel sulfur content. Second, if the T4 rule impacts were “accidentally” included in the estimates, there should be a resultant 90 percent drop in diesel sulfur between 2010 and 2015; so such inclusion is unlikely. Third, the rate of growth between 2015 and 2020 (43 percent *per year* compound or 97 percent *per year* linear) is well beyond any reasonable expectations for rail service; and fuel sulfur content during this period is constant both with and without T4. In short, there appeared to be no rational explanation for the data, yet the same basic relations are observed for thousands of CAIR inventory records.

For the most part, the issue seems to be centered on SO_2 and PM records, which are those records primarily affected by the T4 rule. But, as noted above, there does not seem to be any pattern of consistency that would indicate that either inclusion or exclusion of T4 rule impacts is the underlying cause. Moreover, where they occur, the observed growth extremes generally affect both SO_2 and PM equally, while one would expect PM effects to be buffered if the T4 rule was the underlying cause, since changes in diesel fuel sulfur content will only affect a fraction of PM (i.e., sulfate), while directly reducing SO_2.

The data presented in Figure 2.3-1 illustrates what this meant to the VISTAS forecasting process. Figure 2.3-1 depicts the same data presented above for Autauga County, Alabama, but normalized so that the interpolated 2002 CAIR emissions estimate equals unity. The "raw" CAIR data is depicted by the markers labeled A, B, C, and D. Interpolated data for 2002 and 2009, based on 1996 and 2010 CAIR data, is depicted by the markers labeled "i" and "ii." Interpolated data for 2018, based on 2015 and 2020 CAIR data is depicted by the marker labeled "iii." The relationship between marker "iii" and marker "i" is exactly the relationship used to construct the preliminary (e.g., pre-Base F) 2018 VISTAS inventory (i.e., a linear growth rate equal to 0.7 percent per year). Thus, it is easy to see that although there is a major "dip and rise" between 2002 and 2018, it is essentially masked unless data for intervening years are examined. Since no intervening year was examined for the preliminary 2018 inventory, the "dip and rise" was not discovered. However, upon the development of the 2009 inventory forecast, the issue became obvious, as the marker labeled "ii" readily illustrates. In effect, the 2009 inventory reflected very low negative "growth rates" for some SCCs and pollutants relative to the 2002 inventory, while the 2018 inventory reflected very high and positive growth rates for those same SCCs and pollutants. In effect, the path between 2002 and 2018 that previously looked like the dotted line connecting markers "i" and "iii," now looks like the solid line connecting markers "i", "ii," and "iii." For reference purposes, this path is hereafter referred to as the 1996, 2010, 2015, and 2020 growth basis, since all interpolated data is based on CAIR data for those four years.

Figure 2.3-1 Impacts of the Apparent CAIR Inventory Discrepancy



In light of the apparent discrepancies inherent in the 1996, 2010, 2015, and 2020 growth basis data and the inconsistencies its use would impart into the 2009 and 2018 VISTAS inventories, a secondary forecasting method was developed. This second method relies on the apparent consistency between the 1996 and 2020 non-T4 CAIR inventories, interpolating equivalent 2002, 2009, and 2018 inventories solely from these two inventories. In effect, the CAIR inventories for 2010 and 2015 are ignored. In Figure 2.3-1, this secondary approach is depicted by the data points that lie along the lines connecting markers A and D. Markers A and D represent the 1996 and 2020 CAIR inventories, and the markers labeled 1, 2, and 3 represent the interpolated 2002, 2009, and 2018 CAIR equivalent inventories. The growth rate between 2009 and 2002 is then equal to the ratio of the 2009 and 2002 CAIR inventories, while that between 2018 and 2002 is equal to the ratio of the 2018 and 2002 CAIR inventories. For the example data, the resulting linear growth estimate is 0.3 percent per year. For reference purposes, this path is hereafter referred to as the 1996-2020 growth basis, since all interpolated data are based on CAIR data for only those two years.

It is perhaps worth noting that the only elements of Figure 2.3-1 that have any bearing on the VISTAS inventories are the growth rates. The absolute CAIR data are of importance only in determining those rates, as all VISTAS inventories were developed on the basis of the VISTAS 2002 base year inventory, not any of the CAIR inventories. So referring to Figure 2.3-1, the two growth options are summarized in Table 2.3-13.

Table 2.3-13 Growth Options based on CAIR Data

GROWTH BASIS	PERCENT PER YEAR
1996, 2010, 2015, 2020 Growth Basis:	-9.1% per year (linear) between 2002 and 2009
1996-2020 Growth Basis:	+0.3% per year (linear) between 2002 and 2009
1996, 2010, 2015, 2020 Growth Basis:	+22.9% per year (linear) between 2009 and 2018
1996-2020 Growth Basis:	+0.3% per year (linear) between 2009 and 2018
1996, 2010, 2015, 2020 Growth Basis:	+0.7% per year (linear) between 2002 and 2018
1996-2020 Growth Basis:	+0.3% per year (linear) between 2002 and 2018

Of course, these specific rates are applicable only to the example case (i.e., diesel rail SO_2 in Autauga County, Alabama), but there are thousands of additional CAIR records that are virtually identical from a growth viewpoint.

While forecast inventories for aircraft, locomotives, and CMV were developed for 2009 and 2018 using both growth methods, it was ultimately decided to utilize the 1996-2020 growth basis for Base F since it provided more reasonable growth rates for 2009. Tables 2.3-14 and 2.3-15 present a summary of each Base F inventory, while Tables 2.3-16 and 2.3-17 present the associated change in emissions for each Base F forecast inventory relative to the Base F 2002 base year VISTAS inventory. The larger reduction in CMV SO_2 emissions in 2009 and 2018 (relative to 2002) for Virginia and West Virginia is notable relative to the other VISTAS States, but this has been checked and is attributable to a high diesel contribution to total CMV SO_2 in the 2002 inventories for these two States.

Figures 2.3-2 through 2.3-13 graphically depict the relationships between the various Base F inventories and preliminary 2002 and 2018 projections prepared prior to Base F. There are two figures for each pollutant, the first of which presents a comparison of total VISTAS regional emission estimates for aircraft, locomotives, and CMV, and the second of which presents total VISTAS region emission estimates for locomotives only. This two figure approach is intended to provide a more robust illustration of the differences between the various inventories, as some of the differences are less distinct when viewed through overall aggregate emissions totals. All of the figures include the following emissions estimates:

- The 2002 Base F base year VISTAS emissions inventory (labeled as “2002”),
- The 2002 pre-Base F base year VISTAS emissions inventory (labeled as “2002 Prelim”),
- The Base F 2009 VISTAS emissions inventory developed using growth rates derived from 1996 and 2020 EPA CAIR data (labeled as “2009”),
- The Base F 2018 VISTAS emissions inventory developed using growth rates derived from 1996 and 2020 EPA CAIR data (labeled as “2018”), and
- The pre-Base F 2018 VISTAS emissions inventory estimates as developed using growth rates derived from 1996, 2010, 2015, and 2020 EPA CAIR data (labeled as “2018 Prelim”).

All 12 figures generally illustrate a reduction in emissions estimates between the 2002 pre-Base F emission estimates published in February 2004 (the initial 2002 VISTAS inventory) and the 2002 Base F emission estimates. This reduction generally results from emission updates reflected in the State 2002 CERR submittals used to develop the Base F 2002 base year inventory, although the major differences in aggregate PM emission estimates are driven to a greater extent by modifications in the methodology used to estimate aircraft PM in the Base F 2002 base year inventory (as documented under the base year inventory section of this report).

Base G Revisions:

Table 2.3-18 shows the Base G 2002 base year emissions for each State in the VISTAS region for aircraft, locomotives and CMV. Although some of these data are updated relative to those used as the basis of the Base F emissions forecasts, the methodology used to develop 2009 and 2018 emissions forecasts for aircraft, locomotives, and CMV for Base G is identical to that used for Base F (as documented above). The only exceptions are as follows:

(a) As indicated in the discussion of the Base F forecasts, the CAIR (growth rate) matching criteria were overridden for any record for which States provided local growth data. For Base F, only North Carolina provided such data. However, for Base G, Kentucky regulators provided growth data for aircraft emissions associated with Cincinnati/Northern Kentucky International Airport (located in Boone County, Kentucky). These data were applied to all pollutants and all aircraft types (i.e., military aircraft (SCC 2275001000), commercial aircraft (SCC 2275020000), general aviation aircraft (SCC 2275050000), and air taxi aircraft (SCC 2275060000)). Emissions forecasts for all aircraft operations in counties other than Boone continued to utilize the growth factors developed according to the CAIR matching criteria. Table 2.3-19 presents the locally generated growth factors applied in Kentucky. It should be recognized that although the locally provided growth factors presented in the table are significantly greater than those that would apply under the CAIR matching criteria, this is to be expected as local regulators noted a very significant decline in activity at the Cincinnati/Northern Kentucky International Airport in 2002 (relative to activity in preceding years). Moreover, this downward spike seems to have been alleviated since 2002, so that the provided growth factors represent not only "routine" growth expected between 2002 and the two forecast years, but growth required to offset the temporary decline observed in 2002.

Table 2.3-19 Locally Generated Growth Factors for Kentucky

FIP	2009 Factor	2018 Factor
21015	1.31	1.81

Note:

Growth factor = Year Emissions/2002 Emissions.
Under CAIR approach, 2009 = 0.99 to 1.17.
Under CAIR approach, 2018 = 0.97 to 1.40.

(b) Because of the additional emissions records added in Alabama, as discussed in the Base G 2002 base year inventory section of this report, the total number of emissions records in the Base G 2009 and 2018 forecasts increased to 23,042 (as compared to 22,838 for Base F). The 23,042 data records for aircraft, locomotives, and CMV were assigned growth factors in accordance with the following breakdown:

72 records matched State-provided growth factors,
4,287 records matched using the CAIR-Primary criterion,
240 records matched using the CAIR-Secondary criterion,
7,511 records matched using the CAIR-Tertiary criterion,
720 records matched using the No T4-Primary criterion,
3,858 records matched using the No T4-Secondary criterion, and
6,354 records matched using the No T4-Tertiary criterion.

Tables 2.3-20 and 2.3-21 present a summary of the resulting Base G 2009 and 2018 inventories, while Tables 2.3-22 and 2.3-23 present the associated change in emissions for each forecast inventory relative to the Base G 2002 base year VISTAS. As was the case with Base F, the larger reduction in CMV SO_2 emissions in 2009 and 2018 (relative to 2002) for Virginia and West Virginia is notable relative to the other VISTAS States, but is attributable to a high diesel contribution to total CMV SO_2 in the 2002 inventories for these two States.

Figures 2.3-14 through 2.3-25 graphically depict the relationships between the various inventories, as revised through Base G. There are two figures for each pollutant, the first of which presents a comparison of total VISTAS regional emission estimates for aircraft, locomotives, and CMV, and the second of which presents total VISTAS region emission estimates for locomotives only. This two figure approach is intended to provide a more robust illustration of the differences between the various inventories, as some of the differences are less distinct when viewed through overall aggregate emissions totals. All of the figures include the following emissions estimates:

- The Base G 2002 base year VISTAS emissions inventory (labeled as "2002"),
- The pre-Base F 2002 base year VISTAS emissions inventory (labeled as "2002 Prelim"),
- The Base G 2009 VISTAS emissions inventory developed using growth rates derived from 1996 and 2020 EPA CAIR data (labeled as "2009"),
- The Base G 2018 VISTAS emissions inventory developed using growth rates derived from 1996 and 2020 EPA CAIR data (labeled as "2018"), and
- The pre-Base F 2018 VISTAS emissions inventory estimates developed using growth rates derived from 1996, 2010, 2015, and 2020 EPA CAIR data (labeled as "2018 Prelim").

All 12 figures generally illustrate a reduction in emissions estimates between the pre-Base F 2002 emission estimates published in February 2004 and the Base G 2002 base year emission estimates. This reduction generally results from emission updates reflected in the Base F State CERR submittals, although the major differences in aggregate PM emission estimates are driven to a greater extent by modifications in the methodology used to estimate aircraft PM in the Base F revisions to the 2002 Base F base year inventory (as documented under the base year inventory section of this report).

2.3.4.3 Emissions from NONROAD Model Sources in Illinois, Indiana, and Ohio

Base G projection inventories for 2009 and 2018 for NONROAD model sources in the states of Illinois, Indiana, and Ohio were produced using a methodology identical to that employed to develop a Base G 2002 base year inventory for the same states (as documented earlier in this report). This method consists of the extraction of a complete set of county-level input data applicable to each of the three states (in each of the two projection years) from the latest version of the EPA's NMIM model. This includes appropriate consideration of all non-default NMIM input files generated by the Midwest Regional Planning Organization as documented earlier in the discussion of the Base G 2002 base year inventory. These input data were then assembled into appropriate input files for the Final NONROAD2005 model and emission estimates were produced using the same procedure employed for the VISTAS region.

Changes noted between the base year (2002) and forecast year (2009 and 2018) input data extracted from NMIM include differences in gasoline vapor pressure, gasoline sulfur content, and diesel sulfur content in most counties. All temperature data (minimum, maximum, and average daily temperatures) was constant across years.

As described in the discussion of the Base G 2002 base year inventory, counties in the three states were grouped for modeling purposes using a temperature aggregation scheme that allowed for county-specific temperature variations of no more that 2 ºF from group average temperatures (for all temperature inputs). The same grouping scheme was applied to projection year modeling, so that Illinois emissions were modeled using 12 county groups, Indiana emissions were modeled using 9 county groups, and Ohio emissions were modeled using 10 county groups. Thus, 31 iterations of NONROAD2002 were required per season per projection year, as compared to the 53 iterations per season per projection year required for the VISTAS region.

As was also described in the discussion of the Base G 2002 base year inventory, several non-default equipment population, growth, activity, seasonal distribution, and county allocation files are assigned by NMIM model inputs for these counties. As was the case for the base year inventory development, these same non-default assignments were retained for both projection inventories.

2.3.4.4 Differences between 2009/2018

Methodologically, there was no difference in the way that 2009 and 2018 emissions were calculated for non-road mobile sources. The actual value of the growth factors were different for each type of mobile source considered, but the calculation methods were identical.

2.3.5 Quality Assurance steps

Throughout the inventory development process, quality assurance steps were performed to ensure that no double counting of emissions occurred, to ensure that a full and complete inventory was developed for VISTAS, and to make sure that projection calculations were working correctly. Quality assurance was an important component to the inventory development process and MACTEC performed the following QA steps on mobile source components of the 2009 and revised 2018 projection inventories:

1. All final files (NONROAD only) were run through EPA's Format and Content checking software. Input data files for MOBILE and VMT growth estimates were reviewed by the corresponding SIWG and by the VISTAS Emission Inventory Technical Advisor.
2. SCC level emission summaries were prepared and evaluated to ensure that emissions were consistent and that there were no missing sources (NONROAD only).
3. Tier comparisons (by pollutant) were developed between the 2002 base year inventory and the 2009 and 2018 projection inventories (NONROAD only). Total VISTAS level summaries by pollutant were developed for these sources to compare Base F and Base G emission levels.
4. Data product summaries were provided to both the VISTAS Emission Inventory Technical Advisor and to the SIWG representatives for review and comment. Changes based on these comments were implemented in the files.
5. Version numbering was used for all inventory files developed. The version numbering process used a decimal system to track major and minor changes. For example, a major change would result in a version going from 1.0 to 2.0. A minor change would cause a version number to go from 1.0 to 1.1. Minor changes resulting from largely editorial changes would result in a change from 1.00 to 1.01.

ACKNOWLEDGEMENTS

The authors extend their appreciation to the many individuals that contributed to this study. Particular thanks go to the staff of the Pima Association of Governments. Darcy Anderson was instrumental in providing definition at the outset of the study. Lee Comrie and Natalie Barnes provided considerable assistance with the emissions surveys, made many thoughtful suggestions and contributions throughout the study, and provided helpful comments on the draft final report. Kwame Agyare, Wayne Byrd and Bill Maxwell of the Pima County Department of Environmental Quality offered valuable assistance in providing socioeconomic and PDEQ permit data and in sharing their knowledge of emissions sources in the Tucson Air Planning Area. Dan Catlin of the Arizona Department of Environmental Quality provided insightful comments during the course of the study and reviewed the draft final report.

Many individuals in the Tucson area participated in the annual and day-specific emissions surveys conducted as part of this study. The information they provided is sincerely appreciated.

We also wish to acknowledge Patricia El-Gasseir and Helen Fugate of Rumla, Inc. for their dedicated efforts in building the facilities database.

While emission rates for HC, CO, and NO_x are routinely measured from (new) commercial air carrier engines under the emissions certification component of International Civil Aviation Organization (ICAO) regulations, measurement of PM emissions is not required. As a result, almost all aircraft engine PM emission rate data have been collected under special studies. Currently, such data exists for only about 20 aircraft engines, with a considerable portion of these data collected by the U.S. Air Force for military aircraft engines. While emission factors for these engines are included in the AP-42 database upon which the FAEED and EDMS emission inventory models were developed, they have not been included in either model due to their limited applicability. To date, it has been standard EPA practice not to estimate PM emissions for aircraft engines. However, since the emissions models maintain a placekeeper for PM emission rates and include PM emission estimates for GSE, it can appear to the uninformed user that aircraft PM emission rates are zero. As a result, aircraft are often incorrectly considered to be insignificant PM sources even though those engines tested for PM have demonstrated significant emission rates. This policy of exclusion by omission is not appropriate in developing an accurate modeling inventory, even in the absence of a large emissions database. While a precise emissions estimate cannot be made with available data, it is clear that a zero emission rate is far from accurate.

As an alternative for this study, measured emissions data for aircraft engines that have been tested for PM were statistically analyzed to determine whether or not a relationship to other measured emissions parameters could be established. Intuitively, it was hoped that an inverse relationship with NO_x might be demonstrated, as such a relationship is theoretically attractive. While the level of sophistication of the statistical analysis is constrained by the quantity of data available, simple direct and indirect linear relationships can be examined. Because data are not available for each test engine in each of the four LTO cycle modes and because relationships might be expected to vary by operating mode (due to significant changes in engine and combustion efficiency), all statistical analysis was performed for each operating mode individually.

Statistically significant relationships were found for the direct linear analysis for three of the four LTO cycle modes. Significant in this context means that coefficient t-statistics for one or more of the other measured pollutants (HC, CO, or NO_x) indicated a direct relationship with measured PM (at a confidence level exceeding 95 percent). In all cases, correlation coefficients were poor (as expected), suggesting a high level of variability and poor predictability of PM emissions for any given engine. Nevertheless, statistics were unbiased and should provide an accurate mechanism to initially assess PM emissions on a aggregate basis (i.e., over a range of aircraft engine models such as those associated with an analysis for an entire set of airport operations). Only at idle was no significant relation found, which is not surprising given relative engine inefficiency in this mode.

The indirect linear analysis revealed a consistent and significant inverse relationship between PM and NO_x based on calculated t-statistics. Correlation coefficients continue to be poor, but t-statistics are generally improved over those of the direct linear analysis (all developed inverse relations, including idle, were significant at the 99 percent confidence level). In selecting the most appropriate relationship for estimation of PM emission rates for non-tested aircraft engines, the statistical analysis that produced the best combination of a significant t-statistic, a relatively low root mean square error, and an intuitive engineering basis was identified. This was the inverse NO_x relationship for the takeoff (i.e., full throttle) mode of operation. Figure 4-1 illustrates the selected statistical relationship.

With this relationship established, PM emission rate data for the other aircraft operating modes (i.e., the approach, taxi, and climbout modes) was statistically analyzed against observed PM emission rate data for the takeoff mode. Statistically significant relations were developed for all three modes. Table 4-23 presents the coefficients developed for these PM-to-PM regressions as well as the statistics for the PM-to-NO_x regression developed for the takeoff mode. These four relations were used to develop a set of fleetwide PM emission factors based on measured takeoff NO_x emission rates. These emission factors were then input into the EEA aircraft emissions model and used to generate PM emission estimates for TIA aircraft operations.

FIGURE 4-1. Relationship Used to Estimate Aircraft PM Emission Rates

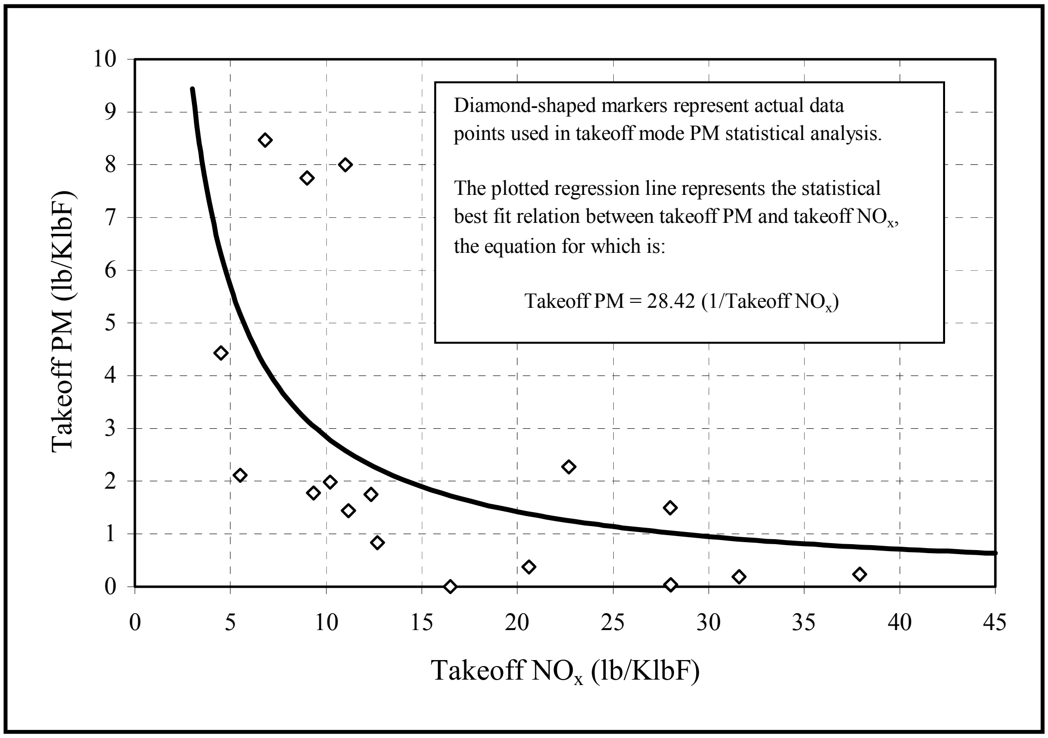

TABLE 4-23. Statistics for Aircraft and APU PM Relations

Statistical Parameter	Takeoff PM	Climbout PM	Approach PM	Taxi PM
Predictive Parameter	1/Takeoff NO_x	Takeoff PM	Takeoff PM	Takeoff PM
Coefficient	28.42	1.42	1.53	3.10
Coefficient t-statistic	5.1	11.8	14.9	5.7
Correlation Coefficient	0.30	0.84	0.91	0.56
F-statistic	7.4	86.1	135.7	21.9
Number of Observations	18	17	15	18

APPENDIX G:

CONVERSION OF MRPO BaseM POINT SOURCE DATA TO SMOKE INPUT FORMAT

Atmospheric Sciences Group

MEMORANDUM

To: Pat Brewer, VISTAS
From: Gregory Stella, Alpine Geophysics, LLC
Re: Conversion of MRPO BaseM Point Source Data to SMOKE Input Format
Date: 13 February 2008

The Midwest Regional Planning Organization (MRPO) periodically produces a five State emission inventory for Illinois, Indiana, Michigan, Wisconsin, and Ohio. These data are used as the basis for various MRPO modeling and regulatory analyses. These data are prepared with the help of each State's emission inventory divisions and are felt to be the most representative account for emissions activities for those States at any one time.

The most recent version prepared and distributed by MRPO is currently called BaseM. Associated with this 2005 base year inventory release is a set of growth and control factors that are used to additionally simulate future year conditions under "On-The-Books" (base case or known control programs requirements to be implemented in future years) or incremental control situations to test sensitivity or strategies which would be implemented in whole or in part during the same future years.

The purpose of this document is to detail the technical steps that were made as part of the conversion of the MRPO BaseM point sources files (electric generating unit [EGU] and non-EGU) into IDA format for ASIP PM-2.5 CAMx modeling of the future year 2009. Because of the timing and complications relative to converting multiple and various emission files for all source types, it was determined that only point source emissions would be converted for processing at this time.

Data Sources and Description

A series of data files and associated documentation was obtained from MRPO staff in 2007. These files were the input data sets for base year 2005 and growth and control factors related to MRPO's BaseM and Round 5 inventories[6]. Because of the emission processing tools that MRPO currently executes for its analyses, these files are in formats that are not read by the SMOKE emissions processor currently in use by VISTAS/ASIP modelers (contract teams and participating states). Alpine Geophysics, under the Emissions Inventory Technical Advisor contract, was asked to obtain and convert these data into the formats that could be used by these modeling agencies.

Through additional contact with MRPO staff, the base year 2005 non-EGU point source files and associated growth and control factors necessary to forecast the data to 2009 base case conditions were identified and extracted from the originally provided data. EGU sources were identified to be already prepared for the future year (2010 substituted for 2009) and were based on recent IPM 3.0 model runs with incremental adjustment made by MRPO states to best reflect expected emission controls and operating conditions. The "will do" simulation series for EGUs was identified as "egu5b_2010."

The main purpose of the SMOKE conversion task was to prepare five state emission inventories provided in National Input Format (NIF) format into the IDA format required by the SMOKE model for the criteria pollutants VOC, NOx, CO, SO2, PM-10, PM-2.5, and NH3. Annual emissions were taken directly from the NIF structured inventories with no alternate temporal calculations performed (e.g., estimate seasonal emissions from annual or annual from seasonal). The temporal allocation module of the SMOKE emissions processor was intended to be used to further define temporal distribution of these emissions.

---

[6] http://www.ladco.org/tech/emis/r5/round5_reports.htm

No quality assurance (QA) related to the reported values in the MRPO was conducted (e.g., it was assumed that reported emission levels were correct) and therefore the QA focus of these tasks was to maintain the integrity of the mass files in the conversion to IDA.

Each set of NIF structured data had a unique set of relational tables necessary to maintain the information required in each source sector based on its reporting requirements. Alpine had previously developed scripts to read the information from each of these relational data sets and convert them to the IDA structures required by this task. Prior to and after each major source sector was converted from NIF to IDA, we developed a list of emission summary reports to check that the emissions input into the conversion process were the same as output into the IDA formatted files.

Non-EGU Point Source Conversion

Non-EGU point source emissions from 2005 BaseM were converted to future year 2009 IDA format using the annual emission records directly from the NIF structured data sets and associated SCC growth factors and unit, facility, county, state, or nationally applied controls[7]. These controls were applied in a hierarchical fashion starting with the most defined (unit-segment-pollutant level) through least defined (national-SCC-pollutant) and when a match was found during the implementation, no additional controls were sought or applied to that emission record. In other words, if a match were found at the unit-segment level of control, no additional controls were applied to that segment/pollutant combination again in the forecast process. This prevented multiple control programs from being implemented when the intent of the originally provided control files were to assign a single applicable reduction.

The Round 5 factors for point sources provided by MRPO were in the RPO Data Exchange Format (RPODx) and had growth and control factors available at the State, county, plant, unit, segment, stack, and SCC level of detail. In order to apply these factors in a fashion consistent with that of the MRPO utilized processing system and duplicative of how MRPO would have generated its BaseM forecasts, a hierarchical approach was utilized to match and assign growth and control values.

Growth Factor Application

Using the 2005 EM table from the BaseM inventory files in NIF format, we first selected each emissions record for forecasting. In this conversion case, these EM records were limited to those emissions identified as annual using the NIF coding convention. As noted in the limitations section below, there oftentimes were emissions provided by MRPO in a summer season convention.

We next selected the base year for application as the RPODx for growth rates allows for the flexibility of input growth factors for multiple base year inventories. In this assignment, the base year was always 2005, as that was the base year provided by MRPO and the future year was 2009, as selected by ASIP.

The next step was to determine the growth basis for each individual emission record of the file. This "growth basis" is the key with which the growth factor is associated. For point sources, this key is based on a combination of FIPS, SCC, and pollutant codes. Multiple keys are calculated for each individual emission record and that key with the highest resolution of matching to the growth factor file using the hierarchy identified in Table 1 below is the one chosen to assign a growth rate to the base year emissions.

---

7 http://www.ladco.org/tech/emis/r5/reports/LADCO%202005%20Base%20Yr%20Growth%20and%20Controls%20Report_Final.pdf

Table 1. Point Source Growth Factor Application Hierarchy.

Order	Key or "Growth/Control Basis"
1	state/county code, 10-digit SCC, pollutant
2	state/county code, 10-digit SCC
3	state code, 10-digit SCC, pollutant
4	state code, 10-digit SCC
5	state/county code, pollutant
6	state/county code
7	state code, pollutant
8	state code
9	10-digit SCC, pollutant
10	10-digit SCC
11	Pollutant

Using the hierarchical application, growth basis, and dates (base year and alternate year), we matched each emission record to the growth table to obtain a growth factor. The factors are defined in the growth table as a multiplier for the base year period that calculates the alternate year of interest. In other words, multiplying the base year emissions value by the growth factor provides you with the emissions for the alternate year of interest.

When no match from any of the hierarchical keys was identified, a growth rate of 1.00 (no growth) was assigned. This maintained the 2005 emission level in the future year inventory.

Control Factor Application

Similar to the process identified above for the assignment and application of growth factors, the control factor assignment was based on a hierarchical key, this time, however, using FIPS, plantid, pointid, stackid, segment, SCC, and pollutant codes applied in a parallel process to the growth factor assignment.

Using the 2005 EM table from the BaseM inventory files in NIF format, we selected each annual emissions record for forecasting. We next selected the base year for application, and again, the base year was always 2005, as that was the base year provided by MRPO.

Once the base year was identified, we determined the alternate year for our forecast. Depending on the specific year used in each conversion, growth rates were limited to those with a base year of 2005 and a future year *less than or equal to* that of our forecast. This variation in method is intended to allow us to identify all controls implemented prior to or during the year of interest and will consider them as viable options at the latest provided level of control.

In other words, since we selected 2009 as the future year of choice, we limit the control factor table to control strategies implemented during or prior to 2009. If in our matching to the control factor table we find that for a certain control basis key there is no match because a program may have been fully implemented in a prior year (say 2007), then we do not want to exclude this reduction from our forecast. Additionally, if we find that there are multiple entries in the control factor table because of incremental implementation of a rule, we select the closest year to that of our intended forecast. So if a particular rule was incrementally implemented from 2005 through 2009 and there were control records available for each year in between, we would select the record with the latest year to apply in our forecast.

The next step was to determine the control basis for each individual emission record of the file. This "control basis" is the key with which the control strategy or technology is associated. Although we developed code to support the hierarchical application of control factors for the BaseM emissions, all control factors provided by MRPO in the Round 5 files were segment-SCC-pollutant specific. This eliminated the need for a search on the key that has the greatest resolution as all matches were at the segment-SCC-pollutant level.

Using the control basis and dates (base year and alternate year), we matched each emission record to the control table to obtain a control factor. The factors are defined in the control table as a group of values (control efficiency, rule effectiveness, and rule penetration) for the future year period that gets assigned to an uncontrolled future year emission value. In other words, we first “backed out” existing base year controls from our future year emissions estimate and then multiplied this uncontrolled value by the control factors for the alternate year of interest. These calculations are defined in Equations 1 and 2 below.

Equation 1. Uncontrolled emissions calculation.

$$Emiss_{Unc} = Emiss_{Base} / (1-((CE_{Base}/100)*(RE_{Base}/100)*(RP_{Base}/100)))$$

Where,

$Emiss_{Unc}$ = Uncontrolled emissions

$Emiss_{Base}$ = Base year emissions

CE_{Base} = Base year control efficiency

RE_{Base} = Base year rule effectiveness

RP_{Base} = Base year rule penetration

Equation 2. Application of new control calculation.

$$Emiss_{New} = Emiss_{Unc} *(1-((CE_{New}/100)*(RE_{New}/100)*(RP_{New}/100)))$$

Where,

$Emiss_{New}$ = Future year emissions

$Emiss_{Unc}$ = Uncontrolled emissions

CE_{New} = Future year control efficiency

RE_{New} = Future year rule effectiveness

RP_{New} = Future year rule penetration

When no match from any of the hierarchical keys was identified, the same control efficiency, rule efficiency, and rule penetration values from the base year inventory were used in the calculation and the only change in emissions would have been the result of growth factor application. In instances where PM-10 annual emissions were found to be less than PM-2.5 annual emission values, the PM-2.5 emission values were changed to equal that of PM-10.

EGU Point Source Conversion

EGU point source emissions from the egu5b_2010 scenario (2010 IPM 3.0 run with modifications) were converted to year 2009 IDA format using the annual emission records directly from the NIF structured data sets. Since these emissions already accounted for growth and control application, no additional modifications were required.

One ASIP requested modification for its PM-2.5 CAMx modeling was to adjust the 2009 file to match W. H. Sammis facility’s planned response to the control requirements from the consent decree USA vs. Ohio Edison; Civil Action No: 2:99-CV-1181; March 18, 2005. These changes were not implemented in the ASIP 2009 CMAQ runs. These adjustments for SO2 are noted in Table 2 below.

Table 2. SO2 Control Requirements from USA vs. Ohio Edison Consent Decree

Units 1-4	Induct Scrubbing
	50% removal (1.1 lbs/MMBtu)
	At least one unit by Sept. 30, 2008
	Second unit by Dec. 31, 2008
	Other two units by Dec. 31, 2009
Unit 5	Flash Dryer Absorber or Electro-Catalytic Oxidation no later than Dec. 31, 2008
	50% removal (1.1 lbs/MMBtu)
Units 6/7	Scrubber no later than December 31, 2010
	95% removal (0.13 lbs/MMBtu)
Plantwide	Emission cap of 101,500 by end of 2009
	Emission cap of 101,500 by end of 2010
	Emission cap of 29,900 by end of 2011

Conversion Limitations

As noted above, Alpine limited our conversion to all records in the MRPO point source files that were identified as annual. In some cases the MRPO NIF files had additional non-annual summer season emission records configured as a higher percentage than the annual average that was used in our emissions comparison.

In other words, the MRPO file sometimes had two emission record types that it uses for its modeling; one for the summer period and one for the rest of the year. Since SMOKE uses temporal allocation factors to make this summer/winter split, our converted values do not match MRPO's summertime reports. We see a high percentage difference in the Alpine converted data compared to the MRPO output reports in these two States for the July 12 example for this reason.

Since we confirmed this difference and reason for this difference in the 2005 data sets with MRPO, our objective for QA on the projections also included delta emissions from the projection year to the base year. Although the absolute daily emission values (in tpd) were found to be different as noted above, in all cases, the difference between 2005 and the projection year calculations as made by Alpine was within confidence ranges of the ratio of future year to base year as posted by MRPO. See Table 3 below. For this reason, we were convinced that our projection methodology is capturing the growth and control factors that MRPO applied in its emissions modeling.

MEMORANDUM

To: VISTAS State Point Source Contacts and VISTAS EGU Special Interest Workgroup
From: Gregory Stella, VISTAS Technical Advisor - Emission Inventories
Date: June 13, 2005
Re: EGU Emission Factors and Emission Factor Assignment

Purpose

The purpose of this memorandum is to discuss the differences currently known to exist in the base year (2002) and future year (2009 and 2018) forecasts of EGU emission factors for PM and NH3. In particular, it has been identified that E.H. Pechan & Associates, Inc. (Pechan) in their development of post-processed IPM output into NIF structure uses a set of PM and NH3 emission factors that are "the most recent EPA approved uncontrolled emission factors" and which are most likely not the same emission factors used by States and emission inventory preparation contractors for estimating these emissions in 2002 for EGUs in the VISTAS domain. Additionally, through review of the code used to post-process the IPM parsed files, it has also been determined that emission factors are assigned in future years based on Pechan assigned SCCs and not necessarily initial base year SCCs as coded in the original VISTAS NIF files.

A second objective of this memorandum is to propose a resolution to the issues at hand and to recommend a set of modifications to be made to the base year PM and NH3 emission estimates for this source category.

Background

VISTAS Base Year EGU Emissions Preparation

A major component to the development of the VISTAS point source sector of the inventory was the incorporation of data submitted by the VISTAS States and local (S/L) agencies to the United States Environmental Protection Agency (EPA) as part of the Consolidated Emissions Reporting Rule (CERR). Work on incorporating the CERR data into the revised base year involved: 1) obtaining the data from EPA or the S/L agency, 2) evaluating the emissions and pollutants reported in the submittal, 3) augmenting CERR data with annual emission estimates for PM10-PRI and PM25-PRI; 4) evaluating the emissions from electric generating units, and 5) completing quality assurance reviews for each component of the point source inventory.

Data from several sources were used: 1) the inventories that the S/L submitted to EPA from May through July 2004; 2) supplemental data supplied by the S/L agencies that may have been revised or finalized after submittal to EPA, and 3) the original VISTAS 2002 inventory in cases where S/L CERR data were not available.

Particulate matter emissions can be reported in many different forms, as follows:

PM Category	Description
PM-PRI	Primary PM (includes filterable and condensable)
PM-CON	Primary PM, condensable portion only (all less than 1 micron)
PM-FIL	Primary PM, filterable portion only
PM10-PRI	Primary PM10 (includes filterable and condensable)
PM10-FIL	Primary PM10, filterable portion only
PM25-PRI	Primary PM25 (includes filterable and condensable)
PM25-FIL	Primary PM25, filterable portion only

State/local agencies did not report PM emissions in a consistent manner. The State/local inventories submitted for VISTAS included emissions data for either PM-FIL, PM-PRI, PM10-FIL, PM10-PRI, PM25-FIL, PM25-PRI, and/or PM-CON. From any one of these pollutants, EPA has developed augmentation procedures to estimate PM10-PRI, PM10-FIL, PM25-PRI, PM25-FIL, and PM-CON. If not included in a State/local inventory, PM10-PRI and PM25-PRI were calculated by adding PM10-FIL and PM-CON or PM25-FIL and PM-CON, respectively. The procedures for augmenting point source PM emissions are documented in detail in Appendix C of *Documentation for the Final 1999 National Emissions Inventory (Version 3) for Criteria Air Pollutants and Ammonia – Point Sources*, January 31, 2004[1].

Briefly, the PM data augmentation procedure includes the following five steps:

- Step 1: Prepare S/L/T PM and PM10 Emissions for Input to the PM Calculator
- Step 2: Develop and Apply Source-Specific Conversion Factors
- Step 3: Prepare Factors from PM Calculator
- Step 4: Develop and Apply Algorithms to Estimate Emissions from S/L/T Inventory Data
- Step 5: Review Results and Update the NEI with Emission Estimates and Control Information.

Ammonia (NH3) emissions from these sources were assigned using direct incorporation of S/L/T provided emission estimates or via the application of emission factors using ratios of NH3 emission factors to other reported pollutants (e.g., VOC, CO, etc.).

IPM Post Processing

ICF via VISTAS contracts provided an initial spreadsheet file containing unit-level records of both (1) "existing" units and (2) committed or new generic aggregates. All records have unit and fuel type data; existing, retrofit (for SO_2 and NO_x), and separate NO_x control information; annual SO_2 and NO_x emissions and heat input; summer season (May-September) NO_x and heat input; July day NO_x and heat input; coal heat input by coal type; nameplate capacity (MW), and State FIPS code. Existing units also have county FIPS code, a unique plant identifier (ORISPL) and unit ID (also called boiler ID) (BLRID); generic units do not have these data.

[1] ftp://ftp.epa.gov/EmisInventory/finalnei99ver3/criteria/documentation/point/point_99nei_finalv3_0204.pdf

The IPM data were further processed by Pechan using data files and methodology recently approved by EPA. The most current documentation related to this subject is the EPA report titled, *Documentation for the 2002 Electric Generating Unit (EGU) National Emissions Inventory (NEI),* September 2004[2]. The processing includes estimating various types of emissions and adding in control efficiencies, stack parameters, latitude-longitude coordinates, and State identifiers (plant ID, point ID, stack ID, process ID). Additionally, the generic units were sited in a county and given IDs.

Pechan developed SCC assignments for all units; unit/fuel/firing/bottom type data were used for existing units' assignments, while only unit and fuel type were used for generic units' assignments. Additional review of the source code used in developing these post-processed files confirmed this fact. In actuality, not only does it exist that the post-processing code assigns different emission factors for the same SCC but that SCCs assigned in future year IPM output are potentially different than those assigned in the base year inventory, leading to additional, propagating differences in the base year and future year estimates. The full extent of these issues is currently under review by VISTAS and MRPO.

Stack parameters were attached, first using matches to data in the VISTAS 2002 NIF files, secondly using the EPA-provided data files, thirdly using a March 9, 2004 Pechan in-house stack parameter file based on previous EIA-767 data, and lastly using an EPA June 2003 SCC-based default stack parameter file.

Plant ID (within State and county), point ID, process ID, and stack ID were then attached, first using the VISTAS-provided data files, or secondly using EPA or Pechan-generated defaults. Default stack IDs within a plant were assigned for each unique stack height-diameter combination. The process ID and stack ID default data were only used when the data were not matched to the original VISTAS 2002 NIF files.

Additional data were required for estimating VOC, CO, filterable primary PM_{10} and $PM_{2.5}$, PM condensable, and NH_3 emissions for all units. Thus, ash and sulfur contents were assigned by first using 2002 EIA-767 values for existing units or SCC-based defaults; filterable PM_{10} and $PM_{2.5}$ efficiencies were obtained from the 2002 EGU NEI that were based on 2002 EIA-767 control data and the PM Calculator program (a default of 99.2% was used for coal units if necessary); fuel use was back calculated from the given heat input and a default SCC-based heat content; and emission factors were obtained from an EPA-approved October 7, 2004 Pechan emission factor file based on AP-42 emission factors. Table 1 provides the emission factor differences between the "old" emission factor file (used in development of EPA's 1999 NEI v.3) and the updated factors as used in VISTAS latest IPM conversion. Note that this updated file was not the one used for estimating emissions for previous EPA post-processed IPM files (including estimates for CAIR). It should also be noted that this component of emission estimation is only for the filterable component of PM and that the emission factors used for condensable PM did not change between the two versions.

Issue Identification

During a VISTAS TAWG meeting held at the Solution Center in Durham, NC on April 5 and 6, 2005, emission summaries were presented as comparisons of 2002 to 2018 forecasts. Table 2 presents the slide originally used in identifying the increase in PM and NH3 emissions. In this comparison, it was noted that PM and NH3 emissions (highlighted in Table 2) from EGUs were significantly higher in 2018 than in 2002 and based on known regulation and activity, no reason could be identified for this increase. After an initial review of the data, it was determined that the PM and NH3 emission factors used between the base year and future year were most likely the culprit. In fact, for some SCCs, the NH3 emission factor increased by over 5,000% (0.000565 to 0.03 lbs/ton coal burned). Changes in PM emission factors were not as large and limited to only a few SCCs. However, this emissions increase was simply an artifact of the change in emission factor, not anything to do with changes in activity or control technology application.

Additionally, after further review of the post-processing code by VISTAS, it was determined that not only were differing emission factors being used for similar SCCs between the base and future year estimates for those SCCs identified in Table 2, but that the same SCCs were not necessarily being used for emission factor assignment in the base and post-processed IPM scenarios. This issue has implications not only for the different PM and NH3 factors, but for other pollutants (CO, VOC) not initially estimated by IPM.

Table 3 presents those unit-segment (SCC) combinations which have been identified in the 2018 OTW run to have been assigned SCCs in the IPM post-processing step different than those in the 2002 base case. In some instances, the SCCs are comparable enough that the emission factors assigned were the same. However, there are additional instances where significant enough difference exists that review and correction may be warranted. An analysis of the differences in assignment of these SCCs and associated factors has not yet been completed.

Proposed Solution

There are two issues which need to be resolved in the estimation of relative differences in EGU emissions between VISTAS base year 2002 emissions inventory and any forecasts of this source sector using IPM and post-processing steps applied using existing programs provided by Pechan; (1) consistent use of emission factors between the base and future years, and (2) the consistent use of SCCs for determining emission factors between the base and future years.

These issues can be resolved using a variety of ways but the proposal provided here positions VISTAS to regenerate some specific pollutant 2002 emissions for the EGU sector in a fashion consistent, and presumably, more up-to-date, than the estimates provided in the 2002 base year inventory. Additionally, this proposal allows for the existing process to be completed in the post-processing steps but adjusts the resulting non-IPM generated emissions using correct SCCs and emission factors.

Base Year Emissions Adjustment

The first step is the adjustment of the 2002 base year emissions inventory. Using the latest "EPA-approved" uncontrolled emission factors by SCC, VISTAS contactors will utilize CERR or VISTAS reported annual heat input, fuel throughput, heat, ash and sulfur content to estimate annual uncontrolled emissions for units identified as output by IPM. This step will be conducted for non-CEM pollutants (CO, VOC, PM, and NH3) only. For PM emissions, the condensable component of emissions will also be calculated and added to the resulting PM primary estimations. When these fuel characteristic variables are found to be zero, out of range (as identified by AP-42 factors), or invalid, average fuel data collected from EPA's AP-42 documentation on heat, sulfur, and/or ash content will be used. The resulting emissions will then be adjusted by any control efficiency factors reported in the CERR or VISTAS data collection effort.

Future Year Scenario Adjustment

Because the assignment of the SCCs to IPM output is a post-processing step which involves the cross-reference file developed to match IPM units to VISTAS 2002 base year inventory, it should be relatively straightforward to modify the code to assign the same base year SCC to the future year. Then, through assignment of SCCs and associated emission factors (via another cross-reference), similar base year and future year emission factor assignments could be made; just using the projected controls and fuel throughput as predicted by IPM. If modifications can not be made directly to the code for this cross-reference step, VISTAS can modify the resulting post-processed NIF files for those sources identified with alternate SCCs assigned in the future year. Using the same methods as described for the 2002 revisions, those non-IPM generated pollutants would be estimated using IPM predicted fuel characteristics and base year 2002 SCC assignments.

Notes:

1. SCCs beginning with 101002 (coal), 101003 (coal), 101008 (coke), or 101020 (waste coal), emission factors in LB/TON; SCCs beginning with 101006 (natural gas), 201002 (natural gas), or 201003 (IGCC), emission factors are in LB/E6FT3.
2. If PMFLAG = 'A', then apply ash content to PM emission factor.
3. "Old" emission factors are used for latest EPA IPM post-processing.
4. "New" emission factors are used for MRPO IPM post-processing.

Methodology to Estimate the Transportable Fraction (TF) of Fugitive Dust Emissions for Regional and Urban Scale Air Quality Analyses

Thompson G. Pace, US EPA (8/3/2005 Revision)

Background and Introduction

For a number of years air quality analysts have recognized that the ambient impact of fugitive dust sources is substantially lower than emissions inventories would suggest. Analysis of the chemical species collected by ambient air samplers suggests that the modeling process may overestimate PM2.5 from fugitive dust sources by as much as an order of magnitude. This overestimation creates problems for those involved in both PM2.5 and regional haze planning and the determination of conformity budgets and significance determinations. Most experts agree that this overestimation is due to a combination of shortcomings in the inventory-modeling process: 1) faulty emission factor algorithms, 2) imprecise or difficult to obtain activity data to apply these algorithms (including inability to account for the effect of actual meteorological conditions on emissions), 3) the multiplier used to infer PM2.5 from PM10 emissions, and 4) modeling deficiencies (especially in the treatment of particles near their point of emissions). The ambient air sample collection and analysis is believed to be a better estimate of overall fugitive dust impact on the environment because of these issues with the inventory-modeling process.

Fugitive dust categories of interest include unpaved and paved road dust, dust from highway, commercial and residential construction and agricultural tilling. Of these, unpaved roads are the highest single emissions category, accounting for about one third of non-windblown fugitive dust emissions. This is followed in importance by dust from tilling, quarrying and other earthmoving. Note: windblown dust from agricultural and other exposed land is also important, but the transport fraction values suggested in this paper are not recommended for application to windblown dust sources.

In the mid 1990's, the U.S. Environmental Protection Agency's (EPA) Office of Air Quality Planning and Standards (OAQPS) began to use a factor to "adjust" the fugitive dust emission estimates in regional modeling analyses to obtain better agreement between the regional model results and ambient data. This adjustment was an ad hoc "divide-the inventory-by-four" approach to reduce the discrepancy between modeling and ambient data. The adjustment factor was conceived as an interim approach until a thorough investigation could identify which specific problems in the inventory and model were causing the discrepancy. Since the late '90s, the EPA has been actively working to understand the nature of those specific problems. This paper discusses some recent studies and proposes a conceptual model to approximate the dust removal near the source that is not accounted for in either the current emissions inventories or commonly used regional scale air quality models.

DRI / EPA Workshop

The EPA/OAQPS and the Desert Research Institute (DRI) conducted a workshop in 2000 to begin the process of understanding why modeled and monitored crustal material fractions do not agree. OAQPS documented that the field measurements underlying the dust emission estimates were generally taken within 5-10 meters of the source and that on average, about two-thirds of the dust plume is less than 2 meters above ground level at the location where the measurements are made. Based on this information and other workshop discussions, the workshop concluded that since the dust plume is still turbulent and very close to the ground, substantial dust removal processes can occur near the source (probably within several hundred meters), including impaction on land cover (vegetation and structures) and other processes that may enhance deposition on a local scale. It also concluded that regional air quality models (as they are currently applied) do not adequately account for injection height, deposition losses and impaction losses near fugitive dust emission sources. They noted that in practice, the fraction removed by surface cover is variable and that additional testing is needed (Watson and Chow 2000).

WRAP Expert Panel on Fugitive Dust

The DRI / EPA Workshop was followed by the formation of an Expert Panel on Fugitive Dust, sponsored by the Western Regional Air Partnership (WRAP) and chaired by Dr. Richard Countess. The panel concluded that not all suspended particles are transported long distances. Specifically, the report supported the conclusion of the DRI Workshop which was that much of the ground level fugitive dust emissions from soil disturbed by man's activities are likely to be removed close to the source. The low release height and turbulence leaves the particles temporarily close to the ground where they are subject to removal by impaction on nearby horizontal and vertical surfaces, including vegetation and structures. The Countess report recommended field studies to expand upon the current knowledge of the removal effectiveness of trees, desert shrub and buildings (Countess 2001) and several studies were conducted in response to this recommendation.

The Role of Surface Cover (Vegetation & Structures) in Removal of Airborne Dust

Early research into the general area of dust removal was done by Slinn for the U. S. Dept. of Energy. Much of Slinn's work focused on particle removal from air flowing above a tree canopy, but he also discussed the concept of a "stilling zone" within and below the canopy. Within the stilling zone, wind velocity is so much reduced that particles have ample time to settle to the ground or impact on the canopy or groundcover (Slinn 1982).

Windbreaks have long been a staple of soil erosion prevention, although most of the research has focused on the use of windbreaks placed upwind of a field to reduce the wind speed (and thus erosion) over the field. More recent work has focused on the effectiveness of vegetation as a removal mechanism. Anecdotally, researchers feel that the forest is a very good filter, both horizontally and vertically. Moreover, field tests suggest that the transmittance of dust through a windbreak is close to the optical transmittance. In other words, if the foliage is dense enough to block light, it also effectively filters particles (Cionco 2002, Raupach 1999, Raupach 2001).

Thus, the combined work of Slinn, Cionco and Raupach, the DRI workshop and the WRAP Expert Panel on Fugitive Dust suggests that fugitive dust particles have ample opportunity to be removed near the source, through impaction or filtration onto vegetation or structures or by other deposition mechanisms. The effect of land cover is expected to be highly variable, depending on the nature and proximity of vegetation to dust sources. They note that surface cover that is taller, denser and closer to the source captures a larger amount of the particles, with the most capture occurring when a narrow source is surrounded on both sides by tall, dense vegetation such as a road within a forest. However, Cowherd and Pace (2002) note that particles transported toward (not generated among) non-porous surfaces such as buildings or very dense vegetation may be diverted above or around those surfaces.

Mechanisms other than impaction and filtration by surface cover may also reduce particles very near the source, while the plume is compact and close to the ground. These mechanisms include electrostatic forces and thermophoresis (which could enhance deposition onto the earth's surface and low ground cover very near the source) and particle agglomeration within the compact plume (which could enhance gravitational settling). These mechanisms aren't as likely to capture particles in thermally buoyant or elevated plumes because those plumes rise above the land cover more quickly. Field testing is needed to quantify these mechanisms. (Cowherd and Gebhart 2003, Flagan 2001, Gieseke 1972).

Fugitive Dust Emissions, Surface Cover Particle Removal and Air Quality Models

As noted above, ground level fugitive dust emissions are measured adjacent to their point of emission; thus, as with emissions from all types of sources, they may be modified or even removed from the atmosphere before they reach receptors. Thus, emission estimates are only meaningful on a very local scale around their release point. In general, this does not present problems if one is concerned with effects on this local scale or when models are available to treat the potential modification or removal. However, these emissions are often used to support analyses on an urban or even larger scale. This could involve inventory tracking budgets (e.g., conformity) but they are also used in grid models whereby they are immediately introduced into model grids much larger than the scale of the removal processes discussed above.

Recently, several researchers and modeling practitioners have identified issues associated with how air quality models treat ground level fugitive dust emissions and how current models and modeling practices can lead to an underestimate of particle removal. Some of these issues were recently documented by staff at the Idaho Department of Environmental Quality (Idaho DEQ 2003). They concluded that Eulerian grid models generally over-predict coarse particle (2.5 ~ 10μm) concentrations, due primarily to the fact that these models artificially re-mix the particles in the lowest modeling layer at each time step (Dong, 2003). DRI, in their work for DOD, also evaluated the removal mechanisms in the Atmospheric Diffusion Equation and in ISC3. They found the ISC better suited to analyze near field dispersion (Etyemezian 2003).

Irwin (2003) noted that both grid and Gaussian models can be configured to estimate particle removal by surface cover, but that many of the parameters are empirical and there is little guidance or supporting research on how to set the input parameters in these models for a range of particle types and surface covers. He also noted that grid models ignore all removal processes in the grid cell into which they are first emitted, so unless the grid size is very small (100 to 1000 times smaller than currently used in regional modeling), they would not be sensitive to removal on the scales (10's to 100's of meters) discussed in this paper (Irwin 2003).

The above discussion suggests that any removal that may occur near the source (on a scale of 10's to100's of meters) is beyond the capability of current grid models, which are intended for use in regional scale analyses, as discussed below. A method is needed to adjust ground level emissions of fugitive dust when they are used to support analyses on a scale larger than 10's to 100's of meters. This paper describes a method to adjust the emissions inventory used in such larger scale analyses as a way to compensate for the model's inability to treat removal by surface cover near the emission source. Note that the adjustment of emissions inventories would be unnecessary if very small grids were used and if the appropriate removal mechanisms were incorporated explicitly into these models. However, use of grid models in this way would be well beyond current computer capabilities. Thus, the method described in this paper may be useful for the foreseeable future, until models are modified / developed to treat near-source particle removal by surface cover.

Conceptual Model: Near Source Capture (NSC) of Dust Emissions by Surface Cover

As an extension of the work begun by DRI and the WRAP Expert Panel, Cowherd and Pace (2002) suggest the use of a "limiting cases" conceptual model as a way to bound the dust removal potential by surfaces near the source of emissions. An unpaved road in the forest would represent one extreme or limiting case whereby most, if not essentially all of the road dust would be captured within the vegetation canopy. At the other extreme or limit, road emissions in barren areas of the arid southwest would be subject to virtually no capture or removal due to vegetation. Other surface characteristics would fall between these limits. Cowherd and Pace refer to the fraction of a source's mass emissions captured by the vegetation (or other surface obstructions) as the "Capture Fraction (CF)" where 0 <= CF <= 1, where 0 is a barren landscape and 1.0 is within a dense forest. They adapt the term "Transportable Fraction" (TF) from the DRI Workshop and use it to describe those particles remaining airborne and available for transport away from the vicinity of the source, after localized removal has occurred (Watson and Chow 2000, Cowherd and Pace 2002).

(1) Transportable Fraction (TF) = TE /SE
= {SE – [SE * CF]} /SE

Where:

Transportable Emissions (TE) =

Source Emissions (SE) – Locally Captured Emissions, and

Locally Captured Emissions = Source Emissions (SE) * CF

Figure 1 illustrates the conceptual model for near source particle removal by vegetation and structures. In this simple model, capture is assumed to increase as the density, leafiness and height of the vegetation increases. Urban areas are considered to be similar to mixed surroundings, on average. This model does not include any enhanced deposition that might occur due to gravitational, thermal or electrostatic forces. Also note that the exact relationship between capture and the nature of the surroundings cannot be known without further testing.

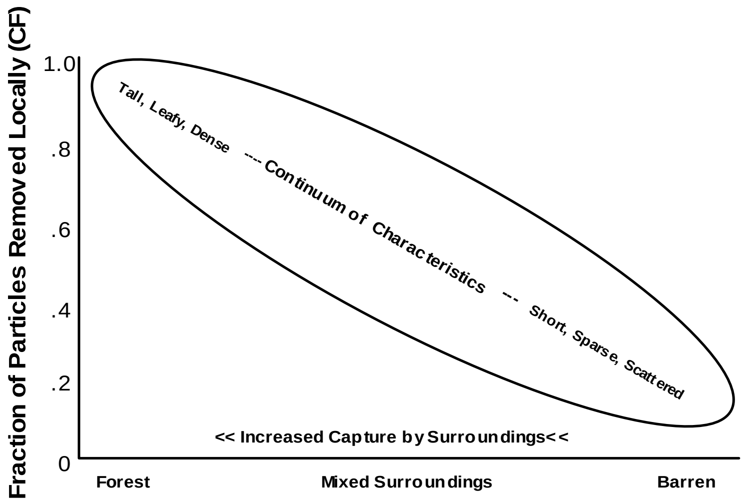

Figure 1. Conceptual Model – Near Source Capture (NSC) of Dust Particles by Surface Cover

Recent and Ongoing Work to Evaluate Near Source Capture (NSC) by Surface Cover

Field work was conducted for the Western States Air Resources (WESTAR) Council by a team of scientists including Dr. Vic Etyemezian at the Desert Research Institute (DRI). The effect of vegetation and structures on nearby unpaved road emissions was documented in this report. The report supports the Countess findings, noting a wide range of downwind removal rates depending on surface conditions. The DRI results showed little removal in daytime tests in a sparse, barren environment, but a nighttime removal rate of 85 percent was found at a distance of 95 meters downwind when structures were present between the road and the sampling apparatus (Etyemezian 2003a).

A field study conducted by the Midwest Research Institute (MRI) for the U.S. Department of Defense (DOD) measured the effect of groundcover on particle removal near an unpaved road. Initial tests were done over an open field 20 meters wide. In this test, the particles were depleted minimally as they passed over the field, but the depletion was about 57 percent when a bank of cedar trees was added downwind about 8 meters from the unpaved road. The amount of particle depletion was comparable for both PM2.5 and PM10 over these distances and test conditions (Cowherd and Gebhart 2003).

The data from these tests is limited and more testing is needed to improve the confidence in the results. However, substantial near source removal of the particles is apparent, even during the daytime for particles passing over an open field. Cowherd suggested that other factors may enhance the deposition process, even over flat surfaces very near the source. However, Etyemezian saw no apparent effect of deposition over barren land.

Note that the effect of atmospheric stability on CF should also be considered in future work to refine the NSC model. The CF would likely be reduced under unstable atmospheric conditions, which can cause the plume to rise above the earth's surface more quickly. Conversely, the removal due to capture could be even higher under very stable conditions such as were present during the nighttime test around buildings (Etyemezian 2003a). In general, one would expect the role of atmospheric stability in near source particle removal to be less important when vegetation or structures are tall and/or are located near the dust source (Etyemezian 2003b).

Figure 2 compares the results of the MRI and DRI field studies with the conceptual model in Figure 1. Test results from the two field studies were added to the schematic of the conceptual model based on descriptions of land cover between the source and the test instruments. The NSC conceptual model shows reasonable agreement with these field tests and thus, it appears to provide a useful framework for making preliminary estimates of CF based on local land cover characteristics.

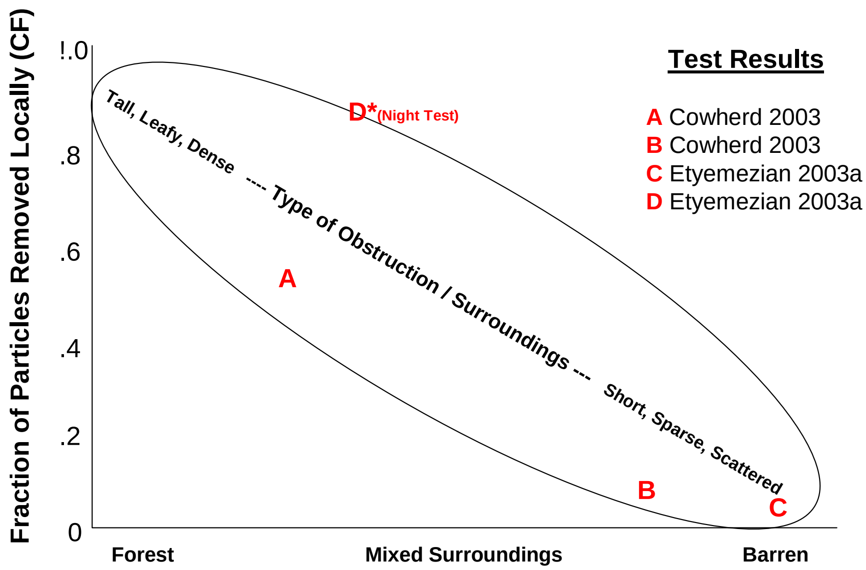

Figure 2. Comparison of Test data with NSC Conceptual Model

Default Recommendations for CF

Estimation of values of CF for specific geographic areas requires use of a land cover dataset such as the Biogenic Emission Land cover Database (BELD). BELD is a compendium of surface cover (mainly vegetation) characteristics used by the Biogenic Emission Inventory System (BEIS) biogenic emission model (Birth & Geron 1995). It contains data on several hundred species of vegetation at a 1 km cell size.

In the analysis presented in this paper, the land cover described in BELD was grouped into five cover type groups, e.g., barren & water; agricultural; grasses, scrub and sparsely wooded; urban; and forested. The estimated ranges and recommended values for CF are given in Table 1 along with the average vegetation heights assumed in BELD. (Urban structures were assumed to range from 5 to over 50 meters). Ranges for the CF for each cover type are based on field work and observations available from Watson and Chow, Raupach, Etyemezian and Cowherd, the height of the ground cover relative to the plume and seasonal changes in the cover characteristics. The ranges conform to the linear conceptual model in Figure 1 in that the CF is assumed to increase linearly with the seasonal presence, height and density of the surface cover. The recommended CF values assigned to Barren and Water (0) and Forest (1) are chosen to be consistent with the limits (extreme values) in the conceptual model, although as noted, the values could in fact be less than 1 for forest and greater than 0 for water & barren. The mid-points of the estimated ranges are used as the recommended CF for the other land cover types. The ranges and recommended CF values should be considered a first approximation and further refinement is welcomed.

Note that the CF's in Table 1 are only generalized defaults and should be modified by local data or as further research becomes available. Also, the estimated CF's herein are believed to be too high for windblown dust events because the wind's turbulence will usually lift particles higher more quickly, and the opportunity for vegetative removal is likely reduced.

Land Cover Type	Average Height (m)	Recommended CF (%)	Estimated CF Range (%)	COMMENT
Forest	18-20	100%	80 to 100%	Forested areas will capture dust effectively
Urban	5 – 50+	50%	25 to 75%	Structures are interspersed with open areas
Scrub, Sparsely Wooded & Grasses	1 – 2	25%	10 to 40%	Portion of plume is below sparse vegetation
Agricultural	1 - 2	25%	10 to 40%	Portion of plume is below crop (seasonally)
Barren / Water	0	0%	0 to 10%	Impediment-free surfaces are ineffective to capture dust

Table 1. Recommended CF (%) for Five Land Cover Types

Method to Estimate the Transportable Fraction in Specific Geographic Areas
The fraction of land area assigned to each land cover type in each US County was obtained from the BELD dataset. The county average transportable fraction was estimated by combining the CF's in Table 1 with the corresponding fractional surface

cover in each county and computing a weighted average CF for each county. The TF for each county is then estimated using equation 1 above. The results are shown in Figure 3. Note that these same surface cover data are available in the BELD dataset at a 1 km resolution detail, and the accuracy of the method could be improved by using grid- instead of county-weighted CF's.

Figure 3 shows how the TF varies by county across the US, depending on the variation in surface cover. The differences are apparent across the heavily forested areas in the southeast and the Pacific NW, the arid areas of the Southwest, the agricultural breadbaskets of the Central US and the San Joaquin Valley in CA. Note that nationally, the county average TF ranges from 0 to 0.92. The TF averages approximately 0.49 across all counties in the US, which is less of a reduction in dust emissions than was realized in the old "divide-by-four: approach. Recent analysis by Pace (2005) suggests that additional reduction in PM2.5 fugitive dust emissions may occur when the EPA completes their investigation of apparent errors in the multiplier used to derive PM2.5 emission factors from old PM10 emission factor field measurements.

The county average TF's in Figure 3 represent the first attempt to apply the conceptual model to estimate how dust removal by ground level airflow obstructions might vary across the US; they will be revised as more information becomes available. The transportable fraction concept can be extended to finer spatial resolution using an emissions processor such as SMOKE (Pace and Cowherd 2003). In fact, the WRAP has estimated the TF at a 2 km resolution in support of some of their analyses (Mansell 2005). In Figure 3, the county-level TF is displayed in five ranges, each containing an equal number of counties.

A preliminary estimate of the county-level TF was provided to the WRAP by OAQPS for use with their unpaved road dust emissions inventory. Countess recently applied the NSC concept to modeling in the San Joaquin Valley. He used the method posed by Pace and Cowherd to develop county specific TF's based on weighted average land use and ground cover information for the SJV counties. He found that use of those TF's resulted in adjusted emission estimates that agree well with ambient measurements in these SJV counties (Countess 2003).

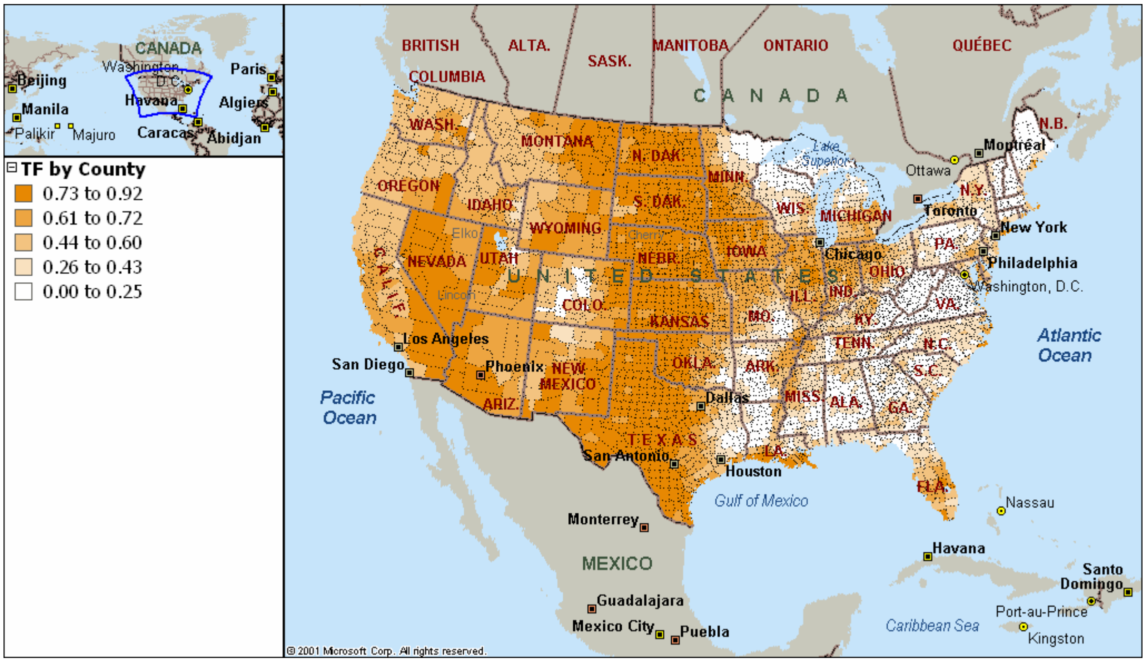

Figure 3. Geographic Variability of the Transportable Fraction

Recommendations and Limitations for Use of the Near Source Capture Adjustment

Based on the discussion above, it is recommended that the NSC adjustment be applied to emission estimates for paved roads, unpaved roads, construction, tilling and quarrying in grid model analyses, until near-source particle removal mechanisms are incorporated into the models (U. S. EPA 2004). EPA has applied the NSC adjustment in regional modeling applications and county-level TF adjustment capability has been incorporated into the SMOKE emissions processor. An important consideration in the application of the NSC concept is the scale represented by the land cover data. Land cover interacts with the source plumes over a scale of several hundred meters from the emission point. Thus, land cover data will be much more representative if it is obtained on a 1 km grid for example instead of the county-level as discussed herein. This is quite practical to do when one is using emission processors to prepare emissions for grid-based modeling since the BELD dataset is available at a 1 km resolution. However, county-level land cover data may be useful to adjust regional and county-level emission inventories for summary reporting and may be useful for use with grid models if finer resolution isn't available.

Note that the NSC adjustment should NOT be used to adjust emission estimates (e.g., permit applications) where local scale impacts are important. Also, the adjustment should not be applied to emissions input to Gaussian models. For Gaussian model applications, one should adjust the appropriate input parameters contained in these models to account for near source dust removal. The NSC adjustment is not applicable to elevated emissions of fugitive dust such as material transfer points, dust generated by wind erosion or low level emissions of buoyant plumes such as open fires or vehicle exhaust since in such cases, the particles are assumed to be above or rapidly rise above the height of the surface cover. Also, the adjustment doesn't currently attempt to account for enhanced deposition on the ground due to thermal, electrostatic or inertial forces.

Future Work

Many refinements have been made to the dust emissions estimation and air quality modeling methodologies over the years. However, significant issues remain and much work is still needed:

1) Improve the emission estimation algorithms, such as correcting (reducing) the emissions for lower vehicle speeds and re-estimating the relationship of PM2.5 to PM10;
2) Improve activity data, such as vehicle miles traveled (VMT), silt content and soil moisture on unpaved roads, surface loading on paved roads and soil conditions during agricultural tilling operations and windblown dust events;
3) Investigate ways to reduce reliance on such difficult to obtain activity data as silt content, surface loading and soil conditions;
4) Improve both the physical and empirical understanding of the near-source enhanced deposition processes (e.g., thermal and electrostatic forces, agglomeration);
5) Compare and critically review the various models for the transmission and removal of suspended particles by different obstructions and surface cover and refine the NSC methodology accordingly;
6) Incorporate the effect of atmospheric stability into the concept of the capture fraction (CF) concept;
7) Extend the NSC methodology to windblown dust models to incorporate removal by NSC;
8) More guidance is needed on the specification of specialized input parameters required by plume models;
9) Continue to improve the removal mechanisms in both grid and Gaussian models.

Conclusions

Our understanding of factors affecting particle removal near ground level fugitive dust sources has improved because of work begun at the EPA-sponsored Fugitive Dust Workshop held at DRI. Models are limited in their ability to fully account for near source removal of particles for a variety of physical and practical reasons, and this limitation is a major reason for the disparity between modeled and monitored estimates of fugitive dust. The recognition that vegetation captures some of this dust has led to a useful, albeit emerging methodology to account for the near source removal of particles in regional and urban scale analyses. This method is an improvement upon the national divide-by-four adjustment that has been used for about ten years. It may be applied in regional scale analyses where fugitive dust is emitted from paved and unpaved roads, construction, agricultural tilling, quarrying and earthmoving. Note that as research in this area evolves, other approaches or assumptions may be deemed more appropriate so it will be prudent to review the NSC adjustment methodology as new studies are published. Also, local knowledge about surface cover should be incorporated when available.

Note: The 080305 revision made minor changes in the values assigned for the capture fractions for several land cover types. Overall effect was to reduce the county-level transport fraction (national grand average) from 0.49 to 0.46. However, some individual county TF's changed by as much as +/- 20%.

1.0 INTRODUCTION

This is the Technical Support Document (TSD) for the Association for Southeastern Integrated Planning (ASIP) regional emissions and air quality modeling to support the southeastern states $PM_{2.5}$ and 8-hour ozone State Implementation Plans (SIPs). The ASIP 2002, 2009 and 2012 annual emissions and air quality modeling was performed by the contractor team of ENVIRON International Corporation (ENVIRON) and Alpine Geophysics, LLC (Alpine). The methods used in this ASIP TSD are the same as reported in the TSD prepared by the Visibility Improvements States and Tribal Association of the Southeast (VISTAS) for the regional haze SIPs (Morris et al., 2009), even though the two TSDs were written and updated at different times. Several interim emissions inventories have been developed and modeled during the course of the ASIP and VISTAS studies. The Base G2 or Base G4 Best and Final inventories were used by states for their SIPs. Both ASIP and VISTAS used the same 2002 Base G2 inventory as the basis for making projections to 2009, 2012 and 2018. The same meteorological, emissions, and air quality modeling methods and assumptions were used to project ozone, fine particle mass, and regional haze for 2009, 2012, and 2018, unless specifically noted otherwise in this document. Note that after the Base G4 Best and Final modeling was completed, in July 2008 the DC Circuit Court vacated the Clean Air Interstate Rule (CAIR), which was the basis for many of the utility controls that were modeled. However, in December 2008 the Court reinstated CAIR. This document addresses modeling results assuming that CAIR is implemented.

1.1 BACKGROUND

On December 17, 2004, EPA made fine particle ($PM_{2.5}$) nonattainment determinations for at least one area in seven of the states participating in the Visibility Improvement State and Tribal Association of the Southeast (VISTAS) regional haze project. VISTAS is one of five Regional Planning Organizations (RPOs) that consists of groups of states and tribes. The seven VISTAS states with $PM_{2.5}$ nonattainment areas are Alabama, Georgia, North Carolina, Kentucky, Tennessee, Virginia, and West Virginia. In addition, South Carolina has one three-county area that was designated as unclassifiable. The $PM_{2.5}$ compliance date is April 2010 unless a state demonstrates that more time is necessary in which case up to five additional years may be granted. Thus, future-year modeling of the 2012 year was also conducted. The nonattainment designations triggered the requirement for development of State Implementation Plans (SIPs) that are due in April 2008.

In April of 2004, EPA determined areas that were not meeting the 1997 0.08 ppm 8-hour ozone standard. States having one or more 8-hour ozone nonattainment areas in the Southeast are Alabama, Georgia, Kentucky, North Carolina, South Carolina, Tennessee, Virginia, and West Virginia. EPA will require attainment of the 8-hour ozone standard in basic nonattainment areas by June 15, 2009 and in moderate nonattainment areas by June 15, 2010. This will require states with basic 8-hour ozone nonattainment areas to model 2008 as the SIP modeling demonstration year while moderate nonattainment areas will require 2009 as the modeling year. Given that North Carolina and Virginia have two year SIP approval processes, there was an immediate need to complete an analysis of ozone attainment using air quality modeling. Note that on March 12, 2008 EPA promulgated a new 8-hour ozone standard with a lower threshold (0.075 ppm) than the current standard (0.08 ppm) that will be addressed in future SIP actions.

The states participating in the VISTAS project (the SESARM EPA Region 4 states plus Virginia and West Virginia from Region 3) have concluded that a collaborative process will be the most efficient approach for the collective states to develop information upon which to base the $PM_{2.5}$ and 8-hour ozone attainment demonstrations. The name of this collaborative effort is the Association for Southeastern Integrated Planning (ASIP). SESARM was awarded a grant from EPA on February 8, 2005 to conduct what was originally called the fine particle SIP development support project but is now known as ASIP.

ASIP is performing the technical analysis needed to support 8-hour ozone and $PM_{2.5}$ attainment demonstrations for nonattainment areas (NAAs) in the ASIP region. ASIP and VISTAS have adopted a "one-atmosphere" modeling approach where the basic modeling results can be used to address ozone, $PM_{2.5}$ and regional haze issues. ASIP and VISTAS are modeling different future years, with ASIP addressing the 2009 and 2012 future years to demonstrate compliance of the 8-hour ozone and $PM_{2.5}$ standards and VISTAS is modeling the 2018 future year to demonstrate reasonable progress in achieving visibility improvements. The VISTAS modeling was initiated first in 2003, so much of the early model set up and sensitivity modeling that was conducted under VISTAS has been adopted by ASIP. ASIP initiated their modeling in 2005 with a contracting team led by ENVIRON International Corporation and Alpine Geophysics, LLC as a subcontractor. Thus, the ASIP modeling is intricately connected to the VISTAS modeling, which is described next.

1.1.1 VISTAS Emissions and Air Quality Modeling

VISTAS is one of five Regional Planning Organizations (RPOs) that have responsibility for coordinating development of SIPs and Tribal Implementation Plans (TIPs) in selected areas of the U.S. to address the requirements of the Regional Haze Rule (RHR). VISTAS is a regional partnership of states, tribes, federal agencies, stakeholders and citizen groups established to initiate and coordinate activities associated with the management of regional haze and other air quality issues within the VISTAS region. The VISTAS region includes the states of Alabama, Florida, Georgia, Kentucky, Mississippi, North Carolina, South Carolina, Tennessee, Virginia and West Virginia. Figure 1-1 identifies the states included in each of the five RPOs in the U.S, including VISTAS. The VISTAS States and Class I areas within the VISTAS region are shown in Figure 1-2.

VISTAS is performing emissions and air quality modeling to project visibility to 2018 to determine the level of visibility improvements expected in 2018 under various emission strategies and assist states to determine their 2018 Reasonable Progress Goal (RPG) toward achieving natural conditions in 2064.

The VISTAS Modeling Team is funded through the Southeastern States Air Resource Managers (SESARM) and has implemented a regional air quality planning process to provide the necessary technical and policy tools needed by states to comply with the Section 308 of the RHR. In March 2003, VISTAS contracted with ENVIRON International Corporation, with Alpine Geophysics, LLC (Alpine) and the University of California at Riverside (UCR) as Subcontractors, to be the VISTAS Modeling Team to perform the emissions and air quality modeling needed to develop the technical basis for the RHR SIPs.

Figure 1-1. Regional Planning Organizations engaged in regional haze planning.

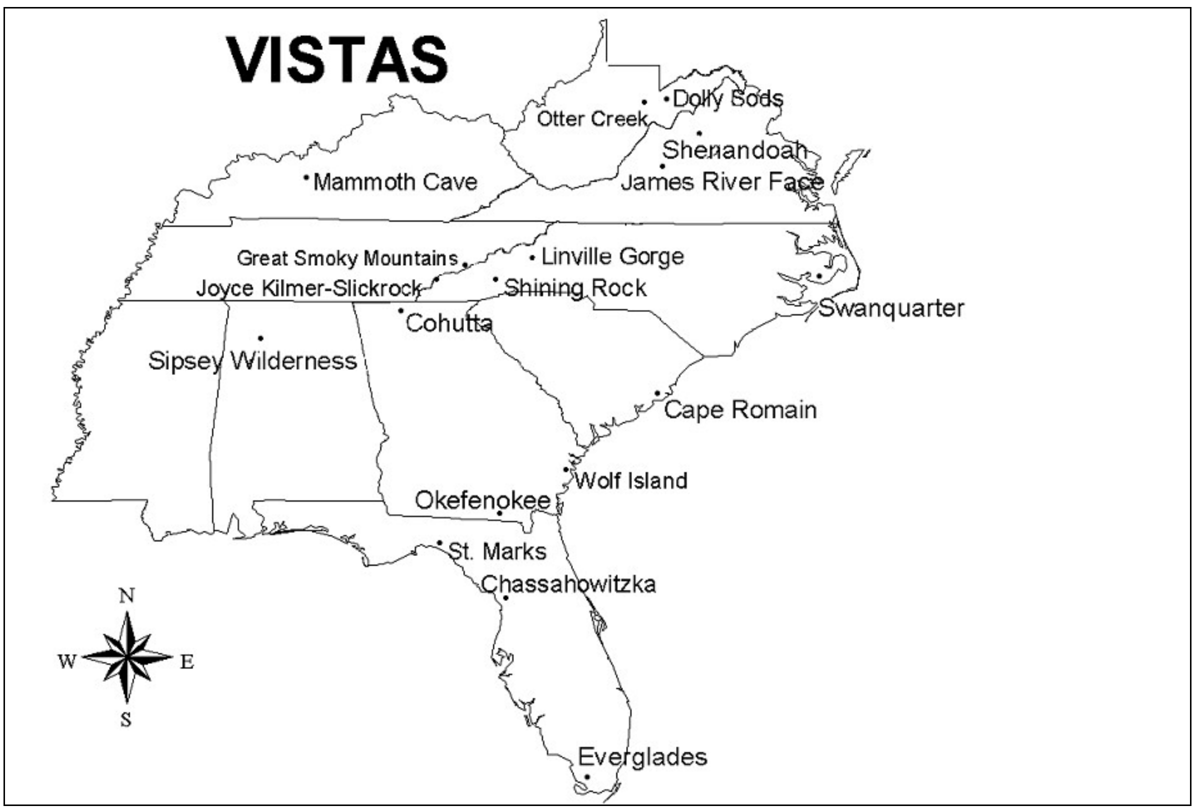

Figure 1-2. VISTAS states and Class I areas within the VISTAS region.

1.2 ASIP/VISTAS Modeling Approach

The ASIP and VISTAS Emissions and Air Quality Modeling Team performs regional ozone, particulate matter (PM) and haze analyses by operating regional scale, three-dimensional air quality models that simulate the emissions, chemical transformations, and transport of gaseous and PM species and consequently effects on ozone and $PM_{2.5}$ attainment in NAAs and visibility in Class I Areas in the southeastern U.S. A key element of this work includes the integration of emissions inventories and models with chemical transport models. The general services provided by the ASIP/VISTAS Emissions and Air Quality Modeling Team include, but are not limited to:

- Emissions processing and modeling;
- Air quality and visibility modeling simulations;
- Analysis, display, and reporting of modeling results; and
- Storage/quality assurance of the modeling input and output files.

1.2.2 VISTAS Two-Phased Approach

The VISTAS Emissions and Air Quality Modeling activities were performed in two Phases. Phase I, which occurred primarily during the 2003 calendar year before the ASIP modeling was initiated, consisted of emissions and regional air quality modeling for three episodes to identify the optimal model configuration(s) for simulating regional ozone, PM and haze in the southeastern U.S. Phase II, initiated in 2004, consists of operating the emissions and air quality models for the 2002 calendar year to develop the regional air quality modeling databases needed to address the requirements of the Section 308 RHR SIPs that can also be used to address the requirements of the 8-hour ozone and $PM_{2.5}$ SIPs.

1.2.2.1 VISTAS Phase I

The objective of VISTAS Phase I was to determine the optimal modeling configuration for use in the subsequent Phase II regional modeling assessment. Accordingly, Phase I entailed a comprehensive literature review of recent relevant visibility studies using various photochemical/aerosol modeling platforms in order to assess and identify appropriate model configurations, data bases, and model testing methodologies that were appropriate for use in conducting the VISTAS Phase I emissions and air quality modeling assessment. Key elements of Phase I included:

- Review all relevant air quality model simulations that have been completed related to regional haze and $PM_{2.5}$ modeling and document the relevant sensitivity analyses, model configuration testing, and performance evaluations that have been performed (ENVIRON, 2003b);

- Review the current science in regional emissions modeling (e.g., EPS, EMS and SMOKE) and PM air quality modeling (e.g., CMAQ, CMAQ-MADRID, CMAQ-AIM, REMSAD, UAM-V/PM, CAMx and PMCAMx) to determine the most appropriate model(s) for use by VISTAS (ENVIRON, 2003b);

- Review available ambient data for evaluating one-atmosphere PM/ozone models (ENVIRON, 2003c);

- Develop and implement a plan or Modeling Protocol for testing and evaluating alternative science configurations of the recommended Phase I model(s) and document the results (ENVIRON, 2003a); and

- Prepare a report prescribing the model set-up, data base development, performance testing, and control strategy evaluation procedures to be implemented in VISTAS Phase II (ENVIRON, 2004a).

The VISTAS Technical Analysis Workgroup provided oversight for the comprehensive model evaluation. In Phase II the modeling system (models and databases) identified and tested in Phase I was implemented following the procedures set forth in the Phase II Modeling Protocol (ENVIRON, 2004a).

For the meteorological component of the Phase I modeling, SESARM contracted with Baron Advanced Meteorological Systems (BAMS) to apply the PSU/NCAR Mesoscale Model (MM5) in multiple configurations and to evaluate its performance against surface and aloft meteorological observations (Olerud, 2003a-f). The emissions modeling component of VISTAS Phase I was carried out by the research team of ENVIRON/Alpine/UCR with staff at Alpine Geophysics taking the lead role in setting up, testing, and applying the emissions modeling system. The air quality modeling component was performed by the team at the ENVIRON/Alpine/UCR modeling centers. A dominant theme during Phase I was the exchange of modeling codes, databases, and evaluation software between the three modeling centers as the air quality modeling was carried out.

1.2.2.2 VISTAS Phase II

The VISTAS Phase II modeling, initiated in 2004, included annual regional ozone, PM and haze simulations with the objective of demonstrating model performance for the selected modeling year, 2002. After detailed model review, testing and performance evaluation, the modeling system was exercised with a variety of emissions scenarios to enable VISTAS to assess the effects of future year emissions on visibility impairment at Class I areas in the VISTAS and nearby states. The modeling system allows VISTAS to estimate 2018 visibility to assist in tracking progress toward regional haze goals. The VISTAS Phase II program applied the SMOKE emissions and CMAQ air quality modeling systems for calendar year 2002 over the same 36/12 km horizontal grid system used in Phase I to estimate 2018 visibility improvements at VISTAS and nearby Class I areas. A number of annual model simulations were performed that included the following:

- **<u>2002 Initial Annual "Actual" Emissions Runs</u>.** Initial 2002 annual model simulations and performance evaluations using the 2002 inventory for VISTAS and non-VISTAS states, Canada and Mexico were performed to confirm the appropriateness of the model science configuration(s) recommended by the Phase I work, to evaluate updates to the model and model inputs and to refine model performance. The 2002 Actual emission scenarios used day-specific fire emissions and emissions from Electric Generating Units (EGUs) using continuous emissions monitoring (CEM) data. The initial CMAQ 2002

36/12 km Base A Actual base case simulation used CMAQ Version 4.4beta and was performed during the summer of 2004. The results of the initial model performance evaluation are documented in Morris et al., (2004b).

- **2002 Revised Annual "Actual" Emissions Runs.** The 2002 emissions inventories for VISTAS and non-VISTAS states, Canada and Mexico were updated with improved assumptions. The CMAQ model was updated to version 4.5 and a modified CMAQ module for Secondary Organics Aerosols (SOA) was developed and tested (Morris et. al., 2006a). Additional annual 2002 simulations were performed using the revised 2002 modeling inventories and revised CMAQ configurations to evaluate model performance. The final VISTAS 2002 Actual Base G2 CMAQ simulation was also used in the ASIP modeling. The ASIP model performance evaluation for the final 2002 Actual Base G2 base case focused on PM model performance is discussed in Chapter 3 and Appendices B and C of this report. The CMAQ 2002 Base G2 actual base case model performance evaluation related to regional haze is described in the VISTAS TSD (Morris et al,. 2007a).

- **2002 Annual Run with "Typical Year" EGU/Fire Inventory.** Typical year emissions inventories were developed for EGU and fire to avoid atypical EGU outages or atypical fire activity in the 2002 modeling year from influencing the assumptions used in the projection year. Continuous emissions monitoring (CEM) data for the 2000-2004 baseline period for EGUs were used to develop the 2002 typical EGU inventories. Available fire activity data in the period 2000-2004 was used to develop 2002 typical fire emissions. All other sectors used the same 2002 actual inventory for the 2002 typical inventory The 2002 typical inventories provide the baseline modeled air quality condition against which future year modeling runs were compared to develop relative response factors (RRFs) for each pollutant species used in the visibility projections.

- **Future Year Annual Base Case Runs.** Future year simulations for 2018 were based on a projected base case inventory of typical EGU emissions and current year baseline typical fire emissions for 2018. The objective of the future year model base case runs was to project 2018 visibility conditions under conditions of growth and current (on-the-books) regulated control measures. These 2018 projections were compared to the Uniform Rate of Progress for 2018 in the VISTAS TSD (Morris et al., 2007a) as one part of VISTAS states' determination of reasonable progress goals for 2018.

- **Future Year Emission Sensitivity Simulations.** VISTAS performed future year sensitivity simulations were performed to assess the effects alternative future year emission assumptions and potential control measures would have on visibility in Class I areas.

Details on the VISTAS modeling results are provided in the VISTAS regional haze SIP Technical Support Document (Morris et al., 2009).

1.2.2.3 ASIP Emissions and Air Quality Modeling

The ASIP emissions and air quality modeling leveraged off of the VISTAS 2002 annual CMAQ 36/12 km modeling set up, only ASIP projected emissions to the 2009 and 2012 future years.

The ASIP model performance evaluation also focused on the performance of ozone and $PM_{2.5}$ mass and components in urban areas and the NAAs, rather than the performance of PM species at Class I areas as studied in VISTAS (Morris et al., 2007a). ASIP also developed projection software to project 8-hour ozone and annual $PM_{2.5}$ Design Values using results from the CMAQ Version 4.5 SOAmods model from the joint ASIP/VISTAS 2002 36/12 km Typical Base G2 base case and ASIP 2009 and 2012 36/12 km Base G4 CMAQ simulations. The ASIP future year 8-hour ozone and $PM_{2.5}$ projection procedures followed the approach in the latest EPA modeling guidance (EPA, 2007a). The final 2009 and 2012 8-hour ozone and $PM_{2.5}$ projections presented in this TSD were made using Version 2.01 of EPA's Modeled Attainment Test Software (MATS) and is presented in Chapter 4 of this TSD. The 8-hour ozone and $PM_{2.5}$ projects using the ASIP projection procedures are presented in Chapter 5 and are used to corroborate the MATS projections.

1.3 AIR QUALITY MODELING OVERVIEW OF 2002 ANNUAL EMISSIONS AND APPROACH

The VISTAS Phase II annual 2002 emissions and air quality modeling was initiated in 2004 and the modeling approach was adopted by ASIP in 2005. It involved the preparation of numerous databases, model simulations, presentations and reports. There were numerous versions and iterations of the modeling with interim results. The results presented in this ASIP $PM_{2.5}$ TSD focus on the final 2002 Base G2 and 2009, 2012 and 2018 Base G2 and Base G4 CMAQ modeling results.

1.3.1 Modeling Protocol

Modeling Protocols were prepared at the outset of both the VISTAS Phase II (ENVIRON, 2004) and ASIP (Morris et al., 2006b) studies. The Modeling Protocols served as a road map for performing the VISTAS and ASIP emissions and air quality modeling and are a form of communication of the modeling plans to the VISTAS and ASIP participants. The Modeling Protocols were prepared following EPA guidance at the time they were prepared (EPA, 1991; 1999, 2001a) and the modeling needs of the Regional Haze Rule (RHR), 8-hour ozone and $PM_{2.5}$ SIPs. The first version of the VISTAS Modeling Protocol was released in March 2004. Based on comments received from VISTAS, the Modeling Protocol was updated to the current version that was dated May 6, 2004.

Under a separate EPA grant and contract from VISTAS, for the ASIP, the modeling team is also performing emissions and air quality modeling for 2009 and 2012 to support southeastern states' demonstration of attainment of the 8-hour ozone and $PM_{2.5}$ national ambient air quality standards. The same model configuration and methods and the 2002 modeling results that are used for VISTAS are also being used for the ASIP modeling. The ASIP Modeling Protocol is dated January 31, 2006 (Morris et al., 2006b) and updated the methods described in the VISTAS Modeling Protocol including procedures for projecting future year 8-hour ozone and $PM_{2.5}$ Design Values.

1.3.2 Quality Assurance Project Plan (QAPP)

Separate Quality Assurance Project Plans (QAPPs) were prepared for the VISTAS (Morris, Tesche and Tonnesen, 2004) and ASIP (Morris and Stella, 2005) annual emissions and air quality modeling studies that described the quality management functions performed by the modeling team. The VISTAS and ASIP QAPPs were finalized November 17, 2004 and November 28, 2005, respectively. The QAPPs were based on the national consensus standards for quality assurance (ANSI/ASQC, 1994), followed EPA's guidelines for quality assurance project plans for modeling (EPA, 2002), for QAPPs (EPA, 2001b) and EPA modeling guidelines (EPA, 1991; 1999; 2001a; 2007) and took into account the recommendations from the North American Research Strategy for Tropospheric Ozone (NARSTO) Quality Handbook for modeling projects (NARSTO, 1998). The EPA and NARSTO guidance documents were developed specifically for modeling projects, which have different quality assurance concerns than environmental monitoring data collection projects. The work performed in this project involves modeling at the basic research level and for regulatory/policy applications. In order to utilize model outputs for these purposes, it must be established that each model is scientifically sound, robust, and defensible. This is accomplished by following a project planning process that incorporates the following elements as described in the EPA guidance document for modeling:

- A systematic planning process including identification of assessments and related performance criteria;
- Peer reviewed theory and equations;
- A carefully designed life-cycle development process that minimizes errors;
- Documentation of any changes from original plans;
- Clear documentation of assumptions, theory, and parameterization that is detailed enough so others can understand the model output;
- Input data and parameters that are accurate and appropriate for the problem; and
- Output data that can be used to help inform decision makers.

A key component of the VISTAS and ASIP emissions and air quality modeling QAPPs were the graphical display of model inputs and outputs and multiple peer-review of each step of the modeling process. This was accomplished through use of the project's modeling Website that posted displays of products (e.g., emissions plots, model outputs, etc.) for review by the VISTAS modeling team, workgroups and others and frequent meetings with the VISTAS/ASIP participants.

1.3.3 Model Selection

The selection of the meteorological, emissions and air quality models for the ASIP/VISTAS annual regional modeling was based on EPA guidance (EPA, 1991; 1999; 2001a; 2005b; 2007), a review of previous modeling studies and the VISTAS Phase I episodic model testing and evaluation (ENVIRON, Alpine and UCR, 2003a,b,c; 2004). The ASIP/VISTAS annual emissions and air quality Modeling Protocols (ENVIRON, 2004; Morris, et. al., 2006b) provide details on the justification for model selection and the formulation of the different models. Based on the VISTAS Phase I comprehensive model testing and evaluation and other work, ASIP/VISTAS selected the following set of models as the primary totals for modeling ozone, particulate matter (PM) and regional haze in the southeastern states:

- **<u>MM5:</u>** The Pennsylvania State University/National Center for Atmospheric Research (PSU/NCAR) Mesoscale Meteorological Model (MM5 Version 3.6 MPP) is a non-hydrostatic, prognostic meteorological model routinely used for urban- and regional-scale photochemical, fine particulate, and regional haze regulatory modeling studies (Anthes and Warner, 1978; Chen and Dudhia, 2001; Stauffer and Seaman, 1990, 1991; Xiu and Pleim, 2000).

- **SMOKE**: The Sparse Matrix Operator Kernel Emissions (SMOKE) modeling system is an emissions modeling system that generates hourly gridded speciated emission inputs of mobile, non-road, area, point, fire and biogenic emission sources for photochemical grid models. (Coats, 1995; Houyoux and Vukovich, 1999). As with most 'emissions models', SMOKE is principally an *emission processing system* and not a true *emissions modeling system* in which emissions estimates are simulated from 'first principles'. This means that, with the exception of mobile and biogenic sources, its purpose is to provide an efficient, modern tool for converting an existing base emissions inventory data into the hourly gridded speciated formatted emission files required by an air quality simulation model.

- **CMAQ:** EPA's Models-3/Community Multiscale Air Quality (CMAQ) modeling system is a 'One-Atmosphere' photochemical grid model capable of addressing ozone, particulate matter (PM), visibility and acid deposition at the regional scale for periods up to one year (Dennis, et al., 1996; Byun et al., 1998a; Byun and Ching, 1999, Pleim et al., 2003).

The comprehensive air-quality model with extensions (CAMx; ENVIRON, 2008) was also used to corroborate the CMAQ modeling results and to provide source apportionment.

1.3.3.1 MM5 Meteorological Model Configuration for VISTAS Annual Modeling

Application of the MM5 for the 2002 annual modeling on a 36 km grid for the continental U.S. and a 12 km grid for the eastern U.S. was performed by Barons Advanced Meteorological Systems (BAMS). As part of Phase I of VISTAS, BAMS performed numerous MM5 simulations to identify the optimal configuration for simulating meteorology to support regional PM and visibility modeling of the eastern U.S. (Olerud, 2003a,b,c,d). Details of the 2002 36/12 km MM5 model application and evaluation are available on the BAMS VISTAS project website (www.baronams.com/projects/VISTAS). ASIP has adopted the VISTAS MM5 modeling results.

Based on the extensive sensitivity testing carried out by Olerud and Sims (2003) as part of VISTAS, the MM5 (Version 3.6, MMP) configuration used by BAMS modelers for the VISTAS Phase II modeling consisted of the following (see Table 1-1 or www.baronams.com/projects/VISTAS for more details):

- Nested 36/12 km grids, with 34 vertical layers;
- Two way nesting, no feedback;
- Initialization and boundary conditions from Eta analysis fields;
- Pleim-Xiu (P-X) land soil model (LSM);
- Asymmetric Convective Mixing (ACM) planetary boundary layer (PBL) model;
- Kain-Fritsch 2 cumulus parameterization;
- Mixed phase (Reisner 1) cloud microphysics;
- Rapid Radiative Transfer Model (RRTM) radiation;

- Snow effect turned on;
- Eta model sea surface temperature;
- 24-category USGS vegetation data sets;
- Thermal roughness by the Garratt method; and
- Standard FDDA analysis nudging on 36 km and 12 km grid nests.

The emissions and air quality modeling team also performed their own independent evaluation and quality assurance of the MM5 (Morris et al., 2004b) to assure that the MM5 modeling fields prepared by BAMS were transferred and processed correctly for input into CMAQ using the Meteorological-Chemical transport model Interface Program (MCIP). MCIP Version 3.0 was used in the processing which invoked the Pleim M3DRY dry deposition scheme in CMAQ that uses the MM5 P-X LSM parameters. MCIP Version 3.0 included a significant update from previous versions in the calculation of layer collapsing. MCIP was also run using the option to specify land-use dependent minimum vertical turbulent exchange coefficients (Kz) that ranged from 0.1 to 2.0 m^2/s.

Table 1-1. MM5 Meteorological Model Configuration for ASIP/VISTAS (Olerud, 2003a,b,c,d).

Science Options	Configuration	Details/Comments
Model Code	MM5 Version 3.6 (MPP)	Grell et al., 1994
Horizontal Grid Mesh	36/12 km	
36 km grid	164 x 128 cells	Continental U.S.
12 km grid	180 x 189 cells	Eastern U.S.
Vertical Grid Mesh	34 layers	Vertically varying; sigma pressure coord.
Grid Interaction	No Feedback	IFEED=0
Initialization	Eta first guess fields/LittleR	
Boundary Conditions	Eta first guess fields/LittleR	
Microphysics	Reisner I Mixed Ice	Look up table
Cumulus Scheme	Kain-Fritsch 2	On both 36/12 Grids
Planetary Boundary Layer	ACM PBL	
Radiation	RRTM	
Vegetation Data	USGS	24 Category Scheme
Land Surface Model	P-X Land Surface Model (LSM)	Cold restart every 5.5 days
Shallow Convection	None	
Sea Surface Temperature	Eta Skin	Spatially varying
Thermal Roughness	Garratt	
Snow Cover Effects	None	
4D Data Assimilation	Analysis Nudging on 36/12	
Integration Time Step	90 seconds	
Simulation Periods	Annual 2002	
Platform	Linux Cluster	Done at BAMS

1.3.3.2 SMOKE Emissions Model Configuration for VISTAS Annual Modeling

SMOKE supports area, mobile, fire and point source emission processing and also includes biogenic emissions modeling through a rewrite of the Biogenic Emission Inventory System, version 3 (BEIS3) (see, http://www.epa.gov/ttn/chief/software.html#pcbeis). SMOKE has been available since 1996, and it has been used for emissions processing in a number of regional air quality modeling applications. In 1998 and 1999, SMOKE was redesigned and improved with the support of the U.S. Environmental Protection Agency (EPA), for use with EPA's Models-3/CMAQ (http://www.epa.gov/asmdnerl/models3) and is currently maintained and available from the CMAS center (www.cmascenter.org).

As an emissions processing system, SMOKE has far fewer 'science configuration' options compared with the MM5 and CMAQ models. Table 1-2 summarizes the version of the SMOKE system to be used and the sources of data to be employed in constructing the required modeling inventories. Details on the SMOKE emissions modeling for the ASIP 2002 annual modeling is presented in Chapter 2 with emissions summary reports available in Appendix A.

Table 1-2. SMOKE Emissions Model Configuration for ASIP/VISTAS.

Emissions Component	Configuration	Details/Comments
Emissions Model	SMOKE Version 2.1	Errors in SMOKE Version 2.1 conversion of lat/lon coordinates to Lambert Conformal modeling grid resulted in displacement of sources and receptors. Discovered in Aug 2007. Receptor locations corrected for Base G2 results.
Horizontal Grid Mesh	36/12 km	
36 km grid	148 x 112 cells	RPO Unified Grid
12 km grid	168 x 177 cells	VISTAS/ASIP eastern US 12 km grid
Area Source Emissions	VISTAS Domain: VISTAS State 2002 EI	Updated '02 developed by VISTAS states
	Other States: EPA '02 NEI augmented with other 2002	Generated from EPA NEI02 v.1 and RPO interaction MRPO Base K, CENRAP Base F, MANE-VU Version 3.1 and WRAP Plan02b

1.3.3.3 CMAQ Air Quality Model Configuration for ASIP/VISTAS Annual Modeling

ASIP/VISTAS used Version 4.51 of the Community Multi-scale Air Quality (CMAQ) modeling system with an enhanced secondary organic aerosol (SOA) module (SOAmods) using the model configuration shown in Table 1-3. The model was set up and exercised on the 36 km grid continental U.S. Inter-RPO modeling domain that was also used by WRAP and CENRAP. ASIP/VISTAS also performed annual 2002 12 km modeling for an eastern U.S. modeling domain that included all of the ASIP/VISTAS states as well as adjacent states to the west (CENRAP), in the Midwest (MRPO) and the Northeast (MANE-VU).

Initial CMAQ 2002 simulations performed by VISTAS found that the model greatly underestimate Organic Carbon Mass (OCM) concentrations, especially in the summer (Morris et al., 2004b). A review of the CMAQ formulation found that it failed to treat Secondary Organic Aerosol (SOA) formation from sesquiterpenes and isoprene and also failed to account for polymerization of SOA so that it is no longer volatile and stays in the particle form. The standard versions of CMAQ V4.51 assume that SOA is always volatile so that once an aerosol is formed it can evaporate from particle to gaseous form depending on atmospheric conditions (e.g., temperature and humidity). After a detailed literature review, VISTAS updated the CMAQ SOA module to include these missing processes and found that the updated CMAQ V4.5 SOAmods produced much better OCM model performance in the summer (Morris et al., 2006c). As this SOAMODS enhancement was developed specifically for VISTAS/ASIP, it is described next. Details in the other components of CMAQ V4.51 are provided elsewhere (e.g., Byun and Ching, 1999).

1.3.3.3.1 CMAQ V4.5 SOAmods Enhancement

The formulation of the CMAQ standard SOA module is described in Binkowski and Roselle (2003). In the CMAQ standard SOA module, SOA is formed primarily from aromatic VOCs and biogenic terpenes. The biogenic SOA precursor emissions were modeled with the Biogenic Emissions Information System – Version 3 (BEIS3) model (Pierce et al., 2002). BEIS3 generates three biogenic VOC species: isoprene (ISOP), monoterpenes (TERP) and other biogenic VOC (OVOC). After testing of alternative gas-phase chemical mechanisms available in CMAQ (SAPRC99 and CBM-IV; ENVIRON, Alpine and UCR, 2003c)), VISTAS selected the Carbon Bond IV photochemical mechanism (Gery et al., 1989) for use in the annual air quality modeling since it produced essentially identical model performance as SAPRC99 and was more computationally efficient. CBM-IV represents VOC compounds based on their carbon bond structure. The BEIS3 ISOP, TERP and OVOC species are speciated into the CB4 species for photochemical modeling in CMAQ as follows (molar speciation):

- ISOP = ISOP (isoprene is an explicit species)
- ALD2 = 1.5 x TERP
- OLE = 0.5 x TERP
- PAR = 6.0 x TERP
- NR = 0.5 x OVOC
- OLE = 0.5 x OVOC
- PAR = 8.5 x OVOC
- TERPB = TERP

Here, ALD2, OLE, PAR and NR are the CBM-IV chemical mechanism representations of the biogenic VOC emissions as high molecular weight aldehydes, olefinic carbon bond, paraffin carbon bond and non-reactive functional groups. In CMAQ, the TERPB species is specified in the emissions inputs, along with its CBM-IV representation of ALD2, OLE and PAR, but does not participate in the photochemical mechanism and is only used in the SOA formation module. The TERPB species forms a SGTOT species based on oxidation parameters extracted from the photochemical module. SGTOT consists of the combined gaseous condensable gas (CG) plus particle SOA that are assumed to be in equilibrium. CMAQ transports the SGTOT species and splits it to a CG gaseous and particle SOA for output.

The CMAQ TERB SOA formation rate is based on a two-product fit to smog chamber data collected at the California Institute of Technology for several biogenic monoterpene species (Binkowski and Roselle, 2003). A review of recent literature of biogenic SOA measurements identified several processes that may be important to biogenic SOA formation that are not treated by the BEIS3 biogenic emissions model and the CMAQ SOA module:

Polymerization: Recent measurements indicate that some SOA species may polymerize, resulting in species that are no longer volatile and cannot evaporate back to a CG. In this case, the equilibrium assumption between the CG and SOA will understate the amount of particle SOA present in the atmosphere (Kalberer et al., 2004; Jang et al., 2002).

Sesquiterpenes: Sesquiterpenes are not accounted for in the BEIS3/CMAQ SOA modeling system (Guenther et al., 2000; Vizuete et al., 2004).

Isoprene: More recent evidence suggests that isoprene can also form particle SOA compounds that are not accounted for in CMAQ (Claeys et al., 2004; Matsunaga et al., 2003; 2005).

Acid Catalyzation: Recent literature also suggests that some SOA formation may have acid catalyzed reactions (Claeys et al., 2004; Jang et al., 2005).

Heterogeneous Reactions: Recent evidence suggests that some SOA formation may occur during heterogeneous aqueous-phase chemical reactions (Yu et al., 2005).

An enhanced SOA module was added to CMAQ that accounted for the first three processes listed above. The last two processes were not included in this work because there are not enough quantitative experimental data yet to establish a parameterization. Modules were added to the CMAQ SOA module under the following constraints:

- The existing CMAQ SOA module for monoterpenes would remain unchanged;
- The same CMAQ model inputs would be used; and
- The basic CMAQ model formulation would remain unchanged, modules would be added to account for polymerization and SOA from sesquiterpenes and isoprene.

Figure 1-3 displays how the enhanced SOA module represented the new processes that were added to the CMAQSOA module to represent SOA polymerization and SOA formation from sesquiterpenes and isoprene along with the existing CMAQ SOA module structure and inputs. The new components of the SOA module are indicated in bold italic, whereas the existing

CMAQ SOA components (Binkowski and Roselle, 2002) use a regular font. There are several parameters that must be defined in the new elements of the enhanced SOA module: emission factors (EF), canopy escape efficiencies for gases (EEG) and aerosols (EEA) and SOA yields (Y). Based on an analysis of recent measurements, primarily from a recent biogenic emissions field study in Duke Forest, North Carolina (Stroud et al., 2005; Matsunaga et al., 2005), a range of values for the factors in Figure 1-3 were developed as shown in Table 1-4. The enhanced SOA module used the mid-point of the range values for the factors from the measurements (Table 1-4), which represent the best estimates of these parameters given the information when they were developed. No attempt was made to optimize the parameters in Table 1-5 for OC/TCM model performance.

The emission factors, EF1 and EF2, relate the monoterpene emissions estimated by BEIS3 to emissions of monoterpenes, EF1 (e.g., α-pinene), and sesquiterpenes (EF2). Table 1-4 displays the range of EF1 and EF2 factors based on recent field study data (Stroud et al., 2005). Using the midpoint of the range results in emission factors of 0.7 for EF1 and 0.4 for EF2. EF1 is assigned a value of 0.7 based on field observations that indicate that the BEIS3 terpene emission factors are likely overestimated due to a tendency of earlier measurements approaches to artificially increase the emissions due to disturbance when leaves were enclosed in the measurement system. Sesquiterpene emissions were included using an EF2 value of 0.4 based on the ratio of the observed sesquiterpene emission from the Duke Forest field study to terpene emissions that are provided by BEIS2 TERP species (Stroud et al, 2005). The net result is that BEIS3 TERP emissions are increased by 10% and split 64% as monoterpenes and 36% as sesquiterpenes. The CG yields from the sesquiterpenes are assumed to partly condense into a non-volatile SOA particle that is modeled in CMAQ using the new secondary organic carbon species (SOC2) species and only some of the gas and aerosol species associated with sesquiterpenes are assumed to escape from the canopy using the mid-range of the Escape Efficiencies (EE) estimated by Stroud et al. (2005). The fraction of BEIS3 TERP emissions that are assumed to be monoterpenes (i.e., 64% of the emissions) are treated with the standard CMAQ two-product SOA module (Binkowski and Roselle, 2003) assuming equilibrium between the CG and SOA with the SOA output in the standard AORGB species (Binkowski and Roselle, 2003). The isoprene SOA formation pathway forms a CG using the mid-point yield rate based on the range of recent measurements (Stroud et al., 2005) and a CG/SOA partitioning rate based on the mid-point of measurements from Matsunaga et al. (2003, 2005) (Table 1-4). The isoprene SOA is assumed to be volatile and is modeled as a new secondary organic carbon species in CMAQ SOAmods (SOC3). Finally, all SOA species, with the exception of the already non-volatile SOC1 (polymerized SOA) and SOC2 (sesquiterpene product) species, are assumed to partially polymerize into non-volatile particles that are stored in the SOC1 species. The polymerization rate is based on the results of Kalberer et al (2004) who found that 50% of the SOA polymerized in 20 hours.

Several levels of Quality Assurance and Quality Control of the enhanced SOAmods module in the CMAQ model were conducted as follows.

<u>QA/QC of SOAmods Coding</u>: The SOAmods implementation was conducted at ENVIRON. Staff at the University of California at Riverside performed independent QA/QC of the SOAmods code implementation and independent testing and evaluation.

<u>QA of SOAmods Formulation</u>: The new processes being added to the CMAQ SOA module were discussed with researchers at EPA's Office of Research and Development

(ORD). Although they have not completed all the laboratory tests, the inclusion of SOA from sesquiterpene and isoprene has been observed and are supported by their preliminary measurements.

Peer Review of SOAmods: The formulation of the SOAmods enhancement to the CMAQ SOA module was documented, reviewed by many parties and comments were provided. The results were also published in a peer-reviewed journal (Morris et al., 2006c).

Model Performance Evaluation of SOAmods: The final level of QA of the SOAmods was comparisons of CMAQ V4.4 model performance with and without including the SOAmods enhancement. Table 1-5 displays fractional bias error for Organic Carbon Mass (OCM) at IMPROVE and STN monitoring sites in the VISTAS, MRPO, MANE-VU and CENRAP states using the standard CMAQ Version 4.4 (V4.4) and then CMAQ V4.4 with the SOAmods enhancement. Here the original IMPROVE equation was used to adjust the IMPROVE measured OC to OCM (i.e., OCM = 1.4 x OC). Whereas the standard CMAQ V4.4 underestimates OCM across IMPROVE sites from –76% (MRPO) to –102% (VISTAS), with the SOAmods enhancement the fractional biases centered on zero and ranged from –14% to +8%. Similar results are seen for OCM fractional bias across the more urban STN sites where the CMAQ V4.4 exhibits an underestimation bias of –67% to –105%, when using SOAmods the under-prediction bias is –27% to –44%. Note that the continued underestimation of OCM across the urban STN sites is likely due to missing primary OCM emissions and uncertainties in the STN OCM measurements. Also note that a 1.4 multiple was used to convert the measured OC to OCM; if a 1.8 factors was used for such conversion, as given in the new IMPROVE equation, than the OCM underprediction bias would be even greater.

With the release of CMAQ Version 4.5 in October 2005, the SOAmods enhancement was added to the AERO3 aerosol module in CMAQ Version 4.5 that was compared against the standard CMAQ Versions 4.5 and SOAmods was found to produce similar improvements in OCM model performance as seen with CMAQ Version 4.4. In March 2006 Version 4.51 of CMAQ was released that included active Sea Salt chemistry and Sea Salt emissions. Given that many of the VISTAS Class I areas are located in the coastal environment then Sea Salt may be important. Consequently, the SOAmods enhancement was implemented in the AERO4 (AE4) aerosol module in CMAQ V4.51 and that was the version used in the final 2002 Base G2 and 2009, 2012 and 2018 Base G4 modeling.

Table 1-3. CMAQ Air Quality Model Configuration for ASIP/VISTAS.

Science Options	Configuration	Details/Comments
Model Code	CMAQ Version 4.51 with SOAmods enhancement	Pleim et al., (2005); Morris et al., (2006c)
Horizontal Grid Mesh	36/12 km	36 km covering cont. U.S; 12 km covering eastern US
36 km grid	148 x 112 cells	RPO National Grid
12 km grid	168 x 177 cells	VISTAS 12 km EUSA grid
Vertical Grid Mesh	19 Layers	First 17 layers sync'd w/ MM5
Grid Interaction	One-way nesting	
Initial Conditions	~15 days full spin-up	Separately run 4 quarters of 2002
Boundary Conditions	2002 3-hourly GEOS-CHEM annual run	Day-specific 3-hour BCs from Global Climate Model
Emissions		
Baseline Emissions Processing	SMOKE (Ver 2.2)	MM5 Meteorology input to SMOKE, CMAQ
Dust Transport Fraction	Applied in emissions before SMOKE	Tom Pace updates
NH3 Inventory Adjustment	Applied in emissions before SMOKE	
Sub-grid-scale Plumes	No Plume-in-Grid (PinG)	
Chemistry		
Gas Phase Chemistry	CBM-IV	
Aerosol Chemistry	AE4/ISORROPIA	Includes active Sea Salt
Secondary Organic Aerosols	Secondary Organic Aerosol Model (SORGAM) w/ SOAmods enhancement	Schell et al., (2001); Morris et al, (2006c)
Aerosol Mass Conservation Patch	Yes	Georgia Institute of Technology Update
Cloud Chemistry	RADM-type aqueous chemistry	Includes subgrid cloud processes
N2O5 Reaction Probability	0.01 – 0.001	
Meteorological Processor	MCIP Version 3.0	Includes dry deposition for Sea Salt and percent urban minimum Kz (PURB)
Horizontal Transport		
Eddy Diffusivity Scheme	K-theory with Kh grid size dependence	Multiscale Smagorinsky (1963) approach
Vertical Transport		
Advection Scheme	Yamartino	V4.5 Mass Conservation (Yamartino)
Eddy Diffusivity Scheme	K-theory	
Diffusivity Lower Limit	Kzmin = 0.1 to 2.0	PURB option in Ver 4.5
Planetary Boundary Layer	No Patch	
Deposition Scheme	M3dry	Directly linked to Pleim-Xiu Land Surface Model parameters
Numerics		
Gas Phase Chemistry Solver	Euler Backward Iterative (EBI) solver	Hertel et al (1993) EBI solver ~ 2x faster than MEBI
Horizontal Advection Scheme	Piecewise Parabolic Method (PPM) scheme	
Simulation Periods	Annual 2002	With~15 day spin-up in December 2001
Integration Time Step	Determined by met conditions	15 minute coupling time step
Platform	Athlon MP 2600+	MPI using 6 processors per quarter

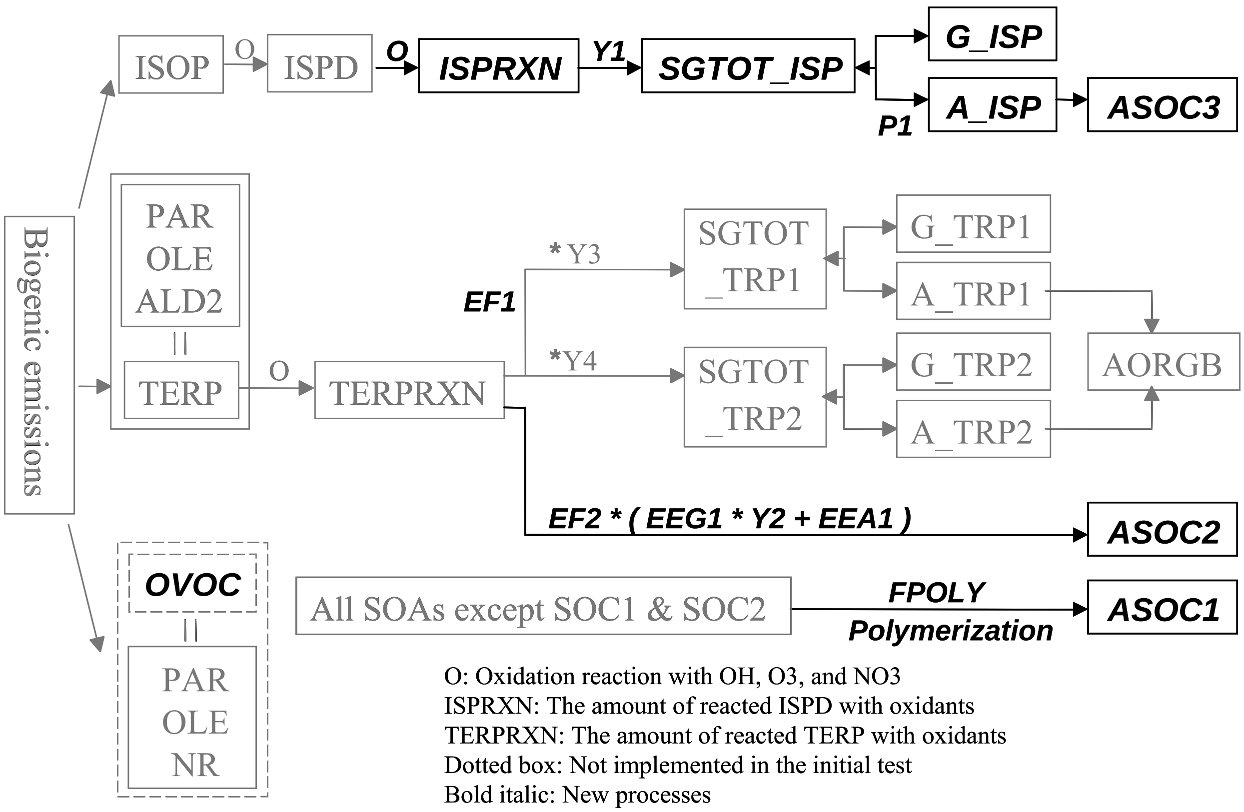

Figure 1-3. Schematic describing the addition of new SOAmods processes (bold italic) to the existing CMAQ SOA module (regular font) to treat polymerization and SOA formation from sesquiterpenes and isoprene (see Table 1-4 for parameters).

Table 1-4. Parameters use in SOAmods module to enhance CMAQ (see Figure 1-3).

Parameter	Mid-Point	Range
EF1	0.7	0.4 ~ 1.0
EF2	0.4	0.2 ~ 0.6
EEG1	0.325	0.2 ~ 0.45
EEA1	0.2	0.05 ~ 0.35
Y2	0.875	0.75 ~ 1.0
Y1	0.11	0.06 ~ 0.16
P1	0.45	0.15 ~ 0.75

EF1 = emission factor of monoterpenes to the TERP emissions estimated by BEIS3
EF2 = emission factor of sesquiterpenes relative to the TERP emissions estimated by BEIS3
EEG1 = escape efficiency of gas phase precursor of sesquiterpenes from canopy
EEA1 = escape efficiency of SOA from sesquiterpenes from canopy
Y1 = SOA yield of oxidated isoprenes
Y2 = SOA yield of sesquiterpenes

Table 1-5. Results of initial evaluation of the SOAmods enhancement comparison of fractional bias performance metric for Organic Carbon Mass (OCM) using the standard CMAQ Version 4.4 (V4.4) and CMAQ V4.4 with the SOAmods enhancement (observed OCM = 1.4 x OC).

July 2002 Fractional Bias	IMPROVE OCM		STN OCM	
	V4.4	SOAmods	V4.4	SOAmods
Southeastern U.S.	-102%	-2%	-105%	-32%
Midwestern U.S.	-76%	+12%	-67%	-24%
Northeast U.S.	-82%	-14%	-95%	-44%
Central U.S.	-98%	+8%	-81%	-27%

1.3.4 Horizontal Modeling Domains

ASIP/VISTAS used the same 36 km continental U.S. and 12 km eastern U.S. modeling domains in the VISTAS Phase I and II modeling. The 36 km Inter-RPO coarse grid continental United States horizontal modeling domain is the same domain used for CENRAP and WRAP modeling. The CMAQ domain is nested in the MM5 domain. The selection of the MM5 domain is described in the VISTAS MM5 modeling protocol (Olerud, 2003a,b,c,d). Figure 1-4 displays the MM5 horizontal domain as the outer bluest grid. Also shown in Figure 1-4 is the CMAQ 36 km domain nested in the MM5 domain. To achieve finer spatial resolution in the eastern U.S., including the ASIP/VISTAS region, ASIP/VISTAS also used a one-way nested higher resolution grid with a 12 km grid resolution. Figure 1-5 displays the 36 km CMAQ continental grid and the high resolution, nested 12 km grid for the eastern U.S. Figure 1-6 shows in more detail the 12 km grid for the eastern U.S. region that is the focus of ASIP/VISTAS.

Both MM5 and CMAQ employ the Regional Planning Organization (RPO) unified grid definition for the 36 km continental domain. The RPO unified grid consists of a Lambert-Conformal map projection using the map projections parameters listed in Table 1-6.

Table 1-6. RPO Lambert Conformal Projection (LCP) unified grid definition.

PARAMETER	VALUE
projection	Lambert-conformal
alpha	33 degrees
beta	45 degrees
x center	97 degrees
y center	40 degrees

The MM5 36 km grid includes 164 cells in the east-west dimension and by 128 cells in the north-south dimension. The CMAQ 36 km grid includes 148 cells in the east-west dimension and 112 cells in the north-south dimension. Because the MM5 model is also nested in the Eta model, there is a possibility of boundary effects near the MM5 boundary that occur as the Eta meteorological variables are being simulated by MM5 and must come into dynamic balance with MM5's algorithms. Thus, a larger MM5 domain was selected to provide a buffer of 8 to 9 grid cells around each boundary of the CMAQ 36 km domain. This is designed to eliminate any errors in the meteorology from boundary effects in the MM5 simulation at the interface of the MM5 and Eta models. The buffer region used here exceeds the EPA suggestion of at least 5 grid cell buffer at each boundary.

Table 1-7 lists the number of rows and columns and the definition of the X and Y origin (i.e., the southwest corner) for the 36 km and 12 km grids for both MM5 and CMAQ. Note that the CMAQ grid is rotated 90 degrees relative to the MM5 grid, so rows and columns are reversed. In Table 4-2 "Dot" refers to the grid mesh defined at the vertices of the grid cells while "cross" refers to the grid mesh defined by the grid cell centers. Thus, the dimension of the dot mesh is equal to the cross mesh plus one. Finally, we note that the grid definition for the CMAQ Meteorology Chemistry Interface Processor (MCIP) and CMAQ Chemical Transport Model (CCTM) are identical. The SMOKE emissions modeling used the same domain definition as CMAQ.

Table 1-7. Grid definitions for MM5 and CMAQ using the RPO LCP unified grid coordinate system.

MODEL	COLUMNS DOT(CROSS)	ROWS DOT(CROSS)	XORIGIN	YORIGIN
MM5 36km	129 (128)	165 (164)	-2952000	-2304000
CMAQ 36km	149 (148)	113 (112)	-2736000	-2088000
MM5 12km	190 (189)	181 (180)	7200	-1656000
CMAQ 12km	169 (168)	178 (177)	108000	-1620000

In Aug 2007 it was discovered that the I/O API subroutine used in SMOKE provided incorrect coordinate transformations from lat/long coordinates to Lambert Conformal coordinates. This error results in a displacement of stack locations of approximately 2-3 km, so point sources in the modeling inventories could be displaced spatially by one 12 km or 36 km grid cell to another. In general, this displacement was of a few kilometers so had a minimal effect on the location of grid cells for the point sources in the ASIP/VISTAS 36/12 km modeling. This error was discovered after the 2002 Base G2 CMAQ base case simulation. ASIP discussed whether this error should be corrected in the 2009 Base G4 modeling and decided not to in order for the 2009 modeling to be consistent with 2002. However, the I/O API coordinate transformation error was corrected for extracting modeling results at monitoring locations for use in the model performance evaluation and $PM_{2.5}$ projections.

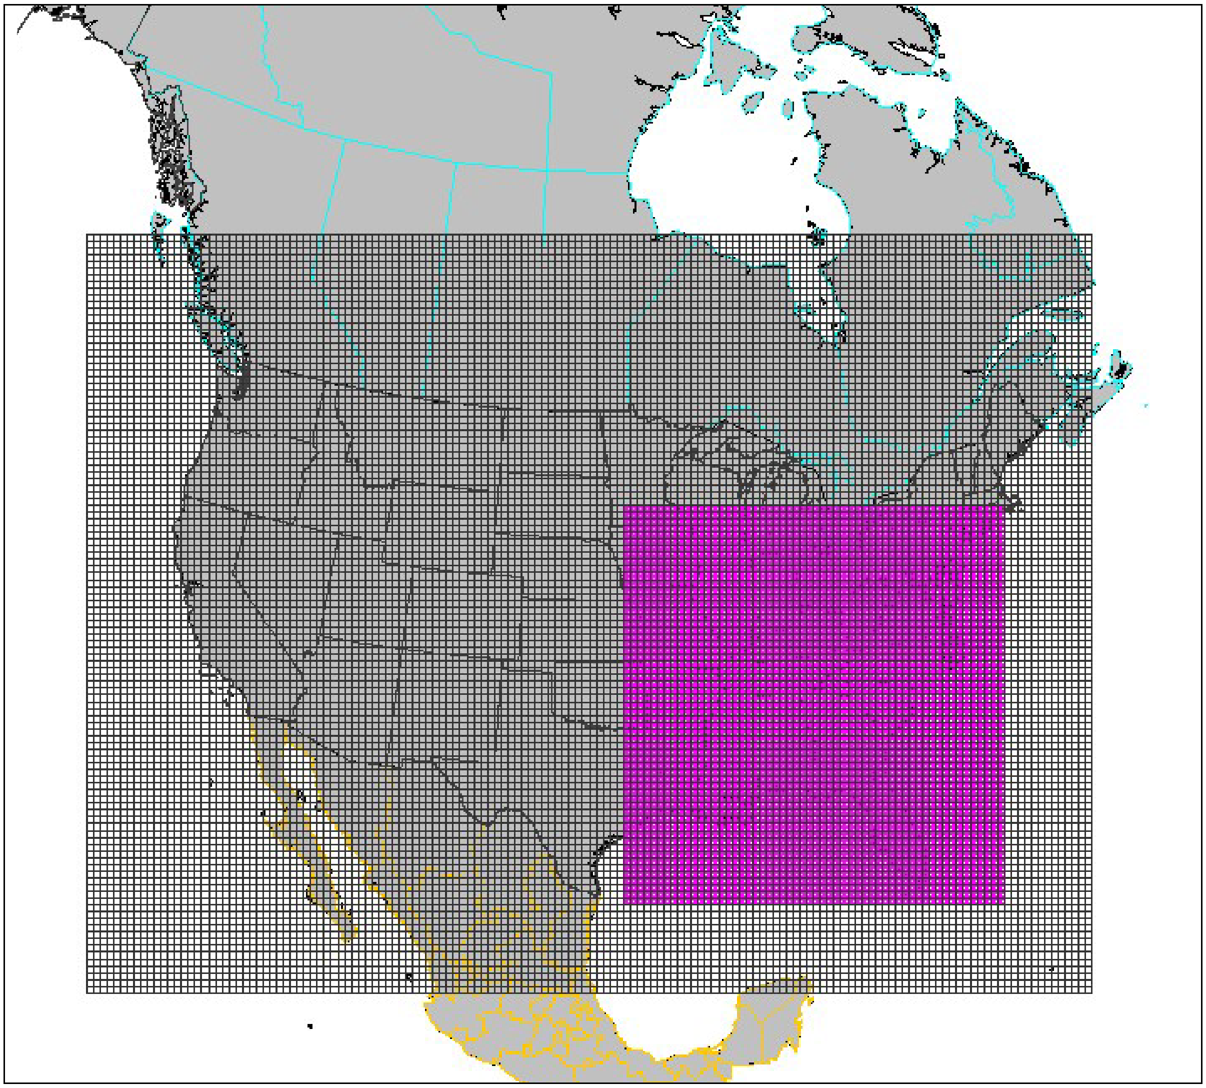

Figure 1-5. Nesting of CMAQ 12-km grid (violet) in the CMAQ 36 km grid (black).

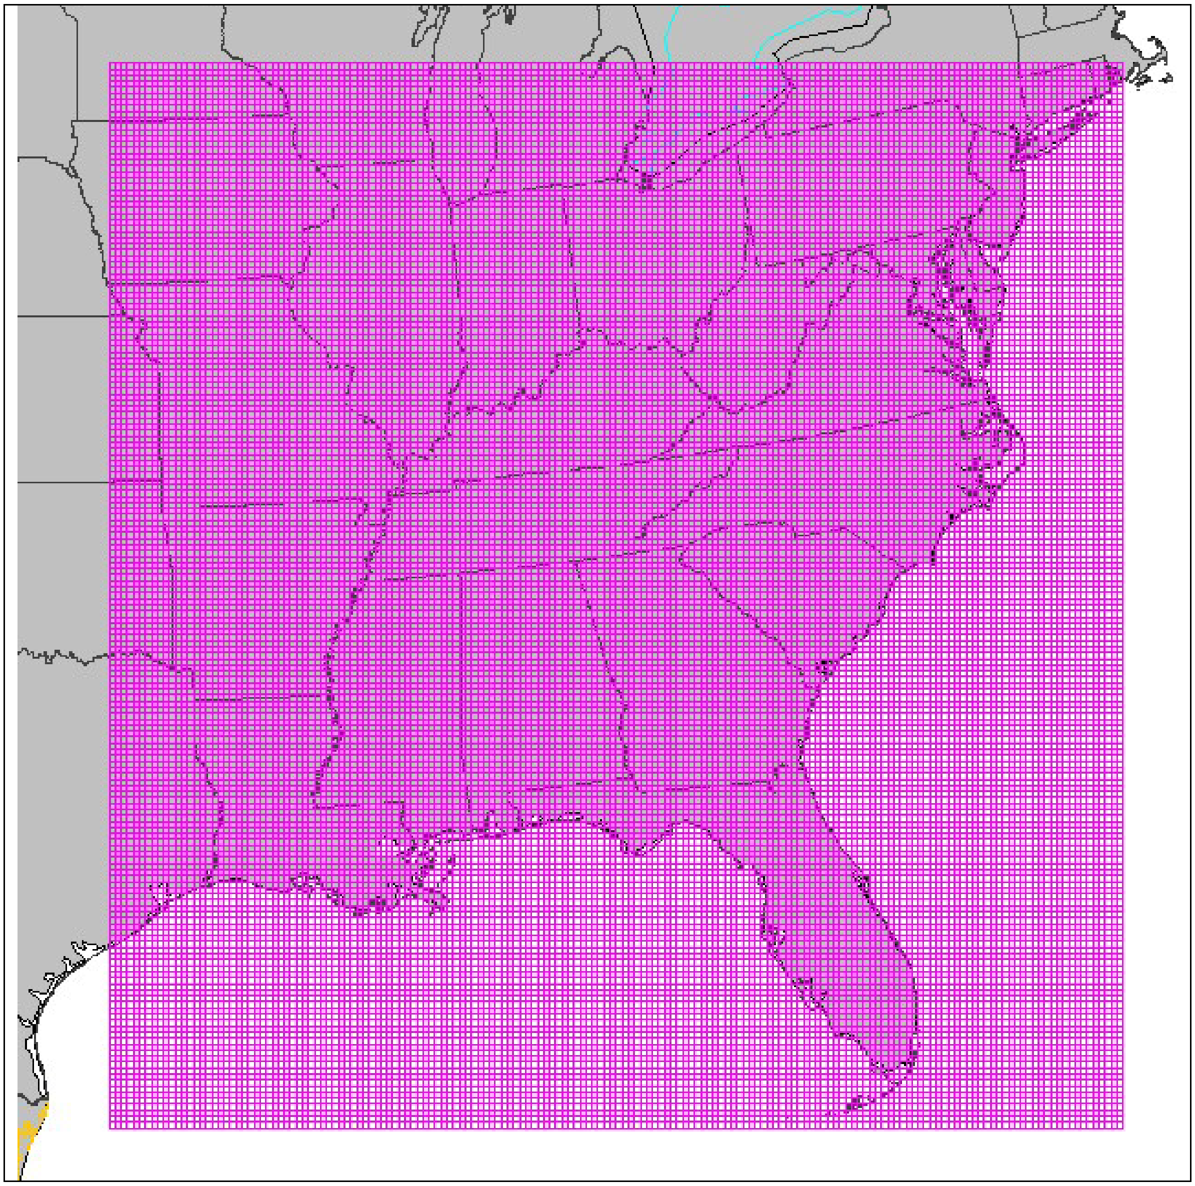

Figure 1-6. Domain definition for the ASIP/VISTAS higher resolution CMAQ 12 km eastern U.S. grid.

1.3.5 Vertical Domain Definition

The CMAQ vertical layer structure is primarily defined by the vertical grid used in the MM5 modeling. The MM5 model employed a terrain following coordinate system defined by pressure, using 34 layers that extend from the surface to the 100 mb pressure level. Table 1-8 lists the layer definitions for both MM5 and for CMAQ. A layer averaging scheme is adopted for CMAQ to reduce the computational time of the CMAQ simulations. The effects of layer averaging were evaluated in the VISTAS Phase I modeling effort and found to have a relatively minor effect on the model performance metrics when both the 34 layer and a 19 layer CMAQ models were compared to ambient monitoring data (ENVIRON, Alpine and UCR, 2003c).

Table 1-8. Vertical layer definition for the VISTAS MM5 simulations (left most columns) using 34 layers and approach for reducing CMAQ layers by collapsing multiple MM5 layers (right columns).

MM5					CMAQ 19L				
Layer	Sigma	Pressure (mb)	Height (m)	Depth (m)	Layer	Sigma	Pressure (mb)	Height (m)	Depth (m)

1.3.6 2002 Calendar Year Selection

The calendar year 2002 was selected for ASIP/VISTAS ozone, PM and regional haze annual modeling as described in the ASIP/VISTAS Modeling Protocols (ENVIRON, Alpine, UCR and UCD, 2004; Morris et. al., 2006b). EPA recommends that the selection of a modeling period for annual $PM_{2.5}$ modeling be based on the following four criteria (EPA, 2007a):

1. Choose time periods from each quarter which reflect a variety of meteorological conditions that represent average concentrations for that quarter and year;
2. Model time periods in which observed concentrations are close to the appropriate baseline design value;
3. Model time periods fort which extensive air quality/meteorological data bases exist; and
4. Model a sufficient number of days so that the modeled attainment test applied at each monitor violating the NAAQS is base on multiple days.

.

EPA also lists several ‘other considerations’ to bear in mind when choosing potential PM episodes including: (a) choose periods which have already been modeled, (b) choose periods which are drawn from the years upon which the current design values are based, (c) include weekend days among those chosen, and (d) choose modeling periods that meet as many episode selection criteria as possible in the maximum number of nonattainment or Class I areas as possible.

ASIP elected to model a complete single Calendar Year (CY) to assure that sufficient days are present to represent each quarter of the Year, which follows EPA recommendations (page 149, EPA, 2007a). The 2002 calendar year was selected by ASIP for annual $PM_{2.5}$ and 8-hour modeling for the following reasons:

- Based on available information, 2002 appears to be a fairly typical year in terms of meteorology;
- 2003 and 2004 appeared to be colder and wetter than typical in the eastern US;
- The enhanced IMPROVE and IMPROVE Protocol and Supersite PM monitoring data were fully operational by 2002 with much less IMPROVE monitoring data available during 2000-2001;
- The STN speciated $PM_{2.5}$ and FRM $PM_{2.5}$ mass monitors were fully operational in 2002.
- Includes the entire summer ozone season of 2002 so is also suitable for 8-hour ozone modeling;
- 2002 was being modeled by VISTAS and other RPOs.

1.3.7 Initial Concentrations and Boundary Conditions

The CMAQ model was operated separately for each of four quarters of the 2002 year using a ~15 day spin up period (i.e., the model was started approximately 15 days before the first day of interest in each quarter in order to limit the influence of the assumed initial concentrations, e.g., start June 15 for quarter 3 whose first day of interest is July 1). Sensitivity simulations demonstrated that with ~15 initialization days, the influence of initial concentrations (ICs) was minimal using the 36 km Inter-RPO continental U.S. modeling domain. Consequently, clean ICs were specified in the CMAQ modeling using a ~15 day spin up period.

Boundary Conditions (BCs) (i.e., the assumed concentrations along the later edges of the 36 km modeling domain, see Figure 1-4) were based on a 2002 simulation by the GEOS-CHEM global circulation/chemistry model. GEOS-CHEM is a three-dimensional global chemistry model driven by assimilated meteorological observations from the Goddard Earth Observing System (GEOS) of the NASA Global Modeling and Assimilation Office (GMAO). It is applied by research groups around the world to a wide range of atmospheric composition problems, including future climates and planetary atmospheres using general circulation model meteorology to drive the model. Central management and support of the model is provided by the Atmospheric Chemistry Modeling Group at Harvard University.

A joint RPO study was performed coordinated by VISTAS in which Harvard University applied the GEOS-CHEM global model for the 2002 calendar year (Jacob, Park and Logan, 2005). The University of Houston (UH) was retained to process the 2002 GEOS-CHEM output into BCs for the CMAQ model (Byun, 2004). The GEOS-CHEM simulations for the RPOs used GEOS meteorological observations for the year 2002. These were obtained from GMAO as a 6-hourly archive (3-hour for surface quantities such as mixing depths). The data through August 2002 were from the GEOS-3 assimilation, with horizontal resolution of $1^o x 1^o$ and 55 vertical layers. The data after August 2002 were from the updated GEOS-4 assimilation, with horizontal resolution of $1^o x 1.25^o$ and 48 vertical layers (note 1^o latitude is equally to approximately 110 km). The horizontal resolution was 4° x 5°. The emissions used in GEOS-CHEM included U.S. anthropogenic emissions from the EPA NEI 1999 inventory, except for ammonia; international emissions for the most recent year available, and forest fire information specific to 2002. Emissions were aggregated to monthly average in acknowledgement that greater accuracy is not feasible for international emissions. This GEOS-CHEM run included the secondary organic aerosol (SOA) formation mechanism from Chung and Seinfeld (2002), prototype soil dust and sea salt simulations, and application of surface emissions and dry deposition to the entire mixed layer column rather than to just the surface layer of the model.

The GEOS-CHEM output was processed by mapping the GEOS-CHEM chemical compounds to the species in the CBM-IV chemical mechanism used by CMAQ and mapping the GEOS-CHEM vertical layers to the 19 layer vertical layer structure used by CMAQ in the VISTAS modeling (Byun, 2004). The results were day-specific three-hourly BC inputs for the CMAQ model.

The BCs generated from the 2002 GEOS-CHEM were subjected to QA/QC. The first QA/QC check was a range check to assure reasonable values. The BCs were compared against the GEOS-CHEM outputs to assure the mapping and interpolation was performed correctly. The code used to map the GEOS-CHEM output to the CMAQ BC format was obtained from UH, reviewed and the BC generation duplicated for several time periods during 2002.

1.3.8 Emissions Input Preparation

Emissions for the CMAQ model were prepared using the SMOKE emissions modeling system with the configuration given in Table 1-2. Four types of emissions inventories were prepared:

- 2002 Actual Base Case;
- 2002 Typical Base Case;
- 2009 Base Case;
- 2012 Base Case; and
- 2018 Base Case.

The differences between the 2002 Actual and Typical Base Cases were emissions from Electrical Generating Units (EGUs) and fires. For the 2002 Actual Base Case day-specific emissions for the EGUs based on measurements from continuous emissions monitoring (CEM) data and day-specific fire emissions were used. For the 2002 Typical Base Case the EGU and fire emissions intensity are representative of the 2000-2004 5-year Baseline period. The 2002 Actual Base Case was used when comparing the CMAQ modeling results to the 2002 measurements in the model performance evaluation (See Chapter 3), whereas the 2002 Typical Base Case results were used with the 2009, 2012 and 2018 modeling results to make $PM_{2.5}$ Design Value projections (see Chapter 4).

The base emissions for the ASIP/VISTAS states were provided by the ASIP/VISTAS emissions contractor (MACTEC, 2008). Emissions for Non-VISTAS states were obtained from the other RPOs during late 2006. These data were either provided in the SMOKE IDA format or in the case of the MRPO converted to the IDA format for input into SMOKE. Emissions for Mexico were based on the EPA Phase II 1999 Mexico inventory and a year 2000 inventory was used for Canada. Emissions for stationary point, area, on-road mobile, non-road mobile, fires and biogenic sources were processed. Day-specific biogenic emissions were generated using the SMOKE-BEIS3 program and the hourly 2002 36/12 km MM5 data discussed previously. In order to account for seasonal and day-of-week effects, on-road mobile sources were simulated for a week from each month of 2002 using the SMOKE-MOBILE6 module and the MM5 meteorological data as input. Holidays were modeled as a Sunday. Similarly, area and non-road emissions were modeled for a Thursday, Friday, Saturday, Sunday and Monday from each month with emissions for Thursday used to represent Tuesday and Wednesday and Holidays used Sunday emissions. More details on the emissions modeling are provided in Chapter 2 and Appendix A.

1.3.9 Meteorological Input Preparation

The VISTAS 2002 36/12 km MM5 modeling was conducted by Barons Advanced Meteorological Systems (BAMS) as described previously (Olerud, 2003a,b,c,d). The VISTAS annual emissions and air quality modeling team processed the 2002 36/12 km MM5 data using the MCIP processor version 3.0 (September 2005) for input into CMAQ and conducted QA/QC on the CMAQ meteorological input files. ASIP used the same 2002 36/12 km MM5 meteorological data as VISTAS.

1.3.10 Photolysis Rates Model Inputs

Several chemical reactions in the atmosphere are initiated by the photo dissociation of various trace gases. To accurately represent the complex chemical transformations in the atmosphere, accurate estimates of these photodissociation rates must be made. The Models-3 CMAQ system includes the JPROC processor, which calculates a table of clear-sky photolysis rates (or J-values) for a specific date. JPROC uses default values for total aerosol loading and provides the option to use default ozone column data or to use measured total ozone column data. . These data come from the Total Ozone Mapping Spectrometer (TOMS) satellite data. TOMS data that is available at 24-hour averages and was obtained from http://toms.gsfc.nasa.gov/eptoms/ep.html. Day-specific TOMS data was used in the CMAQ radiation model (JPROC) to calculate photolysis rates. The TOMS data were missing or bad for several periods in 2002: August 2-12; June 10; and November 18-19. Thus, the TOMS data for August 1, 2002 was used for August 2-7 and TOMS data for August 13 was used for August 8-12. Similarly, TOMS data for June 9 was used for June 10 and data for August 17 was used for August 18-19. Note that the total column of ozone in the atmosphere is dominated by stratospheric ozone which has very little day-to-day variability so the use of TOMS data within a week or two of an actual day introduces minimal uncertainties in the modeling analysis.

JPROC produces a "look-up" table that provides photolysis rates as a function of latitude, altitude, and time (in terms of the number of hours of deviation from local noon, or hour angle). In the current CMAQ implementation, the J-values are calculated for six latitudinal bands (10º, 20º, 30º, 40º, 50º, and 60º N), seven altitudes (0 km, 1 km, 2 km, 3 km, 4 km, 5 km, and 10 km), and hourly values up to 8 hours of deviation from local noon. During model calculations, photolysis rates for each model grid cell are estimated by first interpolating the clear-sky photolysis rates from the look-up table using the grid cell latitude, altitude, and hour angle, followed by applying a cloud correction (attenuation) factor based on the cloud inputs from MM5.

The photolysis rates input file was prepared as separate look-up tables for each simulation day. Photolysis files are ASCII files that were visually checked for selected days to verify that photolysis rates are within the expected ranges.

1.3.11 Air Quality Input Preparation

Air quality data used with the CMAQ modeling system include: (1) Initial Concentrations (ICs) that are the assumed three-dimensional concentrations through the modeling domain at the very start of the simulation; (2) the Boundary Conditions (BCs) that are the concentrations assumed along the lateral edges of the 36 km inter-RPO continental U.S. modeling domain; and (3) air quality observations that are used in the model performance evaluation discussed in Section 3 of this TSD.

The CMAQ default clean Initial Concentrations (ICs) were used along with an approximately 15 day spin up (initialization) period to eliminate any significant influence of the ICs on the modeled concentrations for the days of interest.

The CMAQ Boundary Conditions (BCs) for the Inter-RPO 36 km continental U.S. grid were based on day-specific 3-hour averages from the output of the GEOS-CHEM global simulation model of 2002 (Jacob, Park and Logan, 2005). The 2002 GEOS-CHEM output was mapped to the species and vertical layer structure of CMAQ and interpolated to the lateral boundaries of the 36 km grid shown in Figure 1-4 (Byun, 2004).

1.3.12 2002 Base Case Modeling and Model Performance Evaluation

The CMAQ model was evaluated against ambient measurements of PM species, ozone, gas-phase species and wet deposition within and outside of the ASIP/VISTAS region. Ambient measurements from the IMPROVE, STN, CASTNet, NADP, SEARCH, AQS and FRM monitoring networks were used in the ASIP and VISTAS CMAQ model performance evaluation.

The CMAQ 2002 Base G2 Actual model performance for PM species can be summarized as follows:

- Nitrate (NO3) Underprediction Tendency: NO3 is routinely underpredicted during the summer and adjacent months throughout the ASIP region. This underprediction is due to modeled NO3 concentrations near zero, when observed values are low, but above zero (typically < 1 $\mu g/m^3$). However, NO3 is almost always a very minor to insignificant contributor to total $PM_{2.5}$ mass at FRM monitors in the ASIP region. In fact, the maximum NO3 contribution to a 2009 projected $PM_{2.5}$ Design Value is 1.0 $\mu g/m^3$with a median value of 0.2 $\mu g/m^3$. Thus, the NO3 performance issues are not a big concern in the $PM_{2.5}$ projections.

- Organic Carbon Mass (OCM) Underpredictions: The OCM underprediction bias is a cause for concern since it is a major component of the $PM_{2.5}$ mass at ASIP NAAs with maximum contributions to the 2009 $PM_{2.5}$ Design Values of ~8 $\mu g/m^3$, minimum values of ~3 $\mu g/m^3$ and a median value of ~4 $\mu g/m^3$. The reasons for the underestimation of OCM are unclear, but the fact that the underpredictions are higher in the urban than rural areas suggest that there may be missing anthropogenic emission sources, or possibly the urban OCM emissions are over diluted across the 12 km grid resolution used in the ASIP modeling, or both. The changes in projected OCM concentrations between the current and projected $PM_{2.5}$ Design Values are mostly less than 5% (i.e., $0.95 < RRF_{OCM} < 1.05$). Thus, the changes in OCM between the current and future year are having a minor influence on the projected $PM_{2.5}$ Design Values.

- Elemental Carbon (EC) Performance Issues: The EC underprediction bias at the urban sites is partly due to over dilution of the urban EC emissions due to the coarse (12 km) grid used. For the most part, the CMAQ model performed well for EC and the underprediction would not affect the relative changes in the model response to anthropogenic EC emissions changes. Therefore, any EC performance issues are not a cause for concern, although the model performance for EC was generally good.

- Sulfate (SO4) Underprediction Bias: Although SO4 is performing well, it does have an underprediction bias that is largest in the summer months. But this underprediction is not severe and the model appears to be capturing the temporal and spatial variations in the observed sulfate well and is responding to the SO2 emission reductions between 2002 and 2009 in a manner as expected. Thus the model performance indicates that the modeled relative changes in SO4 concentrations are likely a valid response.

- Soil Performance Issues: The CMAQ performance for the Soil species is quite poor. This Soil component of the 2009 projected $PM_{2.5}$ Design Value ranges from 0.4 to 1.8 $\mu g/m^3$. The RRFs for Soil indicate that it is mostly increasing, with summer (Q3) Soil RRFs typically ranging from 1.0 to 1.3.

SO4 reductions dominate the changes in $PM_{2.5}$ Design Values between 2002 and 2009, 2012 and 2018. SO4 performance is quite good in the CMAQ 2002 Base G2 Actual base case simulation almost always achieving the PM performance goal and frequently also achieving the more stringent ozone performance goal. These factors provide confidence in the $PM_{2.5}$ Design Value projections using the CMAQ Base G modeling results.

The CMAQ 2002 Base G2 base case simulation was also evaluated for ozone concentrations, separately within each ASIP state and combined across all states in the ASIP region. Over most months, the CMAQ ozone model performance achieved EPA's ozone performance goals, albeit with an underestimation tendency. The CMAQ ozone model performance was comparable to ozone model performance of photochemical grid models used in past ozone SIPs so was deemed adequate for making future year 8-hour ozone projections.

More details on the CMAQ 2002 Base G2 model performance evaluation for $PM_{2.5}$ and ozone can be found in Chapter 3 and Appendices B and C. Performance focusing on the constituents that make up regional haze can be found in Morris and co-workers (2009) and detailed model performance for $PM_{2.5}$ ozone and regional haze are available on the VISTAS website (http://www.vistas-sesarm.org/documents/ENVIRON_Air_Quality_Modeling_Technical_Support_Document_11-14-07.pdf). In addition, comparison of the CMAQ performance with CAMx is provided in Appendix D.

1.3.13 Future-Year Modeling and $PM_{2.5}$ and Ozone Projections

Emissions for the 2009, 2012 and 2018 Base G4 base cases were generated following the procedures discussed in Chapter 2 and in the Emissions Inventory report by MACTEC (2008). 2009, 2012 and 2018 emissions for Electrical Generating Units (EGUs) were based on simulations of the Integrated Planning Model (IPM) for the year 2010 and 2018 that took into account the effects of the Title IV controls, NOx SIP Call and Clean Air Interstate Rule (CAIR) on emissions from EGUs. In some cases the IPM projected EGU emissions did not agree with the state projections so those EGU emissions were adjusted to match state expectations for three future years (MACTEC, 2008). Emissions for on-road and non-road mobile sources were based on activity growth and emissions factors from the EPA MOBILE6 and NONROAD models, respectively. Area sources and non-EGU point sources were grown to 2018 levels using assumptions from EPA and DOE. The following controls were assumed in the 2009, 2012 and 2018 Base G4 modeling scenarios:

- Clean Air Interstate Rule (CAIR) and Clean Air Mercury Rule (CAMR) for EGUs using IPM output.
- NOx SIP Call.
- North Carolina Clean Smokestack Act.
- Various Consent Agreements (e.g., TECO, VEPCO, Gulf Power Crist 7).
- 1-Hour Ozone SIPS (Atlanta / Birmingham / Northern Kentucky).
- NOx RACT.
- Heavy Duty Diesel Rule.
- Tier 2 Tailpipe Rule.
- Large Spark Ignition and Recreational Vehicle Nonroad Rule.
- Nonroad Diesel Rule.
- Industrial Boiler/Process Heater/RICE MACT.
- Combustion Turbine MACT.
- VOC 2-, 4-, and 10-year MACT Standards.

The following sources were assumed to remain unchanged between the 2002 base case and the future-years (2009, 2012 and 2018) base cases base case simulations:

- Biogenic VOC and NOx emissions from the BEIS3 biogenic emissions model;
- Off-shore emissions associated with off-shore marine vessels and oil and gas production activities;
- Emissions from wildfires;
- Emissions from Mexico; and
- Global transport (i.e., emissions due to BCs from the 2002 GEOS-CHEM global chemistry model.

The results from the 2002 Typical Base G2 and 2009, 2012 and 2018 Base G4 CMAQ simulations were used to project future-year annual $PM_{2.5}$ and 8-hour ozone Design Values levels that were compared against the NAAQS. The current and future year modeling results were used in a relative sense to scale the observed current year $PM_{2.5}$ and 8-hour ozone Design Values (DVCs) from the 2000-2004 period to obtain the future-year $PM_{2.5}$ and 8-hour ozone projections (DVFs). The ratio of modeling results of the future year model simulations to the 2002 model simulation is called the Relative Response Factor (RRF). EPA guidance for $PM_{2.5}$ projections recommends developing RRFs specific to each PM component and each FRM monitoring site area based on the ratio of the quarterly average modeled PM species concentrations for the future year to 2002 model simulations. Ozone projections are made using RRFs based on modeled high ozone days at ozone monitoring sites. In addition to making future year $PM_{2.5}$ and 8-hour ozone Design Value projections using the ASIP CMAQ 2009 and 2012 Base G4 base cases, future year projections were also made using the VISTAS CMAQ 2018 Base G4 base case results. All future-year projections were made using EPA's Modeled Attainment Test Software (MATS; http://www.epa.gov/scram001/modelingapps_mats.htm).

1.3.13.1. $PM_{2.5}$ Projections

Table 1-9 summarizes the FRM monitoring sites within and adjacent to the ASIP region for which projected 2009 $PM_{2.5}$ Design Values are 14.5 µg/m^3 or higher using the ASIP CMAQ 12 km modeling results and EPA MATS projection approach. EPA guidance has a weight of evidence (WOE) zone where additional analysis is needed to support a modeled attainment demonstration when the projected $PM_{2.5}$ Design Values are close to the $PM_{2.5}$ NAAQS (EPA, 2007a). EPA recommends that a WOE analysis be conducted if the modeled future-year $PM_{2.5}$ Design Value is in the 14.5 to 15.5 µg/m^3 range. If the future-year projected $PM_{2.5}$ Design Value is 15.5 µg/m^3 or higher, EPA notes that no amount of additional analysis is likely to be convincing that attainment would be achieved.

There are three FRM monitors within or adjacent to the ASIP region whose 2009 projected $PM_{2.5}$ Design Values are 15.5 µg/m^3 or greater:

- The North Birmingham monitor (17.0 µg/m^3) in the City of Birmingham in Jefferson County, Alabama;
- The Wylam monitor (15.8 µg/m^3) in the City of Birmingham in Jefferson County, Alabama; and
- An Atlanta, Georgia monitor in Fulton County (16.6 µg/m^3).

An additional two monitors are above the $PM_{2.5}$ NAAQS but within the WOE range (14.5-15.5 μg/m^3):

- A monitor in Clayton County, Georgia (15.1 μg/m^3) in the Atlanta area.
- And a monitor in Hamilton County, Ohio that is part of the Cincinnati NAA (15.5 μg/m^3).

An additional seven FRM monitors have projected $PM_{2.5}$ Design Values that are below the NAAQS but within the WOE zone. These monitors are located in the Atlanta NAA, southern Indiana in the Louisville NAA, southern Ohio in the Cincinnati NAA, the greater Charleston-Huntington NAA and the Knoxville NAA.

The two monitors in Birmingham that are projected to violate the annual $PM_{2.5}$ NAAQS in 2009 are influenced by local sources that are not captured well by the ASIP 12 km CMAQ modeling. Thus, the Alabama Department of Environmental Management (ADEM) and Jefferson County Department of Health (JCDH) are performing the Birmingham Air Pollution Study (BAPS). BAPS is using the ASIP 12 km CMAQ modeling results to provide boundary conditions (BCs) for 4 km urban CMAQ modeling and are also performing AERMOD near-source modeling to address $PM_{2.5}$ attainment issues (ENVIRON and Alpine, 2007; ENVIRON, Alpine and Envair, 2009).

The Georgia Environmental Protection Division (GEPD) is also performing subregional CMAQ modeling using BCs from the ASIP 12 km CMAQ results to address $PM_{2.5}$ attainment demonstration in Georgia.

Table 1-9. 2009, 2012 and 2018 projected $PM_{2.5}$ Design Values within and adjacent to the ASIP region that are 14.5 μg/m^3 or higher using the 2009 CMAQ 12 km Base G4 modeling results.

1.3.13.2 Ozone Projections

EPA's MATS was also used to make the 2009, 2012 and 2018 8-hour ozone Design Value projections using the 2002 Base G2 and 2009, 2012 and 2018 Base G4 CMAQ 12 km modeling results. The EPA default approach (EPA, 2007a) was used to make the future year ozone projections, which includes:

- Use of the modeled highest daily maximum 8-hour ozone concentration within a 3 x 3 array of 12 km grid cells centered on monitor site for the RRFs;
- Calculation of RRFs using modeling results for days in which the model estimated 2002 Base G2 daily maximum 8-hour ozone concentration near the monitor is greater than an Ozone Threshold where:
    - An Ozone Threshold of 85 ppb is used initially that is reduced by 1 ppb until either: (1) 10 modeling days are obtained for the RRF; or (2) a 70 ppb Ozone Threshold floor is achieved.
- If the 70 ppb Ozone Threshold floor is achieved and there are less than 10 modeling days for the RRFs then:
    - If there are 5 or more days the future year ozone Design Value is accepted; or
    - If there are less than 5 modeling days for the RRFs then no future year ozone projection is obtained for that monitoring site.

The modeled ozone attainment test is passed when the future year projected 8-hour ozone Design Value (DVF) is less than 85.0 ppb (i.e., 84.9 ppb or lower). However, EPA requires that a weight of evidence (WOE) analysis be performed to support the attainment demonstration if the projected modeled DVF is between 82.0 ppb and 87.0 ppb. Table 1-10 lists the current year (DVC) and future year (DVF) 8-hour ozone Design Values for all monitoring sites within and adjacent to the ASIP region for which the projected 2009 DVF is above the 82.0 ppb WOE threshold.

There are 20 ozone monitoring sites within and near the ASIP region with 2009 Base G4 DVFs are above the 82.0 ppb WOE threshold. Of these, there are six with 2009 DVFs that are 85.0 or greater so do not pass the modeled 8-hour ozone attainment test. Of these 6 monitors, three are in Maryland, two are in Virginia and one is in Atlanta, Georgia. By 2012, all ozone monitoring sites within and near the ASIP region are not only estimated to attain the 0.08 ppm 8-hour ozone NAAQS, but are also estimated to be below the 82.0 ppb WOE threshold. By 2018 the modeling estimates that not only the 0.08 ppm 1997 8-hour ozone NAAQS is continued to be attained, but that the new 0.075 ppm 2008 8-hour ozone NAAQS is attained at all sites except three each in Maryland and Virginia. The 0.075 ppm 2008 8-hour ozone NAAQS will be addressed in future SIP actions.

Table 1-10. Current year (DVF) and 2009, 2012 and 2018 projected (DVF) 8-hour ozone Design Values for monitoring sites in which the 2009 DVF is above the 82.0 WOE threshold using the 2002 Base G2 and 2009, 2012 and 2018 Base G4 12 km CMAQ modeling results.

1.3.14 Additional Supporting Analysis for $PM_{2.5}$

ASIP performed additional supporting analysis of its modeling results and $PM_{2.5}$ projections to help verify the validity of the future-year $PM_{2.5}$ projections. These additional supporting analyses are discussed in Chapter 5 and include the following:

- Verification of the MATS 2009 $PM_{2.5}$ projections using an alternative projection software. Because EPA's MATS projection tool was not available early on in the ASIP study, ASIP developed their own $PM_{2.5}$ projection tool using Excel spreadsheets. 2009 $PM_{2.5}$ Design Values generated using the ASIP Excel spreadsheet projection approach were compared with those generated by the EPA MATS projection tool and the two methods agreed on which NAAs are estimated to have 2009 $PM_{2.5}$ Design Values above the NAAQS and which ones have projected $PM_{2.5}$ Design Values below the NAAQS across all the monitors in the NAA.

- Use of an alternative model (CAMx) for some sites to corroborate the CMAQ projections. The 2009 $PM_{2.5}$ Design Value projections using the CAMx were slightly higher (0.1 to 0.3 µg/m3) than CMAQ, but the two models agreed on which NAAs would have monitors with 2009 $PM_{2.5}$ Design Values above the NAAQS and which NAAs would have projected 2009 $PM_{2.5}$ Design Values below the NAAQS at all of their monitors.

- Use of PM Source Apportionment Technology (PSAT) to assess contributions of specific facilities to 2009 $PM_{2.5}$ concentrations. CAMx was run using a 12/4 km grid domain and PSAT was used to obtain the $PM_{2.5}$ contributions due to SO2 and primary PM emissions from 31 separate facilities. The maximum contribution of the 31 facilities to projected 2009 $PM_{2.5}$ Design Values was 2.5 $\mu g/m^3$, with the maximum single source contribution 2.1 $\mu g/m^3$. A source's close proximity to an FRM monitor was as important a factor to its contribution as its emissions strength.

2.0 DEVELOPMENT OF EMISSIONS MODEL INPUTS

The 2002 base year emissions inventory for Base G2, 2009 Base G4 and 2012 Base G4 of the ASIP modeling is founded on revised 2002 emissions developed by ASIP emission inventory contractors in NEI Input Format (NIF) 3.0. These revised Base G emissions were reviewed by ASIP stakeholders and considered complete as of April of 2008[1]. Control assumptions, growth rates, and other inputs used to develop the 2009 and 2012 forecasts were initially developed in 2004, many of them carried forward into these documented inventories. Additional growth and control modifications have since been identified or analyzed by ASIP and its participating States or contractors, but for reasons of maintaining consistency between the various scenarios, have not been included in these documented files and associated runs. For purposes of the remainder of this section, Base G refers to the 2002 G2, 2009 G4, and 2012 G4 inventories, also commonly called ASIP's "Best and Final" emissions.

Non-ASIP state emissions for the 2002 episode year were based on inventories obtained by the Study Team during late 2006 through early 2008. Emission inventories for 2002 and 2009 for each of the other four RPOs (MANE-VU, MRPO, CENRAP, and WRAP) were directly acquired from the RPOs or prepared using growth and control files and either converted from their native format into structures or temporal basis consistent with ASIP modeling or used directly in the SMOKE IDA formats provided. The exceptions were for CENRAP, MRPO, and WRAP's 2009 base case, which were not available in the required format, and therefore were prepared using the latest available 2002 base year data and growth and control factors consistent with RPO 2018 inventory preparation. Inventory versions for these emission files are noted in Table 1-2 of this document.

Non-ASIP emissions for the 2012 episode year base case were obtained from individual inventories developed by EPA or other RPOs in support of modeling for ozone and PM SIPs. These inventories were largely developed in an alternate approach to the 2002 and 2009 inventories used previously by ASIP. MANE-VU had a set of 2012 emission files for all categories (which were used directly in their native model-ready format). MRPO had prepared non-road emissions for 2012 and the study team developed point source (EGU + non-EGU) 2012 for MRPO using their Base M 2005 base year, Round 5 growth and control factors and IPM v.3.0 output. The primary objective of the 2012 ASIP modeling was to provide an evaluation of additional EGU controls in the ASIP/VISTAS states to support subregional modeling being performed by Alabama and Georgia for their $PM_{2.5}$ SIPs. In order to provide the 2012 information to the two states in a timely fashion, a simplified methodology for estimating 2012 emissions for the non-ASIP states was used for 2012 than used for the 2002, 2009 and 2018 emission inventories. For this reason, care should be taken in the interpretation of the ASIP 2012 modeling results, especially near the ASIP region border areas where emissions from the non-ASIP states have a larger influence.

For MRPO region, 2012 area, dust, and MAR (marine, aircraft, locomotive) sources as well as for all non-EGU and non-road sources for CENRAP and WRAP, the study team developed interpolated inventories based on EPA's latest release of 2009/2014 emissions used for their

1 "Documentation of the Base G2 and Best & Final 2002 Base Year, 2009 and 2018 Emission Inventories for VISTAS; Revision 1," April 9, 2008." MACTEC.

ozone NAAQS simulations[2]. These files are not entirely consistent with the 2002 emissions ASIP are currently using for 2002 and 2009 in these domains, but were readily available, developed within the scope of the available resources and documented by EPA. For other State EGU and on-road sources, we used IPM v.3.0 output and a national MOBILE6/SMOKE run to generate emissions.

Mexican and Canadian emissions used for 2002 are based on the latest available inventories obtainable by the Study Team in formats lending themselves to emissions modeling. Mexican emissions are based on the EPA Phase II 1999 Mexican National Emission Inventory (MNEI)[3]. 2000 (representing 2002), 2010 (representing 2009) and 2010 (representing 2018) Canadian emissions are based on EPA releases of Environment Canada inventories in SMOKE IDA or preprocessed CMAQ formats[4]. These inventories were collected in the December 2006 timeframe.

For purposes of air quality model validation, actual 2002 calendar year emissions for EGU and fire activity were used within the ASIP domain, whereas for strategy and future-year emission runs, "typical year" emissions for these categories were used. Outside of the VISTAS RPO, 2002 emissions obtained from the non-VISTAS RPOs were used in an "as-is" format with no modification made for actual or typical operation.

All emissions were converted to Inventory Data Analyzer (IDA) format and the data were processed for air quality modeling using Version 2.1 (except for elevated fires where Version 2.0 was used) of the Sparse Matrix Operating Kernel Emissions (SMOKE) model. Included in these runs is the temporal, spatial, and speciation profiles and cross-reference data currently provided with the 2.0 release of the model augmented with recommended and approved emission profile data provided by the ASIP stakeholders or emissions inventory contractor or obtained from EPA prior to initial emissions modeling. The processing was adjusted for each run to account for the specific air quality model (AQM) input required by CMAQ and/or CAMx.

Because of the timing of various air quality simulations and continued review of the input parameters used by ASIP for its 2002, 2009, and 2012 episodes, a number of inconsistencies between inventory years and model runs were introduced. These variations are documented throughout his section.

2.1 EMISSIONS MODELING METHODOLOGY

Emissions inventory development for photochemical modeling must address several source categories including: (a) stationary point sources, (b) area sources, (c) on-road mobile sources, (d) non-road mobile sources, (e) biogenic, and (f) fire sources. For this analysis, inventories were developed for 2002 actual, 2002 typical, 2009 and 2012.

Development of an emissions inventory customized for the ASIP region requires a merging of: (a) the most recent pertinent regional inventory and (b) available high-resolution, locale-specific emissions estimated by local, state, and regional agencies in the ASIP region. Local air

2 http://www.epa.gov/scram001/reports/Emissions%20TSD%20Vol1_02-28-08.pdf
3 http://www.epa.gov/ttn/chief/net/mexico.html
4 http://www.epa.gov/ttn/chief/net/canada.html

regulatory and transportation planning agencies are generally the best sources of domain specific activity and control factors to use in developing the base year emissions. Often, these local emissions data sets come from a variety of sources, frequently in different formats.

Contacts with ASIP's emission inventory contractors and the RPOs were established and formal requests made for inventory corrections, updates and ancillary data pertinent to the modeling of emissions in their jurisdictions. Where feasible and consistent with project resources and schedule, these updated data sets were acquired and used to create day-specific modeling inventories specific to the ASIP domain for the base year modeled.

2.2 SET-UP OF SMOKE OVER THE ASIP DOMAIN

SMOKE was configured to generate point, area, nonroad, highway, and biogenic source emissions. In addition, certain subcategories, such as fires and EGUs were maintained in separate source category files in order to allow maximum flexibility in producing alternate strategies. Settings for each of the source categories are discussed in relevant sections below. With the exception of biogenic and highway mobile source emissions, which are generated using the, respectively, BEIS and MOBILE6 modules in SMOKE, pre-computed annual emissions were processed using the month, day, and hour specific temporal (for point sources with CEM data) profiles of the SMOKE model.

To produce an emissions inventory to support annual modeling, representative time periods were selected and modeled. Area, nonroad, and point sources were modeled as a block of Thursday, Friday, Saturday, Sunday, Monday one per month (total of 60 days modeled). On-Road motor vehicles were represented by an entire single week for each month. This selection criterion allows for the representation of day-of-the-week variability in the on-road motor vehicles, and models a representation of the meteorological variability in each month. EGU sources which mapped to continuous emissions monitoring (CEM) data were processed using CEM-based temporal profiles. Holidays were modeled as Sundays. A list of modeled holidays is provided in Table 2-1. The biogenic emissions were modeled on a day specific basis using the hourly MM5 meteorological data (365 days).

Table 2-1. SMOKE modeled holidays.

Date	Julian Day	Holiday Description
January 1, 2002	2002001	New Year's Day
March 29, 2002	2002089	Good Friday
May 27, 2002	2002147	Memorial Day
July 4, 2002	2002185	July 4th
September 2, 2002	2002245	Labor Day
November 28, 2002	2002332	Thanksgiving Thurs
November 29, 2002	2002333	Thanksgiving Fri
December 24, 2002	2002358	Christmas Eve
December 25, 2002	2002359	Christmas Day

Population was used as a gridding default for all source categories when the assigned surrogate would cause SMOKE to drop emissions. This can be a case when the county-level emission inventories are prepared using surrogates other than those available for modeling purposes.

The domain for the ASIP emissions modeling is based on the Inter-RPO 36-km continental U.S., CMAQ domain, illustrated in Figure 2-1 below.

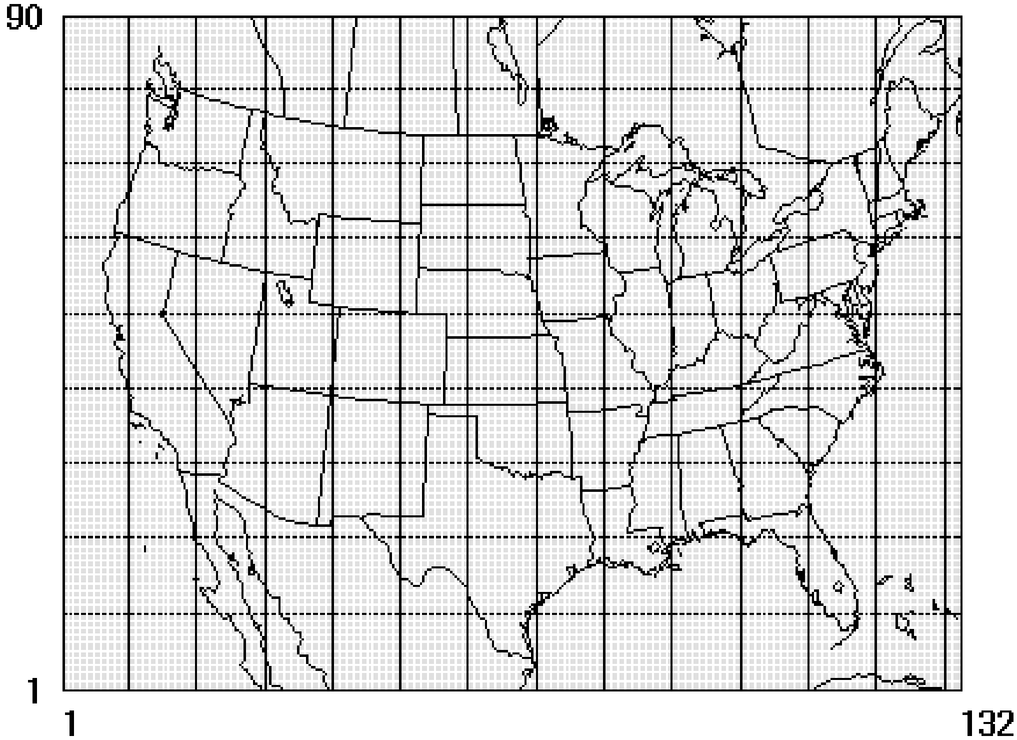

Figure 2-1. Inter-RPO 36-km Continental U.S. CMAQ Domain.

The parameters for the SMOKE runs are as follows:

Episodes:
2002 Calendar Base Year (Actual and Typical)

Future Years:
2009 and 2012.

Output Time Zone:
Greenwich Mean Time (zone 0)

Projection:
Lambert Conformal with Alpha=33, Beta=45, Gamma=-97, and center at (-97,40).

Domain:
36 Kilometer Grid Domain: Origin at (-2736, -2088) kilometers with 148 rows by 112 columns and 36-km square grid cells.

12 Kilometer Grid Domain: Origin at (108, -1620) kilometers with 168 rows by 177 columns and 12-km square grid cells.

Layer Structure:

The CMAQ layer structure is 19 layers, with specific layer positions defined in the meteorology files (see Chapter 1).

CMAQ Model Species:

The CMAQ initial configuration is for the CB-IV chemical mechanism with particulate matter (PM). The model species in the emission input files are: CO, NO, NO2, ALD2, ETH, FORM, ISOP, NR, OLE, PAR, TERPB, TOL, XYL, NH3, SO2, SULF, PEC, PMFINE, PNO3, POA, PSO4, and PMC.

Meteorology Data:

Daily (25-hour). SMOKE requires the following five types of MCIP outputs: (1) Grid cross 2-d, (2) Grid cross 3-d, (3) Met cross 2-d, (4) Met cross 3-d, and (5), Met dot 3-d. These files need to match the grid projection and overlap with the emissions modeling region but can be larger in the horizontal directions than the modeling region shown in Figure 2-1. Therefore, the data files for the 36 Kilometer grid domain were at least 90 columns by 132 rows

Elevated Sources:

All sources were treated by SMOKE as potentially elevated. No plume-in-grid sources were modeled. Where day specific and location specific wildfire data was provided by states and Federal Land Managers, wildfire emissions were handled as point sources.

Producing 365 day-specific input files for all source categories places a burden on available computing facilities, data management systems, and would have adversely affected the modeling schedule. Selecting representative model days for some or all of the source categories reduces the processing and file handling requirements to a more manageable level and in most cases does not compromise the accuracy of the emissions files.

Other current or recent projects undertaken by EPA, WRAP and LADCo have used a selection approach for all of the source categories (except biogenics) that use a representative weekday/Saturday/Sunday either for each month or each season to model all of the emissions files. In an attempt to better represent the level of temporal and spatial detail available for each source category, we have developed and implemented a more detailed strategy.

Biogenic emissions were modeled for each episode day, using the daily meteorology and the SMOKE-BEIS module. Point sources, including CEM and elevated fire emissions, were modeled for each episode day to take advantage of the available day-specific emissions and meteorology. Area sources, including non-road mobile, low level fires and dust emissions, do not utilize meteorological data, and are temporally allocated by monthly, daily and hourly profiles. Reviewing these profiles indicate that maximum temporal definition can be achieved by selecting representative Thursday, Friday, Saturday, Sunday, and Monday profiles for each month.

Motor vehicle emissions are influenced by meteorological variability, but the processing requirements for daily motor vehicle emissions were determined to be prohibitive under the current schedule. Rather than utilizing averaged meteorological data or pre-calculated motor vehicle emissions, a single week per month was selected for modeling. This week was selected from mid-month, to try to best represent the average temperature ranges for the month, and also adjusted to exclude holidays that would require atypical processing. The area source modeling dates were also selected from these ranges to simplify data handling procedures.

Emissions for on-road mobile sources were represented by modeling the following weeks within each month of the year:

January 13-19
February 10-16
March 10-16
April14-20
May 12-18
June 9-15
July 14-20
August 11-17
September 15-21
October 13-19
November 10-16
December 15-21

2.2.1 Processing of Point Source Emissions

Stack parameters are often more important to the reliability of the air quality modeling results than the emissions rates themselves. Stack parameter data are frequently incorrect, especially in some of the current regional modeling inventories and careful QA is required to assure that the point source emissions are properly located both horizontally and vertically on the modeling grid. To screen for simple, but potentially serious inventory errors such as these, the study team has modified procedures originally developed by EPA[5] to quality assure, augment, and where necessary, revise, stack parameters to examine the accuracy of the point source emissions, as well as standardize procedures to identify and correct stack data errors. These procedures were implemented in the NIF to IDA conversion step of the inventory development. Additionally, SMOKE has a number of built-in QA procedures designed to catch missing or out-of-range stack parameters. These procedures were also invoked in the processing of the point source data.

For the final baseline modeling, we separated the point source emissions into EGU and non-EGU categories. The non-EGU category was not processed using any day or hour-specific emissions inputs. All non-EGU point source emissions were temporally allocated to month, day, and hours using annual emissions and source category code (SCC) based allocation factors. These factors were based on the cross-reference and profile data supplied with the utilized SMOKE version

5 ftp://ftp.epa.gov/EmisInventory/2002finalnei/documentation/point/augmentation_point/2002nei_qa_augmentation_report0206.pdf

and were supplemented with relevant data provided to the study team by ASIP and its contractors.

For EGU sources with EPA reported continuous emissions monitoring (CEM) data for 2000-2004 or with hourly emissions provided by stakeholders, actual hourly data were used. For those sources where EPA CEM data are utilized, NOx, SO2, and heat input-based hour-specific profiles were developed and applied to NOx, SO2, and all other emissions, respectively. This ensured that the annual emission values provided by the EI contractor were maintained, but distributed using hourly to annual profiles. For sources providing hour-specific data and where they were approved by the State in which they operated, those data were substituted for EPA CEM-based emissions and distributions.

To temporally allocate the remaining EGU point sources (those which do not report under the CEM program), the NOx, SO2, and heat input data were collected from the 2000-2004 CEM datasets, and used to develop unit-level typical temporal distributions. CEM data from 2002 were used to develop comparable profiles and emission distributions during the actual 2002 model validation runs. The hour, day of week, and monthly specific temporal profiles were used in conjunction with the EI supplied emissions data to calculate hourly EGU emissions by unit.

All point sources were spatially allocated in the domain based on the stationary source geographic coordinates. If a point source was missing its latitude/longitude coordinates and data could not be found to properly site the unit within the domain, the source was placed in the center of its reported county.

2.2.2 Processing of Area and Non-Road Source Emissions

All area and non-road source emissions were temporally allocated to month, day, and hours using annual emissions and source category code (SCC) based allocation factors. These factors were based on the cross-reference and profile data supplied with the utilized SMOKE version and were supplemented with relevant data provided to the study team by ASIP or its contractors. Area and non-road sources were spatially allocated in the domain based on SCC-matched spatial allocation factor files. If an area or non-road source SCC did not have an existing cross-reference profile assigned to it, the county-level emissions were allocated by population density in the respective county.

A county-specific crustal PM transport factor was applied to fugitive dust emission sources that had been identified in U.S. EPA modeling to have only a portion of its mass transportable from the source of the emission generation. These EPA's studies[6] indicate that 60 to 90 percent of PM emissions from fugitive dust sources do not reach an elevated level necessary to be transported out of the grid cell where they were emitted. For this reason, the modeling team applied county-specific fugitive dust emissions transport factors to these sources to adjust PM emissions during the conversion of emission input files from the raw mass emissions. These adjusted PM emissions are reported in summary emissions tables.

6 http://www.epa.gov/ttn/chief/emch/invent/index.html#dust

2.2.3 Processing of On-Road Mobile Source Emissions

The MOBILE6 module of SMOKE was used to develop the base and future-year on-road mobile source emissions estimates for CO, NH3 NOx, PM and VOC emissions. The MOBILE6 parameters, vehicle fleet descriptions, and VMT estimates were combined with gridded, episode-specific temperature data to calculate the gridded, temporalized emission estimates. Typically on-network emissions estimates are spatially allocated based on link location and subsequently summed to the grid cell level, the off-network emissions estimates are spatially allocated based on a combination of the FHWA version 2.0 highway networks and population. For the ASIP 36/12 km modeling, no link based data was used. The MOBILE6 emissions factors are based on episode-specific temperatures predicted by the meteorological model. Further, the MOBILE6 emissions factors model accounts for the following:

- Hourly and daily minimum/maximum temperatures;
- Facility speeds;
- Locale-specific inspection/maintenance (I/M) control programs, if any;
- Adjustments for running losses;
- Splitting of evaporative and exhaust emissions into separate source categories;
- VMT, fleet turnover, and changes in fuel composition and Reid Vapor Pressure (RVP).

The primary input to MOBILE6 is the MOBILE shell file. The MOBILE shell contains the various options (e.g. type of inspection and maintenance program in effect, type of oxygenated fuel program in effect, alternative vehicle mix profiles, RVP of in-use fuel, operating mode) that direct the calculation of the MOBILE6 emissions factors.

For the production of the MOBILE6 emission factors, SMOKE was run using hourly episode-specific meteorological data for temperature and humidity. SMOKE produces emission factors for state and county groups that are selected for regional similarities and consistent MOBILE6 option requirements (i.e. I/M programs, RVP, fuel programs). The hourly average temperature and humidity are calculated from the hourly temperatures in each grid cell in the state/county groups.

SMOKE was run using the daily average speed option for all states except North Carolina. The daily average speed was provided based on state, county, and roadway type. North Carolina provided hourly average speeds, also based on state, county and roadway type.

2.2.4 Processing of Biogenic Source Emissions

A revised version of a commonly used biogenic emissions model, the Biogenic Emissions Inventory System (BEIS), was developed and tested by EPA over two separate modeling domains/episodes. This version of the model (BEIS-3, v.0.9) contains several changes over BEIS-2, including the following:

- Vegetation input data -- are now based on a 1-km Biogenic Emissions Landuse Database (BELD3) vegetation data base,

- Emission factors – many updates including some recent NARSTO modifications,

- Environmental algorithm -- includes a sunlit/shaded leaf solar radiation model.

A series of sensitivity modeling simulations has been completed and concluded that the more recent BEIS-3 methodology will impact base case model ozone predictions in most parts of the U.S. The preliminary tests have also shown that the newer biogenic emissions do not appear to have a large effect on: 1) the control signal response, 2) relative reduction factors resulting from a projected emissions change, or 3) overall regional model performance in the eastern U.S.

For this particular application of BEIS-3, version 0.9 as currently incorporated in the SMOKE processor was used. This means that: (1) soil NO emissions were prepared without the input of specific soil moisture and precipitation data; and (2) MEOH emissions were not be modeled explicitly.

The BELD-3 landuse data on a Lambert conformal grid at 1-km resolution have already been developed, are available, and were used to estimate biogenic emissions in this study. The BEIS model also requires as input hourly, gridded temperature and solar radiation data to estimate biogenic emissions, and these data were provided by the MM5 meteorological model.

2.2.5 Processing of Wildfires and Prescribed Burns

Wildfire, agricultural, and prescribed burn emissions were processed separately from the standard area source input files. We used day specific or monthly estimates of fire emissions from ASIP, which include burn acreage and biomass loading information for the ASIP states. Depending on the completeness and quality of the data received, ASIP-specific calculations were made for spatial and temporal distributions of the fire emissions, rather than relying on standard distribution profiles. We calculated vertical distribution of the fire emissions, based on fire size and biomass involvement. SMOKE v2.0 can model fire plume rise when provided with the following variables:

- PTOP – Top of the fire plume profile (meters above ground level)
- PBOT – Bottom of the fire plume profile (meters above ground level)
- Lay1 – The percent of the emissions entrained in the first modeling layer

For those elevated fires having the necessary data elements with distinct time and space coordinates, these variables were prepared and included in the modeling files used to process this emission source type. For low level fires where these discrete spatial and temporal data were not available, we distributed emissions in the lowest modeled vertical layer using the month, day of week and diurnal temporal profiles calculated from the total ASIP state fire distribution files.

The WRAP Fire Emissions Joint Forum Emissions Inventory Report[7] has documented an approach for calculating these plume descriptors. In this method, which was also used in ASIP modeling, the fires are assigned to one of 5 size categories, based on the total burn acreage, and the biomass fuel loading. These categories are then used to calculate representative hourly plume profiles. These profiles are then used by SMOKE 2.0 to distribute the vertical emissions

7 http://www.wrapair.org/forums/fejf/documents/WRAP_2002_PhII_EI_Report_20050722.pdf

for the fires. To successfully model fires as elevated point sources, the data included both the day or days on which the fire occurs, and a spatial identifier of the fire location.

2.2.6 Windblown Dust

PM10 and PM2.5 emissions from wind erosion of natural geogenic sources (SCCs 2730100000 [total] and 2730100001 [dust devils]) were excluded from the resulting modeling files as these meteorological and episode specific categories could not be accurately reflected using the precalculated emission estimates and temporal profiles available at the time of the modeling.

2.2.7 Sea Salt

In March 2006, Version 4.51 of CMAQ was released that includes Sea Salt emissions and active Sea Salt chemistry. Given the number of ASIP states with coastal areas this could be important so ASIP updated the CMAQ V4.51 with the SOAmods enhancement and it was used for the final 2002 Base G2, 2009 and 2012 Base G4 simulations. CMAQ V4.51 internally generates Sea Salt emissions using a user supplied OCEAN file. Thus, Sea Salt emissions were not addressed in the SMOKE processing.

2.3 SMOKE-SPECIFIC PROCESSING CHARACTERISTICS

The Sparse Matrix Operator Kernel Emissions (SMOKE) modeling system is an emissions modeling system that generates hourly gridded speciated emission inputs of mobile, nonroad mobile, area, point, fire and biogenic emission sources for photochemical grid models. SMOKE is one of the fastest emissions processing tools currently available to the air quality modeling community. The sparse matrix approach utilized throughout SMOKE permits both rapid and flexible processing of emissions data. The processing is rapid because SMOKE utilizes a series of matrix calculations instead of less efficient algorithms used in previous systems. The processing is flexible because the processing steps of temporal projection, controls, chemical speciation, temporal allocation, and spatial allocation have been separated into independent operations wherever possible. The results from these steps are merged together at a final stage of processing. Each of these emissions processing steps is detailed below.

2.3.1 Temporal Allocation

ASIP 2002, 2009 and 2012 annual emissions modeling were configured to generate point, area, non-road mobile, on-road mobile and biogenic source emissions. In addition, certain subcategories, such as fires and EGUs were maintained in separate source category files in order to allow maximum flexibility in producing alternate strategies. With the exception of biogenic and on-road mobile source emissions that are generated using the BEIS and MOBILE6 modules in SMOKE, pre-computed annual emissions were processed using the month, day, and hour specific temporal profiles of the SMOKE model. Area and nonroad sources were modeled as a block of Thursday, Friday, Saturday, Sunday, and Monday one per month (total of 60 days modeled). On-road motor vehicle sources were modeled for one seven-day week per month. Point sources and biogenics were modeled for each day of the annual period.

ASIP based its temporal profiles and source category cross-reference files on the EPA CAIR/CAMR/CAVR modeling platform with files located on EPA's CAIR file transfer website[8]. Modifications were made to reflect State specific profiles or updated state of knowledge application of these profiles. Some of these changes included the reallocation of North Carolina NONROAD generated emission categories to a regional set of temporal profiles more consistent with the operation of these source types in the State. Additionally, EGU CEM-based temporal profiles and onroad emissions modeling were prepared in manners deviating from EPA's original CAIR platform.

As noted previously, on-road mobile modeling in SMOKE was done for selected weeks (seven days) of each month - using these days as a "representative week" of the entire month. This selection allows for the representation of day-of-the-week variability in the on-road motor vehicles, and models a representation of the meteorological variability in each month. ASIP/VISTAS executed sensitivity tests to examine this "representative week" methodology versus an everyday on-road mobile modeling method[9]. ASIP/VISTAS determined that the use of representative week on-road mobile emissions produced ozone and particulate matter concentrations that were nearly indistinguishable from the "everyday" mobile method. ASIP determined that the difference in the modeled air quality resulting from the on-road mobile modeling methods were insignificant.

2.3.1.1 CEM-Based Temporal Profile Development and Application

Two sets of monthly profiles were developed for processing EGU emissions with CEM data:

1. Profiles based solely on actual 2002 CEM-based data at the state level. The 2002-only profiles are intended to be used by ASIP in developing model performance evaluation metrics necessary for configuring air quality models in attainment demonstration analyses.

2. Profiles based on historical averages of 2000 through 2004 CEM-based data. These historical 2000-2004 average profiles were developed and were used to represent consistent "typical" operating conditions at EGUs in the ASIP domain for the base year and future year emission estimates.

Analyses conducted by the modeling team[10] indicate an added benefit to the modeling results with the application of CEM-based day-of-week and diurnal profiles, in addition to the monthly profiles for each state. For the majority of EGU units processed in the ASIP domain, unit specific monthly, weekly, and diurnal profiles were developed and applied using historical CEM averages of heat input and emissions and as further described below. As an additional part of this analysis, specific day-of-week (Monday, Tuesday, Wednesday, etc.) and diurnal profiles were also developed for each month and State to better represent operating conditions at units within a State. These State specific day of week and diurnal profiles were developed from averages of CEM-based emissions and heat input activity occurring on that day-of-week or during that hour-

8 ftp://www.airmodelingftp.com/
9 http://www.epa.gov/ttn/chief/conference/ei15/session9/abraczinskas.pdf
10 http://www.epa.gov/ttn/chief/conference/ei14/session11/stella.pdf

of-day across all units within that State. These profiles were then applied to units were CEM specific matches could not be made to ASIP emission inventories.

Data Obtained

Five years (2000 through 2004) of hourly CEM information from EPA's CAMD website were obtained for each unit in the ASIP states[11]. The "Prepackaged Data" option allows the download of files containing emissions data for a specific state, quarter or month, and year. Each prepackaged data file is in .csv (comma delimited) format and contains the following fields: State, Facility Name, Facility ID (ORISPL), Unit ID, Date, Hour, SO_2 Emissions (lbs), CO_2 Emissions (tons), NO_x Emissions Rate (lb/mmBtu), NO_x Emissions (lbs), Heat Input (mmBtu), Operating Time (hours), Gross Load (MW), and Steam Load (1000 lb/hr). For this analysis, we obtained the prepackaged monthly unit-level hourly emissions data by state and year. Using these data, we reformatted the files and quality assured for applicability to this analysis.

File Contents

The reformatted files were prepared as identified in Table 2-2.

Quality Control / Quality Assurance

Each file was reviewed to determine if NOx, SO2 and heat input values were represented for each hour of every day for each unit in the obtained data. Zero values were considered to be valid if operating time identifiers indicated no operation during that hour (e.g., data value of zero but operating hours greater than zero).

Using the measurement flags and field values in the reformatted files, numerous spot checks were made of anomalous or missing variable data to ensure that data corruption was not impacting the statistical analyses. Additionally, each year's hourly total of NOx, SO2, and heat input (per state) were summed and compared to EPA annual summaries of the same data elements.

When there were facilities or units with no emissions data or unit characteristics, we verified that these sources are not required to report emissions data or had not yet reported emissions data to EPA. In some cases, certain months or quarters of the year were blank for individual units or facilities and using EPA data caveat reports, we verified these units were not in operation during those times.

Inventory Matching

Prior to the development of the unit-specific SO2, NOx, and heat input ratios for each hour, the step of matching CEM units to the ASIP 2002 modeling inventory started. Because naming convention and facility or unit numbering can be unique at the Federal, State, local, or facility level, the step of matching existing units from an emissions inventory to the CEM data base proved to be more complicated than anticipated.

11 http://cfpub.epa.gov/gdm/index.cfm?fuseaction=prepackaged.select

The ASIP EGU emission inventory accounted for approximately 3.7 million tons of SO2 and 1.5 million tons of NOx in calendar year 2002. There were 861 units reporting to the CEM database in 2002 for the ten ASIP States. The primary objective of the inventory matching steps was to account for as many units and tons as possible allowing for the unit-specific application of hourly temporal distribution profiles.

Table 2-2. CEM data file format.

Column	Description
State	State in which the facility is located.
Facility Name	The name given by the owners and operators to a facility.
Facility ID (ORISPL)	The unique six-digit facility identification number, also called an ORISPL, assigned by the Energy Information Administration, a component of the Department of Energy.
Unit ID	Each unit at a facility has a unique identification number. It is alphanumeric and may be from one to six characters in length. For utility units and other units that generate energy for sale, the unit ID used for Part 75 reporting is the same unit ID that appears in the National Allowance Database (NADB) (for Acid Rain Program units) or in the State's allowance allocation list.
Day	Day on which a unit was operating.
Hour	Hour on which a unit was operating.
Operating Hours	Percent of hour in which a unit was operating.
Gross Load (MW)	Gross load is the output of the unit as measured in megawatts.
Steam Load (1000 lb/hr)	Steam load is the output of the unit as measured in 1000 lb/hr of steam.
SO_2 Mass (lbs)	SO_2 released for the hour in pounds.
SO_2 Mass Measurement Flag	Indicates whether the value for SO_2 mass was measured or derived due to missing data.
SO_2 Rate (lbs/mmBtu)	SO_2 emissions rate in pounds per million British thermal units (lbs/mmBtu).
SO_2 Rate Measurement Flag	Indicates whether the value for SO_2 rate was measured or derived due to missing data.
NO_x Rate (lb/mmBtu)	NOx emissions rate in pounds per million British thermal units (lbs/mmBtu).
NO_x Rate Measurement Flag	Indicates whether the value for NO_x rate was measured or derived due to missing data.
NO_x Mass (lbs)	NO_x released for the hour in pounds.
NO_x Mass Measurement Flag	Indicates whether the value for NO_x mass was measured or derived due to missing data.
CO_2 Mass (lbs)	CO_2 released for the hour in pounds.
CO_2 Mass Measurement Flag	Indicates whether the value for CO_2 mass was measured or derived due to missing data.
CO_2 Rate (lbs/mmBtu)	CO_2 emissions rate in pounds per million British thermal units (lbs/mmBtu).
CO_2 Rate Measurement Flag	Indicates whether the value for CO_2 rate was measured or derived due to missing data.
Heat Input (mmBtu)	Heat per hour as calculated by multiplying the quantity of fuel by the fuel's heat content.

Under the direction of ASIP, emissions inventory contract staff prepared comparisons of the ASIP 2002 emission inventory of EGU sources to that of CEM-based emissions, heat input, and operating characteristics. For each unit identified as an EGU source in the ASIP inventory, an attempt was made to match it to a CEM unit and associated data.

Automated facility (ORIS) and unit identification was made for a majority of units who maintained the same numbering and nomenclature between the two data sets. This first computerized step captured the majority of emissions by matching some of the largest units in the ASIP domain. The remaining steps were followed in order to match the outstanding facilities and emissions as reported by ASIP states in the 2002 emission inventory.

Inventory contractors developed county-level reports of the remaining unmatched facilities and units from the ASIP inventory and made comparisons of annual emissions of SO2 and NOx to the CEM-based SO2 and NOx for sources also identified within the same county. This step of the matching process allowed an incremental amount of emissions and units to be accounted for and assigned unit-specific profiles for model performance evaluation.

Finally, remaining ASIP inventory and CEM sources were manually compared to each other in an effort to determine if reporting errors in State or county codes or facility or unit identification codes accounted for this reminder of unmatched sources. These manual matches were confirmed or revised with ASIP state and stakeholder participation and input. With this step, a few sources were identified to have facility identification changes or misreported county codes preventing automated matching from occurring and corrected for the final application of factors.

Once all methods of comparison were exhausted, the remaining unmatched ASIP emission inventory of EGU sources was excluded from the unit-specific profile assignment steps and was allocated more generalized facility or State temporal profiles as described in the following section.

This inventory comparison process allowed for the match of over 650 of the 861 CEM identified units (76%) to the ASIP EGU emission inventory for 2002. More importantly, however, was the match of 99.95 percent of the SO2 emissions and over 99.4 percent of the NOx emissions from these sources in the ASIP domain.

Profile Calculations

Two sets of profile types have been developed for modeling EGU emissions within the ASIP domain. The first set are to be applied to individual units able to be matched to CEM data, the second are to be applied to EGU sources within the ASIP domain where CEM-based matches could not be identified.

The first set of temporal profiles have been developed for specific hour-of-date periods based on historical actual 2002 or average NOx, SO2, and heat input data for sources reporting under EPA’s CEM program between 2000 and 2004. These profiles are based on the actual or statistical average of the CEM data variables (NOx, SO2, and heat input) for each hour-of-date (e.g., Hour 12 of March 3) during the year. In the typical profile calculation, variables are calculated for each hour when the operating time of the CEM is greater than 0 (e.g., the unit is in operation during that hour). In the case of 2002-only calculations, all reported NOx, SO2, and heat input data were used in the averaging, including those identified as non-operating hours. This allowed for the best representation of actual 2002 conditions for the expected use of these profiles for model validation studies.

In the second set of profiles, NOx, SO2, and heat input values were averaged over each unit to allow for the calculation of State level monthly, day-of-week, and diurnal profiles for ASIP states.

For the 2000-2004 averaging period, representation of typical operating conditions was desired, so in the averaging calculation only valid operating hour NOx, SO2, and heat input values were used. This prevented the introduction of equipment shutdown because of power outages, control installation, or planned maintenance into the temporal profile calculation.

Actual 2002 Profiles

Through the EPA's Clean Air Market's Data and Maps website, quarterly unit-level hourly emissions data by State and calendar year 2002 were obtained for purposes of developing temporal allocation factors applicable to EGU sources within the ASIP domain. Key elements in these data sets include the State where the unit is located, facility name, facility identification (ORISPL) code (assigned by the Department of Energy at the Energy Information Administration), unit identification code, date of record, hour of record, SO2, CO2, and NOx mass (in lbs per hour), heat input (million British thermal units [MMBtu]), and NOx emission rate (lbs/MMBtu).

SO2 and NOx mass and heat input values were summed for each unit to an annual level to allow for the calculation of an hour of date-to-annual ratio estimation. The equation below provides this calculation for heat input. Table 2-3 provides an example result of the ratio calculation.

$$hi_{ratio,hr,date} = hi_{hr,date} / \sum_{Dec31}^{Jan1} hi$$

where hi = heat input (MMBtu)

Since it was assumed that all sources in the ASIP EGU inventory would not be matched to individual CEM-based units, the same calculations were performed for each state so that a hierarchical application of ratios (unit first, state second) could be assigned as necessary. Table 2-3 shows example ratios calculated for each month by state. Table 2-4 reflects an example of the state-month-day of week ratio calculation and Table 2-6 shows a state-month-diurnal ratio calculation example. Each of these ratios were calculated for each state in the ASIP domain and used in instances where CEM unit matches could not be made to the ASIP base year emissions inventory.

Three parameter values (SO2 mass, NOx mass, heat input) were calculated at each aggregation as NOx and SO2 emissions vary due to fuel blend, sulfur content, or seasonal control and are not necessarily representative of the other variables' seasonal, daily, or even hourly variation. As seen in Figure 2-2, when viewed on a ASIP-domain total, the monthly variation in relative distribution of SO2, NOx, and heat input differs enough to justify calculating each parameter value set of temporal profiles with CEM data.

Table 2-3. Application of calculated ratios for actual 2002 by unit.

ORISPL	UnitID	Date	Hour	Actual Reported Values [2002]			Calculated Ratios		
				SO2 Mass	NOx Mass	Heat Input	SO2	NOx	Heat Input
3	2	01-01-2002	0	15.563	10.294	13.3	1.417E-06	1.915E-06	1.372E-06

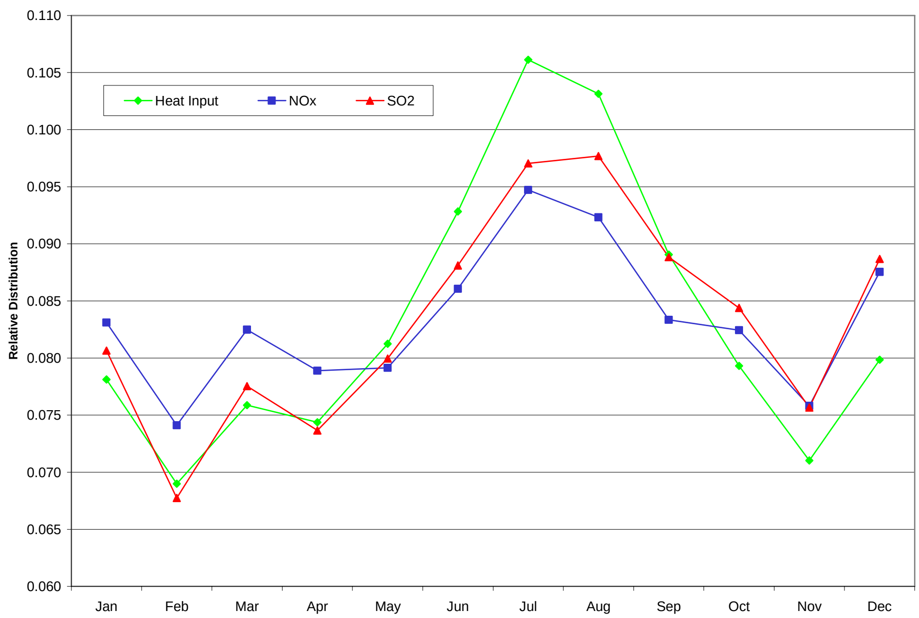

Figure 2-2. Monthly variation in 2002 of CEM reported heat input, NOx mass, and SO2 mass for ASIP domain.

When viewed on a state-by-state basis, the differences in monthly variation are even more pronounced as individual facilities within each state may be affected during any calendar year by extreme temperature variation, shutdowns, or regular maintenance or installation of equipment. As an example, Figure 2-3 represents CEM data from the state of Mississippi during calendar year 2002 and reveals that SO2 emissions increase throughout the year, NOx emissions stay relatively high during the summer months, and heat input peaks during the month of July. Although Figures 2-2 and 2-3 are roughly comparable in shape and monthly distribution, the relative distribution of these values is quite different. In Mississippi's case, close to thirteen percent of the State's CEM-based heat input occurs in July. This compares to the ASIP average of just over ten percent of CEM-based heat input in July.

Finally, when these data are reviewed at a unit level, the differences become incrementally more distinct due to the unique nature of individual facilities, their operating schedules, pollution regulation, fuel characteristics, and applied technologies. For example, a facility that is complying with summertime NOx regulation may have selective catalytic reduction (SCR) installed on its boiler(s) which in practice may only be run during ozone season months. During this period of time, heat input and SO2 emissions may remain consistent with State or regional monthly profiles, but the NOx emissions may drop significantly relative to the rest of the year.

Figure 2-4 represents an extreme unit-specific case for monthly differences from state or regional temporal allocation. The unit presented is a Mississippi baseload coal-fired boiler which in 2002 emitted over 4,000 tons of NOx and over 11,000 tons of SO2. This unit would typically run at consistent levels during the entire period, but due to a planned maintenance outage was not in operation in late January through the middle of April in 2002. Given the unique operation of this boiler during this year, the use of a regional or even state-level monthly temporal distribution would introduce significant inaccuracy to air quality modeling in the immediate or downwind area associated with this facility. While this may not be significant at great distance downwind of the source or for annual concentration estimates, more locally, and especially over shorter time scales (daily or weekly), such simplifications would have a noticeable effect on air quality model predictions.

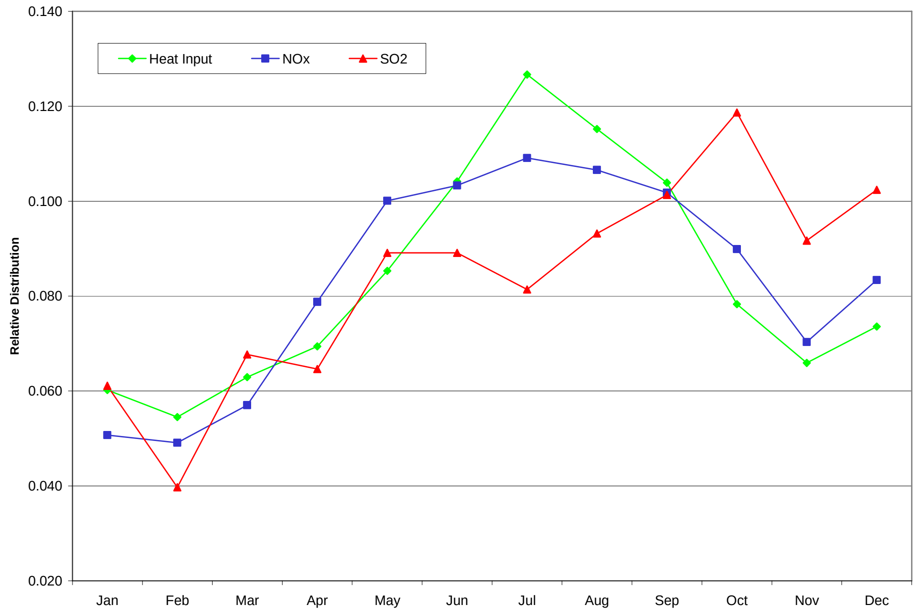

Figure 2-3. Monthly variation in 2002 of CEM reported heat input, NOx mass, and SO2 mass for Mississippi.

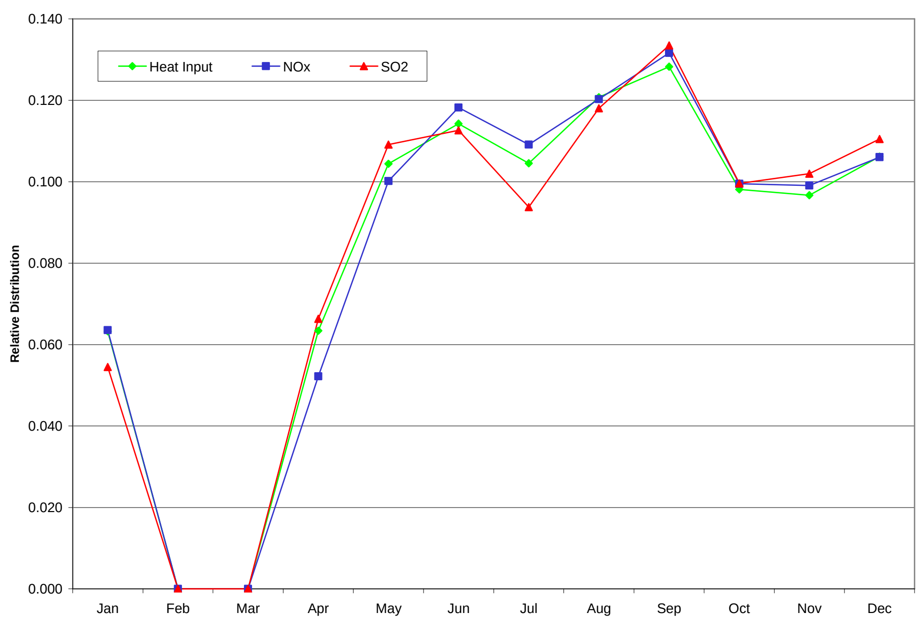

Figure 2-4. Monthly variation in 2002 of CEM reported heat input, NOx mass, and SO2 mass for specific baseload coal-fired unit in Mississippi with planned outage in late January through mid April.

Thus, while improving the representativeness of unit-specific monthly temporal profiles is desirable, providing day and hour-specific values are clearly better. For this reason, during the model performance evaluation process in the ASIP modeling, hour-specific temporal ratios were developed for every CEM reporting unit in the ASIP domain and used for the 2002 Base G2 Actual base case CMAQ 36/12 km simulation used in the model performance evaluation discussed in Chapter 3. These ratios allowed for the hour-by-hour accounting of emissions released at each unit at each facility within the ASIP domain that reported output under the CEM guidelines.

Figure 2-5 represents the actual daily distribution of SO2 and NOx emissions and heat input from the Mississippi baseload unit from the above example. As can been seen in this figure, not only is the planned January through April outage represented correctly, there are significant peaks and valleys throughout the calendar year which could not be accurately represented with the application of average monthly, day-of-week, or hourly distribution factors. In reality, only the actual operating characteristics of this unit could capture the differences from hour to hour which are potentially quite important in terms of correctly modeling the impact of the source on downwind oxidant and fine particulate concentrations[12].

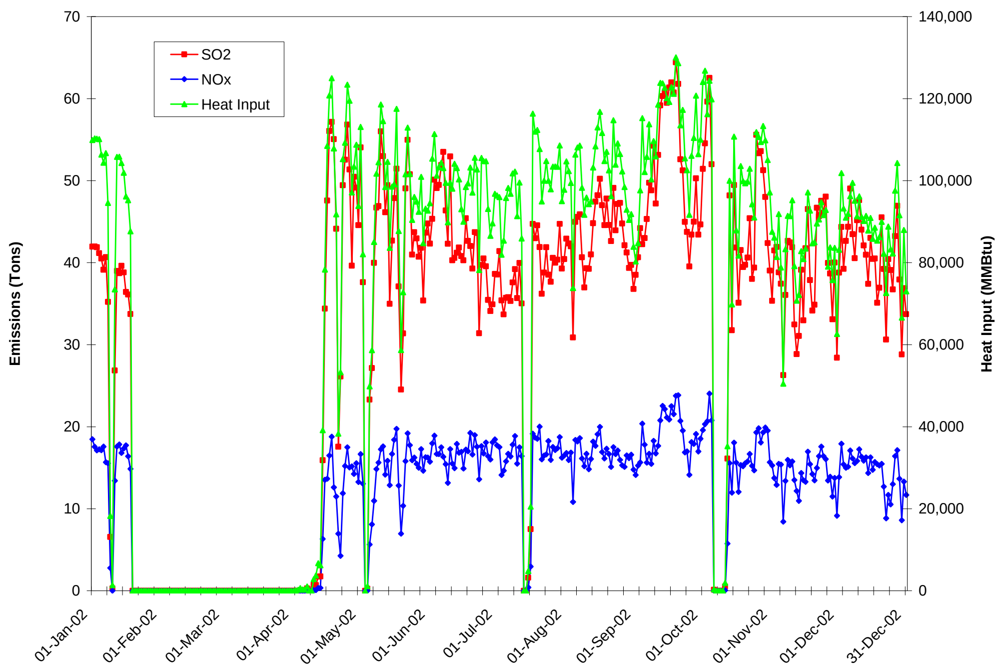

Figure 2-5. Actual daily unit-specific 2002 SO2 (tons), NOx, (tons), and heat input (MMBtu) distribution from CEM data.

Typical EGU Profiles

Hour of day, day of week and month specific temporal profiles were developed by calculating the arithmetic mean of each unit's NOx, SO2, and heat input by specific hour of day per month (e.g., Hour 21 of Wednesdays in July) from the data obtained from 2000 through 2004. In order to accomplish this calculation, each record of CEM data was first assigned a day of week. This assignment was based on the actual CEM's date of record and day of week of that record. An example of this assignment is shown in Table 2-7.

Table 2-7. Example day-of-week per month assignment.

Date	Day of Week
08/01/02	Thu
08/02/02	Fri
08/03/02	Sat
08/04/02	Sun
08/05/02	Mon
08/06/02	Tue
08/07/02	Wed

Once day of week were assigned to each record in the CEM data base, the arithmetic mean of each unit's NOx, SO2, and heat input were calculated for the ORISPL-UNITID-MONTH-DAY OF WEEK-HOUR combination. Only records where the CEMs were operating for more than half the recorded hour (OPTIME > 0.5) were used in the averaging calculation. An example of the averaged results can be seen in Table 2-8.

Table 2-8. Arithmetic mean of CEM-based variables for temporal profile calculation.

These values were then applied to each unit and hour based on the 2002 calendar to match the meteorological data used in the emissions processing. An example of this application can be seen in Table 2-9. The date specific hourly averages were then summed to a unit summer (May – Sept) and winter months total and ratios were developed based on each daily hour's average value divided by the average sum total depending on the season of the day. This permitted the appropriate allocation of summertime NOx (as forecasted by IPM) when summer control only was predicted. Using the annual average ratios instead of the seasonal distributions would produce summertime emissions different than what was output from the model. These typical emissions were used in the 2002 Base G2 Typical base case CMAQ 36/12 km simulation used in the $PM_{2.5}$ projections discussed in Chapter 4.

The equation below reflects this calculation for heat input for a summer hour. Ratios were calculated for NOx, SO2, and heat input values. These ratios were then applied to each unit's seasonal (summer or winter) emission value for NOx, SO2, and all other pollutants, respectively.

$$hi_{ratio,hr,date,sum} = hi_{hr,date,sum} / \sum_{Sep30}^{May1} hi$$

where hi = heat input (MMBtu)

The actual hour-of-day-of-month averages calculated from the CEM data were not used directly as emissions for that hour, but were used only in the calculation of the ratios to be applied to a pre-calculated seasonal (summer or winter) emission value. This allowed for the retention of emission estimates calculated using means other than CEM data, if a State or local agency found them to be more appropriate or if it were derived by other means (e.g., IPM) but an improved distribution of emissions using CEM-based ratios.

As in the actual 2002 profiles calculations, these same calculations were additionally performed for each state so that a hierarchical application of ratios (unit first, state second) could be assigned as necessary. Instead of having variables at the unit level, however, state level values were used. These state value calculations were based on the sum of the unit-level variable averages to the level of aggregation required by the calculation (e.g., state-month. state-month-day-of-week, or state-month-hour). Table 2-10 shows example ratios calculated for each month by state. Table 2-11 reflects an example of the state-month-day of week ratio calculation and Table 2-12 shows a state-month-diurnal ratio calculation example. Each of these ratios were calculated for each state in the ASIP domain and used in instances where CEM unit matches could not be made to the ASIP base year emissions inventory.

Again, three parameter values (SO2 mass, NOx mass, heat input) were calculated at each aggregation as NOx and SO2 emissions vary due to fuel blend, sulfur content, or seasonal control and are not necessarily representative of the other variables' seasonal, daily, or even hourly variation.

Application of Factors

ASIP chose to prepare its air quality modeling inventories with Version 2.1 of the Sparse Matrix Operating Kernel Emissions (SMOKE) model. For this reason, all emissions were required to be converted to SMOKE's data formats. In particular, because hour specific temporal profiles for each day of a year are not accepted directly by the model, it was necessary to develop a set of hourly emissions inputs to circumvent this limitation. These were generated in the SMOKE PTHOUR format as described in SMOKE input file documentation[13].

The CEM format for individual hour-specific data files as available in SMOKE was not utilized for ASIP emissions processing as the emissions allowable by hour would have been limited to NOx, SO2, and CO2. If this file format and optional run configuration were exercised, the NOx, SO2, and CO2 emissions processed by the model would have been accurate for CEM reported emissions, but the remaining pollutants coupled with each CEM unit would have received the

13 University of North Carolina at Chapel Hill, *Sparse Matrix Operator Kernel Emissions (SMOKE) Modeling System*, http://cf.unc.edu/cep/empd/products/smoke/index.cfm.

monthly, daily, and diurnal temporal profiles associated with the source category codes from the unit. This could lead to potentially displaced emissions if a unit were operating at different times than the default profiles indicated. Additionally, in cases where states may not have reported annual emission estimates directly based on CEMs, these emissions would be slightly different that the original annual inventory.

In ASIP modeling, for those EGU sources where CEM data were utilized, NOx, SO2, and heat input-based hour-specific profiles were developed and applied to annual NOx, SO2, and all other emissions, respectively, for both the actual and typical 2002 modeling. Heat input was chosen as a surrogate for non-CEM reported pollutants as the majority of remaining compounds are not as significantly impacted by controls or fuel content, yet the distribution of these emissions would occur during the same times CEM reported pollutants were emitted.

The application of hourly ratios to annual emissions ensured that the annual values provided by states under the CERR were maintained, but distributed using actual hourly to annual profiles. Additionally, for stakeholder sources providing hour-specific data approved by the State in which they operated, data were substituted for state provided emissions and CEM-based distributions.

To temporally allocate the remaining EGU point sources, the NOx, SO2, and heat input data were collected from the 2002 or 2000-2004 CEM datasets, and used to develop State-level temporal distributions. These month-specific hour and day of week temporal profiles were used in conjunction with the emissions inventory to calculate hourly EGU emissions by unit.

Although not as accurate a distribution as the unit-specific factors, the state-based temporal distribution provided improved results to the default profiles provided with the emissions model. Figure 2-6 represents the monthly distribution comparisons of ASIP state heat input to the default monthly distribution from Version 2.0 of SMOKE for source category code (SCC) 10100201, representing External Combustion Boilers; Electric Generation; Bituminous/Subbituminous Coal; Pulverized Coal: Wet Bottom (Bituminous Coal), a relatively common boiler type and fuel configuration in the ASIP domain. This example is for the actual 2002 modeling exercise.

Much like the distinction in month to month variation of the profiles, day of week and diurnal patterns based on CEM data vary from unit to unit. Again, if one were to assign the same day of week or diurnal profile to every unit in the inventory, emissions from these sources would inappropriately be distributed during the episode of interest. In addition to the unique distribution provided by the unit-specific factors based on CEM data, aggregate State level daily and diurnal temporal distribution factors were developed and applied during this process. Figure 2-7 shows the variance in diurnal distribution from Tennessee's average CEM-based NOx emissions data for each of the twelve months of calendar year 2002 as would have been applied to units unmatched to CEM sources.

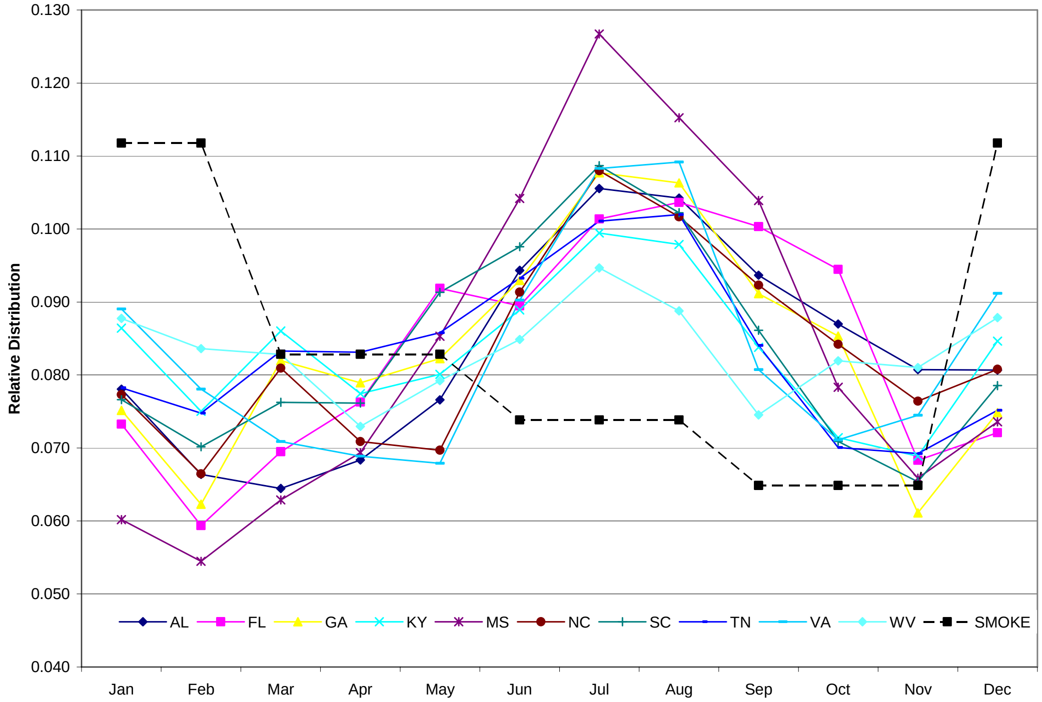

Figure 2-6. Relative distribution of actual 2002 monthly ASIP State CEM-based heat input.

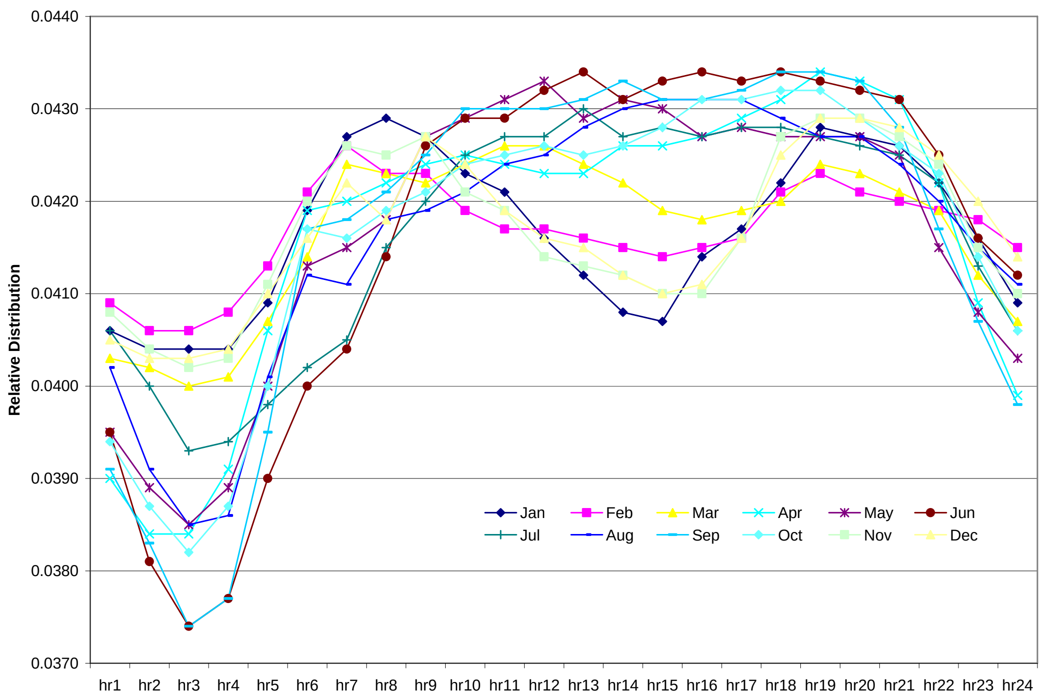

Figure 2-7. Relative distribution of diurnal actual 2002 CEM-based NOx emissions for Tennessee.

The work conducted in this process had the main objective of developing temporal profiles for ASIP EGUs necessary to apply in the generation of SMOKE PTHOUR formatted emissions. Additionally, state-level monthly, day-of-week, and diurnal profiles were developed for application to non-CEM matched units in the ASIP emissions inventory. These temporal distributions represent a significant improvement over the EPA defaults.

Speciation

Speciation is the process of disaggregating inventory pollutants into individual chemical species components or groups of species. The need for speciation is determined by the inventory purpose. Inventory applications that require detailed speciation include photochemical modeling, air toxics inventories, chemical mass balance modeling, and visibility modeling.

Depending on the purpose of a particular emissions inventory, the inventory may include TOG, NOx, sulfur oxides (SOx), CO, total suspended particulate matter (TSP), particulate matter less than 10 micrometers in aerodynamic diameter (PM10), or ammonia (NH3). However, modeling inventories may require these emissions to be expressed in terms of other pollutants. Additionally, for some models, NOx emissions may need to be specified as NO and NO2. Also, PM may need to be separated into various fractions, such as PM10 and PM less than 2.5 micrometers in aerodynamic diameter ($PM_{2.5}$).

SMOKE was configured to speciate the emissions estimates according to the requirements of the Carbon Bond Mechanism version four (CBM-IV, CB-IV or CB4). The SMOKE model reformats the emissions estimates for use in CMAQ modeling based on source category code (SCC) and speciation profile cross-reference files. The speciation profiles and source category cross-references use in ASIP modeling are based on EPA's CAIR/CAVR/CAMR modeling platform with files located on EPA's CAIR file transfer website (ftp://www.airmodelingftp.com/). Minor modifications were made to reflect state specific profiles or updated state of knowledge application of these profiles. One major change made in the ASIP modeling was the modification of coal combustion cross-reference from speciation profile "NCOAL" to profile "22001."

Spatial Allocation

Because air quality modeling strives to replicate the actual physical and chemical processes that occur in an inventory domain, it is important that the physical location of emissions be determined as accurately as possible. In an ideal situation, the physical location of all emissions would be known exactly. In reality, however, the spatial allocation of emissions in a modeling inventory only approximates the actual location of emissions.

Gridding surrogates are used to spatially allocate emission sources from a coarse geographic area to finer grid cells used for modeling. There can be hundreds of unique source categories in an emissions inventory, which is typically developed for counties, states, or other areas. The exact location of most major emission sources is known and their geographic coordinates are usually contained in the inventory. These usually are referred to as major point sources and include electric utilities and major industrial facilities. However, other emission sources are estimated for the entire county or other area as an aggregate since the exact locations of each source are not included in the modeling inventory. Surrogates are human activities or land use information that are used to represent a more precise location of emission source category groups. A gridded surrogate ratio is the ratio of the amount of a surrogate in a modeling grid cell to the total amount of that surrogate in a county. Grid cell emissions are calculated by multiplying the cell's gridded surrogate ratio by the county emissions.

These surrogates and their associated SCC cross-references were originally developed by EPA (http://www.epa.gov/ttn/chief/emch/spatial/newsurrogate.html) and converted to the gridded domain definitions of the ASIP model requirements.

2.3.2 Development of Gridded Surrogate Files

The general process for creating the SMOKE-ready gridded surrogate files from the ArcGis shape files is as follows:

1. Overlay the grid on the surrogates. Generate the grid polygons (36/12 km) with the specifications of the ASIP domain and spatially overlay (intersect) the grid onto the surrogate area polygons or points. The resulting geodatabase contains, for each surrogate, the county FIPS code, the grid column and row number, and the amount (area, miles or count) of the county's portion of the surrogate in that cell.

2. Extract and convert each geodatabase table to a useful dataset. Each table contains the gridded area, miles or count in each county for a specific surrogate. The variables include FIPS code, column number, row number and area, miles or count.

3. Calculate surrogate ratios. Surrogate ratios are calculated for each surrogate using a series of program files. The programs sum the surrogates for each county and calculate each ratio by dividing the county cell surrogate value by the total county surrogate value. Combination surrogates where both are of the same type (i.e., Heavy and High Tech Industrial are both area data) were summed prior to calculating the ratio. Combination surrogates with unlike data (i.e., 3/4 Roadway Miles plus 1/4 Population are line and area data) were summed after calculating the ratios and then normalized. The surrogate cross-reference code was also assigned here.

4. Gap-fill surrogates for counties missing data. There will be many instances where inventory emissions exist for a particular county but there is no spatial data, for that county, for the surrogate assigned. For example, a county with class 1 locomotive emissions may not have data for the class 1 railroad surrogate. In this case we have selected to incorporate, within the assigned surrogate, a secondary source of data (a different surrogate) for that particular county. We incorporate secondary surrogates even if there is no emission source that requires it for that particular county. We denote this process as "gap-filling." All surrogates resulting from the gap-filling process have ratios for all counties.

   For each primary spatial surrogate, we assign a secondary or tertiary spatial surrogate where needed for gap filling. For the class 1 railroad example mentioned above, we chose total railroads as the secondary spatial surrogate since emissions had been estimated for class 1 railroads but no class 1 spatial surrogate was available in that county from our coverage files. The secondary or tertiary spatial surrogate chosen is the same across all counties for a particular primary spatial surrogate and applies to all SCCs that use the particular primary surrogate. We pull in and substitute the secondary surrogate for counties where the primary surrogate is missing to allow for an otherwise omitted spatial distribution of a pre-calculated emission value. Tertiary surrogates are assigned to those counties that are still without surrogates.

For identified counties having no values for each surrogate, we assign the data based on the appropriate secondary or tertiary surrogate to these counties. Checks to see that surrogate ratios for each county sum to approximately 1.00 were also performed in our surrogate development. Ratios will not always sum exactly to 1.00 due to rounding. However, SMOKE will normalize surrogates greater than 1.00.

5. Create SMOKE-formatted spatial surrogate files. The resulting data from the previous steps is then reconfigured into SMOKE-ready format and used in the spatial allocation process.

2.3.3 Development of Modeling Input Inventories/Run Scripts/ASSISGNS Files

The ASIP state emissions inventories modeled for the Base G runs were obtained from the emissions inventory contractor in NIF 3.0 format (exception of fires and onroad mobile inputs). These files were converted to SMOKE IDA format using procedures previously applied for the VISTAS Phase I and earlier Phase II modeling analysis and allocated to subcategory major source level (EGU, non-EGU point, area, nonroad, onroad, fires) for ease of processing and data management. Most of the 2002, 2009 and 2012 modeling files for non-ASIP states were obtained directly from EPA or other RPOs in SMOKE format (MANE-VU, CENRAP and WRAP) or converted from NIF 3.0 (MRPO) as necessary.

Additionally, with the annual episode required for modeling, certain source categories were prepared in a monthly format and the SMOKE model was run for each month of the year. For this reason, individual run scripts and ASSIGNS files were prepared and executed during each SMOKE year/scenario run. An example of the configurations used can be seen in Table 2-13 below. This particular example is for point source processing of the typical 2002 emissions episode. Comparable configurations were developed for stationary area, nonroad mobile, elevated fire, low-level fire, onroad mobile and fugitive dust sources for 2002 typical and actual, 2009 and 2012 episodes.

2.3.4 Products of the Emissions Inventory Development Process for QA

In addition to the CMAQ-ready input files generated for each hour of the days modeled in the annual runs, a number of quality assurance (QA) files will be prepared and used to check for gross errors in the emissions inputs. Importing the model-ready emissions into PAVE and looking at both the spatial and temporal distribution of the emission provides insight into the quality and accuracy of the emissions inputs.

- Visualizing the model-ready emissions with the scale of the plots set to a very low value, we can determine whether there are areas omitted from the raw inventory or if emissions sources are erroneously located in water cells.
- Spot-check the holiday emissions files to confirm that they are temporally allocated like Sundays.
- Normalizing the emissions by population for each state will illustrate where the inventories may be deficient and provide a reality check of the inventories.
- Spot check vertical allocation of point sources using PAVE.

We used state inventory summaries prepared prior to the emissions processing to compare against SMOKE output report totals generated after each major step of the emissions generation process.

To check the chemical speciation of the emissions to CB-IV terms and the vertical allocation of the emissions, we compared reports generated with SMOKE reports to target these specific areas of the processing. For speciation, we compared the inventory import state totals versus the same state totals with the speciation matrix applied.

For checking the vertical allocation of the emissions, we created reports by source, hour, and layer for randomly selected states in the domain. We created these reports for a representative weekday in each of the episodes for each of these selected states.

Table 2-13. Example SMOKE setup for 2002 typical point source processing.

The quantitative QA analyses often reveal significant deficiencies in the input data or the model setup. It was necessary to tailor these procedures to track down the source of each major problem. As such, we only outline the basic quantitative QA steps that we performed in an attempt to reveal the underlying problems with the inventories or processing. Following are some of the reports that were generated to review the processed emissions:

- State and county totals from inventory for each source category
- State and county totals after spatial allocation for each source category
- State and county totals by day after temporal allocation for each source category for representative days
- State and county totals by model species after chemical speciation for each source category
- State and county model-ready totals (after spatial allocation, temporal allocation, and chemical speciation) for each source category and for all source categories combined
- Totals by source category code (SCC) from the inventory for area, mobile, and point sources
- Totals by state and SCC from the inventory for area, mobile, and point sources
- Totals by county and SCC from the inventory for area, mobile, and point sources
- Totals by SCC and spatial surrogates code for area and mobile sources
- Totals by speciation profile code for area, mobile, and point sources
- Totals by speciation profile code and SCC for area, mobile, and point sources
- Totals by monthly temporal profile code for area, mobile, and point sources
- Totals by monthly temporal profile code and SCC for area, mobile, and point sources
- Totals by weekly temporal profile code for area, mobile, and point sources
- Totals by weekly temporal profile code and SCC for area, mobile, and point sources
- Totals by diurnal temporal profile code for area, mobile, and point sources
- Totals by diurnal temporal profile code and SCC for area, mobile, and point sources
- PAVE plots of gridded inventory pollutants for all pollutants for area, mobile, and point sources

Examples of some of these reports are located in the Appendix A of this document.

2.4 2002 BASE G2 AND 2009/2018 BASE G4 BEST AND FINAL INVENTORIES

The current version of the ASIP future year emissions inventory is referred to as the Best and Final (BaF) or Base G4 inventory. After the release of the 2009 and 2018 Base G2 inventory in July 2007, states specified additional changes to the point source inventory to reflect improved information on controls and shutdowns in the 2009 and 2018 future year point source emissions. No changes to the other source sectors (e.g., on-road mobile, non-road mobile, area fires, etc.) were made in going from the 2009 and 2018 Base G2 to the Base G4/BaF emission inventories. The 2018 Base G4/BaF inventory was released in October 2007, and the 2009 Base G4/BaF inventory was released in December 2007. The development of the 2002 Base G2 and 2009 and 2018 Base G4/BaF inventories is given in MACTEC (2008).

Table 2-14 displays the point source SO2 and NOx emissions by ASIP State and ASIP region for the 2002 Base G2 and 2009 and 2018 Base G2 and Base G4 (BaF) emission scenarios. The largest changes in future-year EGU emissions between Base G2 and Base G4 occurred in Florida where SO2 EGU emissions were increased by 57% (2009) and 40% (2018) and NOx emissions were increased by 54% (2009) and 17% (2018). In the other ASIP States there were mostly small reductions or no change in EGU SO2 emissions. EGU NOx emissions were also increased in Mississippi.

With the exception of a 27% and 16% reduction in the 2018 Tennessee and Virginia, respectively, non-EGU SO2 emissions, the non-EGU SO2 and NOx emissions exhibited no or small (<±10%) changes between the future year Base G2 and Base G4 inventories.

Across all ASIP States, the total change in point source SO2 emissions between Base G2 and Base G4 was +1% and -1% for 2009 and 2018, respectively. There were larger changes in the future year Base G2 and Base G4 NOx point source inventories across the ASIP States that were increased by 5% in 2009 and 1% in 2018.

Table 2-14a. Point source SO2 emissions (tons per year) by ASIP State for the 2002 Base G2 and the 2009 and 2018 Base G2 and Base G4/BaF inventories and the differences between the 2009 and 2018 Base G2 and Base G4/BaF inventories.

2.5 UNCERTAINTIES AND CAVEATS

Following the completion of ASIP Base G4 modeling, a number of issues were identified with the input emission inventories and emission processing modeling system that are identified here. Total impact to the overall processed results has not been quantified for these issues although individually each question is felt to have minimal impact on the estimated ozone and PM concentrations in the ASIP domain.

2.5.1 Jefferson County, Kentucky Area Source Correction

In December 2007, KY Division of Air Quality staff identified that Jefferson County, KY was showing zero area source SO_2 emissions. MACTEC was asked to investigate why there were zero emissions. MACTEC's investigation showed that some of the surrounding counties had area source SO_2 emissions, but that Jefferson County's were indeed zero. MACTEC determined that there were emissions in pre-Base F inventories which would have originated from the 1999 NEI grown to 2002. However under their Base F update procedure, they obtained a CERR submittal from Jefferson County. That file contained only emissions for Jefferson County including a limited number of non-ozone pollutant records. Thus under MACTEC's procedure for processing CERR submittals, the file was considered to be full and complete for purposes of inclusion in the Base F inventory and was processed as if it contained more than just ozone pollutant records (i.e., supplemental pollutant records were not required). The file provided, however did not have any SO_2 records. The lack of area source SO_2 emissions was not discovered during the normal State/local review process or during MACTEC's QA process performed on the initial version of the Base F inventory and was thus carried forward into the Base G2 (and thus the Best and Final) inventory and modeling effort where it remained undiscovered until December 2007.

After discovery of the lack of SO_2 records, MACTEC recovered the SO_2 (and some PM) records from the pre-Base F inventories and prepared updated records for 2002, 2009 and 2018. However, because of the timing of the release of these data (December 2007) and the fact that VISTAS could not rerun 2002 and 2009 in time for the final modeling needs with these data, these changes were not included in the final files (Base G2/Best and Final) used in simulations conducted with CMAQ. However, the Best and Final inventory files for 2002, 2009, and 2012 used in ASIP's CAMx simulations do include them.

2.5.2 Updated Non-VISTAS Inventories

As in the normal process among emissions and air quality analysis, non-VISTAS RPOs have continued to update and revise the base year and future year emission inventories used in the development of regional haze and visibility modeling simulations. The non-VISTAS 2002 and 2009 RPO data obtained or derived for this analysis were gathered during the late 2006 through late 2007 timeframe and it is recognized that each of the four sister RPOs to VISTAS has since modified either their 2002 base year and/or their 2009 base case projection inventories.

As noted earlier, additional inventories were obtained from EPA datasets or RPO updates and used for 2012 simulations. Interpolated inventories were derived when RPO specific data were not readily available during the time of this analysis. Development of 2012 emissions consistent with the non-VISTAS 2002 and 2009 would have been resource limited within the time and scope of this study. For this reason, inconsistencies in emission estimates among the three years are noted outside of the ASIP State domain and will have an impact on the direct comparison between future year modeling results for monitors close to non-ASIP State borders.

2.5.3 W.H. Sammis Consent Decree Modification

EGU point source emissions from the MRPO egu5b_2010 scenario (2010 IPM 3.0 run with modifications) were converted to year 2009 IDA format using the annual emission records directly from the NIF structured data sets. These emissions already accounted for growth and control application as specified by the IPM run.

One requested modification for ASIP's $PM_{2.5}$ CAMx modeling[14] was to adjust the 2009 file to match W. H. Sammis facility's planned response to the control requirements from the consent decree USA vs. Ohio Edison; Civil Action No: 2:99-CV-1181; March 18, 2005. The result of this consent decree was an addition of approximately 60,000 tons of SO2 in the 2009 base case inventory for this facility located in Ohio (Table 2-15). While these changes were included in the 2009 CAMx simulations, the changes were not implemented in the ASIP 2009 CMAQ runs.

Table 2-15. SO2 Control Requirements from USA vs. Ohio Edison Consent Decree.

Units 1-4	Induct Scrubbing
	50% removal (1.1 lbs/MMBtu)
	At least one unit by Sept. 30, 2008
	Second unit by Dec. 31, 2008
	Other two units by Dec. 31, 2009
Unit 5	Flash Dryer Absorber or Electro-Catalytic Oxidation no later than Dec. 31, 2008
	50% removal (1.1 lbs/MMBtu)
Units 6/7	Scrubber no later than December 31, 2010
	95% removal (0.13 lbs/MMBtu)
Plantwide	Emission cap of 101,500 by end of 2009
	Emission cap of 101,500 by end of 2010
	Emission cap of 29,900 by end of 2011

2.5.4 Revised IPM Output

During the course of ASIP's modeling efforts, EPA released a revised version of the Integrated Planning Modeling, which is used to forecast EGU emissions under specific environmental and economic constraints. While VISTAS state EGUs were a part of these revisions, VISTAS States

14 CAMx modeling is presented in the Chapter 5 discussions on additional analysis and is used to corroborate the CMAQ future-year PM projections.

chose to maintain the EGU forecasts that were initially developed with the RPO modified version of IPM 2.1.9. For non-VISTAS states, IPM 2.1.9 modified emissions were used for the 2009 simulation, while IPM 3.0 emissions were used for the 2012 simulation. Both instances included the model's forecast of CAIR implementation.

2.5.5 Low Level Fires

During the Base G modeling, a series of low level fire emissions were inadvertently omitted from the processing stream. These fires include emissions for six counties in Kentucky, and one county each in Tennessee and West Virginia for prescribed burning. These fires are data for prescribed burning that were only received from the USFS during the initial file development for these counties. No state data was received for this category in these counties and thus the NEI values from EPA's inventory were maintained for this fire type consistent with the replacement scheme developed when Base D inventories were prepared. During the update process of fire emissions from Base D to Base G, this file was not remerged with the other updated fire types.

2.5.6 MMS Offshore Shipping

During the update of emission inventories from Base D to Base G, ASIP obtained from MMS a set of updated 2000 emission files (GOADS[15]) which included off-shore marine vessel emissions in the Gulf of Mexico oil/gas development area and platform and platform support equipment that has always been included in past MMS inventories. When ASIP overlaid recently obtained offshore emission estimates from shipping lanes, we double counted some of the off-shore marine emissions in the Gulf of Mexico area.

2.5.7 Incorrect Location Parameters

During the quality assurance steps of the Base G emission inventories in preparation for ASIP's best and final modeling, a number of emission release points were identified to have stack location parameters that were of distances greater than 100 miles from the county centroid that the stack's FIPS codes indicated it was situated. Although many of these release points were sited at valid locations (in counties with outer boundaries greater than 100 miles from centroid), those that were incorrectly sited had emission values of very low (less than 80 tons per year) of any single pollutant.

2.5.8 SMOKE/IOAPI Coordinate Transformation Error

During emissions processing of inventories for an unassociated project, the modeling team became aware of an issue[16] with one of the IOAPI libraries used by SMOKE necessary to

15 http://www.gomr.mms.gov/homepg/regulate/environ/airquality/gulfwide_emission_inventory/2000GulfwideEmissionInventory.html
16 http://bugz.unc.edu/show_bug.cgi?id=511

convert input file coordinates into output file locations. This issue occurs with the precompiled version of SMOKE utilized by the modeling team in ASIP emissions processing. During the processing step of point source emissions, the latitude/longitude coordinates of the input files are transformed into Lambert conformal projection, consistent with the CMAQ setup. The error identified in the IOAPI library shifted this location by several kilometers. Although this error was corrected in subsequent versions of SMOKE and the IOAPI libraries, no corrections have been made to Base G modeling or earlier simulations.

3.0 MODEL PERFORMANCE EVALUATION

3.1 INTRODUCTION

This Chapter summarizes the CMAQ 2002 36 km and 12 km Base G2 Actual base case simulation model performance evaluation. The focus of the model performance evaluation is on $PM_{2.5}$ and its component species and ozone in the urban and $PM_{2.5}$ nonattainment areas (NAAs). The evaluation of the same CMAQ 2002 Base G2 base case simulation was also performed for PM species and visibility primarily at Class I areas as part of the VISTAS regional haze assessment. The VISTAS model evaluation focused on the performance of PM component species and visibility at more rural (e.g., IMPROVE) monitors. The VISTAS regional PM components and visibility model performance evaluation is directly relevant to the ASIP $PM_{2.5}$ evaluation as they share many of the same precursor and product species and atmospheric processes that produce elevated $PM_{2.5}$ levels in the urban and NAAs. Appendix B provides details on the ASIP urban and NAAs $PM_{2.5}$ mass and $PM_{2.5}$ component species model performance evaluation that are summarized for each ASIP state in Section 3.5 below. Appendix C provides a qualitative evaluation of the CMAQ base case for $PM_{2.5}$ components and total mass that is summarized in Section 3.6. Before presenting the urban and NAAs $PM_{2.5}$ and ozone model performance results, it is useful and informative to summarize the results of the VISTAS regional model performance evaluation (Morris et al., 2009), which is provided in Section 3.4.

3.2 CMAQ 2002 BASE G2 MODEL EVALUATION METHODOLOGY

VISTAS and ASIP share the same 2002 Base G2 Actual base case modeling results from the Community Multiscale Air Quality (CMAQ) modeling system Version 4.51 (Byun and Ching, 1999) with SOAmods enhancement (Morris et al., 2006a). The VISTAS regional model performance evaluation focused on monitoring sites within the VISTAS states and VISTAS 12 km grid (Morris et al., 2009). The VISTAS and ASIP CMAQ evaluation of the 2002 Base G2 Actual base case is the product of numerous evaluations of predecessor CMAQ base case simulations using interim versions of the modeling inputs and CMAQ model (e.g., Morris et al., 2004b,c; 2005; 2006). With the exception of Organic Carbon Mass (OCM), the basic features of model performance have essentially remained unchanged from the initial evaluations in Phase I and II of VISTAS (e.g., Morris et al., 2004a,b,c) to the current 2002 Base G2 actual base case model performance discussed below. During the course of the VISTAS Phase II and ASIP modeling, VISTAS updated the secondary organic aerosol (SOA) module in CMAQ to include important SOA processes missing in the standard CMAQ model that significantly improved the OCM performance in the summer (Morris et al., 2006a). The processes missing in the current standard versions of CMAQ (e.g., Versions 4.5 and 4.6) that were included as part of the SOAmods enhancement are described in Chapter 1 and included SOA from sesquiterpenes and isoprene and the polymerization of SOA so that it is no longer volatile. EPA updated the CMAQ SOA module in the fall 2008 release of CMAQ (Version 4.7) to include some of the missing SOA processes, which was too late for VISTAS regional haze or the ASIP $PM_{2.5}$ and ozone SIPs. Thus, both VISTAS and ASIP have adopted CMAQ version 4.51 with SOAmods updates (Morris et al., 2006a) as the core model for the modeling analysis.

In the VISTAS and ASIP model performance evaluation, the CMAQ results were compared with observational data from the **I**nteragency **M**onitoring of **PRO**tected **V**isual **E**nvironments

(IMPROVE), **S**peciated **T**rends **N**etwork (STN)[1], **C**lean **A**ir **S**tatus **T**rends **Net**work (CASTNet), **F**ederal **R**eference **M**ethod (FRM) $PM_{2.5}$ mass, **N**ational **A**cid **D**eposition **P**rogram (NADP), **S**outh **E**ast **A**erosol **R**esearch and **CH**aracterization (SEARCH) study and the EPA Air Quality System (AQS) ozone monitoring networks. The ASIP evaluation focuses primarily on the operational model evaluation of the air quality model's performance with respect to individual components of fine particulate matter ($PM_{2.5}$), as good model performance of the PM component species will dictate good model performance for total fine particulate matter ($PM_{2.5}$). The FRM network only collects total $PM_{2.5}$ mass and so is not as relevant for judging how well the model is predicting the components of light extinction so was not stressed in the VISTAS evaluation. However, it is an important component of the ASIP $PM_{2.5}$ evaluation so is included in this TSD. VISTAS also performed a diagnostic evaluation analyzing the ability of the model to reproduce gaseous PM precursor (e.g., SO2 and NOx) and product (e.g., HNO3) species.

The ASIP model performance evaluation focused on ozone and $PM_{2.5}$ performance in urban and nonattainment areas (NAAs). The ASIP $PM_{2.5}$ evaluation is summarized in Sections 3.5, 3.6 and 3.7 below, with more details provided in Appendices B and C. In addition, Appendix D includes a comparative evaluation of the CMAQ and CAMx models.

3.2.1 Evaluation Approach

EPA's integrated ozone, $PM_{2.5}$ and regional haze modeling guidance calls for a comprehensive, multi-layered approach to model performance testing, consisting of the four major components: operational, diagnostic, mechanistic (or scientific) and probabilistic (EPA, 2007a). The CMAQ model performance evaluation effort for $PM_{2.5}$ and ozone discussed in this Chapter focused on the first two components of the EPA's recommended evaluation approach, namely:

- **Operational Evaluation**: Tests the ability of the model to estimate ozone and $PM_{2.5}$ mass concentrations and the components of $PM_{2.5}$, that is sulfate, nitrate, ammonium, organic carbon matter, elemental carbon, and other inorganic $PM_{2.5}$. This evaluation examines whether the measurements are properly represented by the model predictions but does not necessarily ensure that the model is getting "the right answer for the right reason"; and

- **Diagnostic Evaluation:** Tests the ability of the model to predict visibility and extinction, PM chemical composition including PM and ozone precursors (e.g., SOx, NOx, VOC, and NH_3) and associated oxidants (e.g., nitric acid); PM size distribution; temporal variation; spatial variation; mass fluxes; and components of light extinction (i.e., scattering and absorption).

The diagnostic evaluation also includes the performance of diagnostic tests to better understand model performance and identify potential flaws in the modeling system that can be corrected.

In this final model performance evaluation for the ASIP/VISTAS 2002 Actual Base G2 CMAQ 36/12 km base case simulation, the operational evaluation has been given the greatest attention since this is the primary thrust of EPA's modeling guidance. However, we have also examined

[1] The STN network is now referred to as the Chemical Speciation Network (CSN). Throughout the document references to STN should be understood to mean CSN.

certain diagnostic features dealing with the model's ability to simulate sub-regional and monthly/diurnal gas phase and aerosol concentration distributions. In the course of the VISTAS/ASIP studies numerous diagnostic sensitivity tests were performed to investigate and improve model performance and test the model assumptions that are available on the VISTAS modeling website: http://pah.cert.ucr.edu/vistas/vistas2/ and reported by Morris and co-workers (2004a,b,c; 2005; 2006).

3.2.2 Particulate Matter and Component Species

$PM_{2.5}$ attainment is based on $PM_{2.5}$ mass measurements using Federal Reference Method (FRM) monitoring devices that consists of the following $PM_{2.5}$ components:

- Sulfate (SO4)
- Nitrate (NO3)
- Ammonium (NH4)
- Organic Carbon Matter (OCM)
- Elemental Carbon (EC) [also called Black Carbon (BC) and Light Absorbing Carbon (LAC)]
- Other Inorganic $PM_{2.5}$ that is also referred to as Soil (also known as crustal material, fine soil, major metal oxides, or other $PM_{2.5}$)
- Particle Bound Water (PBW)
- Sea Salt (that is mostly NaCl)
- Passive Mass (Blank Correction)

With the exception of the Passive Mass (that is assumed to be a constant 0.5 $\mu g/m^3$) and PBW (that is associated with SO4 and NO3) each of these components is evaluated.

3.2.3 Ambient Air Quality Data for Model Performance Evaluation

A ground-level model evaluation database for 2002 was compiled by the modeling team using several routine and research-grade databases. The focus of the VISTAS evaluation of the CMAQ model was on the PM components that can cause visibility impairment at (rural) Class I areas, whereas the ASIP model performance evaluation focus was on ozone, $PM_{2.5}$ mass and its components in urban areas. The primary monitoring networks available to evaluate this component of the CMAQ are: (a) Interagency Monitoring of Protected Visual Environments (IMPROVE); (b) Clean Air Status and Trends Network (CASTNET); (c) Southeastern Aerosol Research and Characterization (SEARCH); (d) EPA Federal Reference Method (FRM) $PM_{2.5}$ and PM_{10} Mass Networks (EPA-FRM); (e) EPA Speciation Trends Network (STN) of $PM_{2.5}$ species; (f) National Acid Deposition Network (NADP) and (g) EPA's Air Quality System (AQS) network that includes ozone and NOx . The PM monitoring networks may also provide ozone and other gas phase precursors and product species, and visibility measurements at some sites. Table 3-1 and Figure 3-1 summarizes the species collected and locations of the monitoring sites for the IMPROVE, STN, CASTNet, NADP, SEARCH and AQS monitoring networks use in the VISTAS and ASIP model evaluation.

Table 3-1. Ambient monitoring data available in the VISTAS/ASIP region during 2002.

Monitoring Network	Chemical Species Measured	Sampling Frequency
IMPROVE	Speciated $PM_{2.5}$ and PM_{10}	1 in 3 days; 24 hr
CASTNET	Speciated $PM_{2.5}$, Ozone	Hourly, Weekly; 1 hr, Week
SEARCH	24-hr PM_{25} (FRM Mass, OC, BC, SO_4, NO_3, NH_4, Elem.); 24-hr PM coarse (SO_4, NO_3, NH_4, elements); Hourly $PM_{2.5}$ (Mass, SO_4, NO_3, NH_4, EC, TC); and Hourly gases (O_3, NO, NO_2, NO_y, HNO_3, SO_2, CO)	Daily, Hourly;
NADP	WSO_4, WNO_3, WNH_4	Weekly
EPA-FRM	Only total fine mass ($PM_{2.5}$)	1 in 3 days; 24 hr
EPA-STN	Speciated $PM_{2.5}$	1 in 3 days; 24 hr
AIRS/AQS	CO, NO, NO_2, NO_x, O_3	Hourly

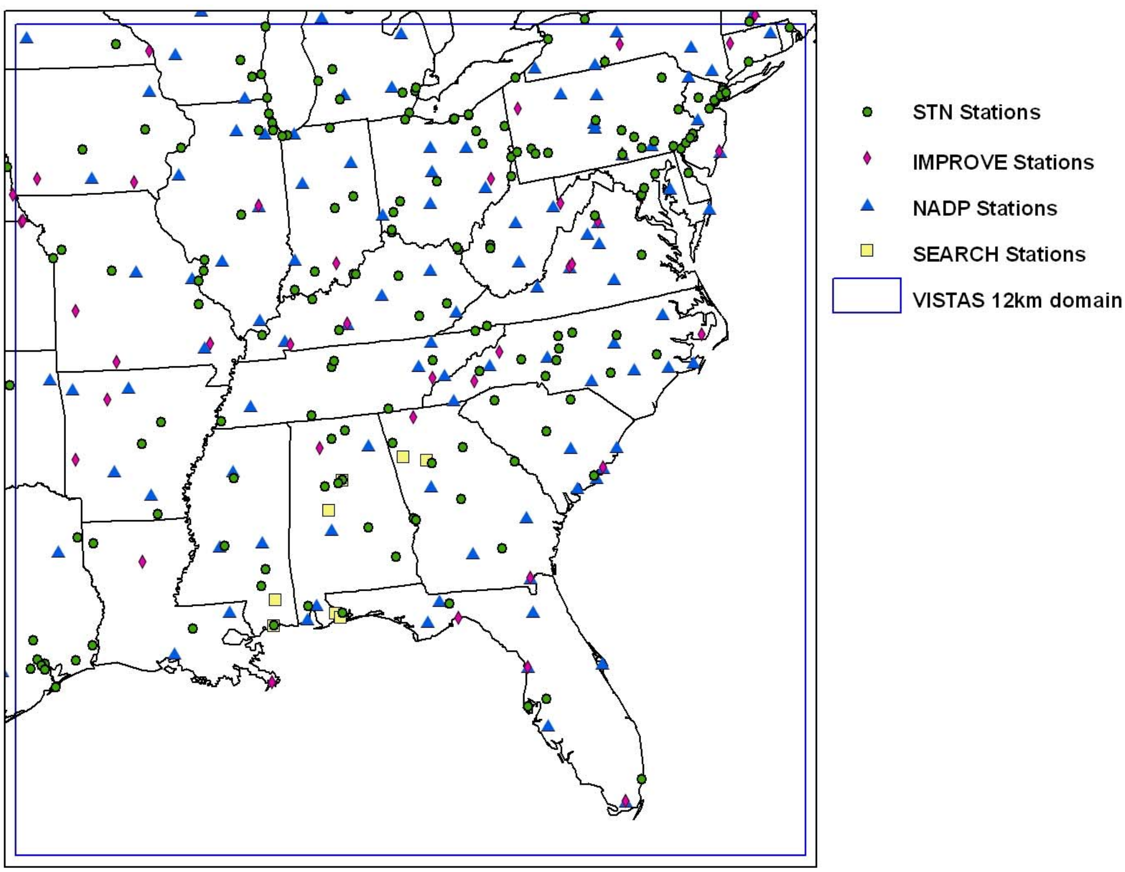

Figure 3-1a. Locations of IMPROVE, STN, SEARCH and NADP monitoring sites within the ASIP 12 km modeling domain.

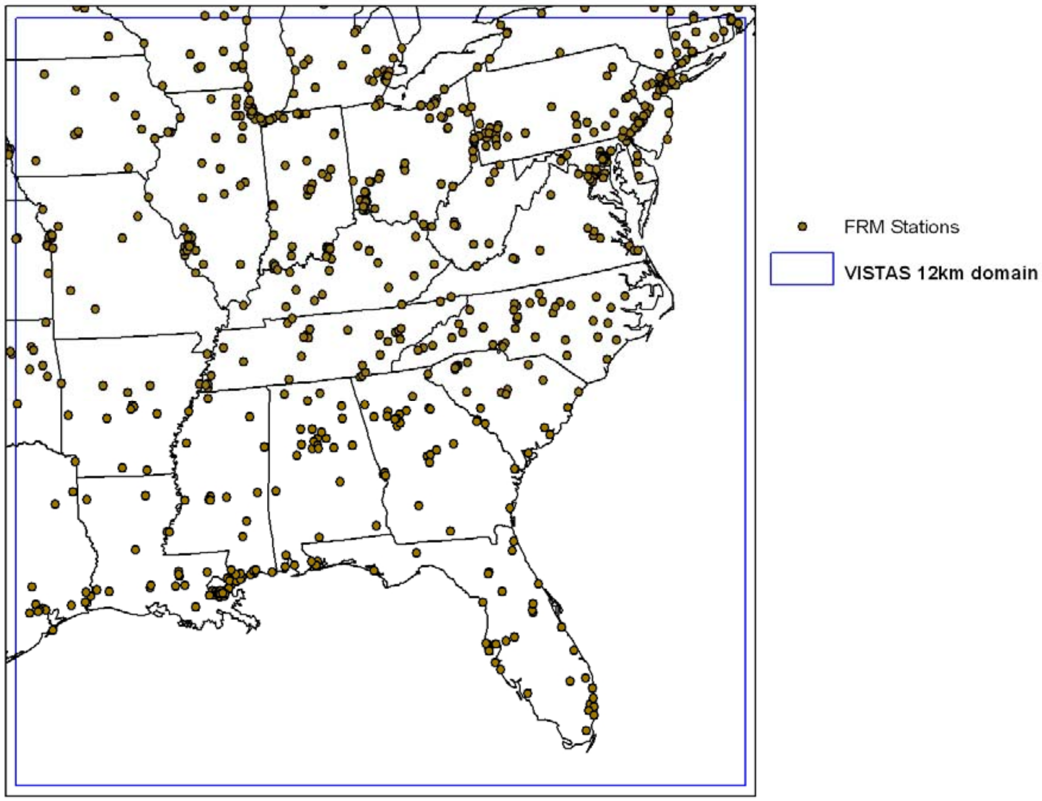

Figure 3-1b. Locations of FRM $PM_{2.5}$ mass monitoring sites within the ASIP 12 km modeling domain.

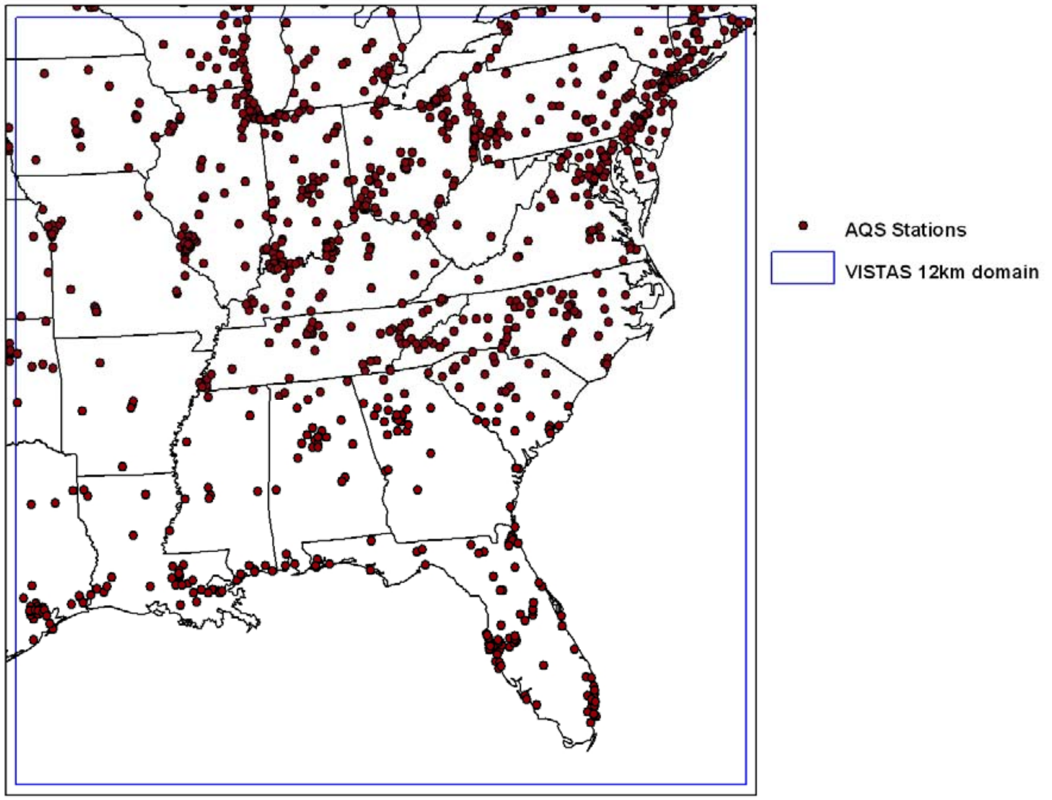

Figure 3-1c. Locations of AQS ozone monitoring sites within the ASIP 12 km modeling domain.

3.3 MODEL PERFORMANCE STATISTICS AND GOALS

To quantify model performance, several statistical measures were calculated and evaluated for all the IMPROVE, STN, CASTNet, SEARCH, FRM, NADP and AQS monitors within the VISTAS/ASIP region or VISTAS/ASIP 12 km domain, individually for each monitoring network and individually for each VISTAS/ASIP state. The statistical measures selected were based on the recommendations outlined in section 18.4 of the USEPA's Guidance On The Use Of Models And Other Analyses for Demonstrating Attainment of Air Quality Goals for Ozone, PM2.5, and Regional Haze (EPA, 2007a).

In 2004, VISTAS established model performance goals and criteria for components of fine particle mass based on previous model performance for ozone and fine particles (e.g., Morris et al., 2004a,b,c). EPA modeling guidance for fine particulate matter at the time noted that PM models might not be able to achieve the same level of performance as ozone models. The VISTAS and ASIP model performance evaluation considered several statistical performance measures and displays. VISTAS/ASIP reviewed numerous model performance evaluation metrics to evaluate their descriptive capabilities for summarizing the salient features of the model performance evaluation. Although numerous model performance statistics measures are routinely calculated, VISTAS/ASIP have found that the fractional bias and fractional gross error provide the best descriptive power over a wide range of concentrations. The fractional bias and error are expressed as a percentage and are normalized by the average of the predicted and gross observed values. Consequently, they are bounded statistics, with the fractional bias bounded by

-200% to +200% and the fractional gross error bounded by 0 to 200%. Table 3-2 summarized the formulas for the fractional bias and gross error statistics. The VISTAS/ASIP model performance goals and criteria are given in Table 3-3. Note that for ozone model performance the traditional (EPA, 1991) ≤ ±15% and ≤ 35% performance goals for mean normalized bias (MNB) and mean normalized gross error (MNGE) using hourly predicted and observed ozone pairs with the observed ozone value greater than 60 ppb are used. The MNB and MNGE statistics are similar to the fractional statistics given in Table 3-2, only the normalized statistics are divided by just the observed value rather than the average of the predicted and observed values.

Table 3-2. Definitions of the fractional bias and fractional error statistical model performance metrics.

Statistical Measure	Shorthand Notation	Mathematical Expression	Notes
Mean Fractional Gross Error (Fractional Error)	MFE	$\frac{2}{N}\sum_{i=1}^{N}\left\lvert\frac{P_i - O_i}{P_i + O_i}\right\rvert$	Reported as %
Mean Fractionalized Bias (Fractional Bias)	MFB	$\frac{2}{N}\sum_{i=1}^{N}\left(\frac{P_i - O_i}{P_i + O_i}\right)$	Reported as %

Table 3-3. VISTAS/ASIP model performance goals and criteria for components of fine particle mass.

Fractional Bias	Fractional Error	Comment
≤±15%	≤35%	Goal for PM model performance based on ozone model performance, considered excellent performance
≤±30%	≤50%	Goal for PM model performance, considered good performance
≤±60%	≤75%	Criteria for PM model performance, considered average performance. Exceeding this level of performance indicates fundamental concerns with the modeling system.

3.4 VISTAS REGIONAL PM MODEL PERFORMANCE EVALUATION

Details on the regional model performance evaluation for PM across the VISTAS/ASIP region km grid are provided in Chapter 3 and Appendix B of the VISTAS Technical Support Document (TSD; Morris et al., 2009). Below we summarizes the key findings of the of the VISTAS regional model performance evaluations of $PM_{2.5}$ component species across the VISTAS region using monthly fractional bias and gross error performance statistics. More details, including scatter plots, quantile-quantile plots, Bugle Plots, etc. can be found in the VISTAS TSD referenced above.

3.4.1 Sulfate (SO4) Model Performance

Figure 3-2 compares the monthly CMAQ SO4 concentration fractional bias and error across the VISTAS/ASIP 12 km grid region for the IMPROVE, STN, CASTNet, SEARCH Daily and SEARCH Hourly monitoring networks. The underprediction bias in SO4 concentrations is clearly evident across most of the year and monitoring networks with the best (i.e., closest to zero) SO4 bias occurring in October. However, this underprediction bias is not severe usually within ±20% and almost always within ±25% usually achieving the PM model performance goals for bias/error (i.e., within ±30%/50%, see Table 3-3). The exception to this is the comparison with the SEARCH Hourly network that exhibits a positive overprediction SO4 bias for several months.

The SO4 monthly fractional error values are usually under 40% and, with one exception, always under 50% thereby achieving the PM performance goal (Figure 3-2). The exception is comparison with the SEARCH Hourly network with error values ranging from 50% to 70%.

The summer SO4 underprediction bias is partly due to overstated convective precipitation in the MM5 simulations (Olerud, 2003c,d). This is somewhat confirmed by the SO4 wet deposition model performance evaluation that exhibits near zero bias during the winter when precipitation is dominated by synoptic weather events, but has a positive overprediction bias during the summer when convective precipitation is greatest (Morris et al., 2009).

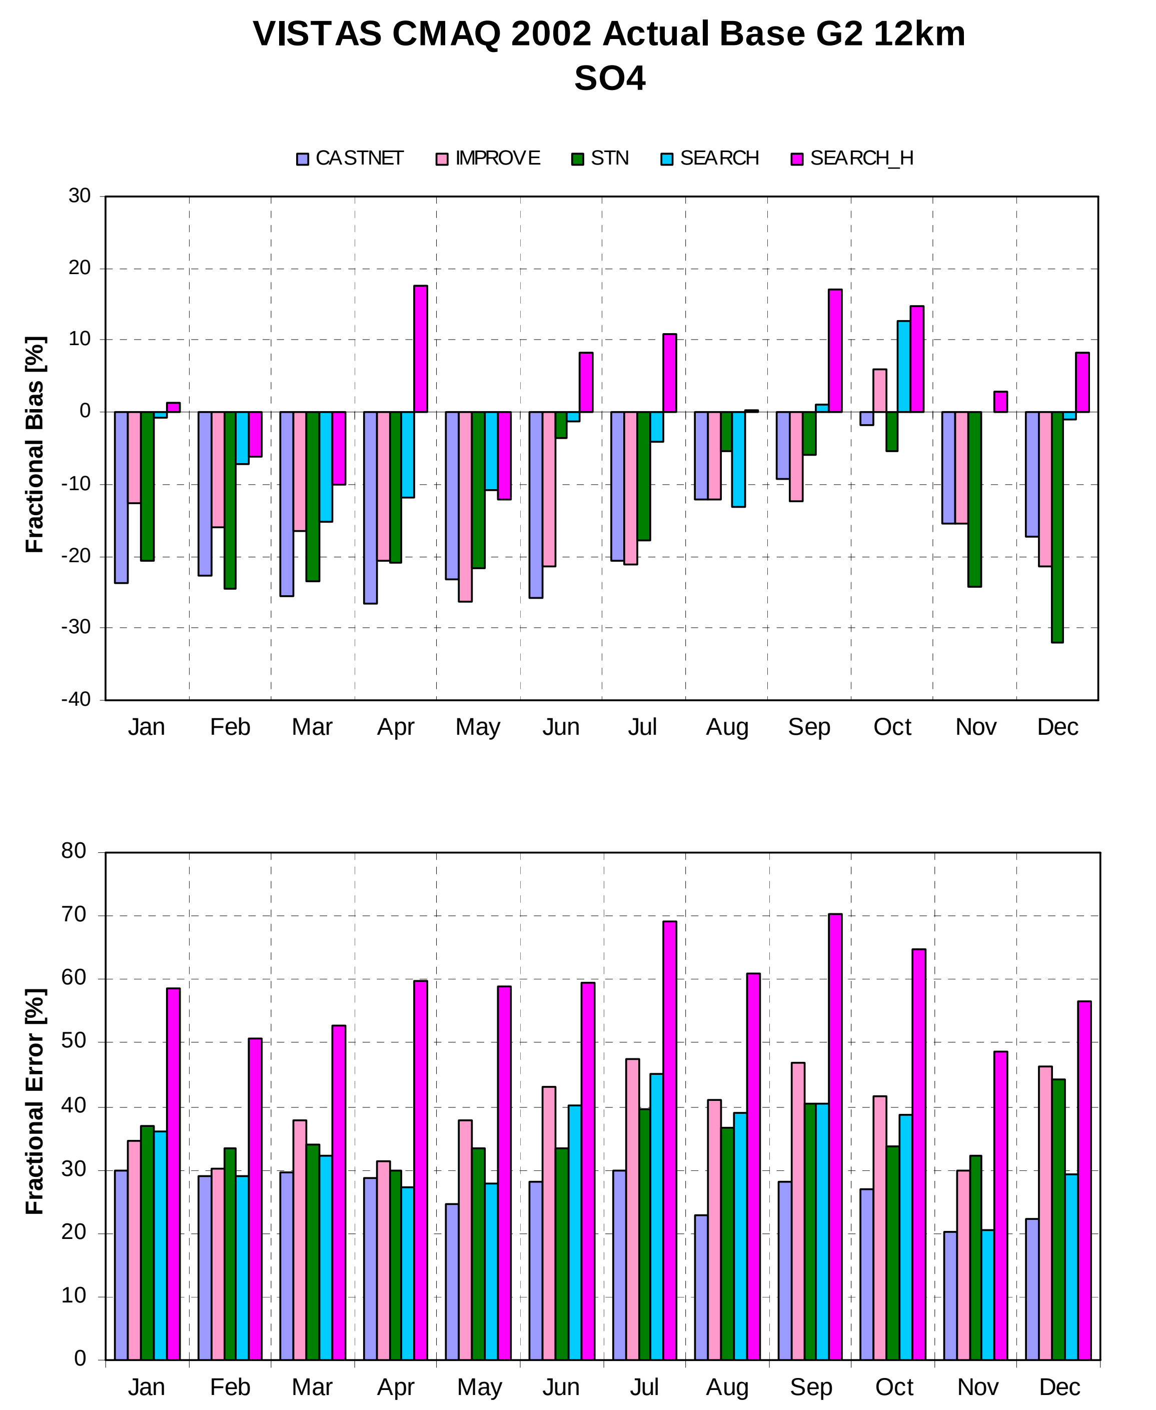

Figure 3-2. Monthly SO4 fractional bias (top) and fractional error (bottom) statistical measures for CASTNet, IMPROVE, STN and SEARCH (daily and hourly) monitoring sites in the ASIP 12 km grid.

3.4.2 Nitrate (NO3) Modeling Performance

The monthly fractional bias time series plot for NO3 clearly shows a seasonal dependence of this performance measure with a severe summer underprediction bias of -100% to -150% and bias values generally within ±50% in the winter (Figure 3-3). The time series of fractional error values also exhibits a seasonal dependence with an 80% error in the winter peaking to a 160% error in the summer with a bell-like distribution. The large summer underprediction bias occurs when NO3 concentrations are extremely low (< 1.0 μg/m^3) and, in fact, when the average observed NO3 concentration exceeds 1 μg/m^3 the model mostly achieves the model performance goal and almost always achieves the model performance criteria for bias as indicated by the Bugle Plots in the VISTAS TSD (Morris et al., 2009). The model performance goal and criteria are achieved less often for NO3 fractional error, however the goal is always achieved across the CASTNet and usually achieved across the IMPROVE monitoring networks.

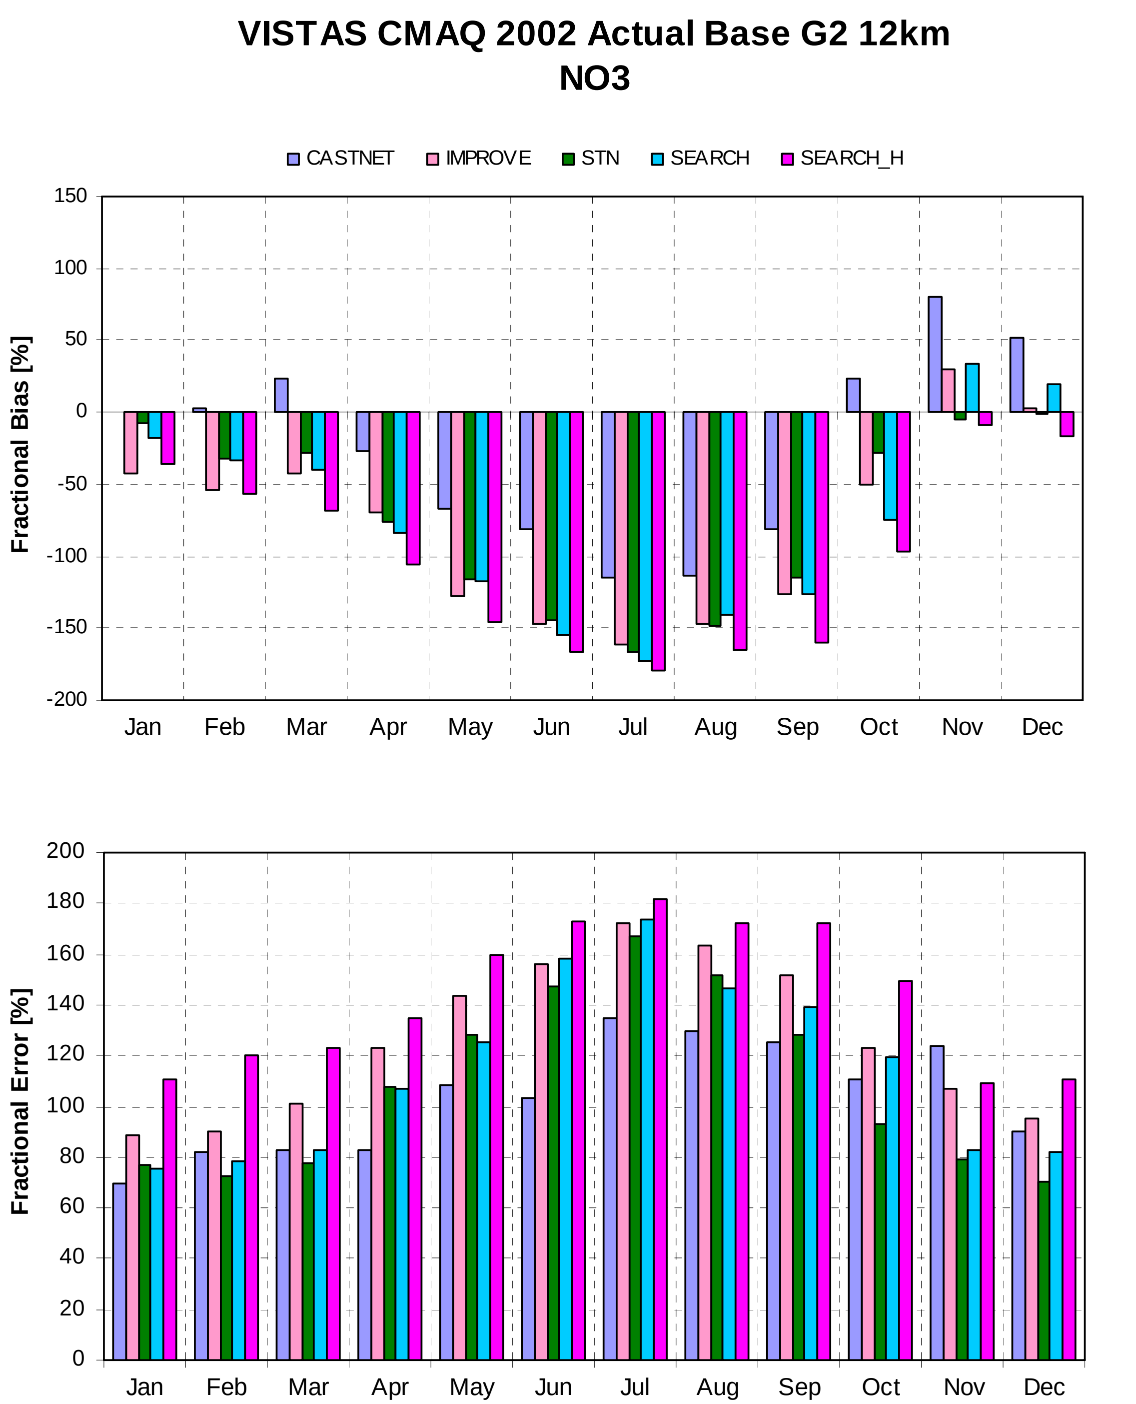

Figure 3-3. Monthly NO3 fractional bias (top) and fractional error (bottom) statistical measures for CASTNet, IMPROVE, STN and SEARCH daily and hourly monitoring sites in the ASIP region.

3.4.3 Organic Carbon Mass (OCM) Performance

The monthly fractional bias and error plots for the 12 km CMAQ base case simulation OCM performance are given in Figure 3-4. Fairly good OCM model performance is seen across the IMPROVE monitors with bias usually within ±15% and errors between 40% and 50%. However, at the urban STN sites the model exhibits a large OCM underprediction bias of -60% to -90%. Part of the underprediction bias at the STN sites may be due to measurement uncertainties and artifacts and part may also be due to the model over diluting the urban OCM emissions through the coarse 12 km grid. There are also evidence that current emission inventories neglect condensable (semi-volatile) organic emissions from gasoline and diesel combustion (e.g., mobile sources) that form OCM. The underprediction of urban OCM is a common problem in PM modeling and likely also points to uncertainties in the OCM and SOA precursor emission inventories.

One source of uncertainty in the OCM measurements is the fact that OCM is actually derived from OC measurements. The amount of additional elements (e.g., oxygen) attached to the OC to form OCM varies with the age and level of photochemical processing of the organic particles with OCM/OC ratios typically ranging from 1.2 to 2.2 with lower ratios for fresh and higher ratios for aged processed OCM. For the OCM model performance evaluation we used a 1.4 OCM/OC ratio that is consistent with the original IMPROVE equation and based on measurements from Los Angeles. The new IMPROVE equation uses a higher 1.8 OCM/OC ratio reflecting the fact that OCM that reaches the mostly rural Class I areas will be aged and subject to photochemical processing. There really is no one right OCM/OC factor to use in all cases. However, in interpreting the model performance it is important to know which OCM/OC ratio was used and recognize that selection of another ratio could make a 30% or so difference in the OCM measurements.

The STN OC measurements are also not blank corrected, which is believed to result in an approximate 0.5 $\mu g/m^3$ positive artifact in the STN OC observations (which would be 0.5-0.9 $\mu g/m^3$ positive artifact in OCM depending on which OCM/OC factor is used). The subtraction of 0.5-0.9 $\mu g/m^3$ from the measured OCM value would greatly improve the CMAQ OCM model performance across the STN network and bring the CMAQ OCM bias closer to zero.

In the preliminary evaluation of the CMAQ model using early VISTAS Phase I and II databases, the OCM performance was a great cause of concern due to a large summer OCM underprediction bias and the importance of OCM to the visibility extinction and PM budgets (Morris et al.., 2004b,c). This resulted in VISTAS conducting a focused research study on the reasons for the summer OCM underprediction, the identification of processes missing in the CMAQ model and the development of the SOAmods enhancement to CMAQ (see Section 1.3.3.3.1) that greatly improved the CMAQ OCM model performance (Morris et al., 2006a). The CMAQ Version 4.51 with the SOAmods enhancements was used in the ASIP modeling as well.

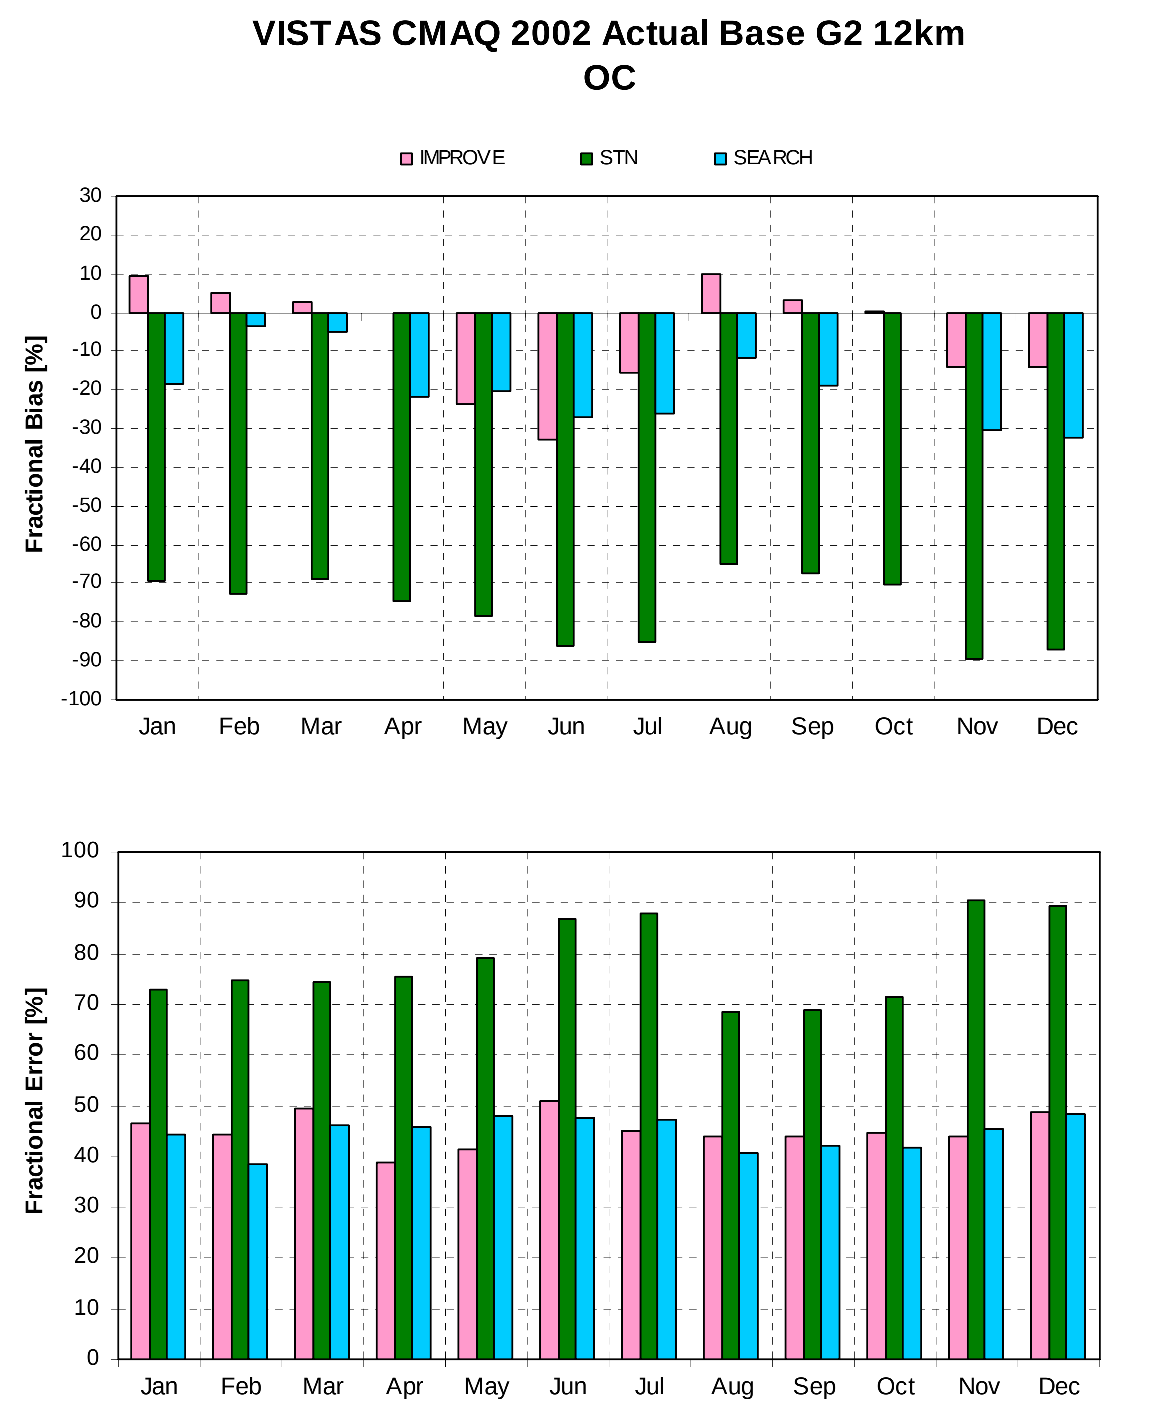

Figure 3-4. Monthly OCM fractional bias (top) and fractional gross error (bottom) statistical measures for IMPROVE, STN and SEARCH monitoring sites in the ASIP region.

3.4.4 Elemental Carbon (EC) Performance

The monthly fractional bias and error performance statistics for EC across the ASIP 12 km domain are shown in Figure 3-5. Bias and error are lower in the first and last quarters of the year. During the summer and adjacent months, EC performance across the IMPROVE network exhibits a large underprediction bias (-40% to -80%) that peaks in June. The EC performance across the SEARCH network is somewhat similar to IMPROVE only the underprediction bias in the summer is not as great. Model performance compared to the STN network has fairly low EC fractional bias during quarters 1, 3 and 4 (achieving the most stringent < ±15% ozone goal), but has larger underprediction bias during quarter 2 (-20% to -40%). The comparison to the STN network very low EC bias during most of the year suggests that the anthropogenic EC emissions inventory may be adequately characterized in urban areas.

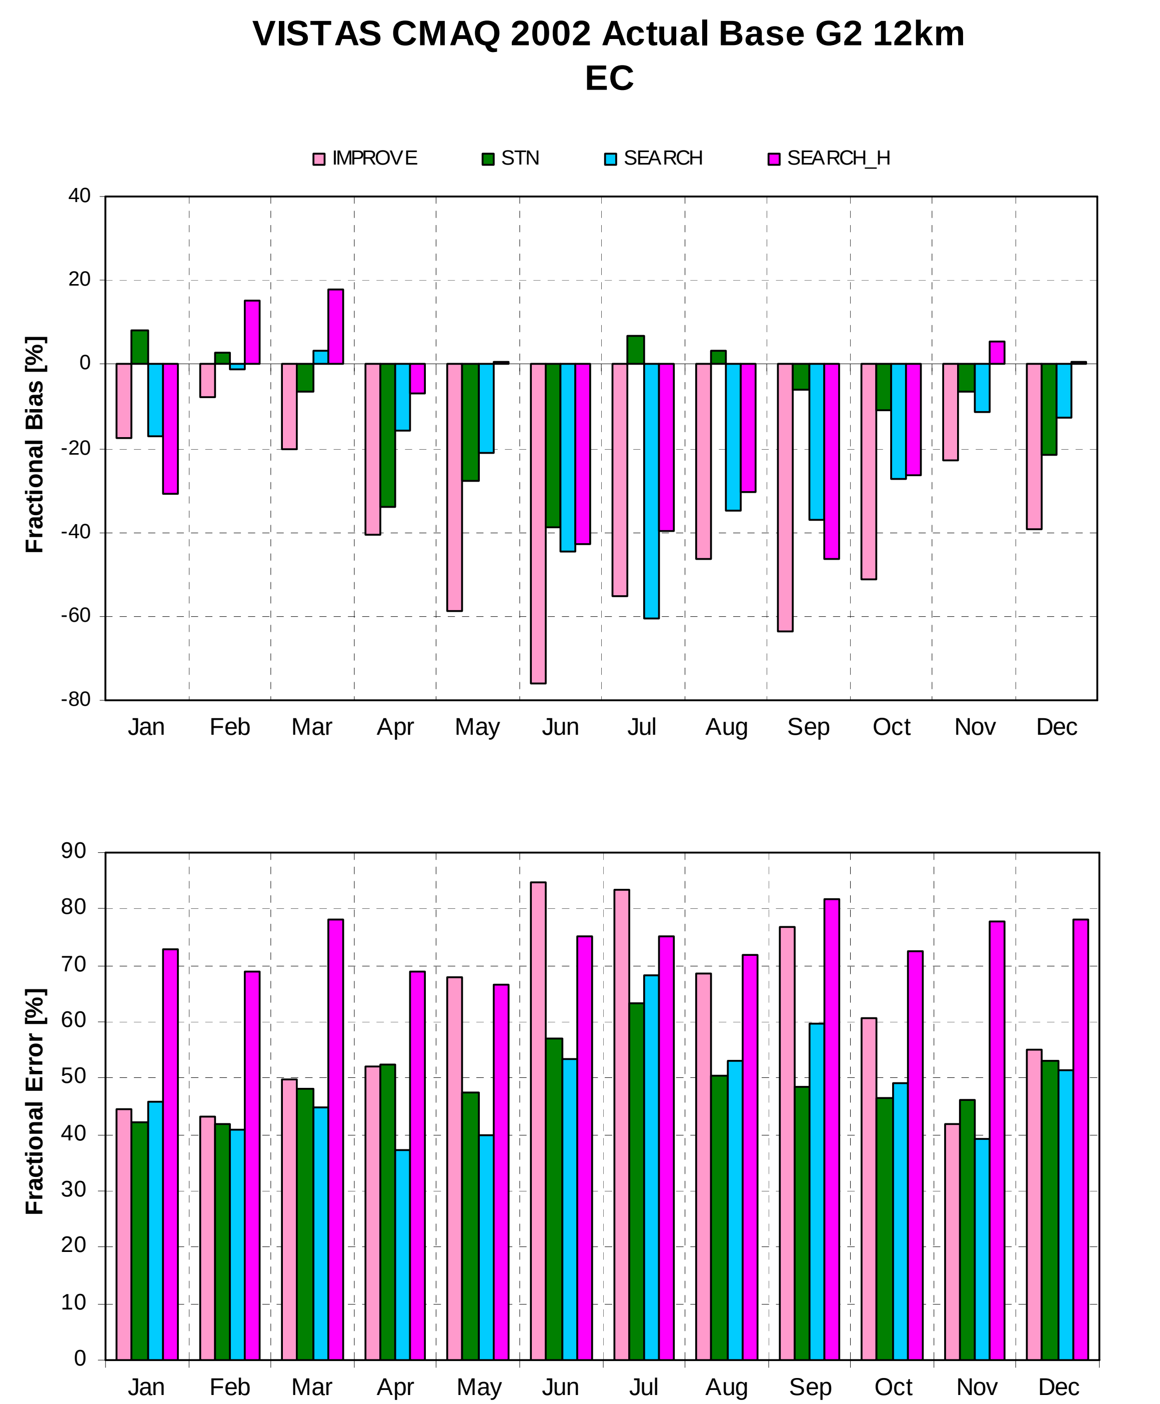

Figure 3-5. Monthly EC fractional bias (top) and fractional gross error (bottom) statistical measures for IMPROVE, STN and SEARCH daily and hourly monitoring sites in the ASIP region.

3.4.5 Other $PM_{2.5}$ or Soil Performance

The seasonal dependence of the Soil model performance across the IMPROVE and STN monitors in the VISTAS region is clearly evident in the monthly fractional bias time series plot in Figure 3-6 that show a large (> 100%) overprediction bias in the winter and near zero (IMPROVE) or much lower (SEARCH) bias in the summer. The modeled Soil values tend to always be between 0 and 2 $\mu g/m^3$ year round, however the observed values are much lower in the winter (0 to 0.5 $\mu g/m^3$) and comparable to the modeled values in the summer. These results suggest that the poorer winter Soil model performance is likely due to incorrect emission temporal adjustment factors. For example, the effect of wetted surfaces that suppresses fugitive dust emissions may not be properly characterized in the seasonal adjustments to the emissions inventory.

The Soil model performance is confounded by the incommensurability between the modeled and measured Soil species. The IMPROVE observed Soil is built up of measured elements. The modeled "Soil", on the other hand, is fine particulate matter emissions that have not been explicitly identified and speciated as SO4, NO3, EC or OC in the PM speciation profiles used in the SMOKE emissions modeling. The emissions PM speciation profiles may have unidentified PM that is lumped in the other PM category that are not the same as the IMPROVE Soil. The measured Soil will typically be associated with fugitive dust emissions, so the separate tracking of fugitive dust may be one approach to separate the true Soil component from the other $PM_{2.5}$ component. VISTAS investigated this issue with an inert (no chemistry) CMAQ sensitivity run that separately tracked just fugitive dust emissions and found improved Soil model performance with lower bias when just other $PM_{2.5}$ concentrations due to fugitive dust emission sources were mapped to the Soil species.

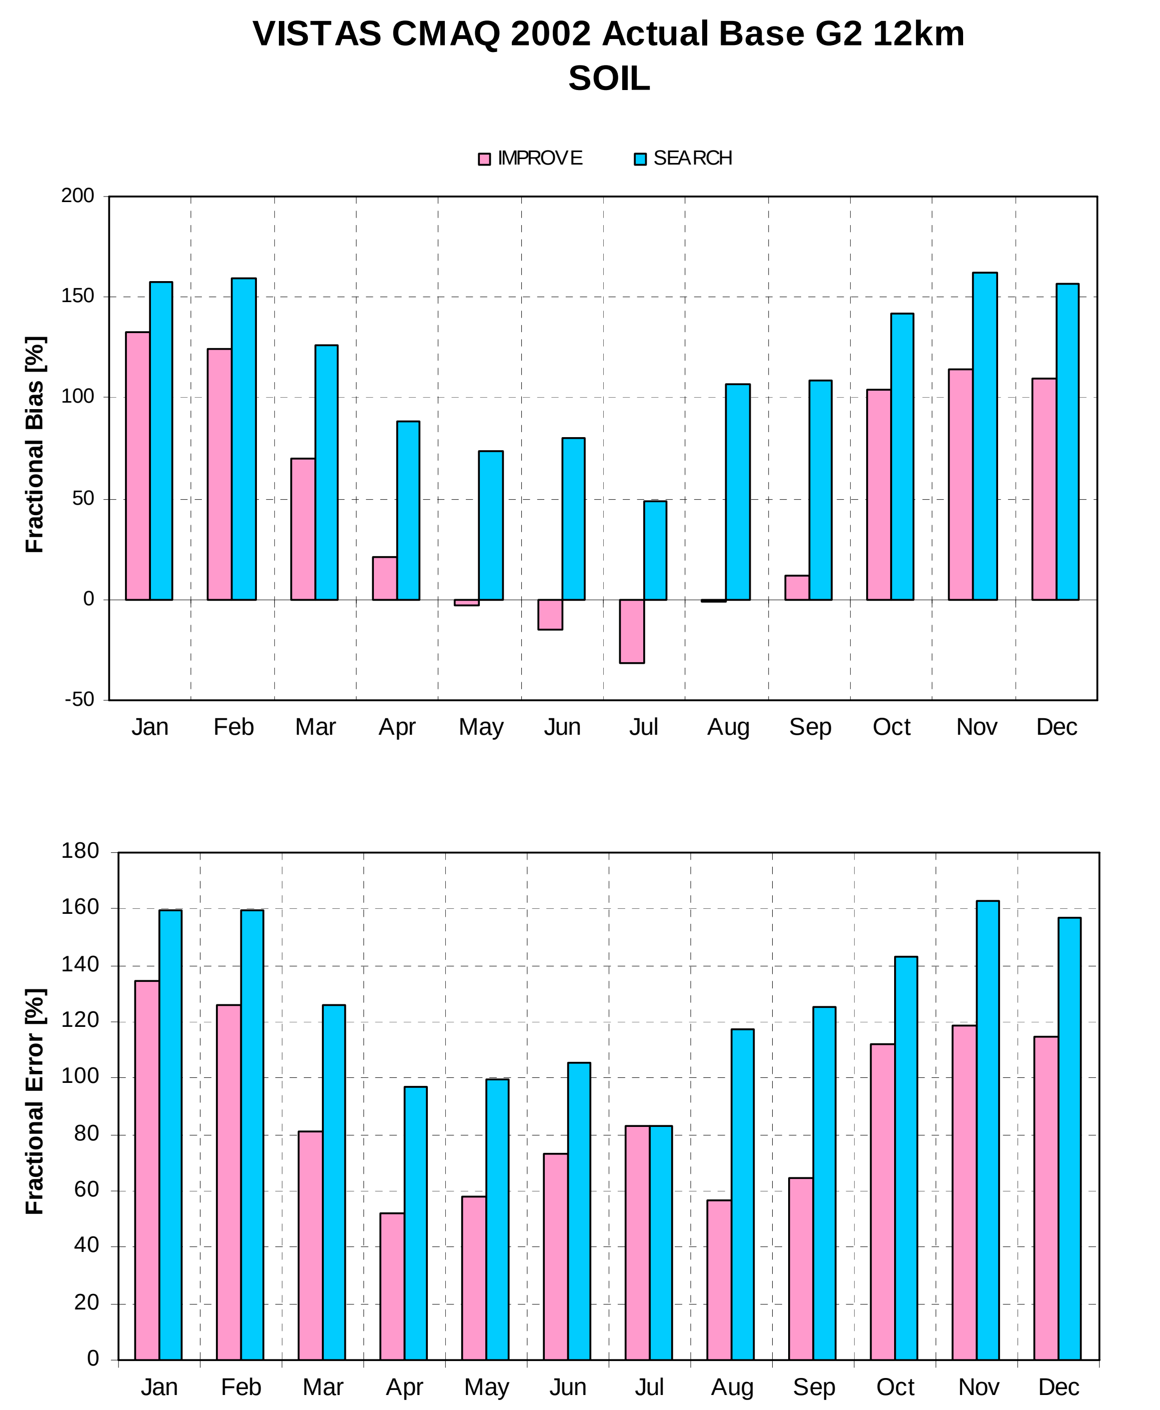

Figure 3-6. Monthly Soil fractional bias (top) and fractional gross error (bottom) statistical measures for IMPROVE and SEARCH Daily monitoring sites in the ASIP region.

3.4.6 Total Fine Particulate ($PM_{2.5}$) Mass Performance

Figure 3-7 displays the monthly time series of fractional bias and error for $PM_{2.5}$ mass concentrations for the IMPROVE, STN, SEARCH Daily, SEARCH Hourly and FRM networks in the VISTAS/ASIP region. The model generally is exhibiting good performance for total $PM_{2.5}$ mass concentrations. For the first three and last three months of the year the model performs well for $PM_{2.5}$ with low fractional bias (<±20%) and error (<40%) except for the SEARCH Hourly network. During April through July, the underprediction bias becomes larger and is in the -20% to -50% range and the errors are also larger. This is driven in part by the SO4 underprediction bias discussed previously as SO4 is a major component of $PM_{2.5}$ in the summer and the southeastern U.S. It is also driven by the OCM summer under prediction bias.

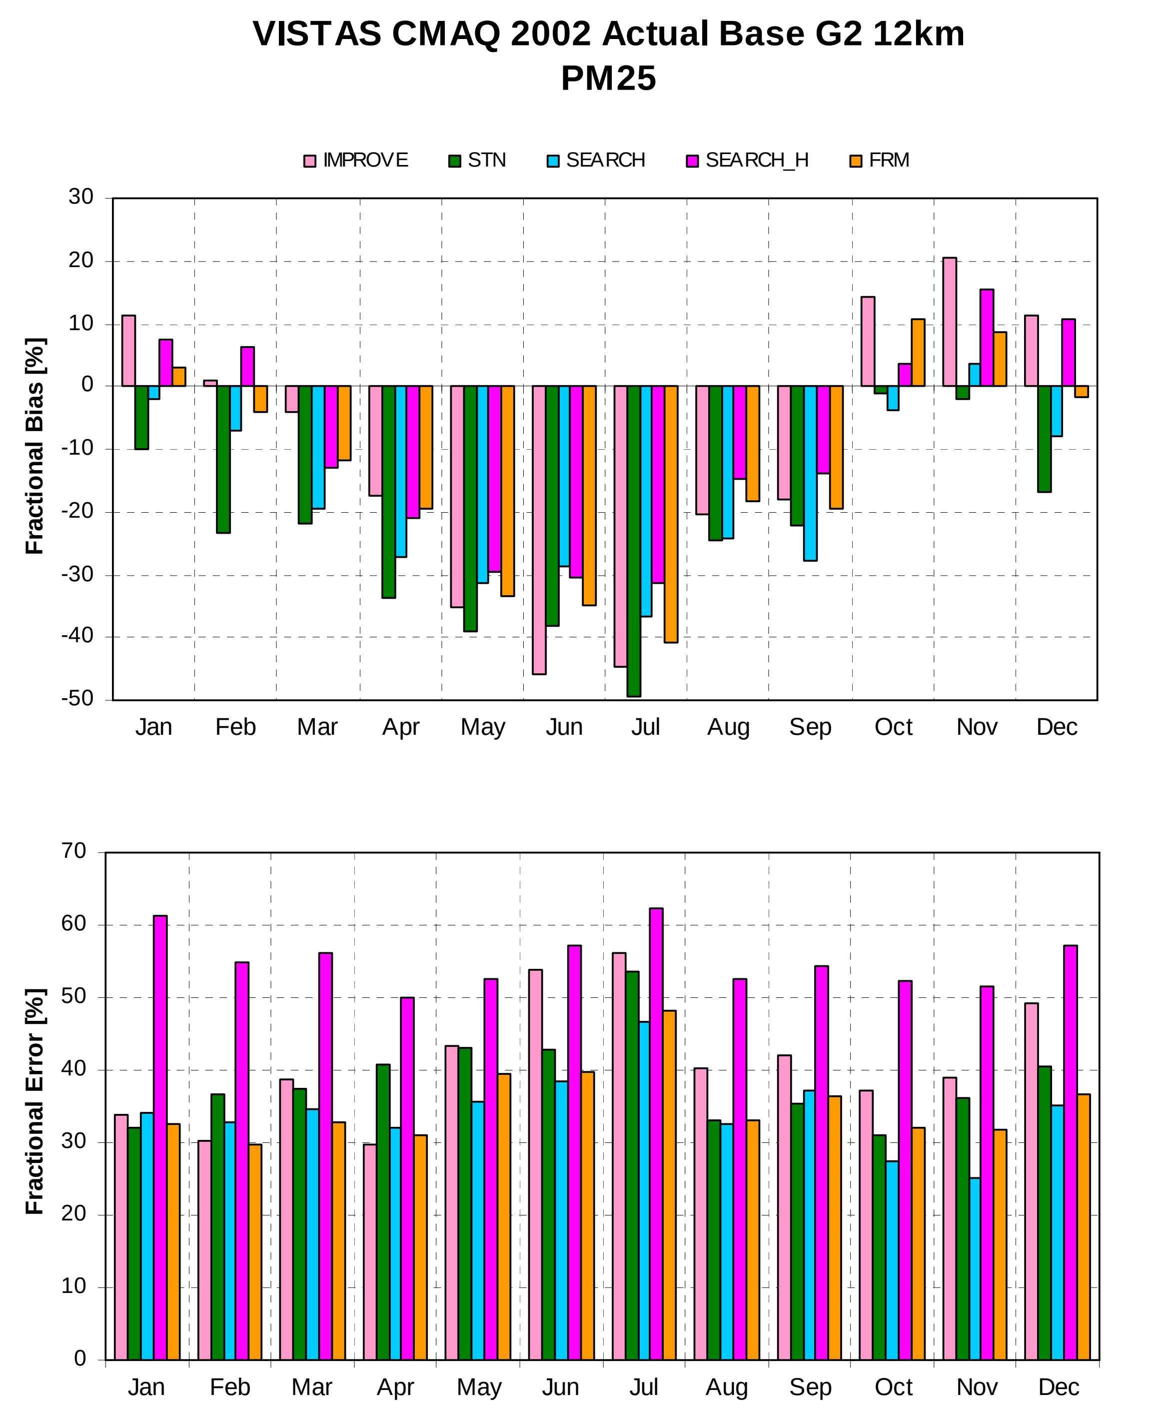

Figure 3-7. Monthly total $PM_{2.5}$ mass fractional bias (top) and fractional gross error (bottom) statistical measures in the ASIP region.

3.5 $PM_{2.5}$ MODEL PERFORMANCE BY STATE

In this section we evaluate the CMAQ base case for $PM_{2.5}$ at the mainly urban STN and FRM monitoring sites. Appendix B presents a detailed model performance evaluation by $PM_{2.5}$ species component and for total $PM_{2.5}$ mass by each state in the ASIP/VISTAS region. An example of the types of displays of model performance from Appendix B are given below for Alabama and SO4 performance; Soccer Plots of fractional bias and error for $PM_{2.5}$ mass are also presented for all states. For the remainder of the state-by-state scatter plots, time series plots and Bugle Plots of $PM_{2.5}$ mass and components model performance the reader is referred to Appendix B.

3.5.1 Alabama

Figure 3-8 is a repeat of Figure B-2a in Appendix B that contains a scatter plot and model performance statistics for SO4 at STN sites located in Alabama and the four quarters of 2002. Similar scatter plots and performance statistics for the other $PM_{2.5}$ component species and total $PM_{2.5}$ mass are shown in Figures B-3b through B-3g in Appendix B. Performance for SO4 is quite good with the points on the scatter plots clustered tightly around the 1:1 line of perfect agreement (Figures 3-8 and B-2a). The SO4 fractional bias and error performance metrics mostly achieve the stringent <±15% and < 35%, respectively, performance goals for ozone (Table 3-2). Performance for NO3 shown in Figure B-2b exhibits an underprediction tendency with fractional bias values of approximately -20% in Q1, -140% in Q2, -160% in Q3 and -30% in Q4. The large summer NO3 underprediction bias occurs when both the model and measured NO3 values are extremely low with the modeled values near zero and the STN NO3 observed values are < 1 $\mu g/m^3$. Note that under these summer conditions, the NO3 will almost completely volatize off the FRM filter so the FRM would measure insignificant $PM_{2.5}$ mass due to NO3. Thus, these large summer NO3 underpredictions are not a concern as NO3 is not an important component of $PM_{2.5}$ mass in the summer. Performance for NH4 is also fairly good achieving the <±30%/50% fractional bias/error goal for PM species (Figure B-2c), which is not surprising given its strong link to SO4.

With the exception of a few outliers, performance for organic carbon mass (OCM or OC) is underestimated by -40% to -70% (Figure B-2d). The reasons for the OCM underprediction bias includes the fact that the STN OC measurements are not blank corrected and have high uncertainties (see SANDWICH discussion in Chapter 4) and there are also large uncertainties in the OC emissions and the form of OC emissions as particles or semi-volatile organic gases. EC model performance at STN sites in Alabama is also fairly good mostly achieving the PM model performance goal, albeit with an underestimation tendency in Q2, Q3, and Q4 (Figure B-2f).

The CMAQ performance for $PM_{2.5}$ mass at ~20 FRM monitoring sites in Alabama is shown in Figure B-2g. Performance for $PM_{2.5}$ mass is generally good achieving the most stringent ozone performance goal in Q1 and Q4 and the PM goal year round.

Time series of predicted (CMAQ 12 km results) and observed 24-hour $PM_{2.5}$ components and model performance statistics at the key North Birmingham STN and SEARCH sites are shown in Figures B-3 and B-4, with the SO4 performance time series at these co-located sites reproduced as Figure 3-9 below. As discussed in Chapter 4, this is the site with the highest projected 2009 $PM_{2.5}$ Design Value in the ASIP region (i.e., North Birmingham). SO4 performance is quite good with annual fractional bias and errors of 6% and 29% achieving the most stringent ozone performance goal at the STN site and fractional bias and error of 18% and 34% that almost achieves the most stringent ozone performance goal at the SEARCH site. NO3 has a large underprediction bias at the North Birmingham site that is driven by near zero modeled NO3 concentrations in the summer when the observed values are < 1 ug/m^3 (Figures B-3a and B-4a, bottom). However, the NO3 performance in the winter when observed values are above 1 ug/m^3 is much better. The EC and OCM performance at the North Birmingham STN site is characterized by an underprediction with fractional bias of approximately -30% and -50%, respectively (Figures B-3b and B-4b). This underprediction is due in part to uncertainties in the carbon measurements as well as the contributions of nearby industrial sources whose impacts are diluted across the 12 km CMAQ grid. Performance for NH4 and $PM_{2.5}$ mass at the North Birmingham STN and SEARCH sites are also quite good with fractional bias/error values of, respectively, -5%/33% and 11%/29% at the STN site that achieves the more stringent ozone performance goal and values of, respectively, -24%/42% and 17%/31% that achieves the PM performance goal at the SEARCH site. The good performance of NH4 and $PM_{2.5}$ mass is not surprising given that they are closely related to SO4 that exhibits good model performance.

Figure 3-10 reproduces Figure B-5 from Appendix B and displays a Soccer Plot of monthly fractional bias versus gross error for $PM_{2.5}$ mass performance across ~20 FRM sites in Alabama and compares them with the three levels of bias/error performance goals in Table 3-3. Total $PM_{2.5}$ mass model performance across the FRM sites in Alabama is best in the winter months when the most stringent ozone < ±15%/35% bias/error goal is achieved. In the summer months, the model tends to underestimate the FRM observed $PM_{2.5}$ mass by -15% to -25%, but still achieves the <±30%/50% PM model performance goal.

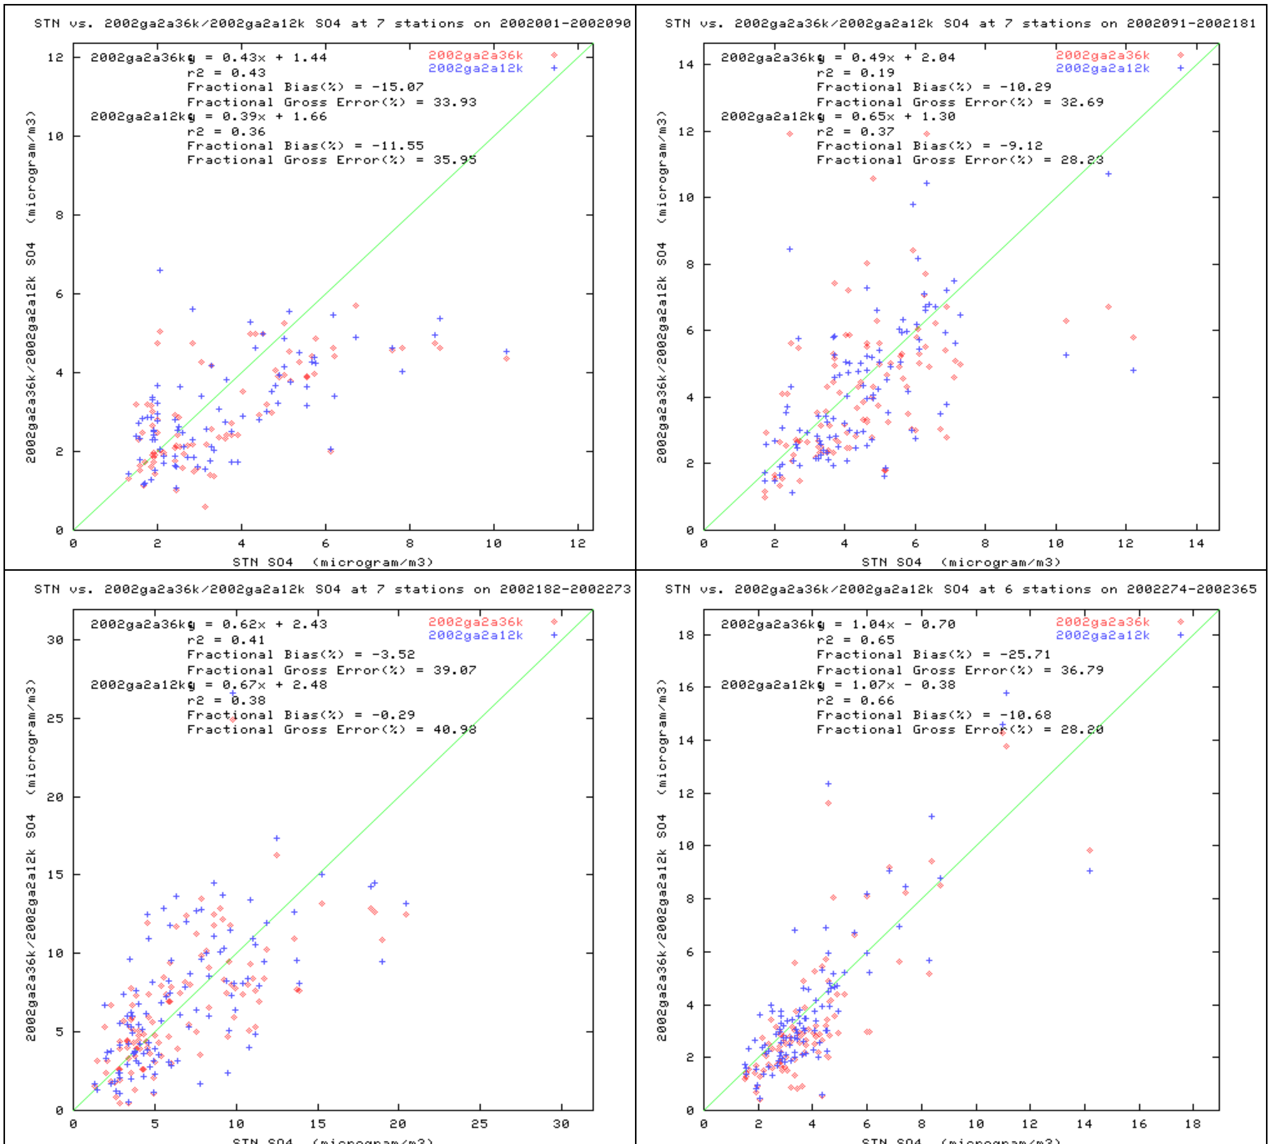

Figure 3-8. Scatter plots of predicted and observed sulfate (SO4) concentrations for Q1, Q2, Q3 and Q4 2002, STN sites in Alabama and the CMAQ 2002 36 and 12 km Base G2 Actual base case simulation (duplicate of Figure B-2a in Appendix B)

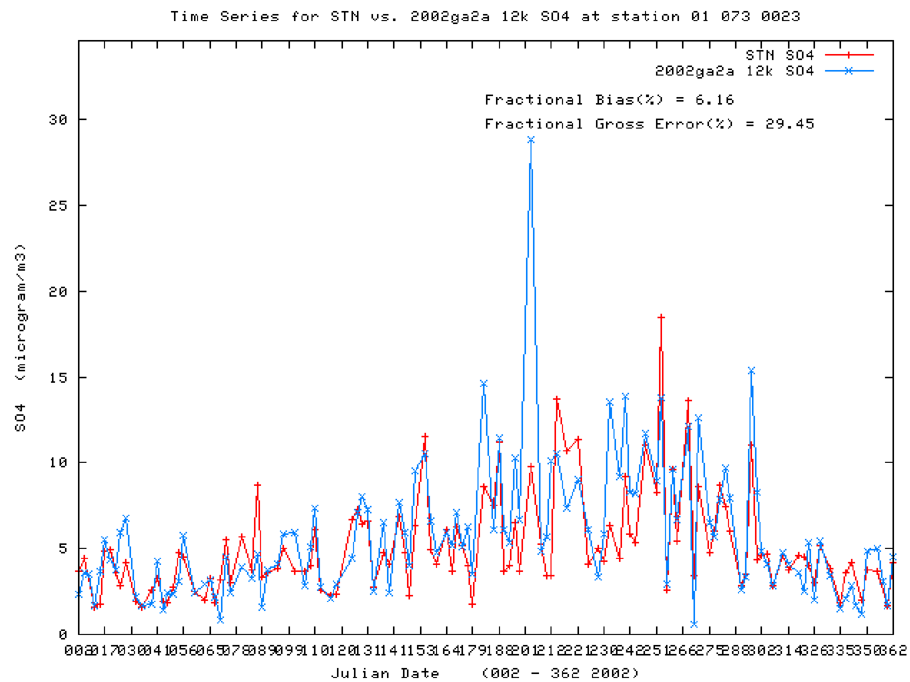

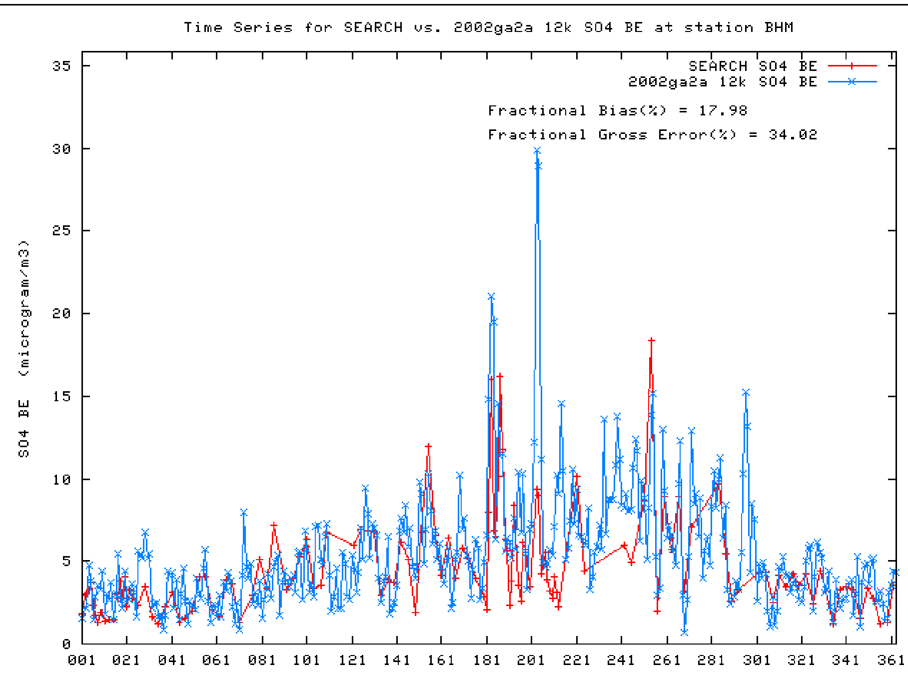

Figure 3-9. Time series of predicted and observed 24-hour sulfate (SO4) concentrations during 2002 at the STN Jefferson County, Alabama Site No. 01-073-0023 (top) and SEARCH BHM (bottom) co-located North Birmingham sites for the CMAQ 12 km 2002 Base G2 Actual base case simulation.

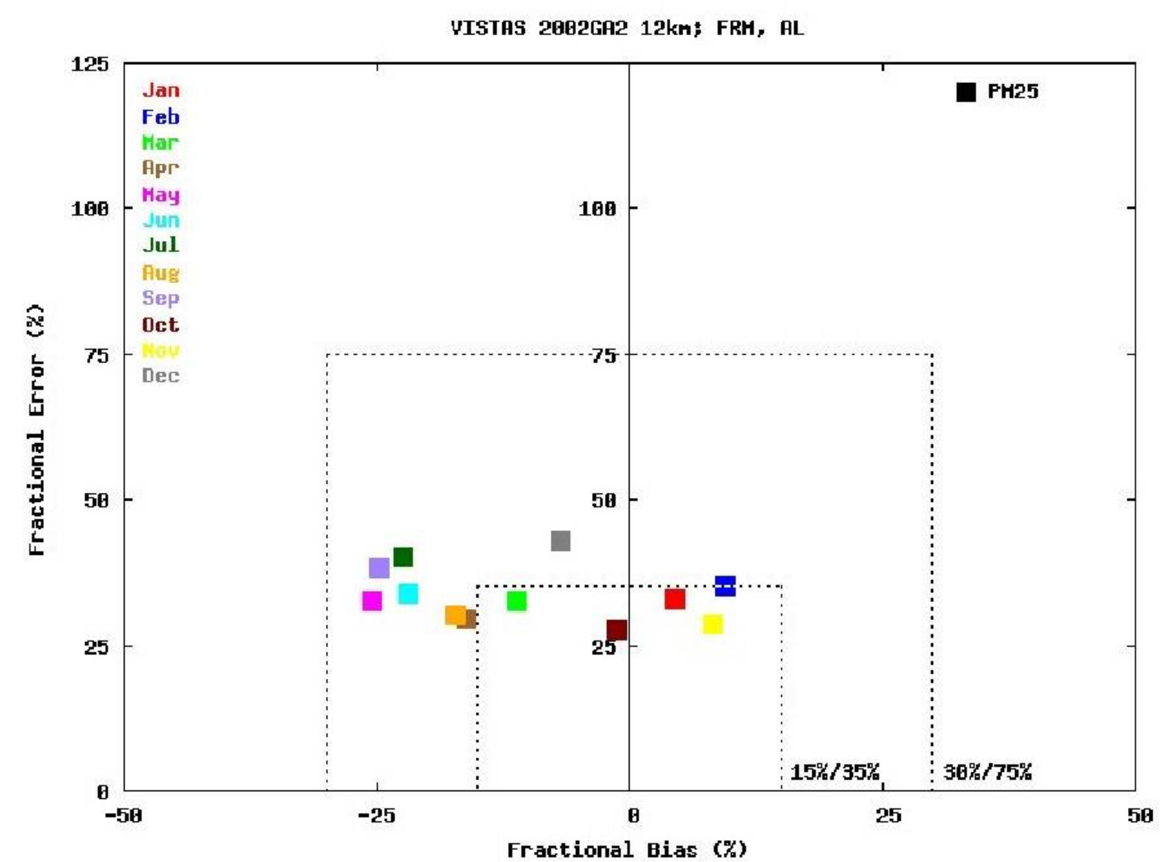

Figure 3-10. Soccer plot of monthly fractional bias versus fractional gross error for $PM_{2.5}$ mass at FRM monitors in Alabama for the CMAQ 12 km 2002 Base G2 Actual base case simulation.

3.5.2 Florida

Figure B-7 summarizes the CMAQ $PM_{2.5}$ species model performance across the ~4 STN sites in Florida and Q1, Q2, Q3 and Q4 2002. SO4 is underestimated at the Florida STN sites (Figure B-7a) with fractional bias values that are closer to zero (i.e., better) in the winter than summer (e.g., -6% in Q4 versus -23% in Q3 for the 12 km CMAQ results). The SO4 bias is also closer to zero using the 12 km than 36 km CMAQ modeling results (e.g., in Q4 bias is -6% using 12 km and -11% using 36 km modeling results). Even with this underestimation bias, SO4 performance at the Florida STN CMAQ sites is fairly good. NO3 performance, on the other hand, exhibits a large underprediction bias with fractional bias values that range from -70% in Q4 to -170% in Q3 (Figure B-7b). NH4 performance at the Florida STN sites is fairly good always achieving the <±30%/50% PM performance goal and sometimes even achieving the more stringent <±15%/35% ozone performance goal (Figure B-7c). It is interesting that in Q1 and Q4 when both SO4 and NO3 exhibit an underprediction bias, NH4 exhibits a slight overprediction bias. Given the linked relationship between these species this is somewhat surprising and may be due to artifacts in the measurements, or the modeled SO4 being more fully neutralized by NH4 than in the measurements. The OCM and EC are characterized by underprediction tendency with the OCM fractional bias ranging from -75% to -110% and the CMAQ 36 km and 12 km producing nearly identical performance metrics (Figure B-7d). The EC performance is better with fractional bias values ranging from -22% to -53% and the 12 km modeling results producing significantly better EC model performance metrics than the 36 km modeling results (Figure B-7e).

The $PM_{2.5}$ mass scatter plots and performance statistics in Florida are summarized across ~3 STN sites and 28 FRM sites in Figures B-7f and B-7g, respectively. The Soccer Plot of monthly $PM_{2.5}$ bias and error performance for FRM sites in Florida is shown in Figure B-9, which is repeated as Figure 3-11 below. For the winter months of Nov, Dec, Jan and Feb, the $PM_{2.5}$ performance statistics are quite good with bias/error values meeting the <±15%/35% ozone performance goal. The spring and fall months either achieve the <±30%/50% or <±50%/125% performance goal and criteria. The May-Jul summer months are at or exceed the -50% bias performance criteria levels (note that in the Soccer Plots if the symbol would be plotted outside of the range of the plot then it is plotted on the axis, such as the May and July -50% values in Figures 3-11 and B-9). Thus, the $PM_{2.5}$ performance in Florida is significantly worse than the other ASIP states and is a cause for concern. Fortunately, Florida is one of the ASIP states without any violating $PM_{2.5}$ monitors (See Chapter 4).

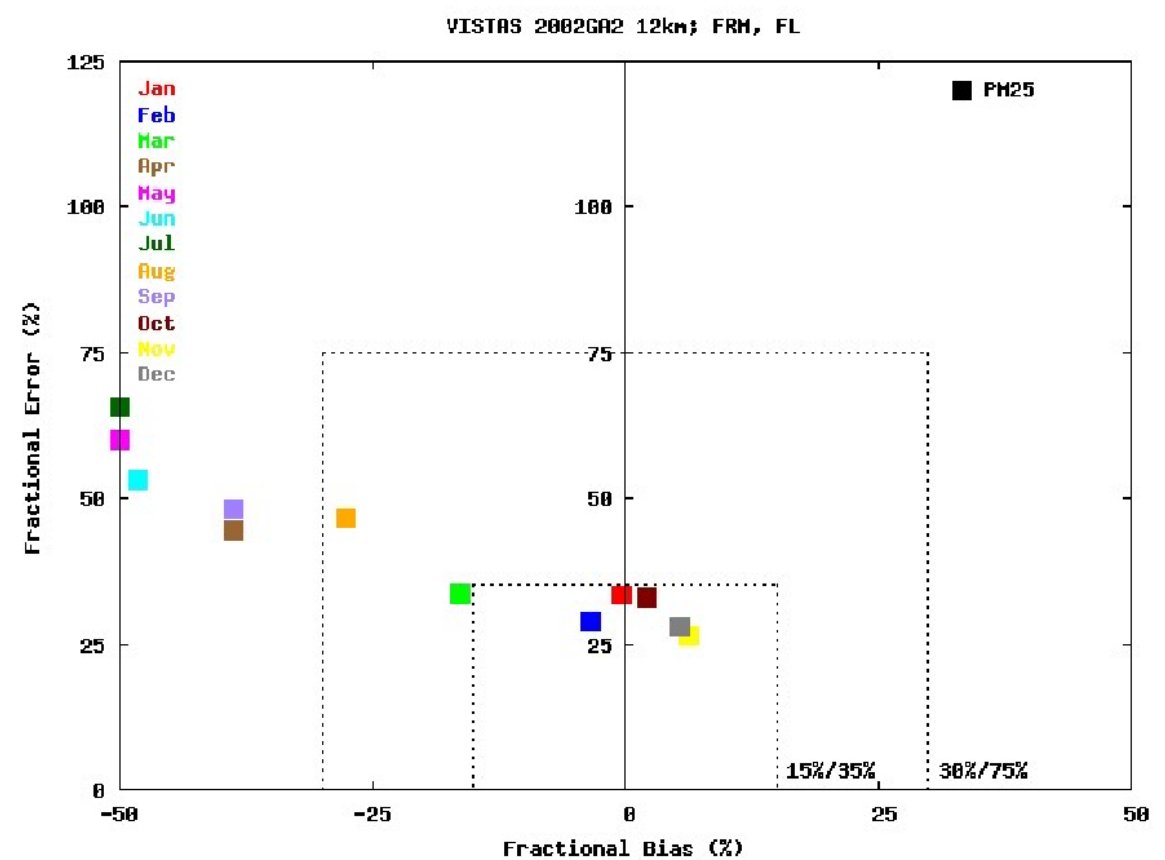

Figure 3-11. Soccer plot of monthly fractional bias versus fractional gross error for $PM_{2.5}$ mass at FRM monitors in Florida for the CMAQ 12 km 2002 Base G2 Actual base case simulation.

3.5.3 Georgia

There appears to be valid data capture issues in the 2002 STN database for Georgia due to the start up of some of the STN sites in 2002 so data are not available in the early months. The CMAQ SO4 performance in Georgia is generally pretty good with bias/error frequently achieving the <±15%/35% ozone performance goal and always achieving the PM goal (Figure B-11a). The STN sites also have the summer nitrate underprediction performance issue as seen in the other states (Figure B-11b). The NH4 model performance falls between the SO4 and NO3 performance and achieves the <±30%/50% PM performance goal for all four quarters (Figure B-11c). The carbon performance in Georgia appears to be slightly better than the other states, although still with a general underestimation tendency of -40% to -67% (Figure B-11d). EC performance is variable with generally low bias in Q3 and Q4 an overestimation bias in Q1 and underestimation bias in Q2 (Figure B-11e).

The performance of total $PM_{2.5}$ mass across the STN (Figure B-11f) and FRM (Figure B-11g) monitoring sites in Georgia is generally fairly good. Q3 exhibits an underprediction tendency with fractional bias values of approximately -25% (STN) and -18% (FRM) that is likely caused by the underestimation of SO4 and especially OCM. But in general the $PM_{2.5}$ performance statistics mostly achieve the more stringent ozone performance goal.

An example time series of predicted and observed PM concentrations and annual statistics for two sites in the Atlanta Georgia (a DeKalb County STN and the SEARCH Jefferson Street sites) are shown in Figures B-12 and B-13. The model tracks the observed SO4 concentrations at these sites extremely well producing low fractional bias (-5% and +9%) and gross error (27% and 30%). NO3 performance exhibits the underprediction tendency seen in the other states, but is not as severe with a fractional bias of -16% and ~80% error. The CMAQ 12 km results reproduces the OCM concentrations at the DeKalb County site surprisingly well with low bias (-14%) and error (31%), with a slight degradation at the SEARCH JST site (-35% bias and 46% error). EC is overestimated (bias of 28%) at the DeKalb site but has zero error at the SEARCH site. Finally, the performance for $PM_{2.5}$ mass at the two Atlanta sites is extremely good with very low bias (2% and -3%) and error (25% and 24%).

Figure 3-12 below is reproduced from Figure B-14 in Appendix B and displays a Soccer Plot of monthly fractional bias and error across the 26 FRM sites in Georgia. All months achieve the PM performance goal and 8 of the 12 months even achieve the more stringent ozone performance goal. The months that the $PM_{2.5}$ mass performance doesn't achieve the ozone performance goal are due to an overestimation bias in January and underestimation bias in the summer months of May-July with the latter primarily caused by an underestimation of SO4 and OCM.

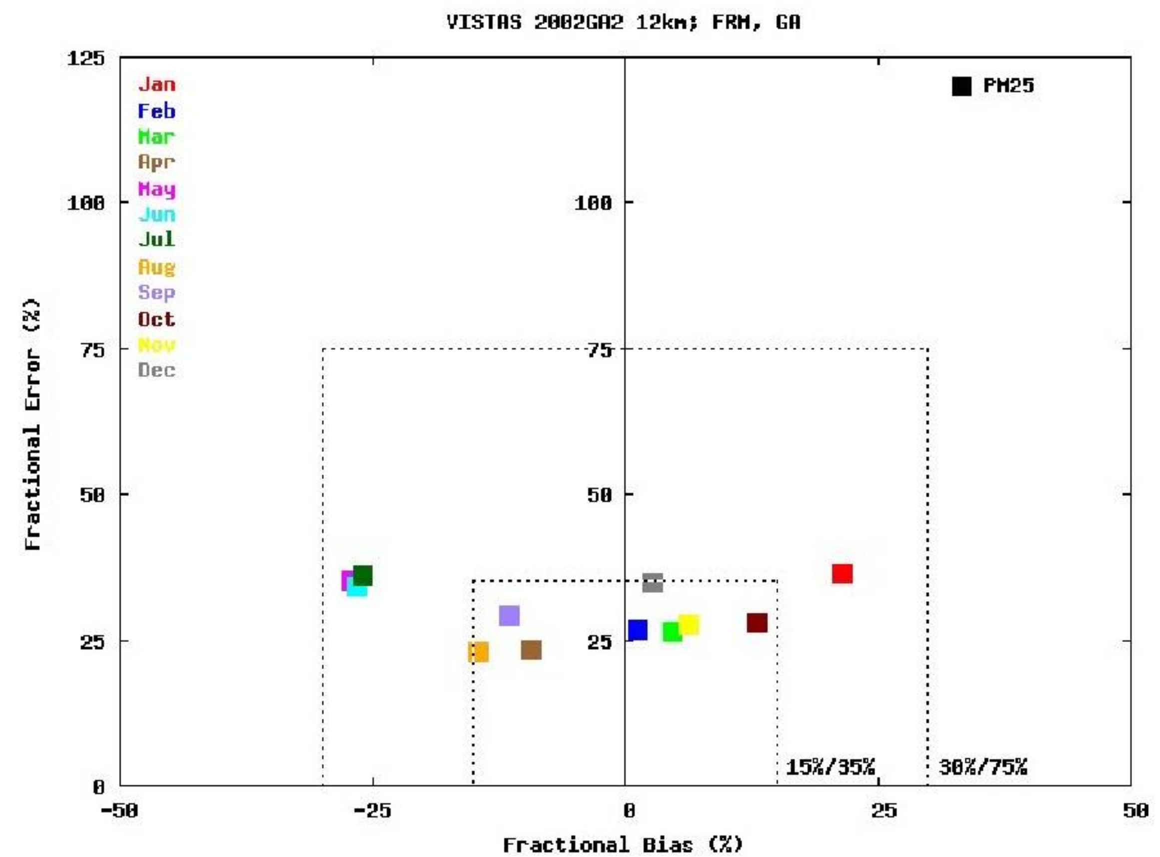

Figure 3-12. Soccer plot of monthly fractional bias versus fractional gross error for $PM_{2.5}$ mass at FRM monitors in Georgia for the CMAQ 12 km 2002 Base G2 Actual base case simulation.

3.5.4 Kentucky

The quarterly scatter plots and performance statistics for 24-hour average PM species and sites in Kentucky are shown in Figure B-16 in Appendix B. The performance for SO4 in Q1 is mixed, with a group of points clustered around the 1:1 line and another further to the right that has been determined to be variations of SO4 performance in Kentucky on different STN sampling days in Q1. Good SO4 performance is seen in Q2 and Q3, whereas Q1 and Q4 exhibit an SO4 underestimation bias. As seen in the other states, NO3 performance in Kentucky is characterized by underprediction bias that is largest in the Q3 with fractional bias of -5% in Q1, -100% in Q2 -120% in Q3 and 8% in Q4. Like SO4, NH4 performance is fairly good albeit with an underprediction bias in Q2 and Q3 (Figure B-16c). As seen for the other states, OCM is underpredicted in Kentucky with the bias ranging from -80% in Q1 to -90% in Q3 (Figure B-16d). The OCM errors are the opposite sign but the same magnitude as the bias suggesting that the OCM underprediction bias is almost systematic. The CMAQ 36 km and 12 km modeling results exhibits different EC performance in Kentucky. The CMAQ 12 km results have better bias that is much closer to zero than the 36 km results (Figure B-16e). This is likely due to the 36 km grid cells over dispersing the urban EC emissions. Both the CMAQ 36 km and 12 km results exhibit a lot of variability producing a lot of scatter and high error metrics.

The performance of total $PM_{2.5}$ mass concentrations in Kentucky is evaluated across 10 STN (Figure B-16f) and 23 FRM sites (Figure B-16g). Given the underprediction of most of the PM component species it is not surprising that total $PM_{2.5}$ mass is underpredicted across the STN sites by -19%, -33%, -20% and 0% for Q1, Q2, Q3 and Q4, respectively. Across the FRM sites in Kentucky, however, the CMAQ model for $PM_{2.5}$ mass bias is much closer to zero with values of -3%, -23%, -22% and 12% for the same four quarters. The FRM $PM_{2.5}$ mass performance always achieves the PM performance goal and sometimes even achieves the ozone model performance goal.

An example PM model performance for STN sites in Lexington (Fayette County) and Kenton County (Cincinnati NAA) are shown in Figures B-17 and B-18. The model performance at these two sites is similar. At the Lexington site the model reproduces the temporal variations in SO4 quite well (Figure B-17a, top) resulting in low bias (-10%) and error (33%). Although the model shows some skill in reproducing the observed higher NO3 values in the winter, especially in the first part of the year, the near zero modeled NO3 during the summer results in a fractional bias value of -62% with 87% error, so does not achieve the PM performance goal (Figure B-17a, bottom). OCM is underpredicted with fractional bias values of -52% and an error of 58% just at the PM performance goal (Figure B-17b, top). EC exhibits much better performance at the Lexington, Kentucky site with a bias near zero (-4%) and error of 36% so almost achieves the ozone performance goal. The fractional bias for NH4 and $PM_{2.5}$ at Lexington are both approximately -10% with NH4 having an error of 36% and $PM_{2.5}$ an error of 28% thereby achieving the ozone performance goal.

Figure 3-13 below reproduces Figure B-19 from Appendix B that summarizes the Kentucky $PM_{2.5}$ mass model performance using a Soccer Plot of monthly bias and error. With the exception of July, whose fractional bias falls slightly below -30%, $PM_{2.5}$ performance in the other 11 months achieves the PM bias/error performance goal of <-30%/75%. In fact 5 months, which occur mainly in the winter, even achieve the more stringent ozone model performance goal.

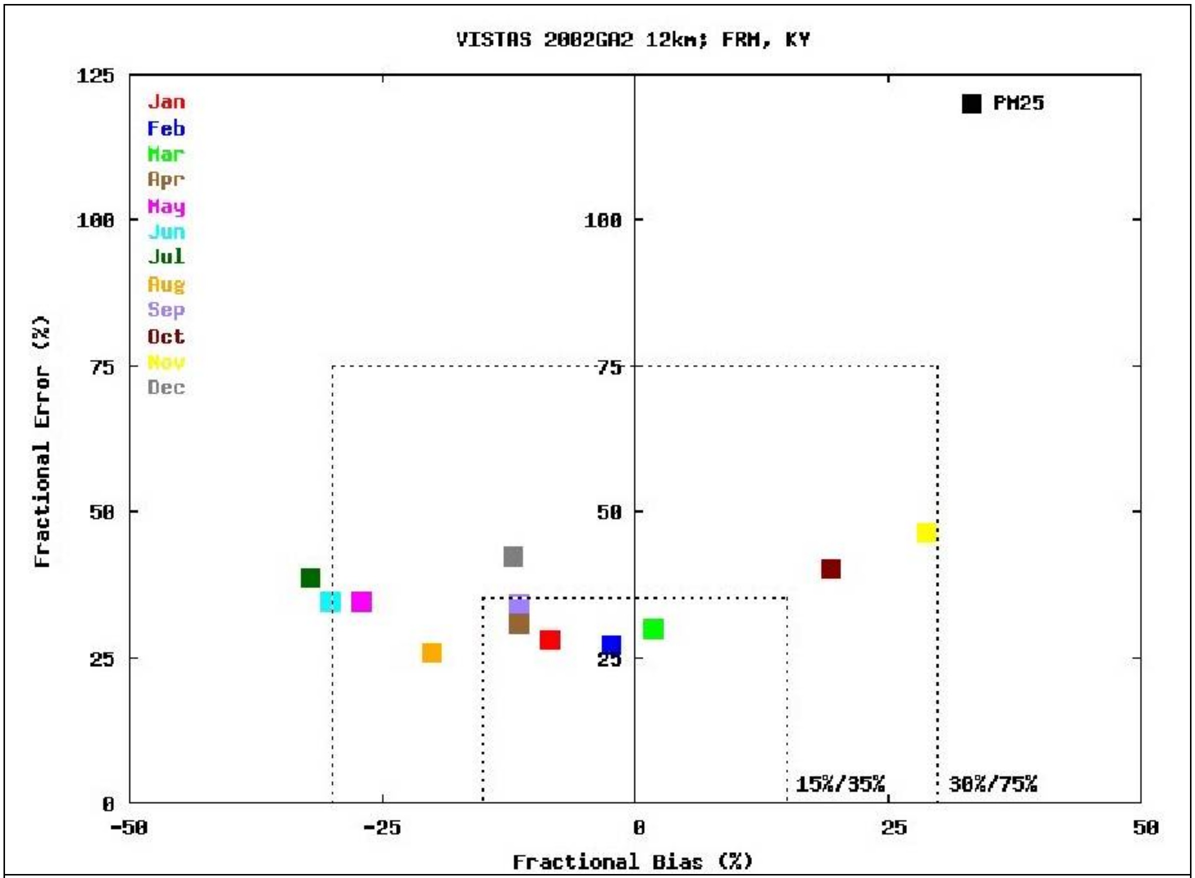

Figure 3-13. Soccer plot of monthly fractional bias versus fractional gross error for $PM_{2.5}$ mass at FRM monitors in Kentucky for the CMAQ 12 km 2002 Base G2 Actual base case simulation.

3.5.5 Mississippi

Performance of PM species across sites in Mississippi is shown in Figure B-21. The CMAQ performance in Mississippi is generally worse than the other ASIP states (with the exception of Florida). SO4 is underpredicted with fractional bias values ranging from -20% to -40% with the worse SO4 performance seen in Q1 and Q4. NO3 performance metrics are extremely poor with fractional bias values of -60% in Q1, -110% in Q2, -150% in Q4 and -30% in Q4. OCM is underpredicted at sites in Mississippi with fractional bias values of -70% to -80%. Performance for EC is better, albeit still with an underprediction bias and, as seen for other states, the CMAQ 12 km modeling results produces much better lower EC bias than the 36 km modeling results (Figure B-21e). $PM_{2.5}$ performance in Mississippi across the STN and FRM networks are shown in Figures B-21f and B-21g, respectively. Across the STN network, $PM_{2.5}$ is underestimated by approximately -40% in Q1 rising to -50% in Q3. Across the FRM network, the $PM_{2.5}$ underprediction bias is lower, at -20% in Q1 and -30% in Q2 and rising to approximately -30% in Q3. In Q4 the model is better able to replicate the observed $PM_{2.5}$ mass with CMAQ 12 km bias and error values across the FRM network of -2% and -33%, respectively, achieving the ozone model performance goals.

The Soccer Plot (Figures 3-14 and B-23) for $PM_{2.5}$ mass performance confirm that $PM_{2.5}$ performance in Mississippi is worse than seen for the other ASIP states, except Florida. Only two months achieve the ozone model performance goal and only 8 months achieve the PM model performance goal. The model underprediction tendency during March through July 2002 produces fractional bias for $PM_{2.5}$ that ranges from -50% to -100% thereby not achieving the PM model performance goal. However, unlike Florida, the Mississippi monthly bias/error for $PM_{2.5}$ always achieves the <-50%/75% PM performance criteria.

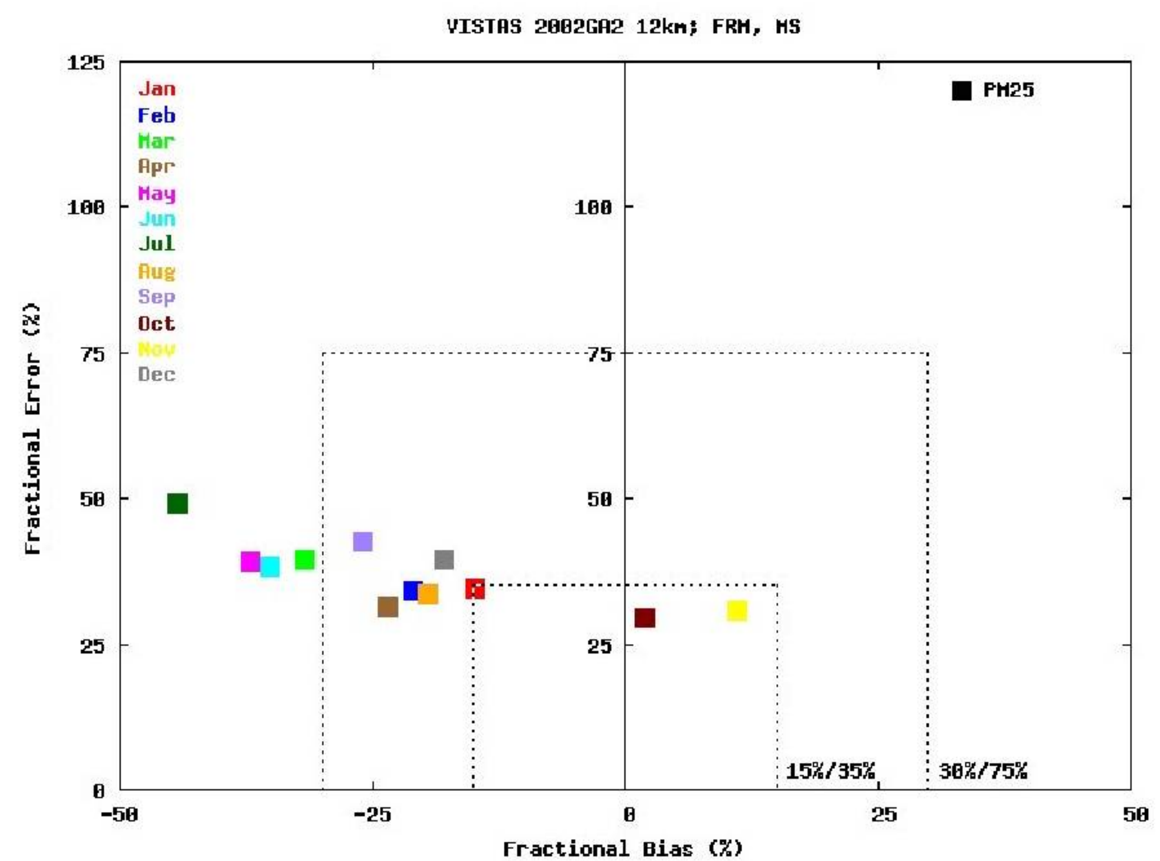

Figure 3-14. Soccer plot of monthly fractional bias versus fractional gross error for $PM_{2.5}$ mass at FRM monitors in Mississippi for the CMAQ 12 km 2002 Base G2 Actual base case simulation.

3.5.6 North Carolina

SO4 performance across 9 STN monitoring sites in North Carolina and four quarters from 2002 is shown in Figure B-25a. SO4 performance achieves the PM performance goal with fractional bias results varying from -13% to -30%. Although NO3 is still greatly underestimated in North Carolina during the summer (Q3 bias of -90% to -120%), during Q1 and Q4 NO3 exhibits an overestimation bias with values of 11% to 30%, respectively (Figure B-25b). This is likely due to overstated ammonia emissions during the winter and adjacent periods which is somewhat verified by the overstated ammonium during Q1 and Q4 that have fractional bias values of approximately +30% (Figure B-25c). OCM is characterized by an underprediction bias ranging from -70% to -90%. EC, on the other hand, achieves the PM performance goal in Q1 and Q4 but has lots of scatter in the other two months exceeding the PM performance goal for bias in Q2 and for error in Q4. $PM_{2.5}$ mass performance across the 9 STN and 36 FRM sites in North Carolina exhibits monthly variations (Figures B-25f and B-25g). FRM $PM_{2.5}$ is overpredicted in January (15% to 18%) and October (25% to 30%), but underpredicted in April (-9% to -16%) and July (-37% to -39%). The STN $PM_{2.5}$ performance is similar except because the STN measurements tend to be higher so the underprediction bias is greater and the overprediction bias is less.

The Soccer Plot summary of FRM total $PM_{2.5}$ mass monthly model performance in North Carolina is shown in Figure 3-15 (reproduced from Figure B-28 in Appendix B). With the exception of the large summer underprediction bias in June and July, the other 10 months $PM_{2.5}$ performance achieves the <±30%/50% PM performance goal with four of the months even achieving the more stringent ozone performance with four additional months right at the ozone goal.

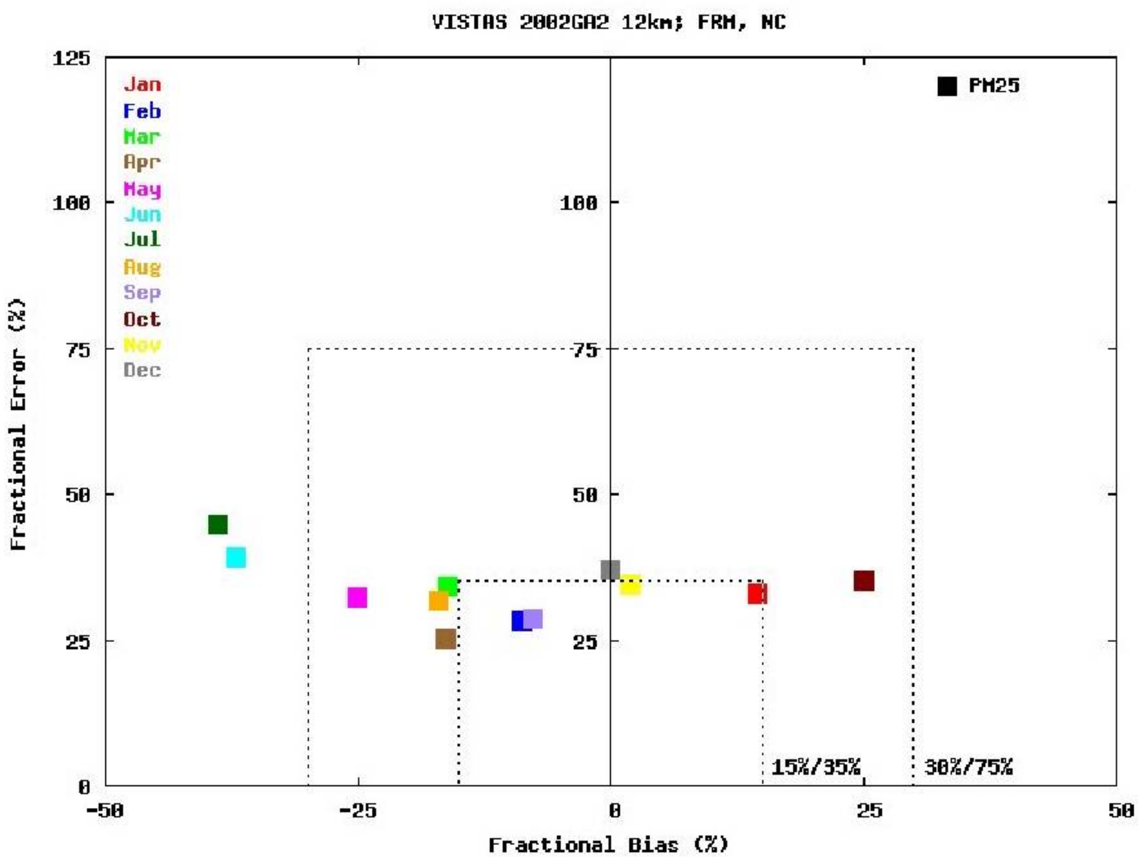

Figure 3-15. Soccer plot of monthly fractional bias versus fractional gross error for $PM_{2.5}$ mass at FRM monitors in North Carolina for the CMAQ 12 km 2002 Base G2 Actual base case simulation.

3.5.7 South Carolina

The CMAQ performance for SO4 across the 4 STN sites in South Carolina has an underprediction bias but is reasonably good, always achieving the PM performance goal and sometimes even achieving the ozone performance goal (Figure B-30a). NO3 performance is poor with an underprediction bias generally from -20% to -170% that is worst in the summer (Q3) when NO3 is lowest and not an important component of the $PM_{2.5}$ (Figure B-30b). NH4 performance is variable frequently achieving the PM performance goal with the worst performance in the summer characterized by a large underprediction tendency. OCM is underestimated with bias of approximately -80%. EC performance also has an underestimation tendency, although not is bad as seen for OCM. The CMAQ 12 km results also exhibits much better EC performance than the CMAQ 36 km modeling results with the 12 km EC model performance always achieving the PM performance goal and sometimes even achieving the ozone performance goal, whereas the CMAQ 36 km EC results never achieves the PM performance goal for the four quarters with an underprediction bias that is approximately twice the 12 km results (Figure B-30e). $PM_{2.5}$ model performance across STN and FRM networks in South Carolina are shown in Figures B-30f and B-30g, respectively. $PM_{2.5}$ mass is usually underpredicted across both networks, with the fractional bias across the STN network worse and approximately 20 percentage points larger underprediction than the FRM network. In fact, the bias/error for $PM_{2.5}$ across the FRM network always achieves the ≤±30%/50% PM performance goal and even achieves the <±15%/35% bias/error ozone model performance goal for Q1 and Q4.

The summary fractional bias and gross error Soccer Plot for total $PM_{2.5}$ mass across the FRM network in South Carolina is shown in Figures 3-16 and B-32. During the fall and winter months of August, September, November, December, January and February, the monthly bias and error statistics for $PM_{2.5}$ achieve the very stringent ozone model performance goal. The three additional months of March, April and October achieve the PM performance goal. Whereas during the summer months of May, June and July FRM $PM_{2.5}$ performance fails to achieve the PM performance goal (but does achieve the PM performance criteria) due to large underprediction bias that is caused by the underprediction of each of the PM component species.

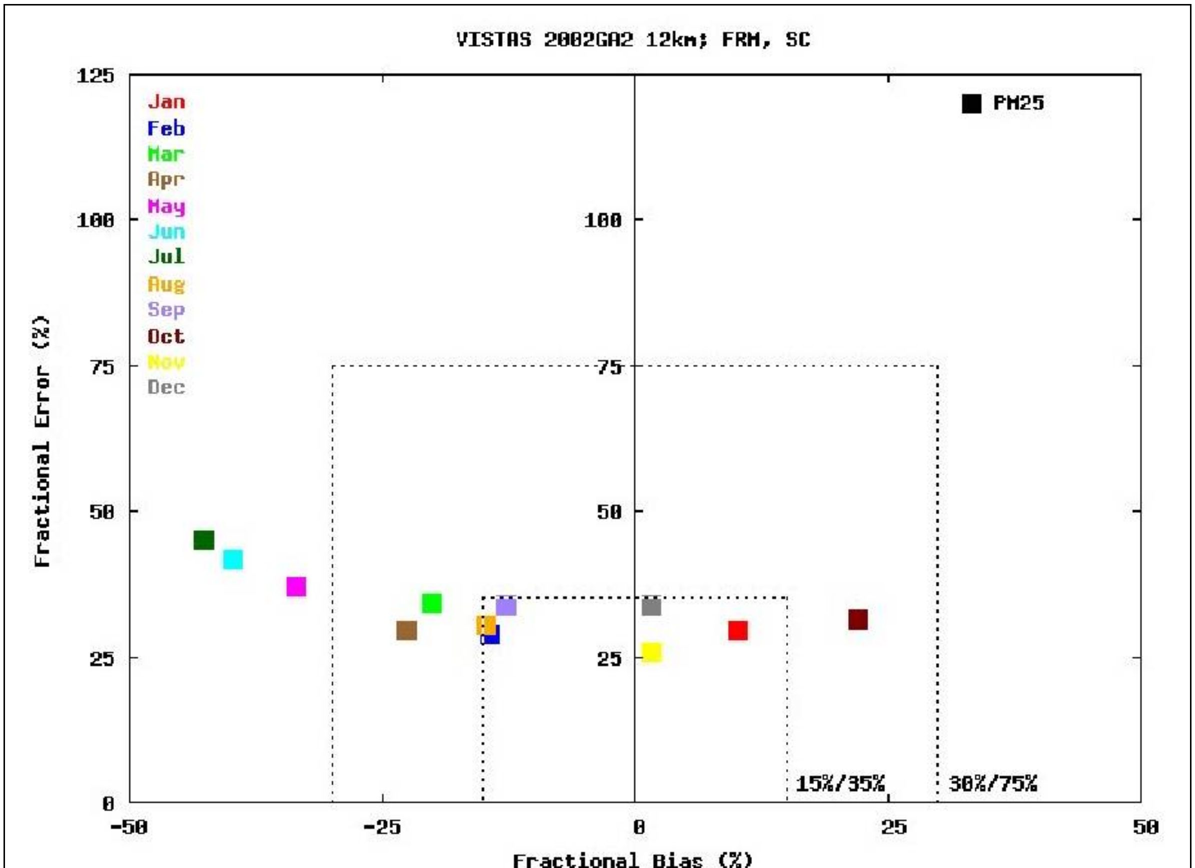

Figure 3-16. Soccer plot of monthly fractional bias versus fractional gross error for $PM_{2.5}$ mass at FRM monitors in South Carolina for the CMAQ 12 km 2002 Base G2 Actual base case simulation.

3.5.8 Tennessee

The CMAQ does a good job predicting the observed SO4 concentrations in Tennessee with bias and error values that either achieve the most stringent ozone performance goal or are right at the edge of the ozone goal (Figure B-34a). The CMAQ 12 km results are slightly better than the 36 km predictions and, unlike the other states where the summer had the largest underprediction bias, in Tennessee the SO4 performance in Q3 is quite good with the 12 km results producing a 8% bias and 36% error. The model exhibits little skill in its NO3 predictions (Figure B-34b) with the usual large underprediction bias in the summer (e.g., -150% in Q3). Although the bias is low in Q1 and Q4 (<±10%), the error is large (60% to 80%). NH4 performance is generally reasonably good with low bias throughout the year.

As seen in the other states, OCM exhibits a large underprediction bias that generally ranges from -60% in Q1 to -80% in Q4 (Figure B-34d). EC performance is quite good for the 12 km CMAQ results, with the 36 km CMAQ results having a larger underprediction bias (Figure B-34f). Tennessee $PM_{2.5}$ mass performance across the STN and FRM networks are shown in Figures B-34f and B-34g. Across the STN network performance for $PM_{2.5}$ achieves the ozone goal in Q1, but exhibits an underprediction bias in Q2 and Q3 but does achieve the PM performance goal. Across the FRM network, the model performs better for $PM_{2.5}$ achieving the ozone performance goal in Q1 and Q4, but with an underprediction bias in Q2 (-17% and -22%) and Q3 (-18% and -29%).

The monthly fractional bias and error Soccer Plot for FRM $PM_{2.5}$ performance in Tennessee shown in Figure 3-17 and indicates that all months of the year achieve the PM model performance goal and that 5 of the months even achieve or are right at the ozone model performance goal. The months that do not achieve the ozone performance goal are due to a summer underprediction bias for May-July and a fall/winter overprediction bias for October and November and a too high error for December.

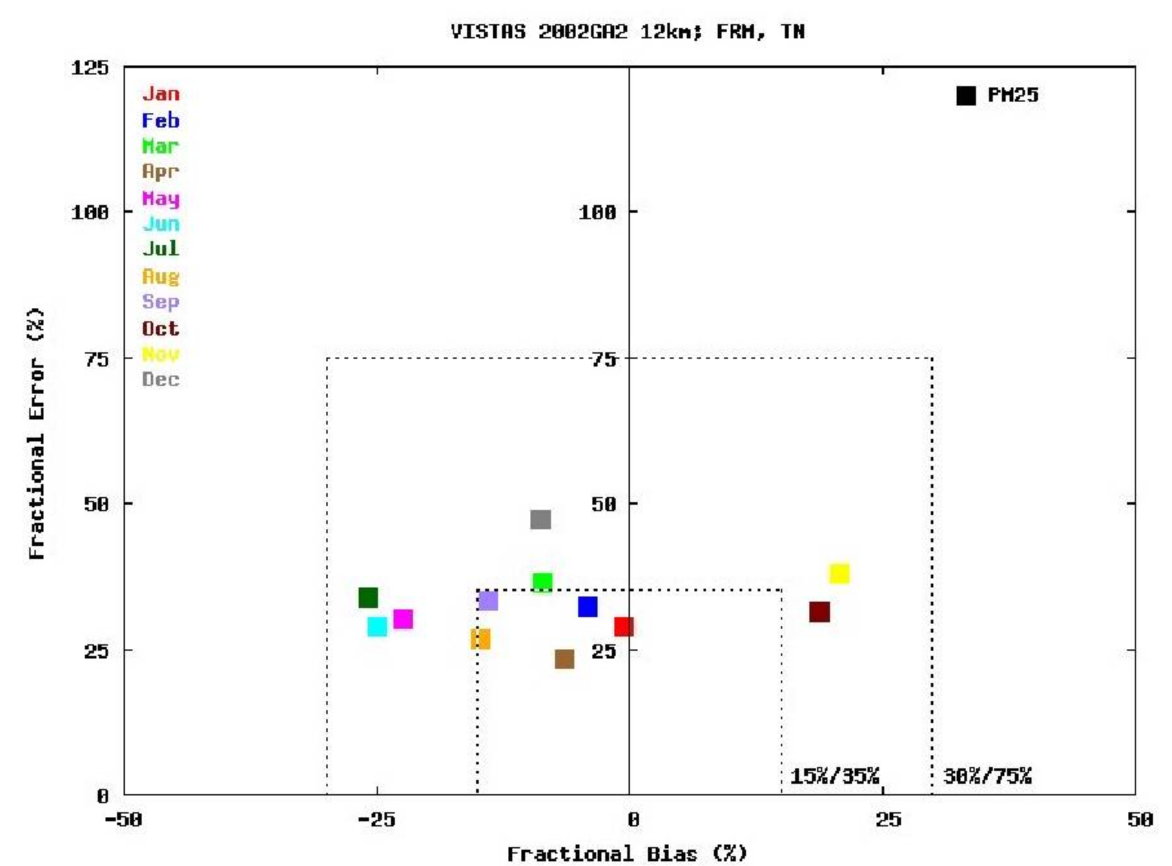

Figure 3-17. Soccer plot of monthly fractional bias versus fractional gross error for $PM_{2.5}$ mass at FRM monitors in Tennessee for the CMAQ 12 km 2002 Base G2 Actual base case simulation.

3.5.9 Virginia

SO4 performance is fairly good in Virginia with low bias and error in Q2 and Q3 that achieves the <±15%/35% ozone bias/error performance goal (Figure B-39a). Although Q1 and Q4 exhibit a -15% to -20% underprediction bias for SO4, it still achieves the PM performance goal. As seen for the other states, NO3 performance is poor and characterized by an underprediction bias that is greatest in the summer (-150%) when CMAQ estimates near zero NO3 predictions. NH4 performance achieves the ozone performance goal in Q1 and Q2 and PM performance goal in Q4 but the -34% to -42% bias in Q4 exceeds the PM performance goal (Figure B-39c).

OCM performance is characterized by an underprediction bias of from -65% to -90% with error of opposite sign and similar magnitude (Figure B-39d). The fractional bias for EC is about 20-30 percentage points higher using CMAQ with a 12 km grid than 36 km grid resulting in the 12 km results always achieving the PM performance goal but the 36 km results underprediction bias in Q2 and Q4 is approximately -40% so does not achieve the PM performance goal.

Figure 3-18 below summarize the $PM_{2.5}$ model performance across 19 FRM sites in Virginia using a Soccer Plot. Monthly fractional bias and gross error for $PM_{2.5}$ mass in Virginia achieves the PM performance goal for every month in 2002, with nine of the months also achieving or almost achieving the more stringent ozone performance goal. As seen in the other states, the three summer months of May, June and July have an underprediction bias that does not meet the ozone performance goal, but still meets the PM performance goal. As noted for other states, the summer SO4 underprediction bias is believed to be due in part to overstated convective precipitation from the MM5 meteorological model that is somewhat verified by an overprediction in wet deposited sulfate in the summer across the NADP network.

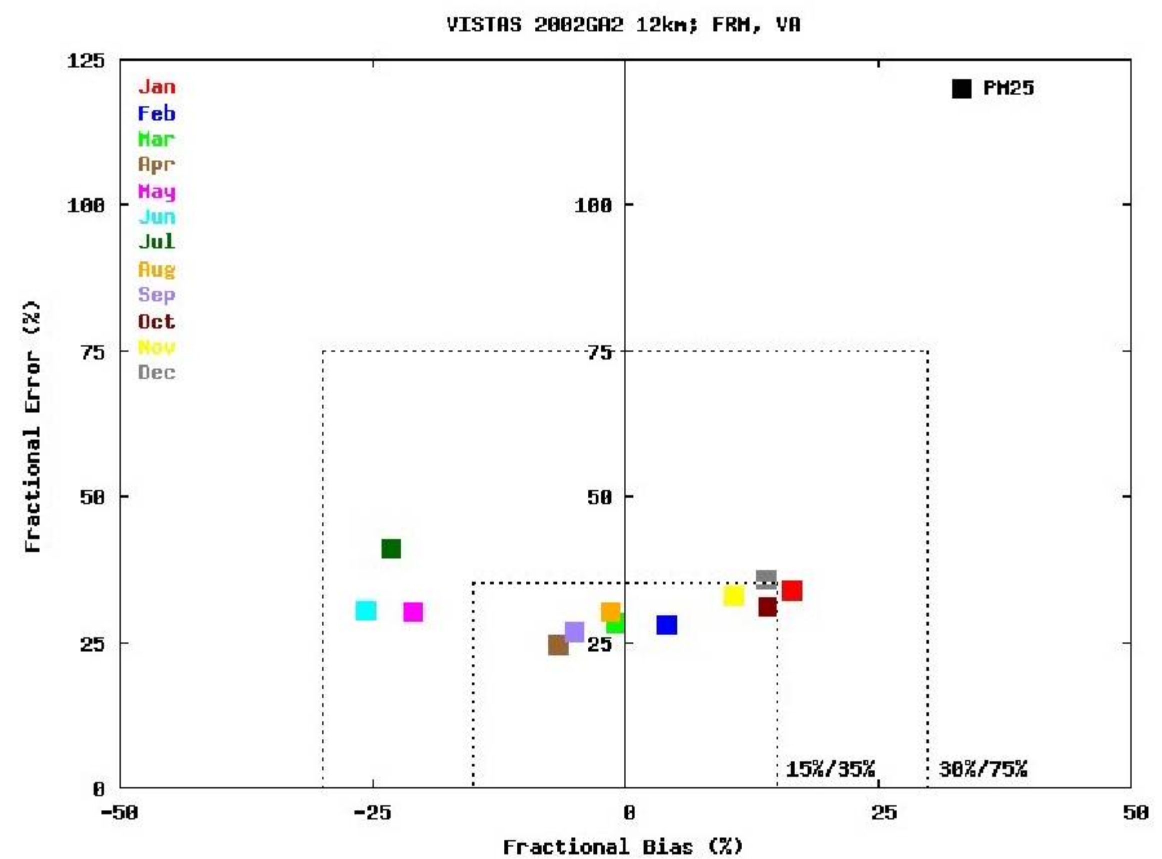

Figure 3-18. Soccer plot of monthly fractional bias versus fractional gross error for $PM_{2.5}$ mass at FRM monitors in Virginia for the CMAQ 12 km 2002 Base G2 Actual base case simulation.

3.5.10 West Virginia

There were no speciated $PM_{2.5}$ STN monitoring sites within West Virginia during the 2002 modeling year, so the $PM_{2.5}$ model evaluation is limited to the 16 FRM $PM_{2.5}$ mass monitoring sites. In Q1, Q2 and Q3, CMAQ underestimates $PM_{2.5}$ mass across the FRM sites in West Virginia by approximately -23%, -37% and -27%, respectively, and achieves the PM performance goal (Figure B-44). In Q4 the model has near zero bias and 32% error so achieves the ozone model performance goal. The Soccer Plot in Figures 3-19 below summarizes the FRM $PM_{2.5}$ mass performance in West Virginia in each month. Nine of the months achieve the PM performance goal, with the winter months even achieving or nearly achieving the ozone model performance goal. As seen for the other states, the underprediction bias during the May-July summer months results in the bias falling outside of the PM performance goal, but within the PM performance criteria.

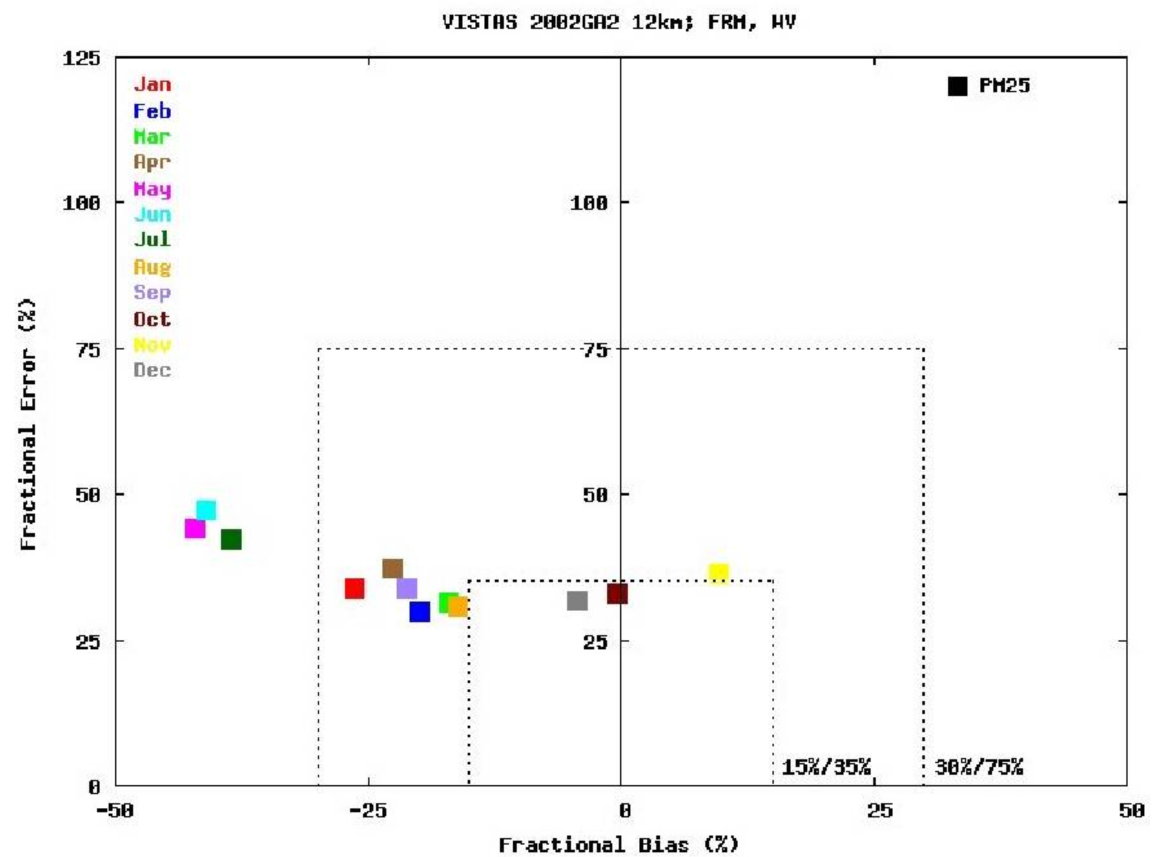

Figure 3-19. Soccer plot of monthly fractional bias versus fractional gross error for $PM_{2.5}$ mass at FRM monitors in West Virginia for the CMAQ 12 km 2002 Base G2 Actual base case simulation.

3.6 SPATIAL AND SEASONAL ANALYSIS OF PM MODEL PERFORMANCE

This section summarizes the results in Appendix C that contains a general qualitative overview of the CMAQ 2002 Base G2 Actual base case model performance across the ASIP 12 km domain, with emphasis on temporal (seasonal) and spatial patterns within the domain. The evaluation is carried out for each of the major $PM_{2.5}$ components separately (sulfate, nitrate, ammonium, organic carbon material, elemental carbon, soil $PM_{2.5}$, sea-salt $PM_{2.5}$), as well as for total $PM_{2.5}$ mass. The performance evaluation summarized in this section and presented in Appendix C present spatial maps of modeled quarterly average $PM_{2.5}$ concentrations with overlaid quarterly average observations. For each $PM_{2.5}$ species, two sets of figures are provided, one comparing model predictions to observations at the STN sites, the other to observations at the IMPROVE network sites (soil and sea-salt are available at the IMPROVE network only). Modeled spatial maps with overlaid observations for total $PM_{2.5}$ mass are compared for the FRM network, in addition to the STN and IMPROVE networks. Four figures are provided for each set corresponding to the average concentrations during the four quarters of the year (Q1: Jan-Mar; Q2: Apr-Jun; Q3: Jul-Sep; Q4: Oct-Dec). In Appendix C all of the spatial maps comparisons are presented, with the figures for the STN $PM_{2.5}$ species components and the FRM $PM_{2.5}$ mass also provided below.

This evaluation allows for a general understanding of model performance and key issues. A more detailed and quantitative performance evaluation for monitoring sites within each ASIP states is provided in Appendix B and summarized in Section 3.5 above.

The observed quarterly average $PM_{2.5}$ mass and $PM_{2.5}$ species concentrations were obtained by averaging all 24-hour measurements at a site that occurred during each three month quarter. The modeled quarterly average spatial maps were obtained by averaging the daily average concentrations for each day in the three month quarter and each grid cell. No attempt was made in the averaging to match the modeled daily average concentrations with the 1:3 day sampling frequency typically used by the monitoring networks. In fact, obtaining modeled quarterly average concentrations trying to match the measurement days is problematic since not all sites collect valid samples on every 1:3 day sampling day. For some STN sites this resulted in a bias in the Q1 quarterly average predicted and observed comparisons since many of the STN sites started up in 2002 and are missing data for the first part of 2002, thus they only have samples near the end of Q1. In the case of species like SO4 that has a strong seasonal variation, basing observed Q1 averages on samples in March and modeled values averaged across January-February-March introduces a seemingly underprediction bias that is artificial and an artifact of the network sampling periods. We know this is occurring at some STN sites, for example see discussion for Georgia in Section 3.5.3.

3.6.1 Sulfate (SO4)

Modeled sulfate concentrations show a very strong seasonal pattern (Figure 3-20 below and Figures C-1a and C-1b in Appendix B), with peak concentrations occurring during summer months (Quarters 2 and 3) when photochemistry is highest. A spatial pattern is also evident, with higher concentrations in the northeast, Ohio River valley, and southeast, compared to the upper Midwest and Florida, caused mainly by the higher and denser SO_2 emissions in those regions compared to the latter two. In Florida, the impacts of individual major sources of SO_2 are evident (such as in the Tampa and Jacksonville areas), as their emissions remain relatively unmixed with emissions from other regions, being surrounded by ocean. However, in most of the domain, a "regional" sulfate field is observed as a result of mixing of emissions from various regions, especially for the long averaging time presented here (three months).

Overall, the model seems to accurately simulate sulfate levels over the domain and captures both the temporal and spatial patterns exhibited in the observations, both from the STN (Figures C-1a and 3-20) and IMPROVE (Figure C-1b) networks. The exception is Quarter 1 for the STN network, in which the observed concentrations seem higher than the modeled ones, and there is not much agreement in the spatial pattern between the two. This is partly due to an artifact in the way the observations are presented here. Since some of the STN sites were not in operation during the first few months of 2002, observed Quarter 1 averages might in fact be driven by observations during the latter (and warmer) part of Quarter 1 (e.g., March samples), and therefore are biased high relative to the modeled Q1 SO4 concentrations.

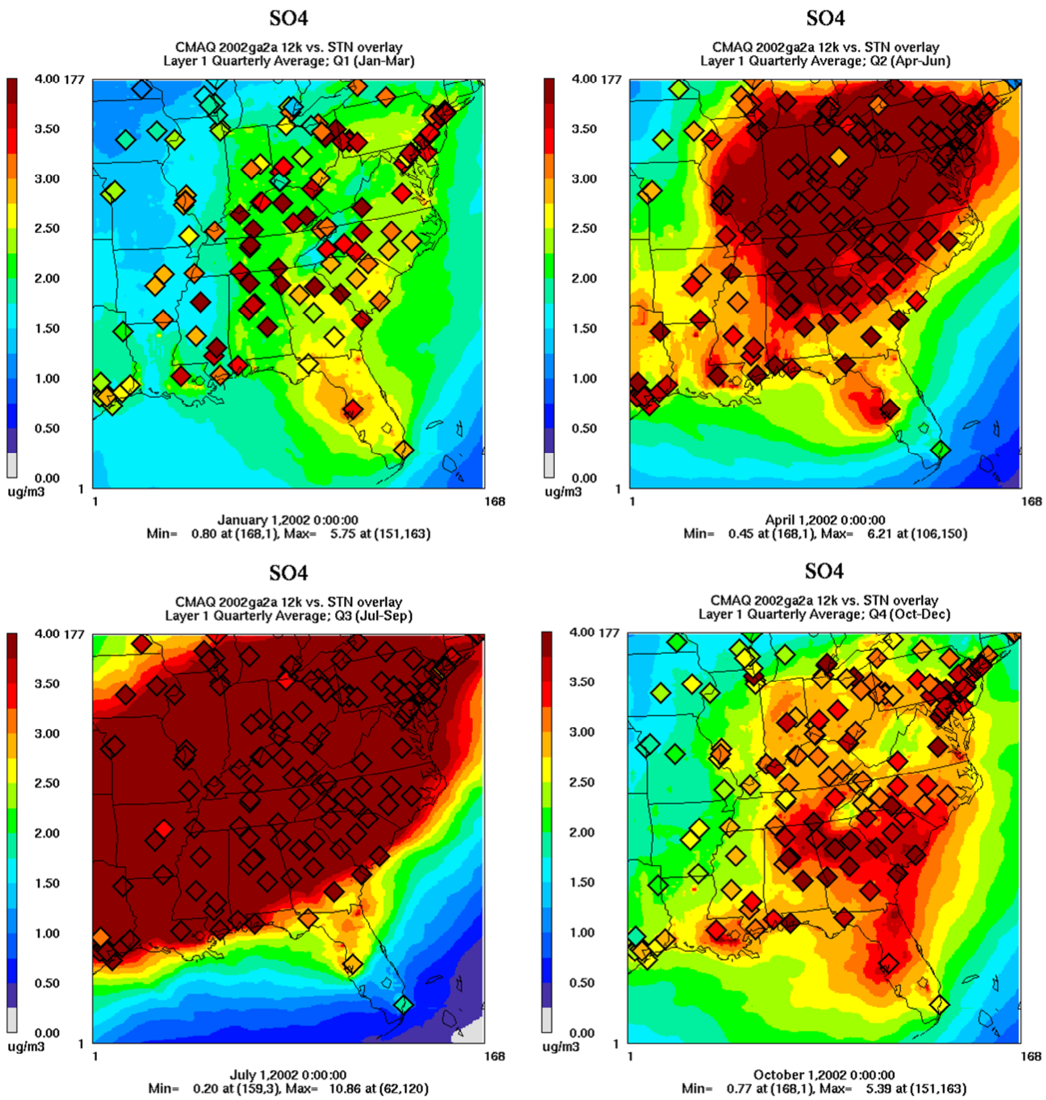

Figure 3-20. 2002 Quarterly averages of CMAQ simulated and STN observed (diamonds) sulfate (SO4) concentrations over the VISTAS 12 km domain (for IMPROVE comparisons see Appendix C).

3.6.2 Nitrate (NO3)

Nitrate is in many ways the “mirror” image of sulfate, with peak concentrations occurring during wintertime, when the cooler temperatures are favorable for particulate nitrate formation, and due to lower SO4 as more ammonia is available to bond with nitrate, rather than sulfate (Figure 3-21 and Figures C-2a and C-2b in Appendix C). Also for this reason, peak particulate nitrate concentrations occur in areas of the domain where ammonia emissions are highest, such as the Midwest.

While overall the model does capture the seasonal and spatial variability in particulate nitrate concentrations (Figures C-2a,b), it does seem to overestimate concentrations during wintertime, especially over urban centers, such as in part of the Northeast and over Atlanta and Birmingham. Winter overestimations are also evident over much of North Carolina. While it is impossible to infer from these data alone on the cause for these overpredictions, they are related to either one or a combination of the model nitrate partitioning between gaseous and particulate phase, and the availability of gaseous ammonia, as reflected by the emissions inventory. The latter can be the common denominator between the overpredictions over the urban centers and over North Carolina as ammonia emissions in these areas, though originating from different sources (mobile sources in the urban centers; agricultural ammonia emissions in North-Carolina), might be overestimated making more ammonia available for particulate formation compared to the observations. Also note that the artifact of the start up of the STN network for some of the sites during the Q1 as discussed for SO4 above also affects NO3 performance. The NO3 observations at the STN sites that started during Q1 will have Q! averaged values biased toward the warmer portion of Q1 which will favor lower NO3 concentrations due to the thermodynamic properties of the partitioning of total nitrate to particulate NO3 and gaseous HNO3. This artifact of the sampling frequency of the observations would results in a seemingly underprediction bias in NO3 during Q1.

In the summer the model estimates near zero (< 0.25 $\mu g/m^3$) particulate nitrate concentrations, whereas the observed values are typically in the 0.25-0.75 $\mu g/m^3$ range. So both the modeled and observed summer NO3 values suggest that it is not an important component of the total $PM_{2.5}$ mass concentrations in the southeastern U.S. during the summer.

Fairly similar trends are observed when comparing the model to either the STN (Figures 3-21 and C-2a) or the IMPROVE (Figure C-2b) networks, however a more detailed analysis is provided based on the STN given its larger size and density.

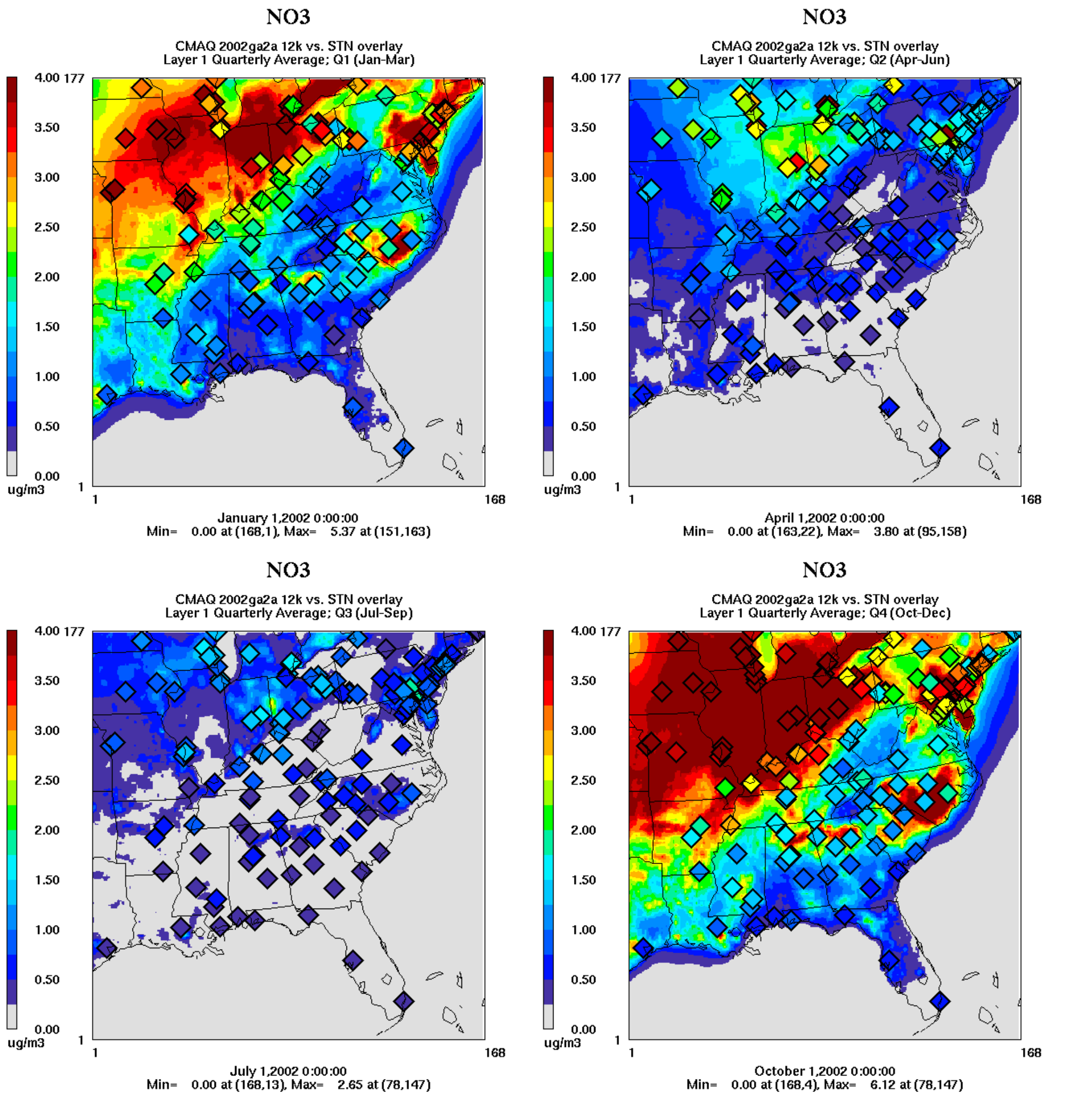

Figure 3-21. 2002 Quarterly averages of CMAQ simulated and STN observed (diamonds) nitrate (NO3) concentrations over the VISTAS 12 km domain (IMPROVE comparisons are provided in Appendix C).

3.6.3 Ammonium (NH4)

Ammonium concentrations depend, to a large degree, on the availability of sulfate and nitrate. Therefore, ammonium levels do not exhibit as strong seasonal pattern, due to the seasonal tradeoff between sulfate and nitrate to which it bonds (Figures 3-22 and C-3).

Model performance when compared to the STN data (Figures 3-22 and C-3a), seems to be better during summertime (Quarters 2 and 3) when the ammonium is mainly associated with sulfate. During wintertime (Quarters 1 and 4), most of the issues observed with nitrate overpredictions are also evident in the ammonium plots, especially over North-Carolina and the urban centers of the Southeast.

Ammonium is not directly measured by IMPROVE, rather it is derived by assuming it completely neutralizes the measured sulfate and nitrate. Although assuming that nitrate is completely neutralized by ammonium is, most of the time, a valid assumption, the same may not be true for sulfate, especially in the summer months. Hence the observed ammonium comparison in the IMPROVE case (Figure C-3b) is likely overstated during the summer months and the seemingly underpredicted observed ammonium concentrations across the Appalachian Mountain IMPROVE monitoring sites in Quarter 3 in Figure C-3b are in part due to using derived observed ammonium.

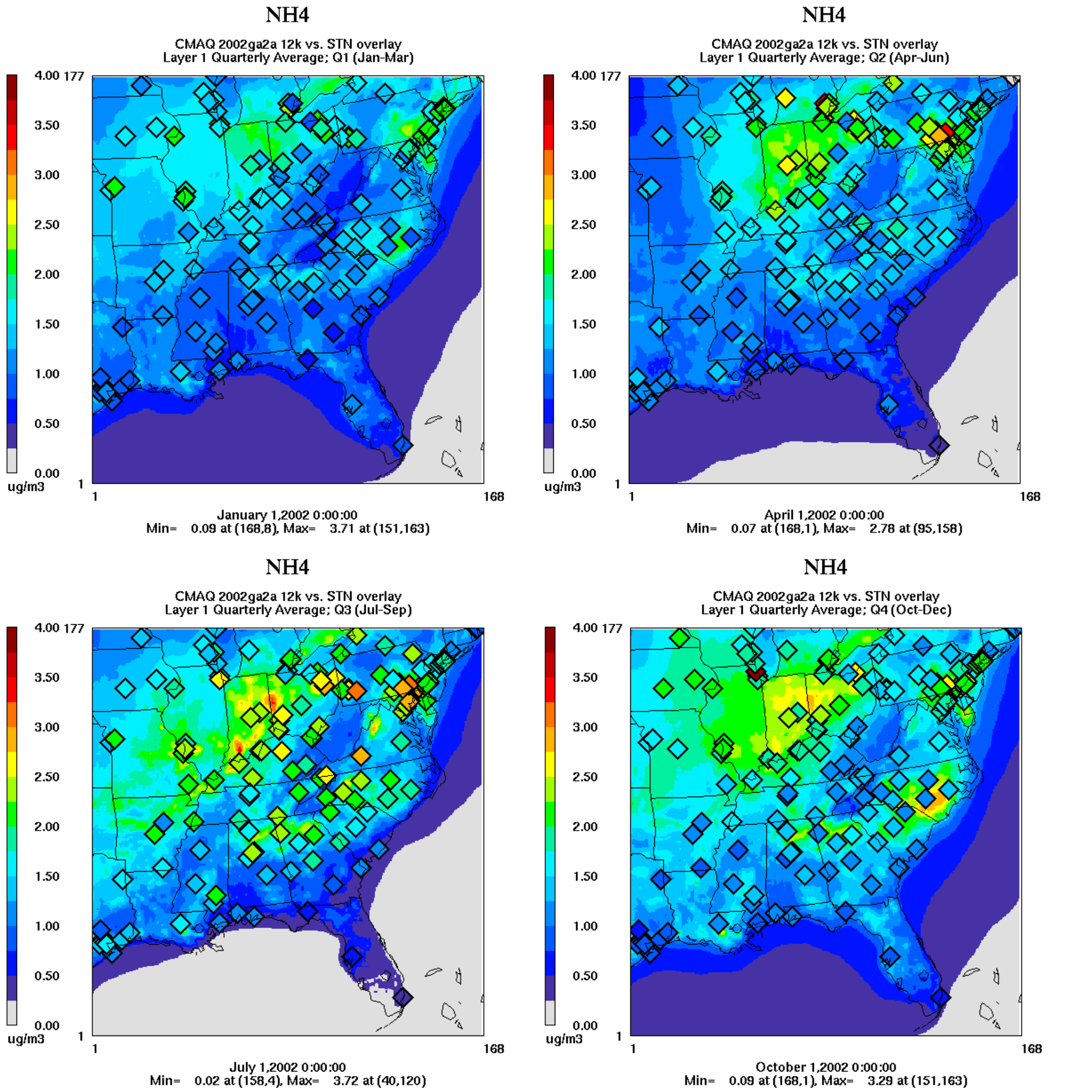

Figure 3-22. 2002 Quarterly averages of CMAQ simulated and STN observed (diamonds) ammonium (NH4) concentrations over the VISTAS 12 km domain (IMPROVE comparisons provided in Appendix C).

3.6.4 Organic Carbon Material (OCM)

Evaluating model performance for OCM is complicated due to its dual primary/secondary nature and anthropogenic/biogenic sources. As a result, the evaluation is dependant on a combination of very different emissions and formation processes. In addition, there is a fair amount of uncertainty associated with OC measurements with the major limitation being the inability to directly measure OCM. Instead, only OC is measured and OCM is estimated (and compared to model results) by multiplying OC by an OCM/OC ratio factor. OCM/OC ratio factors typically range from 1.2 to 2.2 depending on whether the OCM is fresh or aged. For this model performance evaluation analysis, an OCM/OC factor of 1.4 has been used to convert the observed OC to OCM. Another complicating factor is that different analysis methods are used in the STN (NIOSH) and IMPROVE networks that introduce additional measurement artifacts and uncertainties.

The seasonal pattern of OCM concentrations would depend on the relative contributions from secondary OCM (peak concentrations during summertime) and primary OCM. The seasonal pattern of primary OCM would depend on the seasonality of activity and emissions from sources such as biomass burning and transportation. Given a flat activity/emissions profile, primary OCM is would typically be higher in wintertime, due to reduced atmospheric mixing.

Comparing the modeled quarterly OCM predictions to STN observations (Figures 3-23 and C-4a), both exhibit a fairly flat seasonal pattern. Overall, the modeled OCM concentrations are lower compared to the observations. The model seems to exhibit a much stronger spatial pattern, with peak concentrations occurring in the Southeastern U.S. This is likely associated with biomass burning in the winter months, and biogenic secondary OCM formation in the summer months. The increased modeled concentrations of secondary OCM are evident in Quarter 3, especially over the Northeast. When comparing simulated concentrations to IMPROVE observations (Figure C-4b), better agreement is observed. Given that most IMPROVE sites are located in rural areas, this may be an indication that the OCM underprediction at urban sites (STN, Figures 3-23 and C-4a) may possibly be due to local spatial gradients and the comparison of 12 km grid-cell volume average concentrations to point measurements at urban sites. It is also partly due to measurement artifacts where the STN OC observations are not “blank corrected” so are biased high.

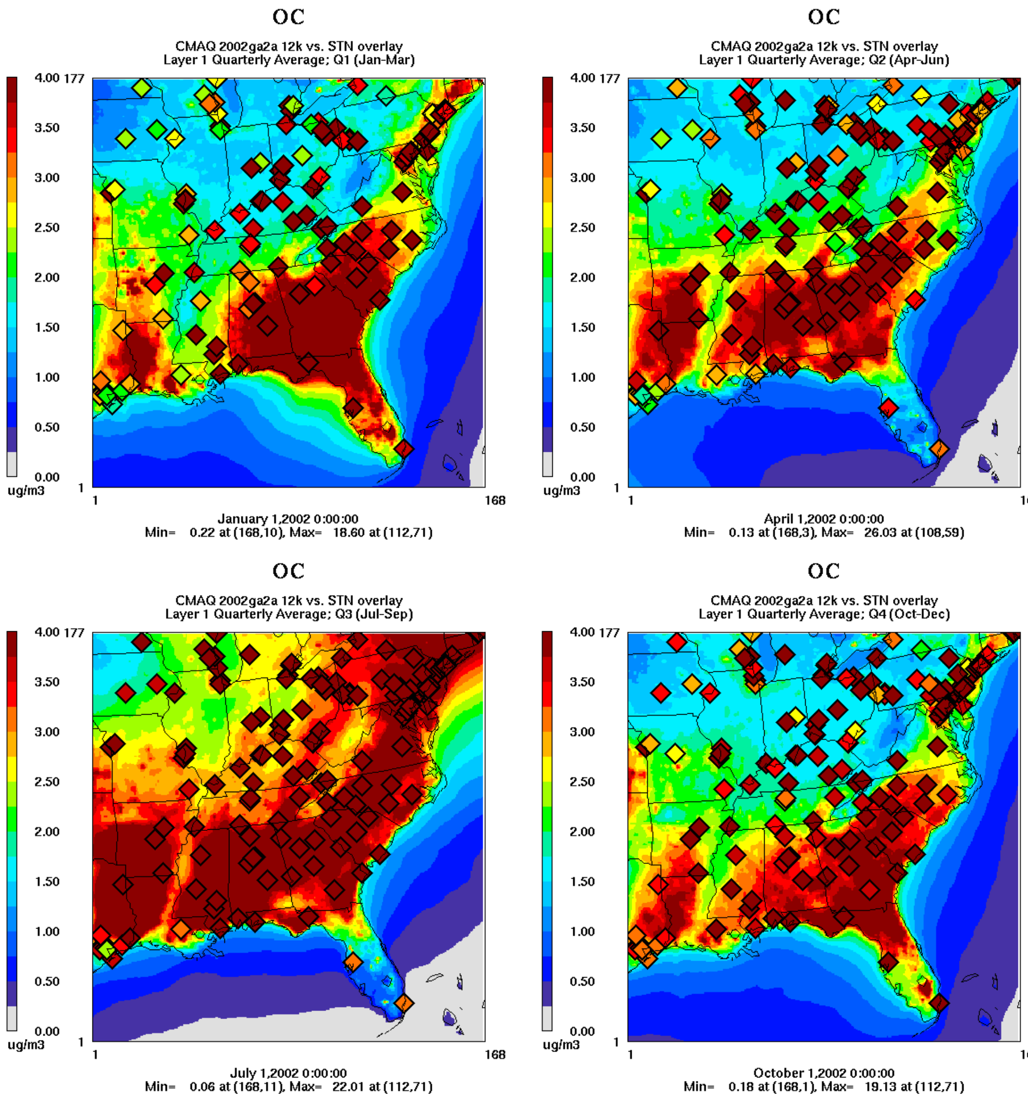

Figure 3-23. 2002 Quarterly averages of CMAQ simulated and STN observed (diamonds) organic carbon material (OCM) concentrations over the VISTAS 12 km domain (IMPROVE comparisons provided in Appendix C).

3.6.5 Elemental Carbon (EC)

Evaluating model performance for EC, the model tends to underpredict concentrations when compared to the STN network (Figures 3-24 and C-5a), while better agreement is observed with the IMPROVE network (Figure C-5b). This follows the same conclusion as for OCM, and may be reflecting the differences between grid-cell volume average concentrations and point measurements. These differences are expected to be more pronounced at urban sites (STN) compared to rural ones (IMPROVE), as at urban locations there are likely stronger local spatial gradients in EC concentrations. The STN and IMPROVE networks also use different methods for measuring EC that may also be contributing to the differences in EC model performance using the two networks. In Section 3.5 and Appendix B we noted that the CMAQ 12 km modeling results exhibited superior model performance to the CMAQ 36 km modeling results across the urban STN network with bias closer to zero with the 12 km grid versus a large underprediction bias with the 36 km grid. Thus, the dilution of the urban EC emissions across coarse grid cell is surely contributing to the EC underprediction tendency at the STN monitoring network.

Both the modeled values and observations (at both networks) exhibit higher concentrations in wintertime (Quarters 1 and 4), that is likely due to reduced atmospheric mixing compared to summertime. However, the seasonal pattern is much stronger in the model results compared to the observations.

Another interesting finding has to do with relatively high modeled EC concentrations in the western part of the Georgia-Florida border, especially in Quarter 1. This is due to modeled emissions from biomass burning activities. However, nearby measurements at both the STN and IMPROVE networks do not exhibit the same trend.

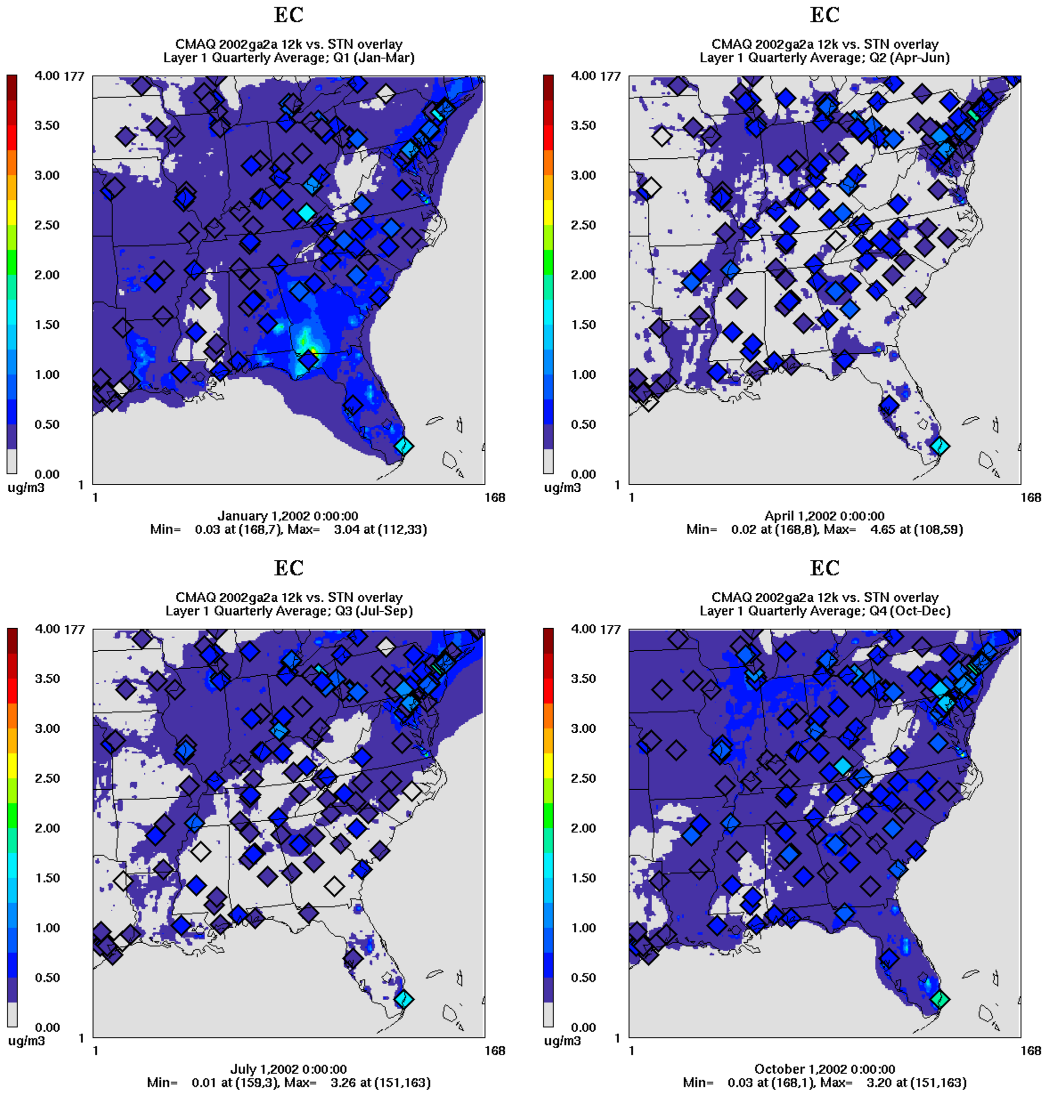

Figure 3-24. 2002 Quarterly averages of CMAQ simulated and STN observed (diamonds) elemental carbon (EC) concentrations over the VISTAS 12 km domain (IMPROVE comparisons provided in Appendix C).

3.6.6 Soil $PM_{2.5}$ (SOIL)

Soil $PM_{2.5}$ was evaluated just at the IMPROVE monitoring sites (Figures 3-25 and C-6). In general, soil $PM_{2.5}$ is overpredicted compared to the observations. This is a common issue in grid-based models, where resuspended fugitive dust is assumed to be mixed uniformly in the first layer of the model, whereas in practice most of it is removed locally by impaction onto surfaces such as cars, buildings and vegetation. Higher concentrations are especially evident in urban centers, due to the way the model calculates the emission and dispersion of resuspended road dust. However, this is not very evident in this comparison, since most IMPROVE sites are located at rural areas. The ASIP/VISTAS modeling did apply fugitive dust transport factors (FDTF) to fugitive dust emission source categories to account for dust that is deposited locally and not transported.

Another issue associated with the Soil evaluation is the mismatch between how Soil is defined in the measurement versus modeled values. The measured Soil values are derived by building it up from the elements, whereas the modeled values are obtained from the emission speciation profiles that are assigned all $PM_{2.5}$ to the other $PM_{2.5}$ species that is not explicitly speciated as SO4, NO3, EC or OCM.

Also evident in the figures are the higher modeled concentrations in the western portion of the ASIP/VISTAS 12 km domain. This could be originating from various reasons, such as possibly higher emissions in that region, transport into the domain from the west, or differences in methodologies used to calculate soil emissions between the various Regional Planning Organizations (RPOs). The latter is likely the case, since a sharp spatial gradient is observed between the Midwest RPO states (and west of Mississippi, in the portions of the CENRAP states) and the MANE-VU (northeast) and VISTAS (southeast) states (see Figure 1-1 for definition of the RPO states).

Regardless of actual model performance, in the context of State Implementation Plan (SIP) development and future attainment tests, modeled levels of soil components are of relatively little importance, since they are normalized according to observations, and little to no controls are being applied (so the Relative Reduction Factor would be equal or close to unity).

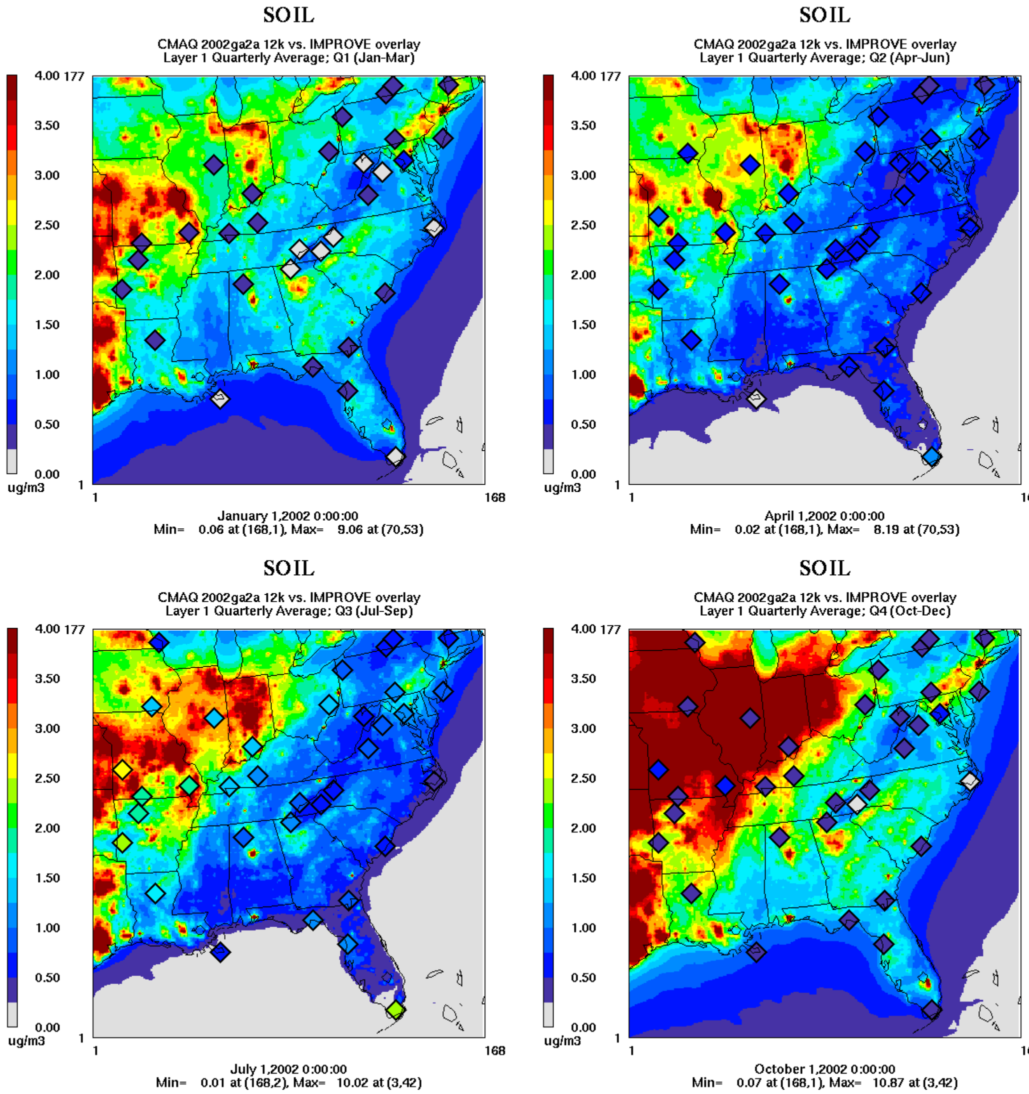

Figure 3-25. 2002 Quarterly averages of CMAQ simulated and IMPROVE observed (diamonds) soil $PM_{2.5}$ (SOIL) concentrations over the VISTAS 12 km domain.

3.6.7 Sea Salt $PM_{2.5}$ (Sea Salt)

Sea Salt $PM_{2.5}$ is measured/calculated at some of the IMPROVE sites only (see Figure C-7 in Appendix C). As expected, higher concentrations are measured at sites along the coastline. This spatial pattern is captured by the model as well; however, concentrations along the coastline are underpredicted compared to the measurements.

The model-estimated Sea Salt $PM_{2.5}$ is not used in the future year $PM_{2.5}$ projections (see Chapter 4; EPA, 2007a), thus the model performance in this case is of relatively little importance. In the future year $PM_{2.5}$ projections, the measured Sea Salt is one of the components of the current year $PM_{2.5}$ and it is assumed to remain constant from the current to future years.

3.6.8 Total $PM_{2.5}$ Mass ($PM_{2.5}$)

A comparison of the quarterly modeled spatial distribution of total $PM_{2.5}$ mass concentrations with observations from the FRM, STN and IMPROVE network are provided in Figure C-8, with the results for the FRM network repeated in Figure 3-26 below. The conclusions on the model performance for total $PM_{2.5}$ mass vary by which network is examined. For Q1 there are elevated $PM_{2.5}$ concentrations in the major urban areas (e.g., Chicago-Gary, St. Louis, Atlanta, Northeast Corridor, etc.) due to concentrated urban emissions. There are also elevated $PM_{2.5}$ mass concentrations for Q1 in the western part of the Georgia-Florida border that is due to biomass burning. The mainly rural IMPROVE monitors fail to capture many of these elevated areas, but does confirm the relative clean conditions in the Appalachian Mountains (Figure C-8c, top left). The IMPROVE St. Marks measured $PM_{2.5}$ levels appears to refute the elevated $PM_{2.5}$ in Q1 along the western Florida-Georgia border. However, the STN (Figure C-8b) and FRM (Figures 3-26 and C-8a) spatial plots confirm that elevated $PM_{2.5}$ levels existed in this area; the lack of elevated $PM_{2.5}$ at St. Marks is likely due to its coastal location and the sea breeze.

During Q2 the model predicts elevated total $PM_{2.5}$ mass levels from St. Louis across the Midwest into Ohio with highest values centered on Indianapolis, in southeastern Pennsylvania and up the Northeast Corridor and in the Birmingham and Atlanta urban areas in the southeast. The IMPROVE monitors suggest that the model is capturing the rural aspect of the spatial distribution of the total $PM_{2.5}$ mass patterns, albeit with an underprediction bias (Figure C-8c, top right). However, the FRM (Figures 3-26 and C-8a) and STN (Figure C-8b) plots indicates that the model is underestimating the spatial extent of the elevated total $PM_{2.5}$ mass levels.

The highest seasonal $PM_{2.5}$ levels occur in the Q3 summer period when increased photochemistry produces the highest SO4 concentrations. The observations indicate that the entire interior portion of the ASIP/VISTAS 12 km grid domain is covered by elevated $PM_{2.5}$ levels, which is reproduced reasonably well by the model. However, the model is estimating slightly lower values and relatively cleaner areas over the Appalachian Mountains that are not supported by the observations. In addition, the observed $PM_{2.5}$ concentration gradient from high to low occurs further south than predicted by the model. However, in general the model is doing a good job in reproducing the spatial distribution of $PM_{2.5}$ in Q3.

In Q4 the model estimates elevated $PM_{2.5}$ levels across the upper Midwest (MO-IL-OH) and southwest (Northern AL and GA, SC and NC) that is split by the Appalachian Mountains and elevated levels in the Northeast Corridor. The IMPROVE network plots confirm the relative cleaner area in the Appalachian Mountains (Figure C-8c) and the STN network plot confirms the three areas of high $PM_{2.5}$ (Figure C-8b). The FRM network spatial map (Figure 3-26 and C-8a) confirms the three areas of elevated $PM_{2.5}$ concentrations, but suggests the southeast area is not as high as the others and that the $PM_{2.5}$ distribution should be spottier.

In conclusion, the model appears to do a good job in reproducing the spatial and temporal variations in $PM_{2.5}$ concentrations across the ASIP/VISTAS 12 km grid albeit with an underprediction bias. The spatial distribution of the modeled $PM_{2.5}$ concentrations is smoother and less spotty than the observed distributions, which is due in part to the coarse 12 km grid spacing used in the modeling.

3.7 OZONE MODEL PERFORMANCE

Ozone model performance for the 2002 Base G2 Actual base case CMAQ 12 km simulation was performed separately for each of the 8 ASIP states, as well as combined across all ASIP states. The ozone model evaluation was conducted for both hourly and 8-hour ozone concentrations and included scatter plots and time series plots of predicted and observed ozone, NOx, NOy and CO concentrations and ozone/NOx and ozone/NOy ratios. Spatial maps of daily maximum hourly and 8-hour predicted ozone concentrations with superimposed observations were also generated for each day of the 2002 calendar year. The graphics and statistical performance measures were calculated separately for each month from 2002. The complete ozone model performance for the 2002 Base G2 CMAQ base case simulation can be found on the project website:

- http://pah.cert.ucr.edu/vistas/vistas2/evaluation_results/2002ga2a.mpe/2002ga2a/

The original ozone model performance goals of ≤±15% and ≤35% were developed for the, respectively, Mean Normalized Bias (MNB) and Mean Normalized Gross Error (MNGE) performance metrics for all predicted and observed hourly ozone concentration pairs for which the observed value is greater than a 60 ppb cut off concentration (EPA, 1991). We have extended this performance goal to PM and the fractional bias and error statistical metrics (see Table 3-3). Below we present some of the key ozone model performance results for hourly ozone and across all 8 VISTAS states and the 5 key months in the ozone season (May through September). Results for 8-hour ozone are similar. Results of the ozone model performance for each individual ASIP state and for 8-hour ozone concentrations are provided on the Project Website listed above.

Table 3-4 lists a summary of the 1-hourly ozone model performance statistics across the 8 VISTAS states using a 60 ppb observed hourly ozone concentrations cutoff threshold. The bias and error performance metrics are compared against EPA's ≤±15% and ≤35% performance goals (EPA, 1991), respectively. Although these performance goals were developed for the MNB and MNGE performance statistics, we also compare them to the Mean Fractional Bias (MFB) and Error (MFE) statistics and Normalized Mean Bias (NMB) and Error (NME) statistical performance measures. The CMAQ 2002 Base G2 model achieves EPA's ozone model performance goals across the ASIP states during May, June, and July. During August and September, the MNB of -15.8% and -16.2% falls barely outside of EPA's performance goal, although the MNGE is well within EPA's performance goal. When looking at the other bias performance metrics, the bias NMB and MFB performance statistics also fail to achieve the ≤±15% performance goal during August and September but are close (≤±17% and ≤±20%, respectively) and the error statistics always achieves the ≤35% performance goal by a wide margin.

Figure 3-27 displays scatter plots of the predicted and observed daily maximum hourly ozone concentrations across sites in the ASIP states for May through August 2002. The data points tend to be centered on the 1:1 line of perfect agreement, although with an underestimation tendency. This underestimation tendency is confirmed with the plots of hourly Normalized Mean Bias (MNB) and Normalizes Mean Gross Error (MNGE) for May through September given in Figure 3-28 (these plots do not use the 60 ppb observed ozone cutoff as used in Table 3-4). During the day, the hourly MNB achieves EPA's performance goal on most days. The MNGE achieves the EPA performance goal almost always during most of the summer of 2002.

Figure 3-29 displays a time series of the predicted and observed hourly ozone concentrations averaged across all monitoring sites in the ASIP region. On average, the modeled hourly ozone concentrations match the observed average during most days during the ozone season, although there is a tendency to underestimate the observed nighttime low ozone concentrations that is likely partly due to the coarse grid (12 km) spacing used that fails to accurately account for the local titration of ozone by fresh NO emissions..

Table 3-4. Summary hourly ozone model performance statistical performance measures across the 8 VISTAS states for the 2002 Base G2 CMAQ 12 km base case.

Month	MNB (%)	MNGE (%)	AOBS (ppb)	APRD (ppb)	RATIO	MB (ppb)	NMB (%)	MFB (%)	ME (ppb)	NME (%)	MFE (%)

3.8 CONCLUSIONS OF MODEL PERFORMANCE EVALUATION

The quarterly average CMAQ $PM_{2.5}$ component species results near the FRM monitors are used in the Speciated Model Attainment Test (SMAT) to project the current year $PM_{2.5}$ Design Values to the 2009 future year for comparison with the $PM_{2.5}$ NAAQS. SMAT uses the relative changes CMAQ 2002 and 2009/2012 modeling results to scale each of the $PM_{2.5}$ components of the current year $PM_{2.5}$ Design Values. These model derived scaling factors are referred to as Relative Response Factors (RRFs). In Chapter 4 of this TSD, we present the results of the SMAT $PM_{2.5}$ Design Value projections for FRM monitoring sites in and near the ASIP states. These results indicate that most of the reductions in the $PM_{2.5}$ Design Values between 2002 and 2009/2012 are primarily due to reductions in sulfate concentrations. Thus, performance of the model for sulfate is of most importance in the model performance evaluation.

Below we discuss the implications of the major findings in the ASIP model performance evaluation in the context of the modeling results are used to project future year $PM_{2.5}$ attainment through SMAT. The model evaluation of the $PM_{2.5}$ component species was performed by comparing the model predictions against the observed $PM_{2.5}$ components as measured in the IMPROVE and STN networks. The procedures used to speciate the FRM $PM_{2.5}$ mass measurements is different than the IMROVE and STN $PM_{2.5}$ speciation as it accounts for the measurement artifacts in the different networks (see Chapter 4).

- Nitrate (NO3) Underprediction Tendency: NO3 is routinely underpredicted during the summer and adjacent months throughout the ASIP region. This underprediction is due to modeled NOx concentrations near zero, when observed values are low, but above zero (typically < 1 μg/m^3). However, NO3 is almost always a very minor to insignificant contributor to total $PM_{2.5}$ mass at FRM monitors in the ASIP region (see stacked bar charts in Chapter 4). In fact, the maximum NO3 contribution to a 2009 projected $PM_{2.5}$ Design Value is 1.0 μg/m^{3}with a median value of 0.2 μg/m^3. Thus, the NO3 performance issues are not a big concern in the $PM_{2.5}$ projections.

- Organic Carbon Mass (OCM) Underpredictions: The OCM underprediction bias is a cause for concern since it is a major component of the $PM_{2.5}$ mass at ASIP FRM monitoring sites with maximum contributions to the 2009 $PM_{2.5}$ Design Values of ~8 μg/m^3, minimum values of ~3 μg/m^3 and a median value of ~4 μg/m^3. The reasons for the underestimation of OCM are unclear, but the fact that the underpredictions are higher in the urban than rural areas suggest that there may be missing anthropogenic emission sources, or possibly the urban OCM emissions are over diluted across the 12 km grid resolution used in the ASIP modeling, or both. The changes in projected OCM concentrations between the current and projected $PM_{2.5}$ Design Values are mostly less than 5% (i.e., $0.95 < RRF_{OCM} < 1.05$). Thus, the changes in OCM between the current and future year are having a minor influence on the projected $PM_{2.5}$ Design Values.

- Elemental Carbon (EC) Performance Issues: The EC underprediction bias at the urban sites is partly due to over dilution of the urban EC emissions due to the coarse (12 km) grid used. For the most part, the CMAQ model performed well for EC and the underprediction would not affect the relative changes in the model response to anthropogenic EC emissions changes. Therefore, any EC performance issues are not a cause for concern, although the model performance for EC was generally good.

- Sulfate (SO4) Underprediction Bias: Although SO4 is performing well, it does have an underprediction bias that is largest in the summer months. But this underprediction is not severe and the model appears to be capturing the temporal and spatial variations in the observed sulfate well and is responding to the SO2 emission reductions between 2002 and 2009/2012 in a manner as expected. Thus the model performance indicates that the modeled relative changes in SO4 concentrations are likely a valid response.

- Soil Performance Issues: The CMAQ performance for the Soil species is quite poor. This Soil component of the 2009 projected $PM_{2.5}$ Design Value ranges from 0.4 to 1.8 μg/m^3. The RRFs for Soil indicate that it is mostly increasing, with summer (Q3) Soil RRFs typically ranging from 1.0 to 1.3.

SO4 reductions dominate the changes in $PM_{2.5}$ Design Values between 2002 and 2009. SO4 performance is quite good in the CMAQ 2002 Base G2 Actual base case simulation almost always achieving the PM performance goal and frequently also achieving the more stringent ozone performance goal. These factors provide confidence in the future-year $PM_{2.5}$ Design Value projections using the CMAQ Base G modeling results.

The ozone model performance almost always achieves EPA's ozone model performance goals (EPA, 1991), albeit with an underestimation tendency. The ozone performance is comparable to that seen in many SIPs and it was judged sufficiently good, that the modeling system can produce reliable future year ozone projections.

4.0 $PM_{2.5}$ AND 8-HOUR OZONE PROJECTIONS

This section presents the future-year $PM_{2.5}$ and 8-hour ozone Design Value projections for, respectively, $PM_{2.5}$ Federal Reference Method (FRM) and ozone compliance monitoring sites within and near the ASIP region and their comparison with the annual $PM_{2.5}$ and 8-hour ozone National Ambient Air Quality Standards (NAAQs). Future-year annual $PM_{2.5}$ and 8-hour ozone Design Value projections are made for the 2009, 2012 and 2018 years. These projections are based on the ASIP 2002 Typical Base G2 and 2009 and 2012 Base G4 and VISTAS 2018 Base G4 CMAQ 12 km modeling results. The 2009, 2012 and 2018 Base G4 modeling results are also referred to as the Best and Final emission scenarios. The results the unmonitored area analysis is also presented in this section. All of the $PM_{2.5}$ and 8-hour ozone projections presented in this chapter are made using EPA's Modeled Attainment Test Software (MATS; http://www.epa.gov/scram001/modelingapps_mats.htm).

4.1 GUIDANCE FOR $PM_{2.5}$ PROJECTIONS

EPA has published final modeling guidance that includes recommendations on how modeling results should be used to project future-year $PM_{2.5}$ and 8-hour ozone levels:

> "Guidance on the Use of Models and Other Analyses for Demonstrating Attainment of Air Quality Goals for Ozone, $PM_{2.5}$ and Regional Haze" (EPA, 2007a)[1].

EPA recommends that the modeling results be used in a relative fashion to scale the observed current-year $PM_{2.5}$ Design Value (DVC) to project a future-year $PM_{2.5}$ Design Value (DVF). The model derived scaling factors are called Relative Response Factors (RRFs) and are defined as the ratio of the future-year to current-year modeling results. The future-year $PM_{2.5}$ Design Values (DVF) are obtained from the current-year $PM_{2.5}$ Design Values (DVC) by applying the RRF to the DVC:

$$DVF = DVC \times RRF$$

Separate RRFs are applied for each major component of $PM_{2.5}$ using a procedure called the Speciated Modeled Attainment Test (SMAT). The RRFs are PM species-specific and monitoring site-specific and are derived using modeling results "near" each monitor. The SMAT procedure applies the PM species-specific RRFs to the six major components that make up the $PM_{2.5}$ DVC to obtain future-year $PM_{2.5}$ species estimates that are summed to obtain the DVF that is compared with the $PM_{2.5}$ NAAQS. The six major components of $PM_{2.5}$ that are projected from the current to future-year are:

- Sulfate (SO4);
- Nitrate (NO3);
- Ammonium (NH4);
- Elemental Carbon (EC);
- Organic Carbon Mass (OCM); and
- Other $PM_{2.5}$ or Fine Crustal Matter (also called Soil).

[1] http://www.epa.gov/scram001/guidance/guide/final-03-pm-rh-guidance.pdf

Also included in the current-year and future-year $PM_{2.5}$ concentrations are particle bound water (PBW), which is associated with the hygroscopic species (SO4 and NO3), sea salt and a blank correction measurement artifact that is assumed to be 0.5 $\mu g/m^3$. Both sea salt and the blank correction remain constant from the current-year to future-year. The PBW is calculated using site-specific meteorological parameters and the hygroscopic components of the $PM_{2.5}$, which is assumed to be SO4 and NO3.

The current $PM_{2.5}$ State Implementation Plans (SIPs) are addressing the 1997 $PM_{2.5}$ NAAQS that have thresholds of 15.0 $\mu g/m^3$ annual and 65 $\mu g/m^3$ 24-hour $PM_{2.5}$ concentrations. Currently, all FRM monitors in ASIP states attain the 65 $\mu g/m^3$ 24-hour $PM_{2.5}$ NAAQS so projections are only made for the annual $PM_{2.5}$ NAAQS. Note that in 2006 EPA revised the 24-hour $PM_{2.5}$ NAAQS with a new threshold of 35 $\mu g/m^3$. The new 35 $\mu g/m^3$ 24-hour $PM_{2.5}$ NAAQS will be addressed in future $PM_{2.5}$ SIP actions.

$PM_{2.5}$ attainment is based on $PM_{2.5}$ mass measurements collected at FRM monitoring sites. In order to apply the $PM_{2.5}$ species-specific RRFs, the FRM $PM_{2.5}$ mass measurements must be speciated into the components of $PM_{2.5}$. There are two routine $PM_{2.5}$ speciation networks being operated in the U.S.: (1) the Speciated Trends Network (STN)[2]; and (2) the Interagency Monitoring of Protected Visual Environments (IMPROVE) networks. Thus, the $PM_{2.5}$ speciation from these two networks need to be mapped to the FRM $PM_{2.5}$ mass measurements in order to apply the RRFs to project future-year $PM_{2.5}$ Design Values. This results in two main components for using modeling results to project future-year $PM_{2.5}$ Design Values:

> Speciation of Measured FRM $PM_{2.5}$ Mass using the SANDWICH Method: The FRM $PM_{2.5}$ mass and STN/IMPROVE $PM_{2.5}$ speciation measurements have positive and negative artifacts that need to be accounted for when mapping observed $PM_{2.5}$ speciation data to the FRM mass measurements. As $PM_{2.5}$ attainment is based solely on the FRM $PM_{2.5}$ mass measurements, then the STN/IMPROVE $PM_{2.5}$ speciation measurements must be adjusted to mimic the FRM $PM_{2.5}$ mass measurements. EPA has developed the **S**ulfate **A**djusted **N**itrate, **D**erived **W**ater **I**nferred **C**arbon **H**ybrid material balance approach (SANDWICH) for estimating $PM_{2.5}$ mass composition produced by the FRM $PM_{2.5}$ mass measurements to account for measurements artifacts (Frank, 2006a,b).

> Projection of Current-Year $PM_{2.5}$ Components to Future-Year using SMAT: The procedures for using the relative changes in modeled concentrations to project current observed $PM_{2.5}$ Design Values to the future is termed the Speciated Modeled Attainment Test (SMAT) (EPA, 2007a; Timin, 2007).

EPA has codified the SMAT recommended procedures (EPA, 2007a) for projecting future-year 8-hour ozone and $PM_{2.5}$ Design Values and regional haze in a software tool known as the Modeled Attainment Test Software (MATS; http://www.epa.gov/scram001/modelingapps_mats.htm). The latest version of MATS at this writing (Version 1.5.1 dated June 6, 2008) includes procedures for projecting 8-hour ozone, annual $PM_{2.5}$ and regional haze, but not 24-hour $PM_{2.5}$. Previous versions of MATS before January 2008 did not have a capability for making annual $PM_{2.5}$ projections. Thus, ASIP had to develop their own $PM_{2.5}$ projection software that was used to make the ASIP $PM_{2.5}$ Design Value

[2] The STN network is now referred to as the Chemical Speciation Network (CSN).

projections in previous versions of the ASIP $PM_{2.5}$ TSD. In this version of the TSD, we have switched to using the MATS $PM_{2.5}$ projection procedures in this Chapter. The $PM_{2.5}$ projections using the ASIP projection approach are used to corroborate the MATS $PM_{2.5}$ projections and are presented as additional analysis in Chapter 5.

The MATS $PM_{2.5}$ projection procedures used SANDWICH STN and IMPROVE speciated $PM_{2.5}$ data that have been imported in the MATS tool. The speciated $PM_{2.5}$ measurements are then interpolated to the FRM monitoring sites where they are used to speciate FRM $PM_{2.5}$ mass measurements. As stated in EPA modeling guidance (EPA, 2007a), the starting point for the future-year $PM_{2.5}$ Design Value projections (i.e., the current year Design Value, DVC) is the average of the three years of Design Values straddling the 2002 modeling year. Thus, this results in an average of the $PM_{2.5}$ Design Values from 2000-2002, 2001-2003 and 2002-2004. This has the effect of weighting the annual average PM concentrations by factors of 1, 2, 3, 2 and 1 for the years 2000-2004, respectively.

In the SMAT procedure, the RRFs are applied separately to the quarterly average components of the current year $PM_{2.5}$ Design Value (DVC). When developing the quarterly PM species components of the monitor DVCs from the FRM $PM_{2.5}$ mass and SANDWICH $PM_{2.5}$ speciation, the 24-hour average concentrations from each sample day are averaged across each quarter with quarters defined in 3-month increments (e.g., Quarter 1 is January-February-March). The FRM, STN and IMPROVE typically use a 1:3 day sampling frequency, which results in approximately 30 days per quarter used in the averaging for one year assuming complete data capture. For the quarterly averaged modeled RRFs, the quarterly averages are obtained by averaging across every modeled day in each quarter of 2002. Thus, Quarters 1 through 4 are based on modeled averages across 90, 91, 91 and 91 days, respectively. Note that the full day of December 31, 2002 is not simulated by the model because the MM5 meteorological data stops at midnight GMT so the conversion to local standard time loses the end of the day. Also note that no attempt was made to develop modeled quarterly average RRFs using the same 1:3 day FRM/STN/IMPROVE monitoring site sampling frequency. Although the FRM/STN 1:3 sampling frequency protocol specifies the same days, in practice samples at some sites may be skipped. Also if a sampling day is missed there may be a make up day outside of the standard 1:3 day protocol, in addition samples at some sites may be declared invalid so will be missing. And finally some sites use a 1:6 day sampling frequency.

4.2 PROCEDURES FOR SANDWICH SPECIATION OF STN/IMPROVE $PM_{2.5}$ COMPONENTS

The SANDWICH procedure is designed to map the STN/IMPROVE $PM_{2.5}$ speciation measurements to the FRM $PM_{2.5}$ mass measurements accounting for the artifacts and sampling protocols of both of the sampling devices. $PM_{2.5}$ attainment is based solely on the FRM $PM_{2.5}$ mass measurements, which were developed by design to emulate the $PM_{2.5}$ mass measurements from the epidemiological studies that formed the basis for the $PM_{2.5}$ NAAQS (CFR, 1997). The FRM mass sampling procedures include a specific sampling protocol that involves sampling PM at a 2.5 μm cut point and filter temperature control, rapid sample retrieval and cold filter shipping. The $PM_{2.5}$ mass is determined by gravimetrically weighing the pre- and post-sampling Teflon filters that have been equilibrated for a minimum of 24 hours at standardized conditions of 25-30 degrees C temperature and 30-40% relative humidity (RH). This results in the FRM $PM_{2.5}$ mass measurements not capturing all particles and reflects loss of volatile species including ammonium nitrate [NH_4NO_3] and semi-volatile organic compounds (SVOC), which are negative artifacts in the FRM sampling. The FRM measurements also include particle bound water (PBW) associated with hygroscopic species, which is a positive artifact.

The SANDWICH uses a mass balance approach to adjust the STN and IMPROVE speciated $PM_{2.5}$ measurements to characterize the FRM $PM_{2.5}$ mass. In addition to addressing the artifacts of the FRM sampling procedures, it also addresses the artifacts and sampling protocol of the STN filter measurements accounting for blank correction and inaccuracies in the STN organic carbon measurements. In particular the SANDWICH approach uses the STN measured sulfate, adjusted nitrate, derived PBW and inferred organic carbon. The SANDWICH assumes that the FRM $PM_{2.5}$ mass consists of the following components:

FRM $PM_{2.5}$ Mass = [SO4] + [EC] + [$NO3_{FRM}$] + [$NH4_{FRM}$] + [OCM_{mb}] + [water] + [crustal material] + [sea salt] + [blank correction]

where,

[SO4] is the measured sulfate ion, which for ASIP is taken as the SO4 fraction of the STN $PM_{2.5}$ from the STN site associated with the FRM monitor;

[EC] is the measured elemental carbon from the associated STN monitor;

[$NO3_{FRM}$] is the NO3 ion retained on the FRM filter after a portion as been volatilized in the FRM measurement process;

[$NH4_{FRM}$] is the NH4 cation retained on the FRM filter after partial volatilization;

[OCM_{mb}] is the organic carbon material that is obtained as the difference between the FRM $PM_{2.5}$ mass measurements and the remainder of the $PM_{2.5}$ components;

[water] is particle bound water to the hygroscopic PM components;

[crustal material] is soil and other inorganic fine particulate matter;

[sea salt] is the measured sea salt that is assumed to remain constant between the current- and future-years; and

[blank correction] is the passively collected PM material in the STN measurement process that is assumed to be 0.5 µg/m^3 and is assumed to remain constant from the current- to future-year.

4.2.1 Retained Particulate Nitrate [$NO3_{FRM}$]

The first step in the SANDWICH procedure for identifying mass components was to estimate the retained nitrate mass on the FRM filters. The FRM does not capture all of the semi-volatile components of the ambient air, such as ammonium nitrate. The retained amount of nitrate ion, however, can be reasonably estimated by a simple thermodynamic model that uses 24-hour ambient nitrate speciation concentrations (as measured by a standard speciation sampler using a nylon filter preceded by a HNO3 denuder) together with hourly ambient temperature and humidity. Atmospheric nitrates are higher during the cooler months. Retention on the FRM is also higher during the cooler months and essentially all the nitrates are lost during the summer. The retention does not appear to depend on ambient NH3 or HNO3. More NO3 is retained at low temperatures and high humidity which varies by sampling location and time of year.

Because nitrate retention varies by site and season, the Aerosol Inorganic Model (AIM) ammonium nitrate equilibrium model is used to predict the amount of nitrates retained on the FRM Teflon filter under the FRM sampling conditions (35% RH and 21 C). As used by Hering and Cass (Hering and Cass, 1999; Zhang and McMurry, 1992) the amount of volatilized nitrate (delta NO3) is defined by:

$$\text{delta NO3 } (\mu g/m^3) = 745.7/T_R * 1/24 * \sum_{i=1}^{24} (\mathbf{K}_i^{1/2})$$

where, T_R is the reference temperature for the sampled air volume in degrees Kelvin and $\mathbf{K_i}$ is the dissociation constant for ammonium nitrate evaluated at the ambient temperature for hour i. This volatilization prediction characterizes depletion of some or all of the nitric acid and ammonia vapors ahead of the filter and specifies a 3-5 degree Kelvin increase in the filtration temperature above ambient.

This model is used to adjust 24-hour STN nitrate ion (NO3-) concentrations [$NO3_{STN}$] to estimate FRM NO3 [$NO3_{FRM}$] as follows:

$$NO3_{FRM} = NO3_{STN} - \text{delta NO3 } (\mu g/m^3)$$

For each hour of the day, the equilibrium dissociation constant for ammonium nitrate, K_i, was calculated from hourly ambient temperature and hourly ambient relative humidity based on formulas developed by Mozurkewich (1993) and as applied by Chang and co-workers (2000).

When RH is less than deliquescence point of ammonium nitrate (61%), then:

$$\ln(K) = 118.87 - (24084/T) - 6.025 \ln(T)$$, where K is in nanobars and T is in Kelvins

When RH is higher than 61%, K is replaced by

$$K' = [P_1 - P_2(1-a) + P_3(1-a)^2]\,(1-a)^{1.75} * K$$

where ln(P1), ln(P2) and ln(P3) are specified as:

$$\ln(P_1) = -135.94 + 8763/T + 19.12\ln(T)$$
$$\ln(P_2) = -122.65 + 9969/T + 16.22\ln(T)$$
$$\ln(P_3) = -182.61 + 13875/T + 24.46\ln(T)$$

The above equation for K' assumes crystallization of ammonium nitrate when RH is less than 61%. Thus, predicted NO3 loss may be underestimated for situations where solids do not form on the filter. For supersaturated solutions and with lower RH, the estimated dissociation for the solution will be larger than K for the solid. However, there is little (or no) data that can be used to give a reliable result for how much larger.

Based on the equations above, Figure 4-1 illustrates the potential nitrate loss as a function of temperature and relative humidity. Temperature is presented as degrees F for more convenient interpretation. It shows that at 50 deg F and RH of 80%, approximately 1.6 $\mu g/m^3$ nitrate would be lost. At RH less < 61% an additional 0.4 ug/m3 could be lost. In both cases, the loss cannot exceed the amount of ambient NO3, as depicted by the STN NO3.

When these predictions are compared with measured FRM nitrates at six eastern US monitoring locations, the annual average prediction errors are less than -0.3 to +0.1 $\mu g/m^3$ (Frank, 2006a).

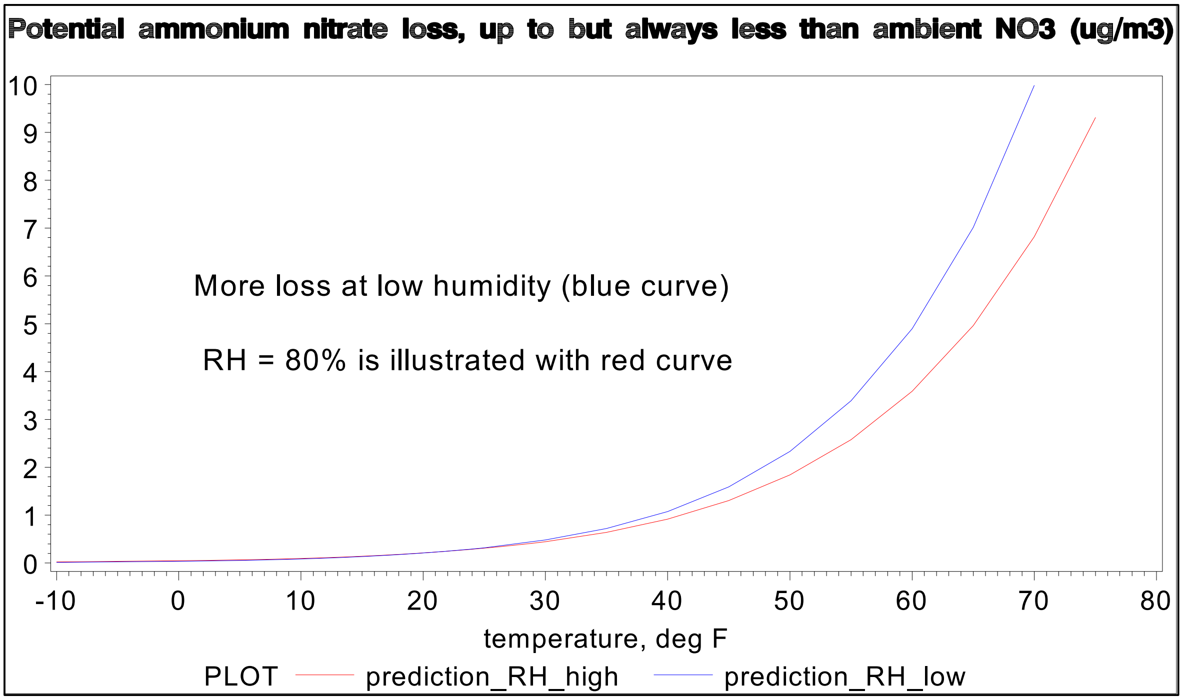

Figure 4-1. Potential NO3 loss (delta NO3) as a function of temperature and relative humidity.

4.2.2. Estimated Ammonium Associated with Sulfate and Retained Nitrates and Sulfates

To determine the mass associated with nitrates, the SANDWICH approach assumes that all retained nitrate is in the form of ammonium nitrate, which is likely an accurate assumption over most of the ASIP southeastern U.S. region. Although in coastal areas, nitrate may also be neutralized by sodium. However, sodium nitrate concentrations would mainly be in the coarse PM mode so would not be collected on the FRM or STN $PM_{2.5}$ samplers. Assuming that all of the particulate nitrate is in the form of ammonium nitrate, the ammonium associated with nitrates can be derived directly from the FRM retained $NO3_{FRM}$ as:

$$NH4_{NO3} = 0.29 * NO3_{FRM}$$

Similarly, the dry $PM_{2.5}$ mass associated with ammonium nitrate is:

$$[\text{Retained dry FRM Ammonium Nitrates}] = 1.29 * NO3_{FRM}$$

4.2.3 Ammoniated Sulfate Mass

The mass associated with sulfates is first estimated as its dry mass. All estimated sulfates are assumed to be associated with ammonium, but the form of the sulfate compound and the amount of ammonium must be estimated. The form of the ammoniated sulfate compound(s) and the amount of associated ammonium, however, is somewhat uncertain.

Sulfates may not be fully neutralized in all geographic areas or seasons of the year. During winter-time conditions, when nitrates are prevalent in the ambient aerosol, sulfates tend to be fully neutralized and exist as ammonium sulfate [$(NH_4)_2SO_4$]. During the summer, when sulfates are higher and nitrates are lower and ammonia is less available for reaction with H_2SO_4, the resulting aerosol can be acidic and the form of sulfates can include ammonium bisulfate [NH_4SO_4] or even H_2SO_4.

The amount of ammonium associated with the sulfate ion can be estimated as:

$$NH4_{(SO4)} = NH4_{FRM} - 0.29 * NO3_{FRM},$$

where, 0.29 is the molar ratio of NH4 to NO3 and
$NH4_{FRM}$ and $NO3_{FRM}$ reflect the amounts retained on the FRM filter.

The amount of $NH4_{(SO4)}$ is not allowed to exceed the fully neutralized amount of 0.375 multiplied by the estimated sulfate ion concentration.

Because of uncertainties in NH4 speciation measurements and the fact that the IMPROVE monitoring network does not measure NH4, NH4 is calculated by deriving the degree of sulfate neutralization (DON) from the estimated $NH4_{(SO4)}$ as:

$$DON = NH4_{(SO4)} / SO4$$

The DON is assumed to remain constant from the current-year to future-year. Values of DON, sulfate and estimated FRM nitrate (adjusted nitrate) are used to estimate the adjusted ammonium at each FRM site as follows:

$$NH4_{FRM} = DON * SO4 + 0.29*NO3_{FRM}$$

where, DON, SO4 and $NO3_{FRM}$ are the quarterly average values at each FRM site.

Thus, in the standard SANDWICH SMAT application $NH4_{FRM}$ is not a direct measured value, but is derived from the DON, SO4, and $NO3_{FRM}$ values. In the default EPA $PM_{2.5}$ Design Value projection approach, interpolated DON values are used to estimate ammonium, this is due to uncertainties in the ammonium measurements and the lack of NH4 measurements at IMPROVE sites.

4.2.4 Particle Bound Water

Because ammoniated sulfate and ammonium nitrate are hygroscopic, the retained sulfate and nitrate mass will include water[3]. Particle bound water (PBW) is estimated using the Aerosol Inorganic Model (AIM) (Clegg, Brimblecombe and Wexler, 1998). PBW was derived from quarterly average FRM concentrations of sulfate, ammonium, nitrate as describe above. Estimated hydronium ion, H+, needed to achieve ionic balance was derived from the latter values. The model enables the distribution of water and ions to be calculated between liquid, solid and vapor phases for specific temperature and relative humidity conditions. Typical filter equilibration conditions of 35% RH and 22 deg C (295 deg K) temperature are used.

Application of AIM at the specified FRM filter equilibration conditions show that PBW is much more dependent on sulfate concentration compared to nitrate and that the relationship varies somewhat by season to differentiate the relative amounts of sulfate and nitrate aerosol. There is proportionally less estimated PBW water for wintertime aerosol which has higher NH4 and NO3 and lower SO4.

For computational convenience, a polynomial regression equation was fit to the calculated water mass from AIM under the FRM equilibration conditions and the three input values that fed into AIM (sulfate, nitrate and ammonium). The polynomial equation was used in all SMAT analyses to estimate water. Due to the non-linear nature of the water calculation, the measurements were divided into 2 regimes; all measurements (site-days) where DON > 0.225 and all measurements where DON ≤ 0.225. A separate equation was developed to represent each regime.

The equations are as follows:

$$S = SO4 / (SO4 + NO3_{FRM} + NH4_{FRM})$$
$$N = NO3_{FRM} / (SO4 + NO3_{FRM} + NH4_{FRM})$$
$$A = NH4_{FRM} / (SO4 + NO3_{FRM} + NH4_{FRM})$$

If DON ≤ 0.225 then:

PBW = 595.56
- 1440.58*S
- 1126.49*N
+ 283.91*(S**1.5)
- 13.38*(N**1.5)
- 1486.71*(A**1.5)
+ 764.23*(S**2)
+ 1502.00*(N*S)
+ 451.87*(N**2)
- 185.18*(S**2.5)
- 375.98*(S**1.5)*N
- 16.90*(S**3)
- 65.81*(N**1.5)*S

[3] Note that some organic carbon (OC) species are also likely hygroscopic but due to uncertainties the PBW associated with hygroscopic OC species it is not accounted for in SANDWICH.

+ 96.83*(N**2.5)
+ 83.04*(N**1.5)*(S**1.5)
- 4.42*(N**3)
+ 1720.82*(A**1.5)*S
+ 1220.38*(A**1.5)*N
- 311.50*(A**1.5)*(S**1.5)
+ 148.77*(A**1.5)*(N**1.5)
+ 1151.65*(A**3)) * (SO4 + $NO3_{FRM}$ + $NH4_{FRM}$)

If DON > 0.225 then:

PBW = 202049.0
- 391494.6*S
- 390912.1*N
+ 442.4*(S**1.5)
- 155.3*(N**1.5)
- 293406.8*(A**1.5)
+ 189277.5*(S**2)
+ 377992.6*N*S
+ 188636.8*(N**2)
- 447.1*(S**2.5)
- 507.2*(S**1.5)*N
- 12.8*(S**3)
+ 146.2*(N**1.5)*S
+ 217.2*(N**2.5)
+ 30.0*(N**1.5)*(S**1.5)
- 18.6*(N**3)
+ 216267.0*(A**1.5)*S
+ 215419.9*(A**1.5)*N
- 621.8*(A**1.5)*(S**1.5)
+ 239.1*(A**1.5)*(N**1.5)
+ 95413.1*(A**3)) * (SO4 + $NO3_{FRM}$ + $NH4_{FRM}$)

4.2.5 Passively Collected $PM_{2.5}$ Components (Blank Correction)

Another quantifiable component of $PM_{2.5}$ mass include passively collected mass, represented by the field blank concentration that is typically 0.3-0.5 μg/m^3 (EPA, 2002). This appears to constitute a contamination of the filter resulting from handling or contact with the FRM cassette. This value is deemed to be an important constituent of $PM_{2.5}$ mass (it is assumed to not be dependent on pollutant emissions). A nominal blank mass value of 0.5 μg/m^3 is assumed in mass construction computations. This value is assumed to remain constant from the current-year to future-year.

4.2.6 Calculation of Carbonaceous Mass

Carbonaceous mass is estimated from blank corrected $PM_{2.5}$ speciation data, where organic carbonaceous mass (OCM) is first estimated by multiplying the organic carbon (OC) concentrations by 1.4 (OCM = 1.4 x OC) to account for the oxygen, hydrogen and other elements associated with ambient carbon particles. Note that the 1.4 OCM/OC ratio was based on limited organic compound speciation data in Los Angeles (Watson, 2002). More recent analysis by Turpin and Lim (2001) have found OCM/OC ratios that vary from 1.6±0.2 for urban areas to 2.4±0.2 for rural areas. However, since the SANDWICH derivation of the initial OCM is just used as a "floor' for the OCM calculation, the lower OCM/OC ratio of 1.4 is used. To that amount is added the elemental carbon (EC) concentration. An alternative approach to estimate carbon contribution to $PM_{2.5}$ mass is used for SMAT because of: (1) many uncertainties in estimating carbonaceous mass from carbon measurements (Turpin and Lim, 2001; Chow et al., 2004); (2) differences in carbon measurement protocol between urban and rural monitoring locations; (3) a relatively "bumpy" surface of urban carbon concentrations as derived from these urban and rural organic carbon measurements; and (4) lack of carbon measurements at all FRM locations. The SANDWICH approach estimates carbon by mass balance comparing precisely measured FRM $PM_{2.5}$ mass (EPA, 2003) with the sum of its non-carbon components. The latter are sulfates, ammonium, nitrates, estimated particle bound water, sea salt, estimated crustal material plus 0.5 $\mu g/m^3$ passively collected mass blank correction as discussed earlier.

This approach estimates retained carbonaceous FRM mass and explicitly accounts for the following important and difficult to estimate carbon mass properties: (1) regional and urban-rural differences in the mix of carbonaceous aerosols (i.e. the amount of oxygen, hydrogen, etc that is associated with the organic carbon); (2) retained water associated with hygroscopic carbon compounds (Saxena and Hildemann, 1996; Yua, et. al., 2004); (3) volatile carbonaceous material measured by speciation samplers, but not retained in FRM mass; and (4) uncertainties associated with blank corrections of measured organic and elemental carbon.

Total Carbonaceous Mass by mass balance (TCM_{mb}) is defined as:

$$TCM_{mb} = FRM\ PM_{2.5} - \{[SO4] + [NO3_{FRM}] + [NH4_{FRM}] + [water] + [crustal\ material] + [sea\ salt] + [0.5]\}$$

In this expression, all of the above quarterly average components represent the mass retained on FRM Teflon filters.

The mass associated with organic compounds is defined as:

$$OCM_{mb} = TCM_{mb} - [EC]$$

where, EC is STN measured elemental carbon.

This approach completely accounts for FRM mass and OCM_{mb} is often greater than the amount that would be derived directly from speciation measurements. Because of uncertainties in speciation measurements and their estimates from interpolated surfaces, a lower limit (floor) for OCM_{mb} was set so that the OCM_{mb} was not unreasonably low. The floor was set so that OCM_{mb} could not be more than 30% lower than measured OCM. For the ASIP projections, the STN measured OCM was used to calculate the floor assuming a 1.4 OCM/OC ratio. The lower limit is equal to interpolated (measured) OC * 1.4 * 0.7. If the OCM_{mb} concentration was less than the lower limit, it was set equal to the lower limit.

4.2.7 Sea Salt

Sea salt is estimated from the measured chloride ion using the following equation:

$$[\text{sea salt}] = 1.8 \times [Cl^-]$$

4.2.8. Summary of $PM_{2.5}$ Composition Calculations

As presented in the beginning of this section, the application of the SANDWICH speciated STN/IMPROVE data to the FRM $PM_{2.5}$ mass produces the following composition of PM species as they relate to the measured FRM values for each quarter of 2002. Quarterly average FRM mass is equal to the sum of the seven species plus blank mass.

$$PM2.5_{FRM} = \{ [OCM_{mb}] + [EC] + [SO4] + [NO3_{FRM}] + [NH4_{FRM}] + [water] + [\text{crustal material}] + [\text{sea salt}] + [0.5] \}$$

The SANDWICH species data is generated in the following order:

1. Adjusted nitrate is calculated using hourly meteorology and 24-hour average nitrate measurements.

2. Quarterly averages are calculated for adjusted nitrate, sulfate, elemental carbon, degree of sulfate neutralization (DON), crustal mass , and measured OCM.

3. Quarterly average ammonium is calculated from the adjusted nitrate, sulfate, and DON values.

4. Calculated ammonium, sulfate, and nitrate values are input into the water equation to derive particle bound water concentrations.

5. Carbon mass by difference (OMC_{mb}) is calculated from the $PM_{2.5}$ mass, adjusted nitrate, ammonium, sulfate, water, elemental carbon, crustal, sea salt and blank mass values.

6. The sum of the 7 species plus blank mass is equal to the FRM mass.

4.3 DEFINING CURRENT-YEAR $PM_{2.5}$ DESIGN VALUES (DVC)

The $PM_{2.5}$ component species fractions are applied to current-year $PM_{2.5}$ Design Values (DVC) that are then projected to the future using the model derived RRFs. EPA's $PM_{2.5}$ modeling guidance recommends using the average of the 3 years of $PM_{2.5}$ Design Value periods that straddle the emissions year. The average of the 3 design values is not a straight five year average. It is, in effect, a weighted average of the annual averages. The base year inventory and modeling year for the ASIP modeling is 2002. Therefore, the design value period is from 2000-2004. In the average of 2000-2002, 2001-2003, and 2002-2004 $PM_{2.5}$ Design Values for the DVC, the annual average $PM_{2.5}$ concentrations for 2002 is "weighted" 3 times, 2001 and 2003 are weighted twice, and 2000 and 2004 are weighted once. EPA notes that this has the desired effect of weighting the projected $PM_{2.5}$ values towards the middle year of the five year period, which is the emissions and meteorology year for the ASIP modeling (i.e., 2002).

There are several steps in the derivation of the average $PM_{2.5}$ design values for projections to the future. Quarterly average values are needed for each FRM site. The following steps were used to derive the quarterly average FRM values.

1. The analysis began with quarterly average FRM data for all quarters from 2000-2004.

2. A quarterly average 3 year design value was calculated for each design value period in which a site had at least one of three quarters complete data (2000-2002, 2001-2003, and 2002-2004). This results in four quarterly averages for up to three design value periods for each FRM site.

3. The (up to) 3 quarterly design value periods were averaged together to get a single quarterly average design value for each site.

4.4 SPECIATED MODEL ATTAINMENT TEST (SMAT)

The EPA default procedure for projecting future-year $PM_{2.5}$ Design Values using the Speciated Model Attainment Test (SMAT) is as follows:

1. Derive current quarterly mean concentrations for each of the major components of $PM_{2.5}$. This is done by multiplying the monitored quarterly mean concentration of Federal Reference Method (FRM) (EPA, 1997) derived $PM_{2.5}$ mass by the monitored fractional composition of $PM_{2.5}$ species (at speciation monitor sites) for each quarter. In the case of the ASIP projections using MATS, the PM composition at each FRM site is defined from the SANDWICH PM speciation at STN and IMPROVE sites that are interpolated to the location of the FRM sites.

2. Use the ASIP current year 2002 Typical Base G2 Base Case and future-year 2009, 2012 and 2018 Base G4 Base Case CMAQ modeling results to estimate current and future quarterly average concentrations for each of the components of $PM_{2.5}$ near the FRM monitor. Take the ratio of future to current predictions for each component. The result is a component-specific quarterly average relative response factor (RRF).

3. For each quarter, multiply the current quarterly mean component concentration from Step 1 times the component-specific RRF obtained in Step 2. This leads to an estimated future quarterly mean concentration for each $PM_{2.5}$ component.

4. Derive the future-year ammonium concentrations assuming the future-year nitrate is completely neutralized and that the DON stays constant from the current-year to future-year. Derive PBW concentrations from the future-year $PM_{2.5}$ components (SO4 and NO3) and atmospheric conditions for the FRM monitor. Assume that sea salt and the blank correction stay constant from the current-year to future-year.

5. Average the four quarterly mean future concentrations to get an estimated future annual mean concentration for each $PM_{2.5}$ component. Sum the annual mean concentrations of the $PM_{2.5}$ components to obtain an estimated future annual concentration for $PM_{2.5}$.

The FRM data is used for nonattainment designations. Therefore it is important that the SMAT procedures described above use the FRM data as the base value for projecting future $PM_{2.5}$ concentrations. As can be seen from the list of steps, the modeled attainment test is dependent on the availability of species component mass representative of the FRM sites.

4.5 ESTIMATING FUTURE YEAR $PM_{2.5}$ DESIGN VALUES

Future-year concentrations of $PM_{2.5}$ component species are estimated by assuming that the quarterly average component concentration will change in the same proportion as the model predicted change. Model predicted changes in species concentrations (from a current-year to a future-year) are used to calculate RRFs. RRFs are calculated for each grid cell and species as the ratio of the quarterly average future-years (2009, 2012 and 2018) model predictions to the current-year (2002) base case model predictions "near" the FRM monitor. The RRF for each $PM_{2.5}$ species is then multiplied by the estimated base year ambient $PM_{2.5}$ species mass for the site to estimate future species concentrations.

4.5.1 Projecting $PM_{2.5}$ Component Species

In the SMAT methodology, RRFs are calculated for five of the $PM_{2.5}$ component species: sulfate (SO4), nitrate ($NO3_{FRM}$), organic carbon mass (OCM_{mb}), elemental carbon (EC), and crustal mass (Soil). Note that future-year values for the other four $PM_{2.5}$ component species are either derived from the projections of these five $PM_{2.5}$ component species (i.e., NH4 and PBW) or held constant (i.e., blank correction and Sea Salt). The future year concentrations of the five $PM_{2.5}$ components are calculated for each site and each quarter. The future-year ammonium concentrations are calculated from the future-year sulfate, nitrate, and (current-year) DON values. Assuming that the DON is unchanged from the current year, the ammonium is calculated using the following formula:

$$NH4_{future} = DON * SO4_{future} + 0.29*NO3_{future},$$

The $NH4_{future}$, $SO4_{future,}$ and $NO3_{future}$ concentrations are then run through the water equation to predict a future-year particle bound water (PRB) concentration. The future-year $PM_{2.5}$ species concentrations at each FRM site are then summed over the seven species plus blank mass to estimate the future quarterly average $PM_{2.5}$ concentration. The four quarterly values are then averaged to obtain the estimated future annual average $PM_{2.5}$ for each FRM site.

4.6 DEFINING RRFS BASED ON MODELING RESULTS "NEAR" THE MONITOR

When defining the model derived RRFs, EPA recommends using current-year and future-year modeling results "near" the monitor. By "near" EPA recommends using spatially averaged modeling results for a grid resolution NX by NY array of grid cells centered on the FRM monitor. In the ASIP modeling grid resolutions of 36 km and 12 km are being used for which

EPA recommends that NX=NY=1 and NX=NY=3, respectively. Thus, for the ASIP 2009 $PM_{2.5}$ Design Value projections, RRFs were based on the modeling results within the grid cell containing the FRM monitoring when using the CMAQ 36 km modeling results, and in the 9 grid cells centered on the FRM monitor for the CMAQ 12 km modeling results.

4.7 $PM_{2.5}$ DESIGN VALUE PROJECTIONS USING BASE G4 MODELING RESULTS

The 2000-2004 current-year $PM_{2.5}$ Design Values at FRM sites within and near the ASIP region were projected to 2009, 2012 and 2018 using the SMAT/SANDWICH procedures described above that were implemented in MATS tool and the 2002 Typical Base G2 and 2009, 2012 and 2018 Base G4 CMAQ 12 km modeling results. The ASIP future-year Base G4 $PM_{2.5}$ Design Value projections are discussed next by state.

Attainment of the annual $PM_{2.5}$ NAAQS is achieved when the projected $PM_{2.5}$ Design Value (DVF) is less than 15.0 $\mu g/m^3$ rounded (i.e., DVF < l5.05$\mu g/m^3$). However, EPA requires a supplemental weight of evidence analysis if a DVF lies between 14.5 and 15.5 $\mu g/m^3$.

Across all sites within and near the ASIP region there is a consistent reduction in the projected $PM_{2.5}$ concentrations in the future years. These reductions are primarily due to reductions in SO4. Only small changes are seen in the other components of $PM_{2.5}$.

4.7.1 Alabama

Figure 4-2 and Table 4-1 display the current-year (DVC) and projected future-year $PM_{2.5}$ Design Values (DVFs) using the 2002 Base G2 Typical and 2009, 2012 and 2018 Base G4 CMAQ 12 km modeling results for FRM sites in Alabama. The stacked bar charts of current-year (based on average of three year Design Values from 2002-2002, 2001-2003 and 2002-2004) and future-year $PM_{2.5}$ Design Values includes the contributions of each of the $PM_{2.5}$ component of the Design Values. The largest two PM components by far for sites in Alabama are sulfate (SO4) and organic carbon mass (OCM). Next most important PM components to annual $PM_{2.5}$ concentrations in Alabama are crustal material, ammonium (NH4), particle bound water (PBW) followed closely by elemental carbon (EC). Nitrate (NO3) and sea salt are an extremely small to insignificant component of the annual average $PM_{2.5}$ Design Values in Alabama.

In addition to the current-year and projected future-year $PM_{2.5}$ Design Values using the CMAQ 12 km modeling results, Table 4-1 also lists the differences between the future-year and current-year Design Values. With the exception with sites in the Birmingham area, the $PM_{2.5}$ Design Values in Alabama are projected to go down as we go further out in time (2002, 2009, 2012 and 2018). These reductions are primarily due to reductions in SO4 due to the regional reductions in SO2 emissions.

For the Birmingham sites (Jefferson and Shelby Counties), there is a large contribution from local sources. This issue is being addressed in the Birmingham Air Pollution Study (BAPS) that is performing urban-scale 4 km CMAQ modeling along with local source impact modeling using the AERMOD plume model. The 2002 Base G2 emissions were based on the original estimates of PM emissions from the Birmingham local sources. These emissions were grown to the future years for the 2009 and 2018 Base G4 emission inventories. In the mean time, BAPS has updated the 2002 emissions for the Birmingham local sources that substantially reduced their PM emission estimates. These lower 2002 emissions estimates were then grown to 2012 for the 2012 Base G4 modeling. This resulted in more reductions in PM concentrations in Birmingham between the 2002 Base G2 and 2012 Base G4 CMAQ simulations then there should be. As the SMAT $PM_{2.5}$ projection procedure uses the relative changes in the modeling results between the current and future years, the ASIP 2012 $PM_{2.5}$ projections for sites in Birmingham overstate the level of $PM_{2.5}$ improvements due to the inconsistencies in the local source PM emissions between the 2002 Base G2 and 2012 Base G4 emission scenarios. The BAPS is performing 2012 $PM_{2.5}$ projections for Birmingham using consistent 2002 and 2012 local source emissions and should be used instead of the ASIP 2012 projections.

There are two $PM_{2.5}$ monitors in Alabama that the CMAQ 12 km 2009 Base G4 modeling project to exceed the annual $PM_{2.5}$ NAAQS in 2009:

- North Birmingham in Birmingham, Alabama (01-073-0023) with 2009 Base G4 projected $PM_{2.5}$ Design Values of 17.0 $\mu g/m^3$; and

- Wylam in Birmingham, Alabama (01-073-2003) with 2009 projected $PM_{2.5}$ Design Values of 15.8 $\mu g/m^3$.

In the past, these two sites were Community Monitoring Zone (CMZ) monitoring sites whose values were averaged for comparisons with the NAAQS. However, their CMZ status is no longer recognized by EPA. The ASIP CMAQ Base G4 2009 modeling results project that all other FRM monitors in Alabama will attain the annual $PM_{2.5}$ NAAQS in 2009.

Both of these Birmingham sites, along with all other sites in Alabama, are projected to attain the annual $PM_{2.5}$ NAAQS in 2012. Note that the North Birmingham site is projected to exceed the $PM_{2.5}$ NAAQS in 2018, however as noted above that is due to an assumption of too high growth in emissions from local sources.

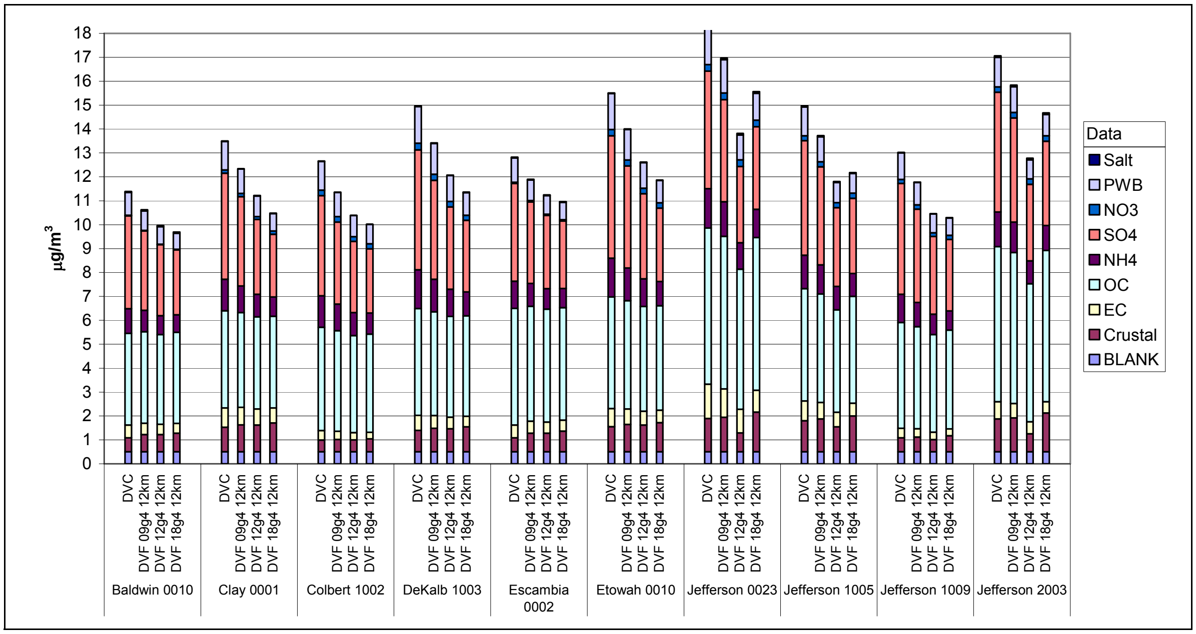

Figure 4-2a. Current (2000-2004) $PM_{2.5}$ Design Values (DVC) and Projected 2009, 2012 and 2018 $PM_{2.5}$ Design Values (DVF) in Alabama using the CMAQ 12 km Base G4 modeling results.

* 2012 emissions for local sources in Birmingham were updated with lower values from BAPS for the 2012 emissions scenario, with the original higher emissions estimates used in the 2002, 2009 and 2018 inventories. Thus, the 2012 $PM_{2.5}$ projections in Jefferson and Shelby Counties will overstate the amount of $PM_{2.5}$ reduction between 2002 and 2012.

4.7.2 District of Columbia

Figure 4-3 and Table 4-2 display the current-year and future-year $PM_{2.5}$ Design Values at FRM monitoring sites in the District of Columbia (DC) that is adjacent to the ASIP region. Two of the three sites current-year Design Values exceed the NAAQS. However, by 2009 all three monitoring sites are estimated to be well below the annual $PM_{2.5}$ NAAQS. The PM levels are projected to continue to decrease in 2012 and 2018. The reduction in PM concentrations at the Washington DC sites is due primarily to reductions in SO4 and the NH4 and PBW that is associated with the SO4.

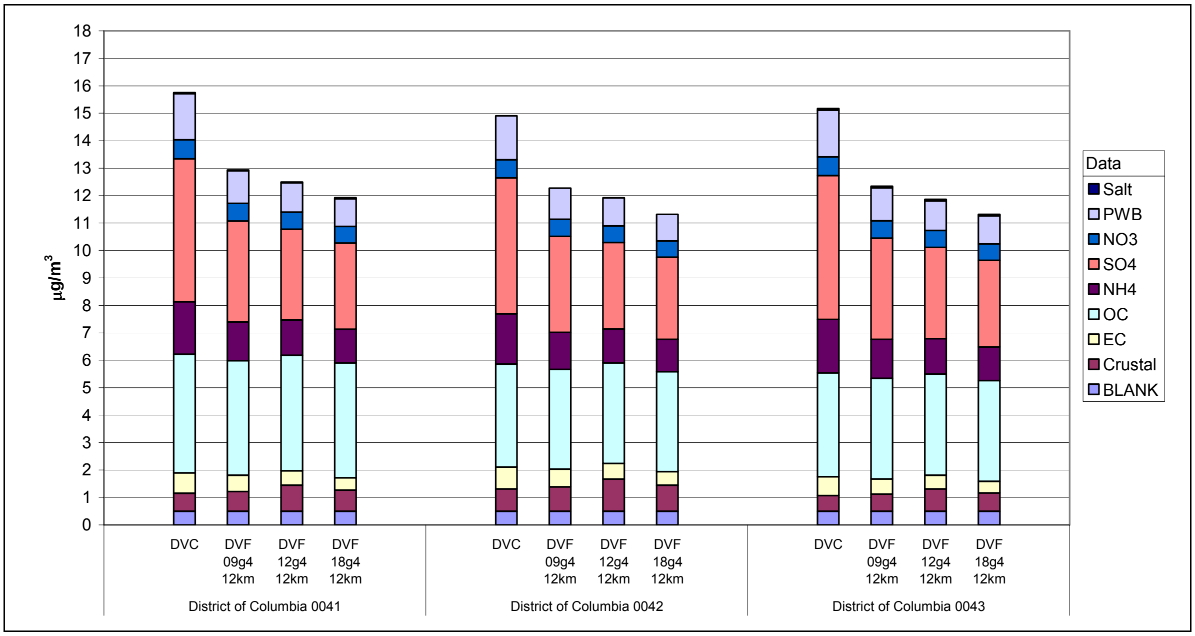

Figure 4-3. Current (2000-2004) $PM_{2.5}$ Design Values centered on 2002 and Projected 2009 $PM_{2.5}$ Design Values (DVF) in the District of Columbia using the CMAQ 36/12 km 2009 Base G4 modeling results.

Table 4-2. Current-year (DVC) and projected future-year (DVF) $PM_{2.5}$ Design Values (µg/m^3) in the District of Columbia using the 2002 Typical Base G2 and 2009, 2012 and 2018 Base G4 CMAQ 12 km modeling results.

AIRS ID	State	County	2002 Annual DVC	Annual DVF			Difference

4.7.3 Florida

There are 28 FRM monitoring sites in the state of Florida (Figure 4-4 and Table 4-3). The maximum current-year $PM_{2.5}$ Design Value is only 12.7 µg/m^3, which is projected to be reduced to 11.8 µg/m^3 by 2009. The future year $PM_{2.5}$ Design Values are projected to be further reduced for the farther out future years (2012 and 2018). These reductions are primarily due to reductions in sulfate. Thus, none of the Florida FRM sites are currently or projected in the future to exceed the annual $PM_{2.5}$ NAAQS.

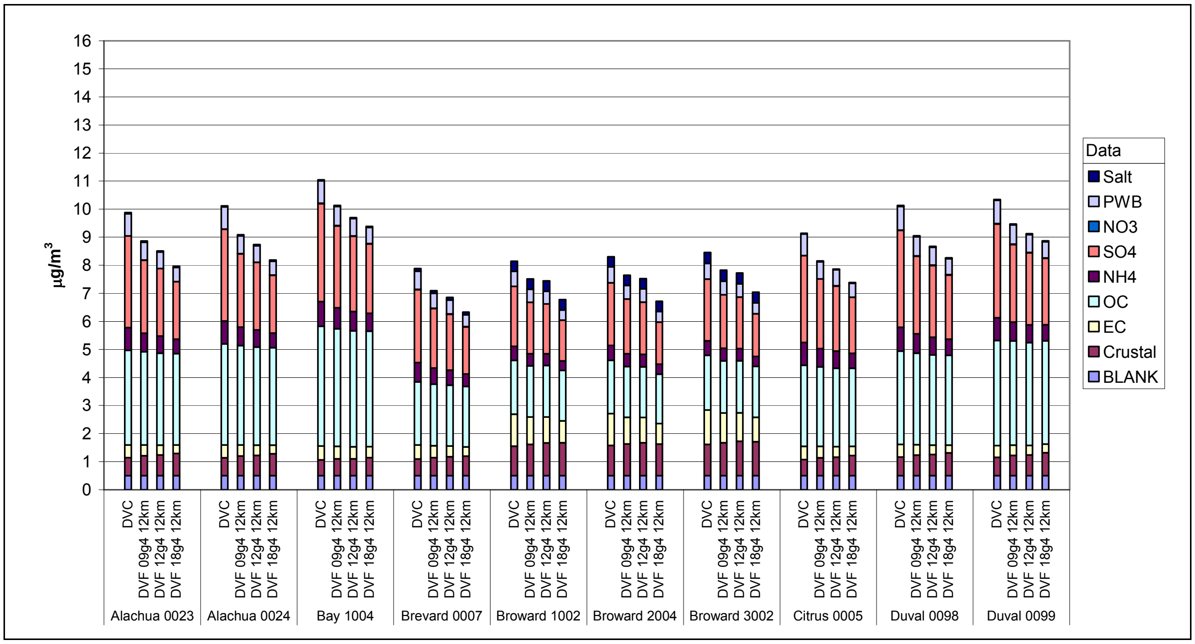

Figure 4-4a. Current (2000-2004) $PM_{2.5}$ Design Values (DVC) and Projected 2009, 2012 and 2018 $PM_{2.5}$ Design Values (DVF) in Florida using the CMAQ 12 km Base G4 modeling results.

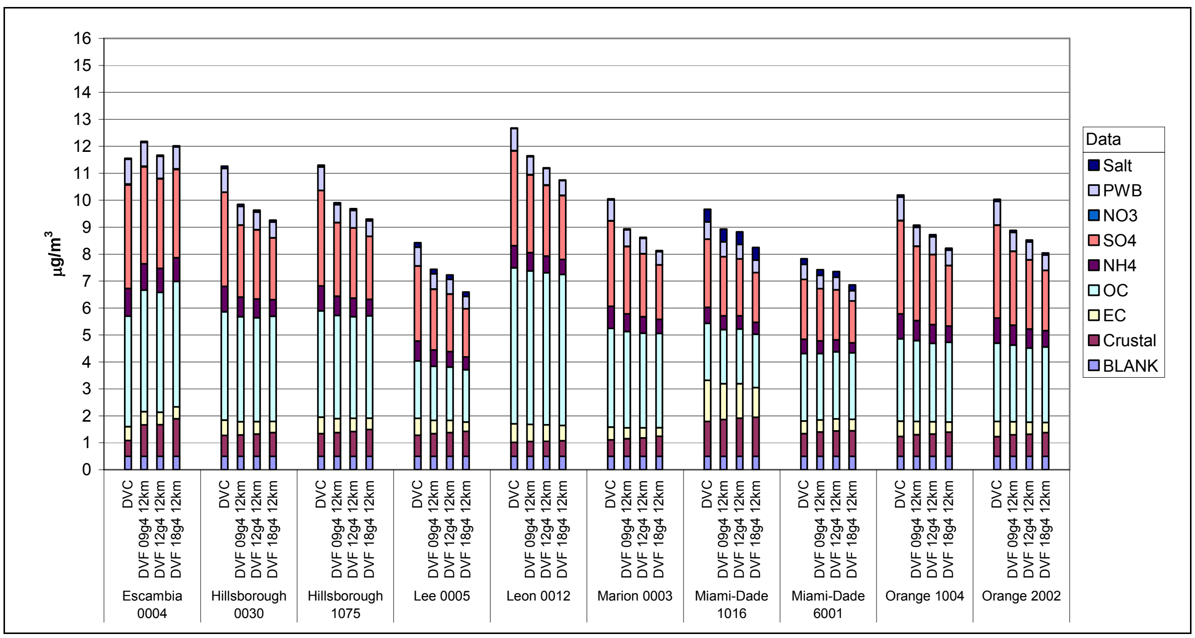

Figure 4-4b. Current (2000-2004) $PM_{2.5}$ Design Values (DVC) and Projected 2009, 2012 and 2018 $PM_{2.5}$ Design Values (DVF) in Florida using the CMAQ 12 km Base G4 modeling results.

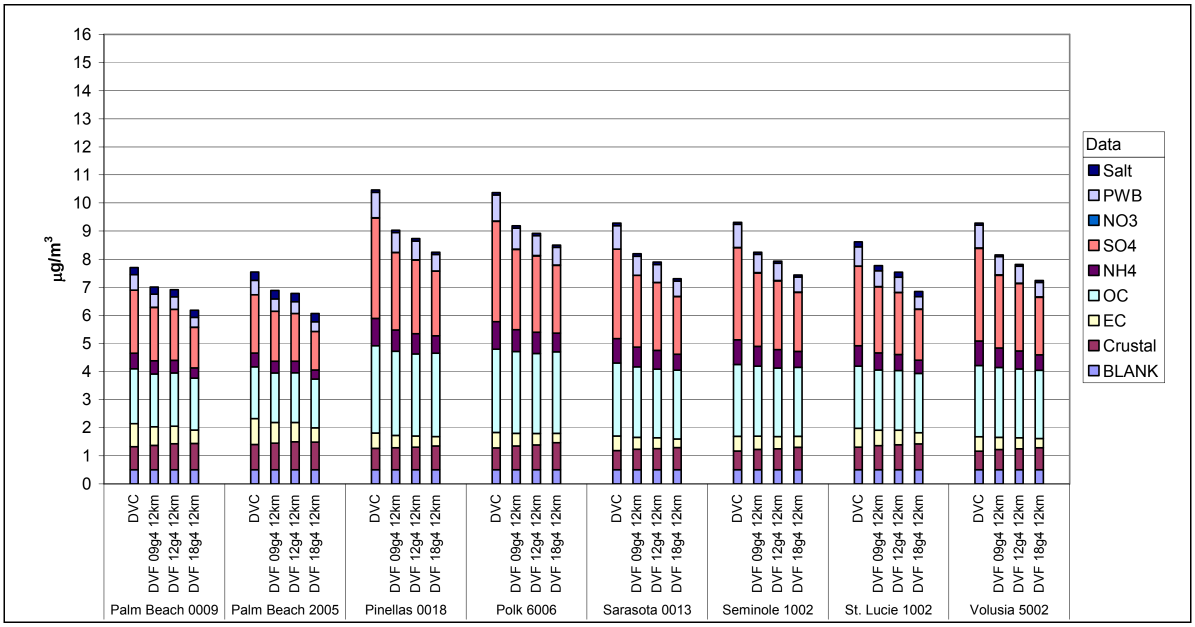

Figure 4-4c. Current (2000-2004) $PM_{2.5}$ Design Values (DVC) and Projected 2009, 2012 and 2018 $PM_{2.5}$ Design Values (DVF) in Florida using the CMAQ 12 km Base G4 modeling results.

4.7.4 Georgia

Of the 26 FRM monitoring sites in the state of Georgia, 15 of them have current-year $PM_{2.5}$ Design Values (DVCs) that exceed the annual $PM_{2.5}$ NAAQS. The highest of these is in Fulton County (Atlanta; 13-121-0039) that has a DVC of 18.3 $\mu g/m^3$ (Figure 4-5; Table 4-4). The ASIP 2009 modeling projects that of the 15 Georgia monitoring sites that currently exceed the NAAQS, just the Fulton County 13-121-0039 and Clayton County 13-063-0091 FRM sites would still be violating the annual $PM_{2.5}$ NAAQS in 2009, with the values of, respectively, 16.6 $\mu g/m^3$ and 15.1 $\mu g/m^3$. There are three Georgia FRM sites with projected 2009 $PM_{2.5}$ Design Value within the 14.5-15.5 $\mu g/m^3$ WOE range (including the Clayton County site mentioned previously) that requires additional weight of evidence (WOE) analysis, in addition to the Fulton County site whose 2009 $PM_{2.5}$ Design Value projections is above the WOE range (16.6 $\mu g/m^3$).

In 2012, only the Atlanta Fulton County monitor is estimated to continue to violate the annual $PM_{2.5}$ NAAQS with a 2012 DVF projection of 15.3 $\mu g/m^3$. All of the other Georgia monitoring sites 2012 $PM_{2.5}$ Design Values are projected to not only be below the NAAQS, but also below the WOE zone of additional analysis.

All of the Georgia FRM monitoring sites are projected to achieve the annual $PM_{2.5}$ NAAQS by 2018. The Atlanta Fulton County site is still the highest (14.9 $\mu g/m^3$) and is the only site whose 2018 Design Value projection lies within the WOE range.

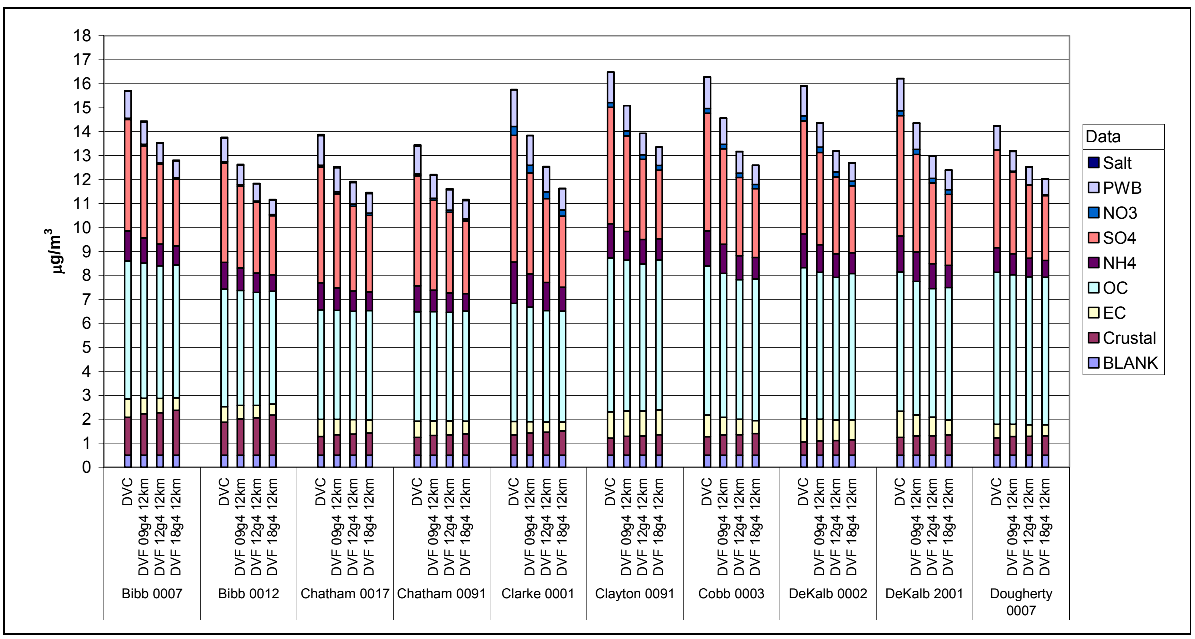

Figure 4-5a. Current (2000-2004) $PM_{2.5}$ Design Values (DVC) and Projected 2009, 2012 and 2018 $PM_{2.5}$ Design Values (DVF) in Georgia using the CMAQ 36/12 km Base G4 modeling results.

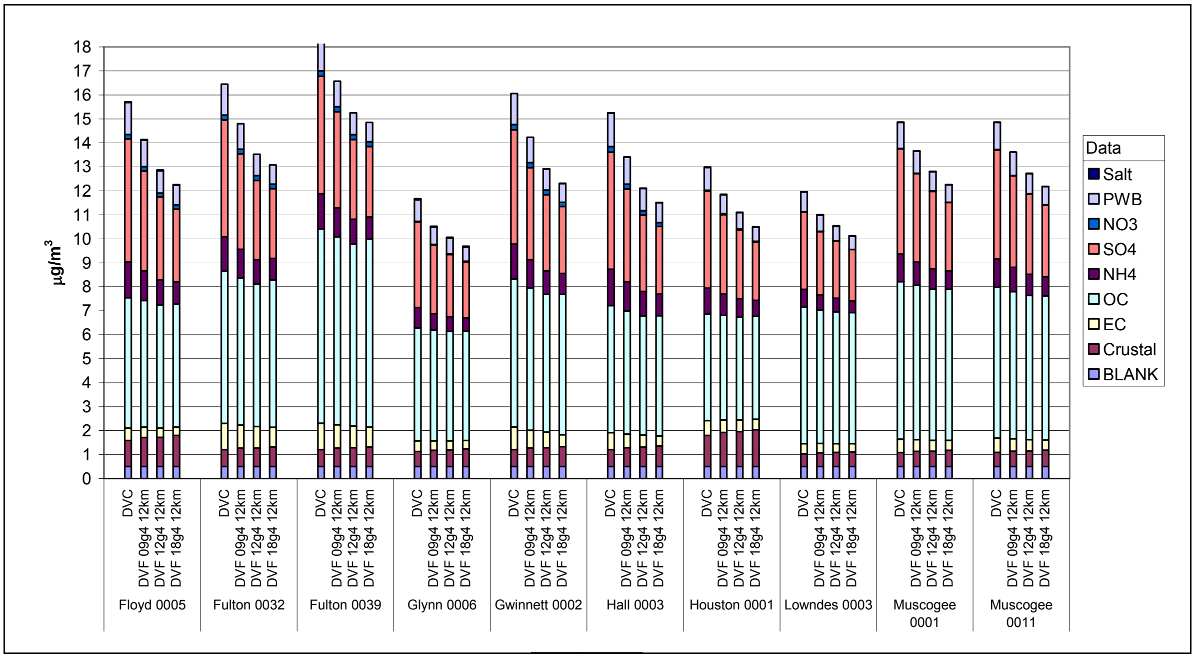

Figure 4-5b. Current (2000-2004) $PM_{2.5}$ Design Values (DVC) and Projected 2009, 2012 and 2018 $PM_{2.5}$ Design Values (DVF) in Georgia using the CMAQ 36/12 km Base G4 modeling results.

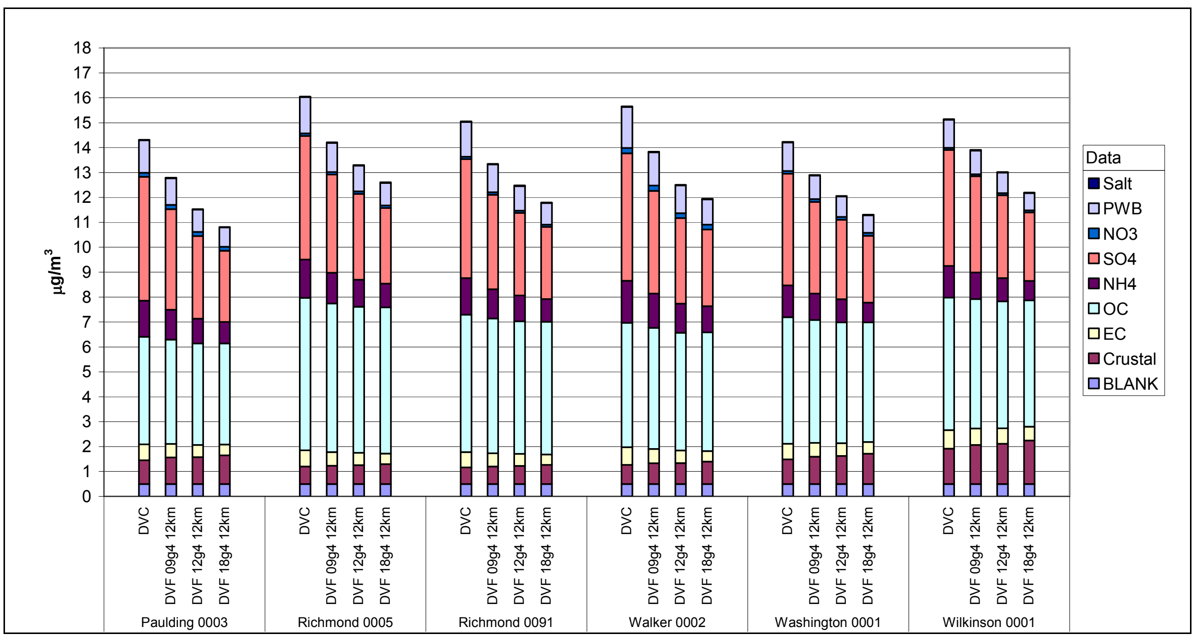

Figure 4-5c. Current (2000-2004) $PM_{2.5}$ Design Values (DVC) and Projected 2009, 2012 and 2018 $PM_{2.5}$ Design Values (DVF) in Georgia using the CMAQ 36/12 km Base G4 modeling results.

4.7.5 Kentucky

Of the 23 FRM monitoring sites in the state of Kentucky, 5 have current-year $PM_{2.5}$ Design Values (DVCs) that exceed the annual $PM_{2.5}$ NAAQS (Figure 4-6 and Table 4-5). The highest of these is in Jefferson County (Louisville) that has a DVC of 16.6 $\mu g/m^3$ (site 21-111-0044). This site has a projected 2009 DVF of 14.5 $\mu g/m^3$ using 12 km CMAQ results, which is below the NAAQS but within the WOE range (Table 4-5). All other FRM monitoring sites in Kentucky are projected to be below the annual average $PM_{2.5}$ NAAQS in 2009.

In 2012, the $PM_{2.5}$ Design Values in Jefferson County are projected to increase, whereas they are projected to decrease at the other FRM sites in Kentucky. This increase is large enough so that one site (21-111-0044) is projected to violate the $PM_{2.5}$ NAAQS in 2012 (15.3 $\mu g/m^3$). As noted in Chapter 2, the 2012 emissions for the non-VISTAS states were developed using an alternative approach to those developed for the 2002, 2009 and 2018 emission scenarios, whereby some of them were interpolated rather than grown and controlled inventories. The main objective of the 2012 inventories were to address the benefits of additional VISTAS EGU controls for the Alabama and Georgia $PM_{2.5}$ SIP activities and, due to time constraints, some simplifications in the 2012 inventories were made for the non-VISTAS states. Consequently, care should be taken in the interpretation of 2012 $PM_{2.5}$ projections in border areas of the VISTAS states, such as Louisville, Kentucky, as those projections will not be as accurate as those for 2009 and 2018. The 2012 $PM_{2.5}$ increases in Jefferson County, Kentucky are due to increases in OCM, not SO4.

By 2018 all sites in Kentucky are projected to achieve the annual $PM_{2.5}$ NAAQS and be below the WOE zone.

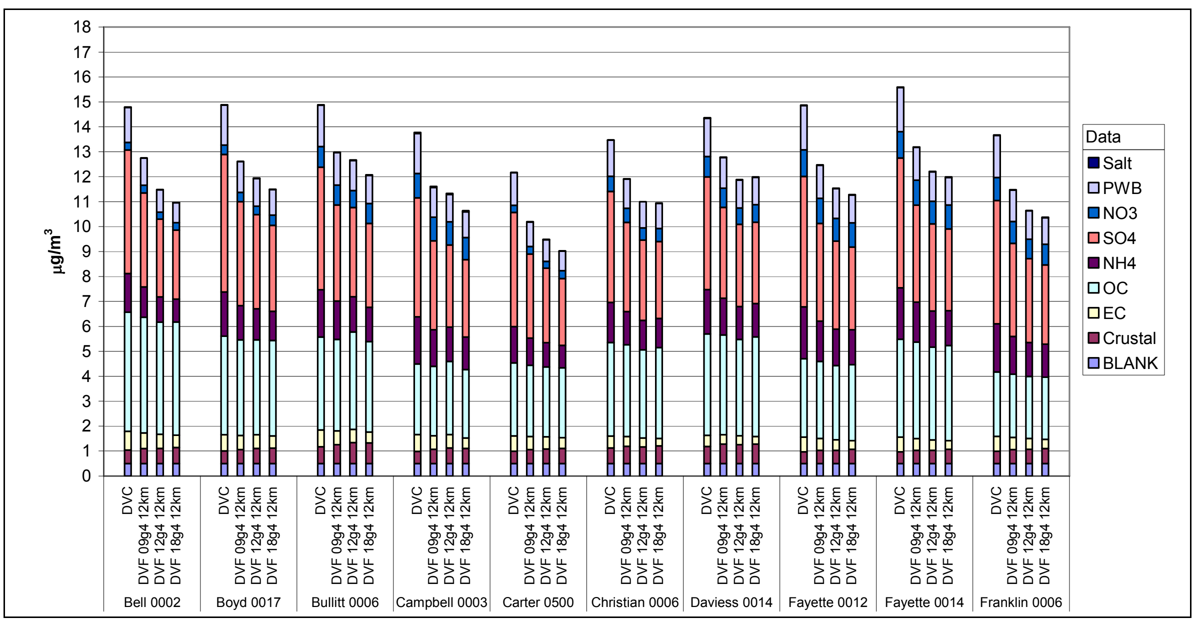

Figure 4-6a. Current (2000-2004) $PM_{2.5}$ Design Values (DVC) Projected 2009, 2012 and 2018 $PM_{2.5}$ Design Values (DVF) in Kentucky using the CMAQ 36/12 km Base G4 modeling results.

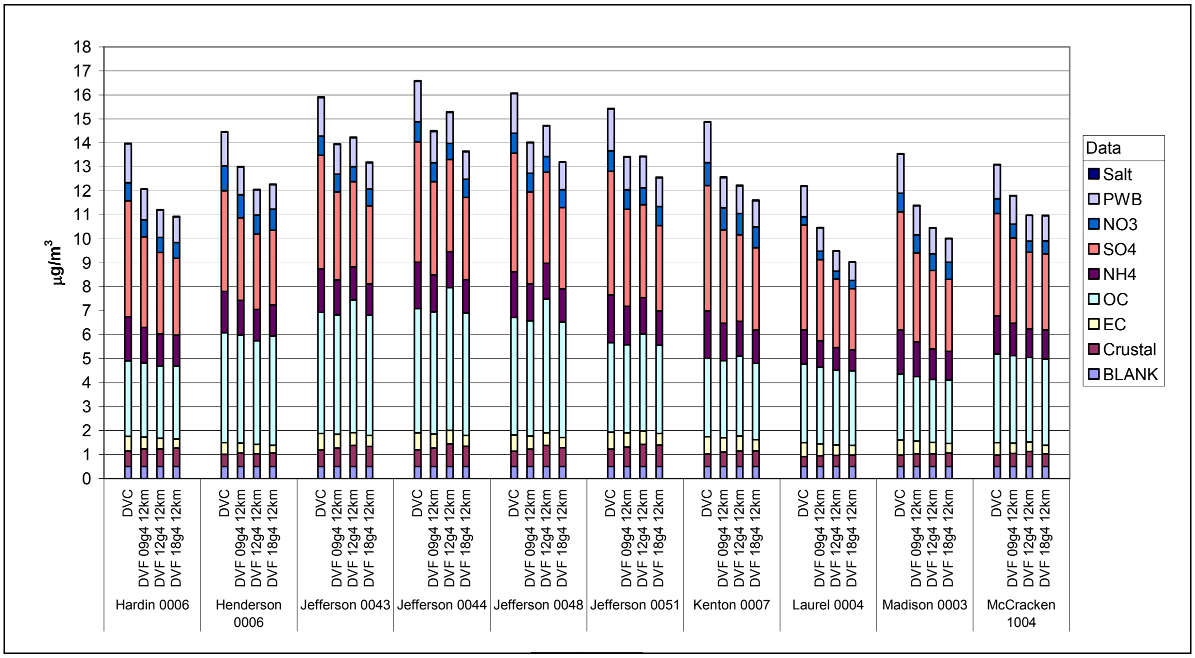

Figure 4-6b. Current (2000-2004) $PM_{2.5}$ Design Values (DVC) Projected 2009, 2012 and 2018 $PM_{2.5}$ Design Values (DVF) in Kentucky using the CMAQ 36/12 km Base G4 modeling results.

4.7.6 Mississippi

The maximum current-year $PM_{2.5}$ Design Value in Mississippi is 14.5 $\mu g/m^3$ in Jones County which is projected to be reduced to 13.6 $\mu g/m^3$ in 2009. All FRM monitoring sites in Mississippi currently and are projected to attain the annual $PM_{2.5}$ NAAQS in 2009, 2012 and 2018 (Figure 4-7 and Table 4-6).

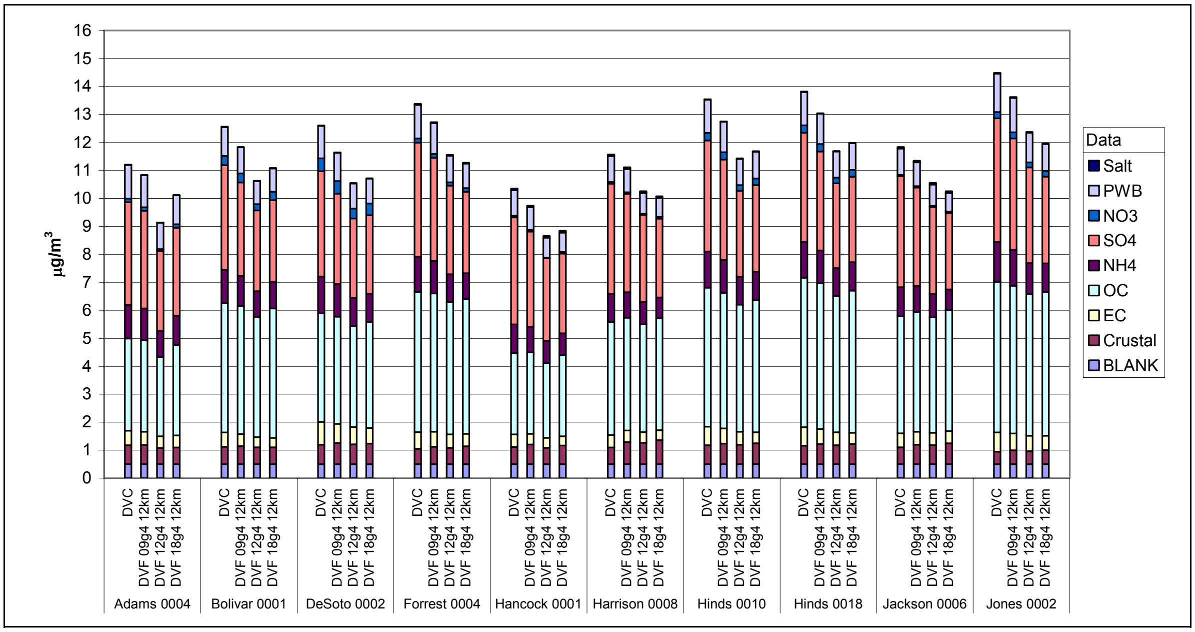

Figure 4-7a. Current (2000-2004) $PM_{2.5}$ Design Values (DVC) and Projected 2009, 2012 and 2018 $PM_{2.5}$ Design Values (DVF) in Mississippi using the CMAQ 12 km Base G4 modeling results.

4.7.7 North Carolina

Of the 34 FRM monitoring sites in North Carolina, 3 have DVCs that currently exceed the annual $PM_{2.5}$ NAAQS that are in Mecklenburg and Catawba Counties (Charlotte NAA) and Davidson County (Winston-Salem-Greensboro NAA). The highest DVC is 15.9 μg/m^3 that occurs in Davidson County and is reduced to 13.1 μg/m^3 in 2009. All North Carolina FRM monitoring sites are projected to attain the annual $PM_{2.5}$ NAAQS in 2009 and are also projected to be below the range of WOE. The $PM_{2.5}$ Design Values are projected to be even lower in 2012 and 2018 (Figure 4-8 and Table 4-7).

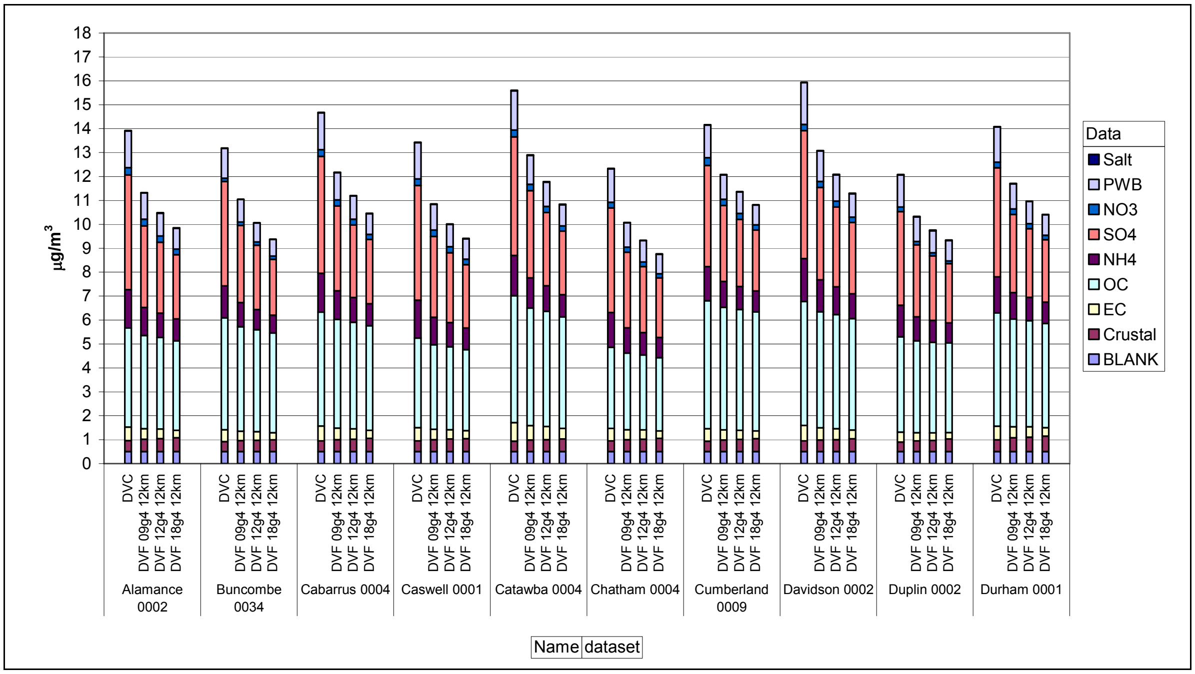

Figure 4-8a. Current (2000-2004) $PM_{2.5}$ Design Values (DVC) and Projected 2009, 2012 and 2018 $PM_{2.5}$ Design Values (DVF) in North Carolina using the CMAQ 36/12 km Base G4 modeling results.

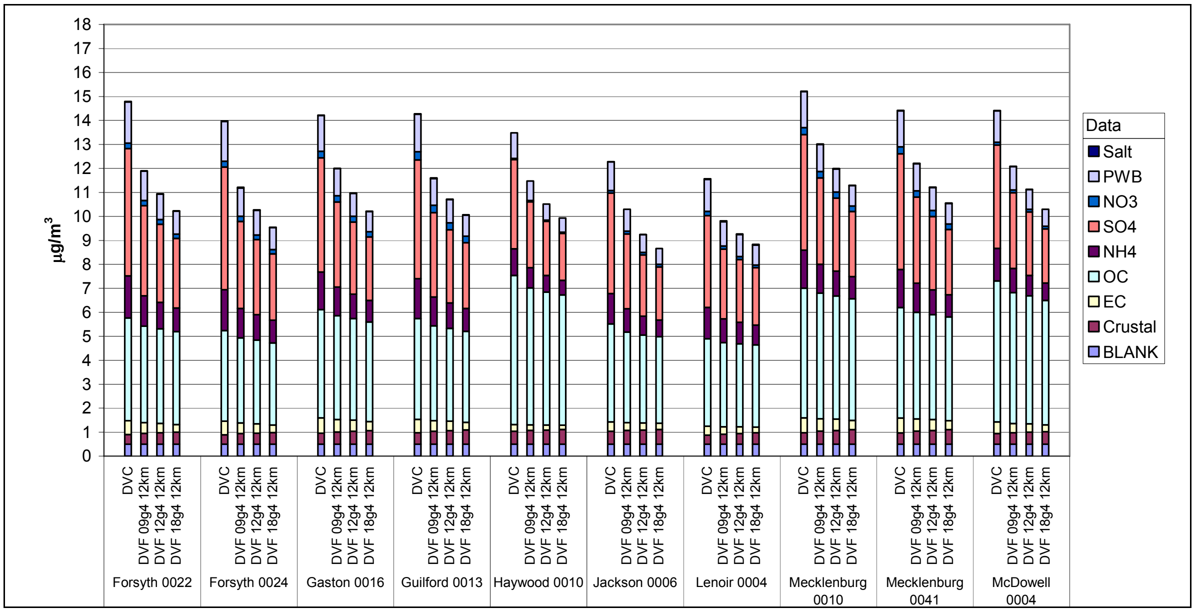

Figure 4-8b. Current (2000-2004) $PM_{2.5}$ Design Values (DVC) and Projected 2009, 2012 and 2018 $PM_{2.5}$ Design Values (DVF) in North Carolina using the CMAQ 36/12 km Base G4 modeling results.

4.7.8 South Carolina

There is one monitoring site in Greenville County, South Carolina (city of Greenville) whose DVC currently exceeds the annual $PM_{2.5}$ NAAQS at 15.8 μg/m^3 (Figure 4-9 and Table 4-8). It is estimated to be reduced to 13.6 μg/m^3 in 2009. Thus, all South Carolina FRM monitoring sites are projected to attain the annual $PM_{2.5}$ NAAQS in 2009, with further reductions projected to occur in 2012 and 2018.

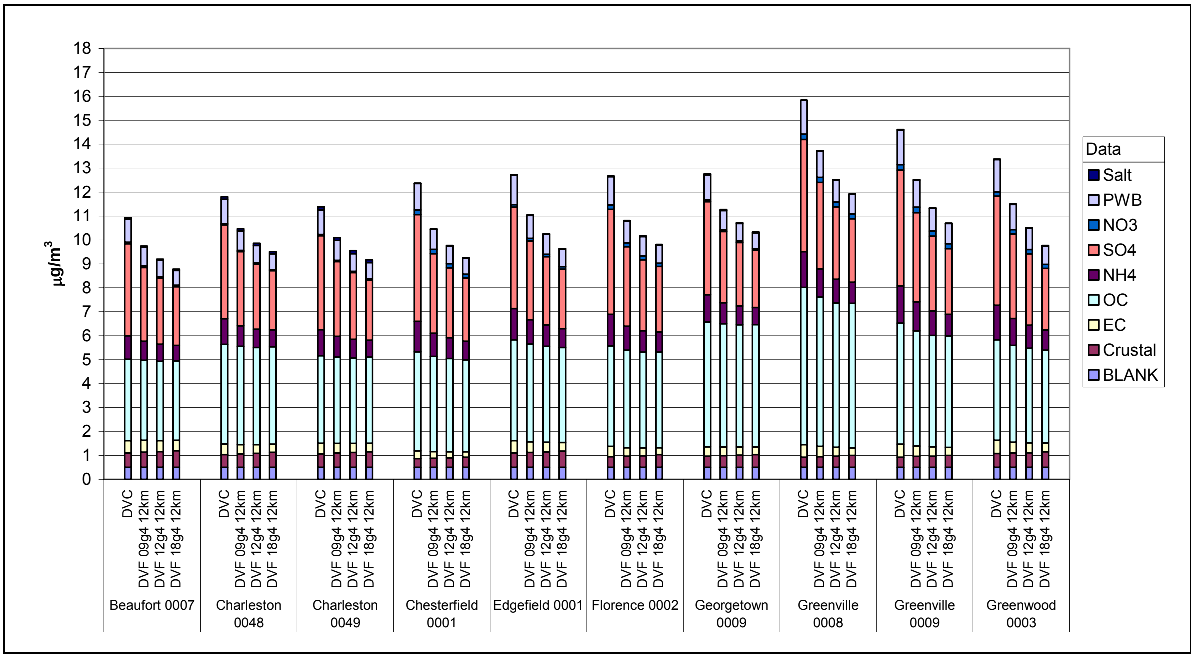

Figure 4-9a. Current (2000-2004) $PM_{2.5}$ Design Values (DVC) and Projected 2009, 2012 and 2018 $PM_{2.5}$ Design Values (DVF) in South Carolina using the CMAQ 12 km Base G4 modeling results.

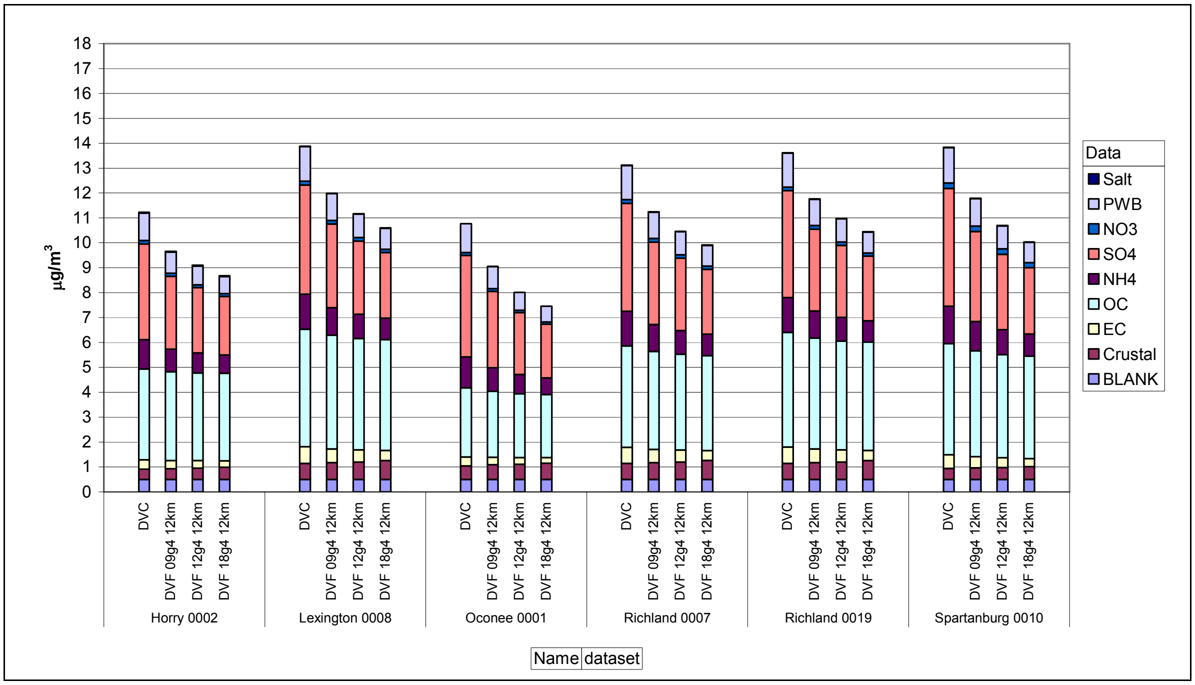

Figure 4-9b. Current (2000-2004) $PM_{2.5}$ Design Values (DVC) and Projected 2009, 2012 and 2018 $PM_{2.5}$ Design Values (DVF) in South Carolina using the CMAQ 12 km Base G4 modeling results.

Table 4-8. Current-year (DVC) and projected future-year (DVF) $PM_{2.5}$ Design Values (µg/m^3) in South Carolina using the 2002 Typical Base G2 and 2009, 2012 and 2018 Base G4 CMAQ 12 km modeling results.

4.7.8 Tennessee

Five monitoring sites in Tennessee have DVCs that exceed the annual $PM_{2.5}$ NAAQS, with three of them at 16.0 µg/m^3 or greater that occur in the Knoxville (Knox County) and Chattanooga (Hamilton County) NAAs (Figure 4-10 and Table 4-9). However, all of the 2009 $PM_{2.5}$ Design Values in Tennessee are projected to be below the annual $PM_{2.5}$ NAAQS with a maximum projected DVF of 14.4 µg/m^3 that occurs in both the in Knoxville and Chattanooga areas and are below the WOE range. For most sites there are further reductions in the $PM_{2.5}$ Design Values in 2012 and 2018. The exception to this are Dyer and Shelby counties where the $PM_{2.5}$ projections are flat or even go up between 2012 and 2018, These counties are on the western edge of Tennessee and are highly influenced by emissions from the CENRAP states and in particular Arkansas that is not included in the CAIR PM controls. As discussed for the Kentucky projections in Section 4.2.5, the purpose of the ASIP 2012 modeling was primarily to support the Georgia and Alabama SIPs. Thus, a simpler emissions projection approach was used for the non-VISTAS states 2012 projections than used for 2009 and 2018 so that the ASIP 2012 $PM_{2.5}$ projections at sites along the border of the ASIP region (e.g., Dyer and Shelby Counties, Tennessee) are more uncertain.

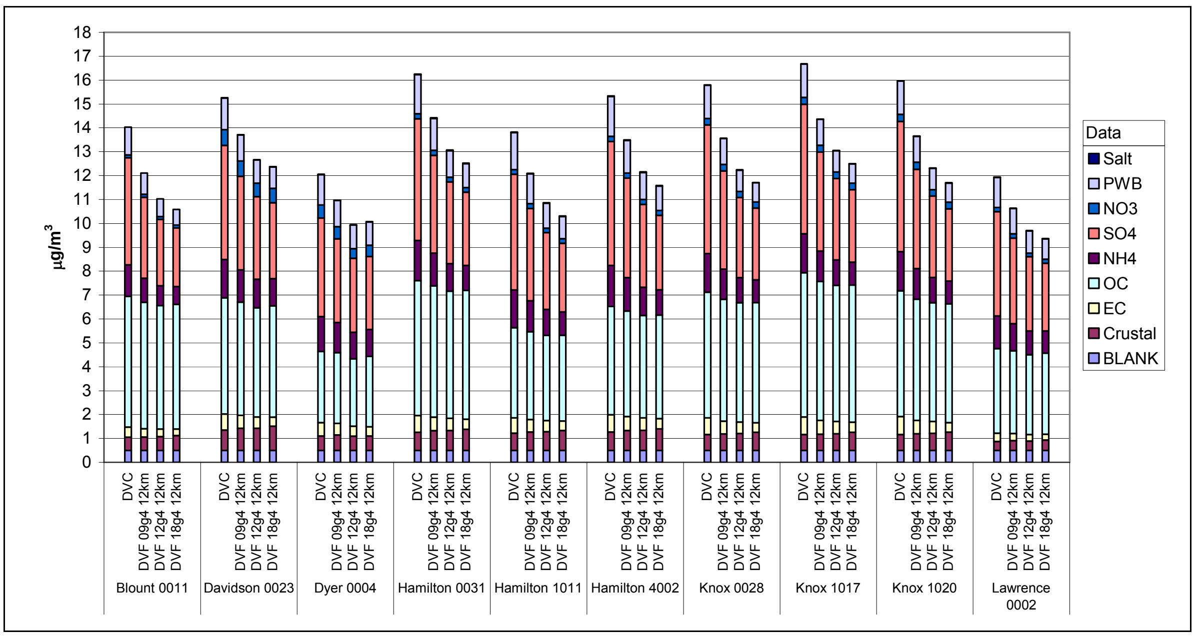

Figure 4-10a. Current (2000-2004) $PM_{2.5}$ Design Values centered on 2002 and Projected 2009 $PM_{2.5}$ Design Values (DVF) in Tennessee using the 2009 CMAQ 36/12 km Base G4 modeling results.

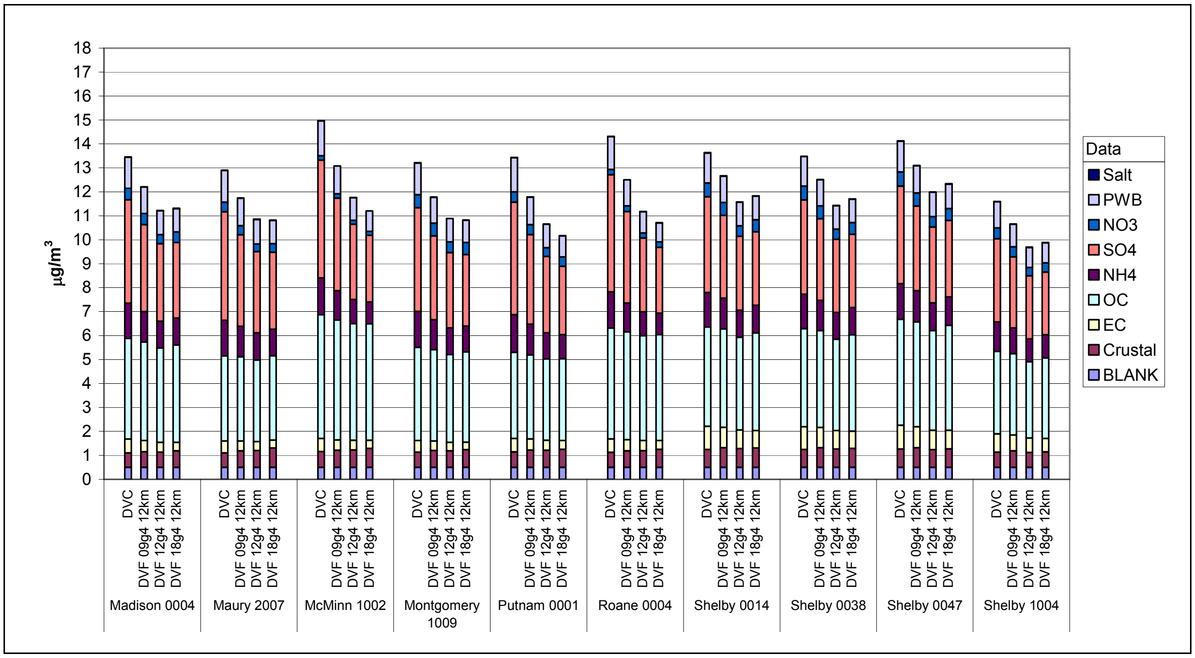

Figure 4-10b. Current (2000-2004) $PM_{2.5}$ Design Values centered on 2002 and Projected 2009 $PM_{2.5}$ Design Values (DVF) in Tennessee using the 2009 CMAQ 36/12 km Base G4 modeling results.

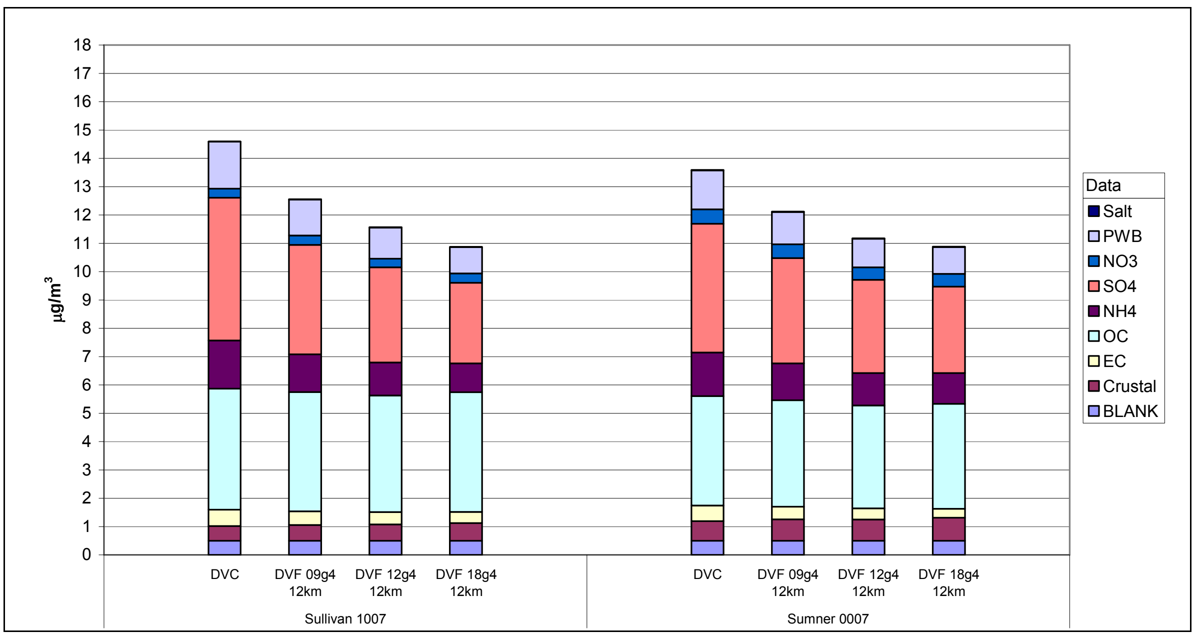

Figure 4-10c. Current (2000-2004) $PM_{2.5}$ Design Values centered on 2002 and Projected 2009 $PM_{2.5}$ Design Values (DVF) in Tennessee using the 2009 CMAQ 36/12 km Base G4 modeling results.

Table 4-9. Current-year (DVC) and projected future-year (DVF) $PM_{2.5}$ Design Values (µg/m^3) in Tennessee using the 2002 Typical Base G2 and 2009, 2012 and 2018 Base G4 CMAQ 12 km modeling results.

4.7.9 Virginia

For Virginia, all of the current-year and future-year $PM_{2.5}$ Design Values are below the annual $PM_{2.5}$ NAAQS (Figure 4-12 and Table 4-11). There are large reductions in the projected $PM_{2.5}$ Design Values between 2002 and 2009, with further reductions in the further out years.

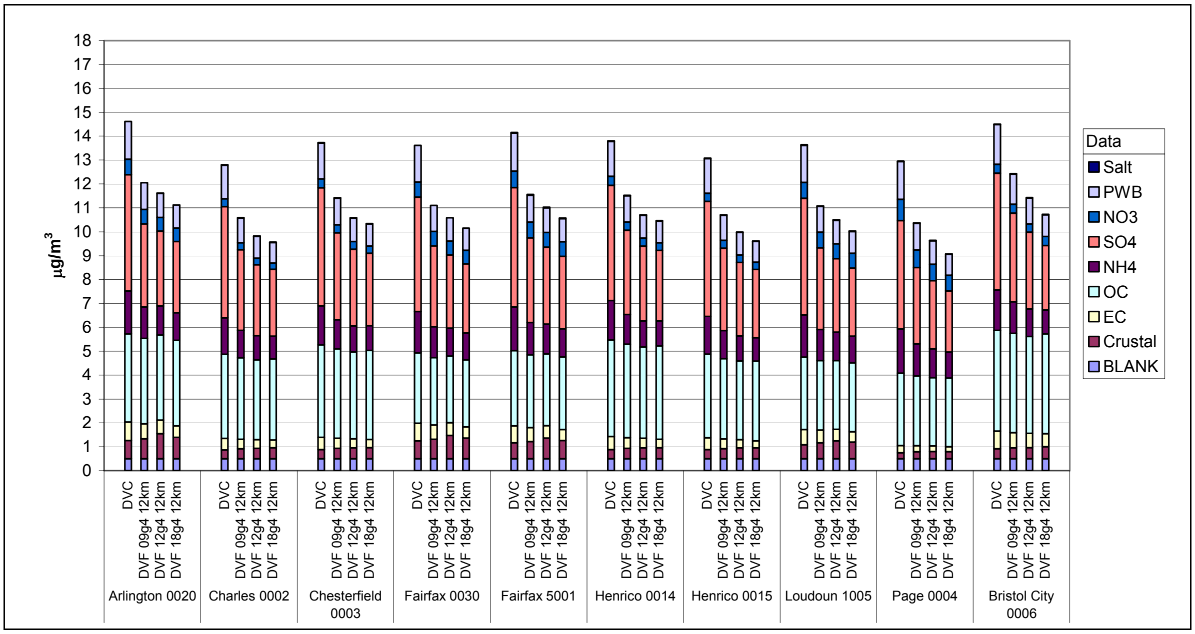

Figure 4-12a. Current (2000-2004) $PM_{2.5}$ Design Values (DVC) and Projected 2009, 2012 and 2018 $PM_{2.5}$ Design Values (DVF) in Virginia using the CMAQ 36/12 km Base G4 modeling results.

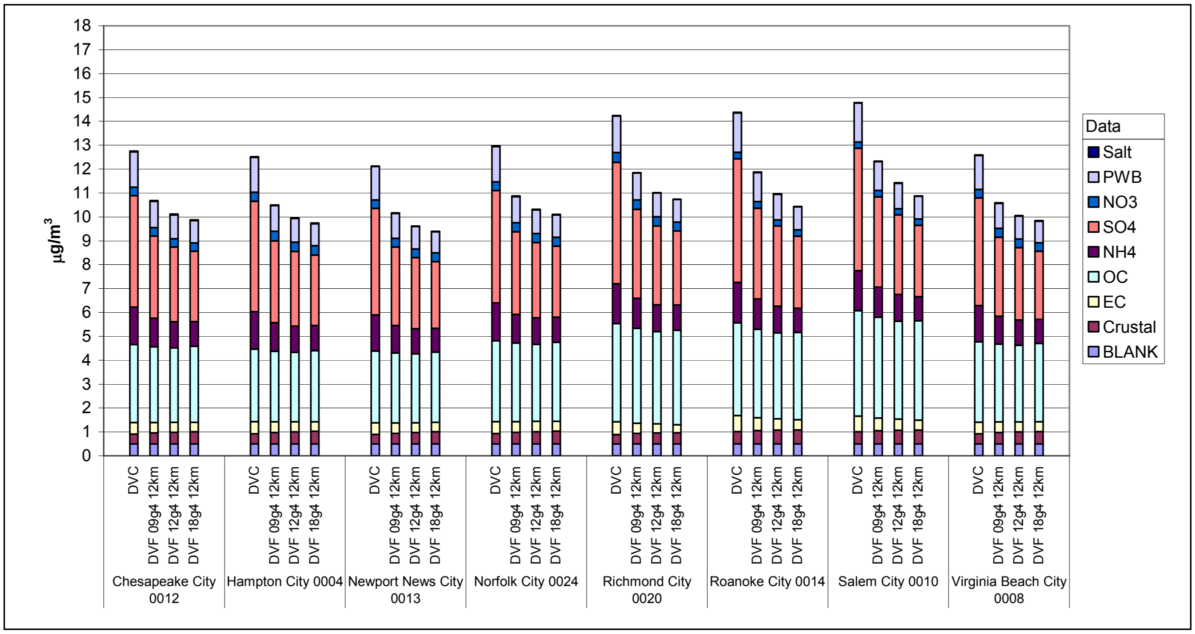

Figure 4-12b. Current (2000-2004) $PM_{2.5}$ Design Values (DVC) and Projected 2009, 2012 and 2018 $PM_{2.5}$ Design Values (DVF) in Virginia using the CMAQ 36/12 km Base G4 modeling results.

Table 4-10. Current-year (DVC) and projected future-year (DVF) $PM_{2.5}$ Design Values (μg/m^3) in Virginia using the 2002 Typical Base G2 and 2009, 2012 and 2018 Base G4 CMAQ 12 km modeling results.

4.7.10 West Virginia

Eleven of the 16 FRM monitors in West Virginia have current-year $PM_{2.5}$ Design Values that exceed the annual $PM_{2.5}$ NAAQS. The ASIP modeling estimates that by 2009 all of the FRM monitors in West Virginia would achieve the annual $PM_{2.5}$ NAAQS. Although one of the Kanawha County monitors (14.7 µg/m^3) in the Charleston NAA is within the 14.5-15.5 µg/m^3 WOE range. Additional reductions are seen in the further out future-years.

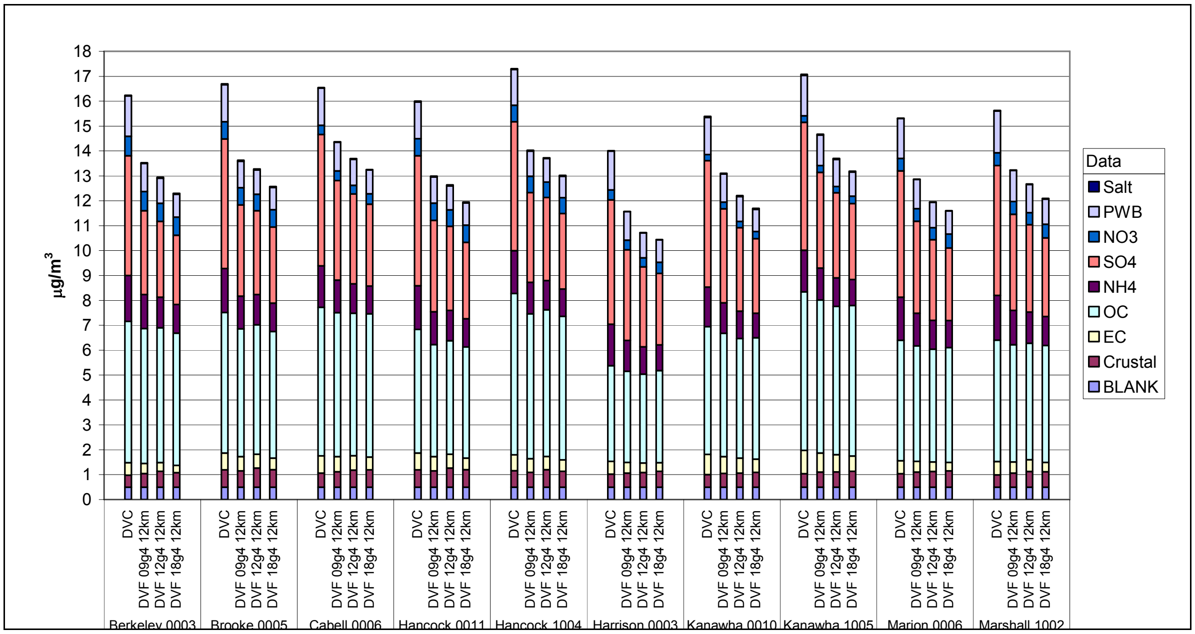

Figure 4-13a. Current (2000-2004) $PM_{2.5}$ Design Values (DVC) and Projected 2009, 2012 and 2018 $PM_{2.5}$ Design Values (DVF) in West Virginia using the CMAQ 36/12 km Base G4 modeling results.

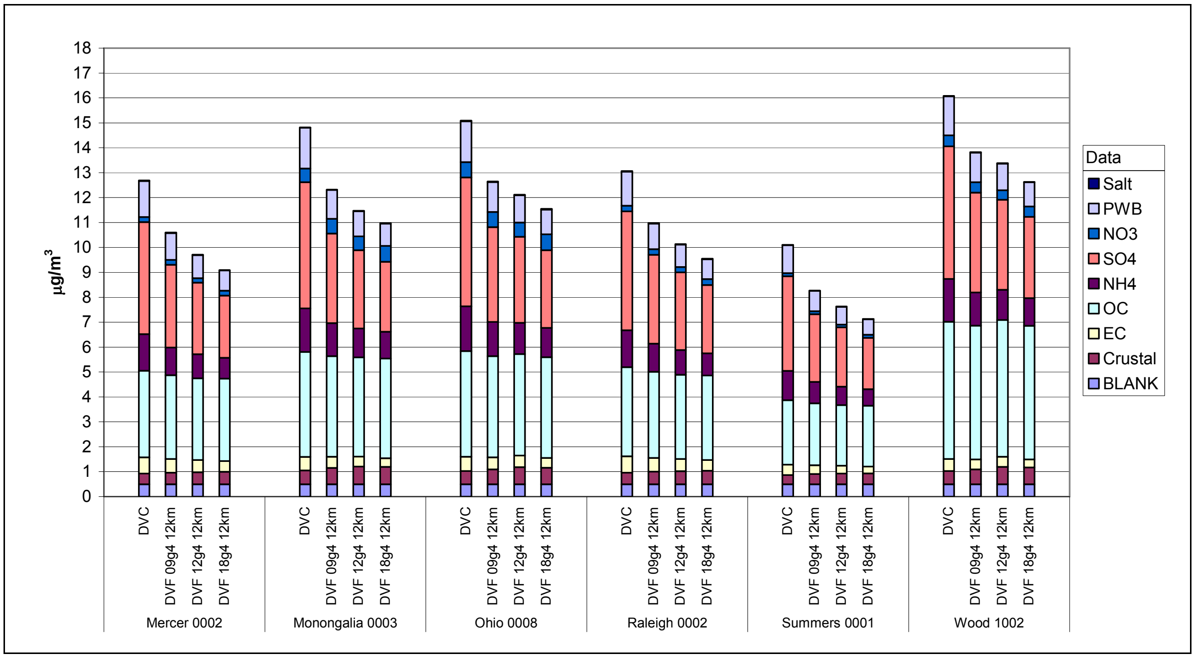

Figure 4-13b. Current (2000-2004) $PM_{2.5}$ Design Values (DVC) and Projected 2009, 2012 and 2018 $PM_{2.5}$ Design Values (DVF) in West Virginia using the CMAQ 36/12 km Base G4 modeling results.

4.7.11 Southern Indiana

Although Indiana is not an ASIP state, future-year $PM_{2.5}$ Design Value projections are presented for those FRM monitors in southern Indiana due to their close proximity to Kentucky (Table 4-12). Four of the six FRM monitors in southern Indiana have DVCs that exceed the annual $PM_{2.5}$ NAAQS. The ASIP modeling estimates that all southern Indiana FRM sites would achieve the annual $PM_{2.5}$ NAAQS by 2009, with additional reductions seen in the further out future-years (Table 4-12).

Table 4-12. Current-year (DVC) and projected future-year (DVF) $PM_{2.5}$ Design Values (µg/m^3) in Southern Indiana using the 2002 Typical Base G2 and 2009, 2012 and 2018 Base G4 CMAQ 12 km modeling results.

4.7.12 Maryland

Maryland is also not an ASIP state, but is adjacent to two ASIP states (Virginia and West Virginia) so would be influenced by their emissions. There are five FRM sites in Maryland that currently violate the annual $PM_{2.5}$ NAAQS (Table 4-13). All Maryland sites are projected to attain the NAAQS by 2009 with a maximum $PM_{2.5}$ Design Value of 13.8 µg/m^3.

Table 4-13. Current-year (DVC) and projected future-year (DVF) $PM_{2.5}$ Design Values (µg/m^3) in Maryland using the 2002 Typical Base G2 and 2009, 2012 and 2018 Base G4 CMAQ 12 km modeling results.

4.7.13 Southern Ohio

PM concentrations at FRM monitors in southern Ohio are adjacent to the Kentucky and/or West Virginia ASIP states. Of the 18 FRM monitors in southern Ohio, 16 have current DVCs that exceed the annual $PM_{2.5}$ NAAQS. Of these, only one remaining FRM site (39-061-0014) is projected to still exceed the annual $PM_{2.5}$ NAAQS in 2009 and that is in Hamilton County (Cincinnati) in the southwest corner of Ohio adjacent to Kentucky and Indiana. By 2012 there are two sites in Hamilton County estimates to exceed the annual NAAQS, however as noted in Chapter 2 and in the discussion on the Louisville Kentucky projections, care should be taken in the interpretation of the 2012 projections in and near the borders of the VISTAS region due to the simplifications in developing the 2012 emissions for the non-VISTAS states to meet the objectives of the 2012 modeling. In any event, by 2018 and FRM sites in southern Ohio are projected to attain the annual $PM_{2.5}$ NAAQS.

Table 4-14. Current-year (DVC) and projected future-year (DVF) $PM_{2.5}$ Design Values (µg/m^3) in Southern Ohio using the 2002 Typical Base G2 and 2009, 2012 and 2018 Base G4 CMAQ 12 km modeling results.

4.8 SUMMARY OF HIGH 2009 $PM_{2.5}$ DESIGN VALUES

Table 4-15 summarizes the FRM monitoring sites within and adjacent to the ASIP region for which projected 2009 $PM_{2.5}$ Design Values are 14.5 µg/m^3 or higher using the ASIP CMAQ 12 km modeling results and EPA MATS projection approach. EPA guidance has a weight of evidence (WOE) zone where additional analysis is needed to support a modeled attainment demonstration when the projected $PM_{2.5}$ Design Values are close to the $PM_{2.5}$ NAAQS (EPA, 2007a). EPA recommends that a WOE analysis be conducted if the modeled future-year $PM_{2.5}$ Design Value is in the 14.5 to 15.5 µg/m^3 range. If the future-year projected $PM_{2.5}$ Design Value is 15.5 µg/m^3 or higher, EPA notes that no amount of additional analysis is likely to be convincing that attainment would be achieved.

There are three FRM monitors within or adjacent to the ASIP region whose 2009 projected $PM_{2.5}$ Design Values are above 15.5 µg/m^3:

- The North Birmingham monitor (17.0 µg/m^3) in the City of Birmingham in Jefferson County, Alabama;
- The Wylam monitor (15.8 µg/m^3) in the City of Birmingham in Jefferson County, Alabama; and
- An Atlanta, Georgia monitor in Fulton County (16.6 µg/m^3).

An additional two monitors are above the $PM_{2.5}$ NAAQS but within the WOE range (14.5-15.5 µg/m^3):

- A monitor in Clayton County, Georgia (15.1 µg/m^3) in the Atlanta area.
- And a monitor in Hamilton County, Ohio that is part of the Cincinnati NAA (15.5 µg/m^3).

An additional 7 FRM monitors have projected $PM_{2.5}$ Design Values that are below the NAAQS but within the WOE zone (Table 4-15). These monitors include ones in the Atlanta NAA, southern Indiana in the Louisville NAA, southern Ohio in the Cincinnati NAA, the greater Charleston-Huntington NAA and the Knoxville NAA.

The two monitors in Birmingham that are projected to violate the annual $PM_{2.5}$ NAAQS in 2009 are influenced by local sources, which are not captured well by the ASIP 12 km CMAQ modeling. Thus, the Alabama Department of Environmental Management (ADEM) and Jefferson County Department of Health (JCDH) are performing the Birmingham Air Pollution Study (BAPS). BAPS is using the ASIP 12 km CMAQ modeling results to provide boundary conditions (BCs) for 4 km urban CMAQ modeling and are also performing AERMOD near-source modeling to address $PM_{2.5}$ attainment issues (ENVIRON and Alpine, 2007).

The Georgia Environmental Protection Division (GEPD) of the Georgia Department of Natural Resources (GDNR) is also performing subregional CMAQ modeling using BCs from the ASIP 12 km CMAQ results.

Table 4-15. 2009 projected $PM_{2.5}$ Design Values within and adjacent to the ASIP region that are 14.5 µg/m^3 or higher using the 2009 CMAQ 12 km Base G4 modeling results.

4.9 $PM_{2.5}$ UNMONITORED AREA ANALYSIS

EPA's $PM_{2.5}$ projection procedure also includes an unmonitored area analysis (EPA, 2007a) that has been codified in MATS. The unmonitored area analysis uses the future-year annual $PM_{2.5}$ Design Value projection procedure applied to each grid cell in the modeling domain. In this procedure, the current-year annual $PM_{2.5}$ Design Values (DVC) are interpolated to each grid cell in the modeling domain. This interpolation scheme uses the modeled concentration gradients so that it is possible for the gridded DVCs to be higher than the DVCs at all the FRM monitors in locations where the model predicts higher $PM_{2.5}$ concentrations that are away from the monitoring sites. RRFs are then obtained for each grid cell in the modeling domain using essentially the same approach as used for the $PM_{2.5}$ projections at the FRM monitors described previously, only using the model predictions within each grid cell rather than near a grid cell as done for the projections at the monitor (i.e., average across 3 x 3 12 km grid cells).

Figure 4-14 displays the DVCs interpolated to the 12 km CMAQ domain using MATS and the CMAQ 12 km 2002 Base G2 modeling results. The spatial distribution of the gridded DVCs are displayed with the monitoring site locations in Figure 4-14a so you can see the locations of the monitors, and then without the monitoring site locations in Figure 4-14b so that they don't obscure any of the interpolated DVCs. There is the expected locations of the interpolated DVCs above the annual $PM_{2.5}$ NAAQS in several of the urban areas where DVCs at FRM monitors are above the NAAQS, such as Birmingham, Atlanta, Charlotte, Chattanooga, Knoxville, Cincinnati, Washington DC and along the Ohio River. But there are also unexpected areas of interpolated DVCs that exceed the NAAQS, including between Atlanta and Chattanooga and just west of Savannah, Georgia.

Figure 4-15 displays the MATS unmonitored area analysis projected 2009 $PM_{2.5}$ Design Values using the CMAQ 12 km modeling results for the 2009 Base G4 emissions scenario. As expected based on the monitored 2009 projections presented in Table 4-15 above, there are areas of projected 2009 $PM_{2.5}$ violations in the Birmingham and Atlanta area. But there are also other areas of continued violations in 2009: in Georgia just south of Chattanooga; just west of Savannah, Georgia; Pensacola, Florida; between Columbus and Montgomery Alabama; near Albany, Georgia; scattered areas along the Ohio River (e.g., Louisville); and other isolated areas.

The projected $PM_{2.5}$ Design Values unmonitored area analysis and the 2012 and 2018 future-years are shown in, respectively, Figures 4-16 and 4-17. By 2018, there appears to be only a few isolated areas of continued projected violations of the annual $PM_{2.5}$ NAAQS in the VISTAS states: Birmingham; in Georgia just south of Chattanooga; and just west of Savannah, Georgia.

EPA guidance stresses that the unmonitored area test has more uncertainties than the projections at the monitors and it should be treated separately from the monitor based attainment demonstration test (EPA, 2007a). EPA further notes that while it is expected that additional emission controls will likely be needed to eliminate predicted exceedances of the NAAQS in the monitor based attainment test, the same requirements may not be appropriate in unmonitored areas. In any event, EPA recommends that areas of predicted violations in the unmonitored area test be scrutinized and understood to determine whether they are likely to really exist in the ambient air, or whether they may be caused by an error or uncertainties in the modeling system. At a minimum, it may be appropriate to deploy additional $PM_{2.5}$ monitors to such areas.

In the case of the ASIP $PM_{2.5}$ modeling, the continued violations of the NAAQS in Birmingham and Atlanta areas are confirmed by the monitor-based attainment tests and each of the states involved are performing subregional analysis. The violations west of Savannah Georgia that continue in 2009, 2012 and 2018 appear to be due to wildfires that are assumed to stay constant between the current-year and future-years. The reasons for the other high PM areas (e.g., Pensacola, southeast Alabama, north Georgia and southwest Georgia) are unclear at this time.

4.10 FUTURE YEAR 8-HOUR OZONE DESIGN VALUE PROJECTIONS

In this section we present the 2009, 2012 and 2018 8-hour ozone Design Value projections using the 2002 Base G2 and 2009, 2012 and 2018 Base G4 12 km CMAQ modeling results. The EPA Modeled Attainment Test Software (MATS) tool was used to make the future year 8-hour ozone Design Value projections.

4.10.1 Ozone Projection Procedures

The EPA modeling guidance for 8-hour ozone attainment demonstration modeling contain specific procedures that use current and future year modeling results in a relative fashion to scale current year observed 8-hour ozone Design Values to project future-year 8-hour ozone Design Values for comparisons with the NAAQS (EPA, 2007a). The EPA guidance projection procedures were used to estimate future year 8-hour ozone Design Values for all monitoring sites within the ASIP 12 km modeling domain. If the future-year projected 8-hour ozone Design Value for a monitor is less than or equal to 84 ppb, the modeled attainment test is passed. If the future-year Design Value is greater than or equal to 85 ppb, the modeled attainment test is not passed. If the future-year Design Value lies between 82 and 87 ppb, a weight of evidence (WOE) determination is required that provides corroborative information that attainment will be achieved in the future-year.

The EPA guidance procedure for projecting future-year 8-hour ozone Design Values has been codified in EPA's MATS tool. This procedure starts with a current-year observed 8-hour ozone Design Value (DVC) for each monitor. The modeling results are then used to scale the observed 8-hour ozone DVC to obtain a future-year 8-hour ozone Design Value projection (DVF). This is done through the calculation of model-estimated relative response factors (RRFs) that are the ratio of the model-estimated 8-hour ozone concentrations for the future-year to current-year emission scenarios. The RRF is monitor-specific and is used to scale the current year observed design value (DVC) to estimate the projected future-year 8-hour ozone design value (DVF):

$$DVF = DVC \times RRF$$

The RRF is defined as the ratio of the average of the maximum 8-hour ozone concentrations "near a monitor" for the future-year emissions scenario to the average for the current year base case emissions scenario. The EPA default definition of "near a monitor" is to select the maximum model-estimated daily maximum 8-hour ozone concentrations from an array of grid cells centered on the monitor. The size of the array of grid cells is grid cell size dependent and for the 12 km grid cell resolutions used in the ASIP modeling, EPA recommends use of an array of 3 x 3 grid cells (EPA, 2007a), which was used in the ASIP ozone projections.

EPA's 8-hour ozone modeling guidance includes the following language for selecting the current-year observed 8-hour ozone design values that are used in the modeled attainment demonstration test:

> *"For the modeled attainment tests we recommend using the average of the three design value periods which include the baseline inventory year…The average of the three design value periods best represents the baseline concentration, while taking into account the variability of meteorology and emissions (over a five year period)."* (EPA, 2007a, pg. 22).

For the ASIP modeling that used a 2002 baseline inventory and modeling year, that would mean the current year 8-hour ozone Design Value (DVC) is based on the average of three years of Design Values from 2000-2002, 2001-2003 and 2002-2004.

EPA recommends that at least of 10 modeling days be included in the calculation of the RRFs and future-year design values with an absolute 5 day minimum. The criterion for using an episode day in calculating the episode average Design Value for a monitor is that the model estimateds daily maximum 8-hour ozone near the monitor for the current year base case simulation exceeds a minimum Ozone Threshold value. EPA recommends use of an 85 ppb Ozone Threshold in the future-year 8-hour ozone Design Value calculations, but if insufficient number of modeling days are available to calculate the RRFs, then the Ozone Threshold can be reduced by 1 ppb until sufficient modeling days are obtained, or until a 70 ppb Ozone Threshold floor is obtained. When the 70 ppb Ozone Threshold floor is reached and there are less than 5 days available for calculating a RRF, then no RRF is calculated for that monitor.

In the final step of the 8-hour ozone modeled attainment test, the projected future-year 8-hour ozone Design Value is truncated to the nearest ppb and then compared with the NAAQS; if it is 84 ppb or lower at all monitors in the area then the modeled attainment test is passed. As noted above, even if the modeled attainment test is passed, if there are any projected 8-hour ozone Design Values above 82 ppb, then a weight of evidence (WOE) analysis is required that presents corroborative evidence that attainment would be achieved. Even if the modeled attainment test is not passed, if the projected future-year 8-hour ozone Design Values at all monitors are 87 ppb or lower, a WOE attainment demonstration may still be conducted.

4.10.2 4.10.2 Future Year 8-Hour Ozone Design Value Projections

Table 4-16 displays the projected future year 8-hour ozone Design Values at all monitoring sites within and adjacent to the ASIP region in which the current year DVC violates the 1997 0.08 ppm 8-hour ozone NAAQS. The modeling results estimate that there are six monitoring sites within and near the ASIP region that would continue to violate the 8-hour ozone NAAQS in 2009:

- Three sites in Maryland with projected 2009 DVFs of 85.8, 86.1 and 87.1 ppb.
- Two sites in Virginia with projected 2009 DVFs of 86.8 and 87.0 ppb.
- One site in Fulton County, Georgia (Atlanta) with a projected 2009 DVF of 85.6 ppb.

By 2012, all monitoring sites within and near the ASIP region are projected to achieve the 1997 0.08 ppm 8-hour ozone NAAQS. By 2018, the modeling estimates that not only is the 1997 0.08 ppm 8-hour ozone NAAQS is continued to be attained, but that the new 2008 0.075 ppm 8-hour ozone NAAQS is attained at all sites but three each in Maryland and Virginia. The 2008 0.075 ppm 8-hour ozone NAAQS will be addressed in future SIP actions.

Table 4-17, which is presented at the end of this Chapter, lists the current 8-hour ozone DVCs and future 8-hour ozone DVFs for 2009, 2012 and 2018 and all monitoring sites in the ASIP 12 km modeling domain calculated using the MATS tool, rather than just those sites with current DVC that violate the ozone NAAQS as given in Table 4-16. Note that for some monitoring sites, there are no future year 8-hour ozone DVFs. There are two potential reasons why there are no DVFs for a particular monitoring site in Table 4-17:

- There is insufficient ozone observations from 2000-2004 to calculate the DVC, in which case there will be no DVC for that site in Table 4-17; or
- Even using the Ozone Threshold floor of 70 ppb there are less than 5 modeling days for calculating the RRF for the particular site (in which case there will be a DVC but no DVFs in Table 4-17).

Table 4-16. Current (DVC) and future (DVF) year 8-hour ozone Design Values for all monitoring sites in the ASIP 12 km modeling domain whose current DVC exceeds the 0.08 ppm 8-hour ozone NAAQS.

4.10.3 8-Hour Ozone Unmonitored Area Analysis

EPA's 8-hour ozone projection procedure also includes an unmonitored area analysis that has been codified in MATS. The unmonitored area analysis uses the future-year 8-hour ozone Design Value projection procedure described above applied to each grid cell in the modeling domain. In this procedure, the current-year Design Values (DVC) are first interpolated to each grid cell in the modeling domain. This interpolation scheme uses the modeled concentration gradients in its interpolation procedures. RRFs are then obtained for each grid cell in the modeling domain using the procedures described above except using the actual modeled daily maximum 8-hour ozone concentrations in each grid cell (co-located) is used, rather than values near the grid cell. The same rules are used to assure there are sufficient days to calculate a robust and reliable RRF. Namely, pick the highest days above an ozone threshold value so that at least 10 modeling days are used in the RRFs by reducing the Ozone Threshold from 85 ppb until the 70 ppb floor is reached. If even with the 70 ppb Ozone Threshold floor there are 5 or more days, the RRF is still used. However, for grid cells in which there are less than 5 modeling days with daily maximum 8-hour ozone concentrations greater than 70 ppb no RRF is calculated and consequently no future year projected DVF is obtained for that grid cell.

Figure 4-18 displays the current year DVCs interpolated to the ASIP 12 km domain using MATS. There are several areas within and near the ASIP region that are current violating the 0.08 ppm (85 ppb) 8-hour ozone NAAQS: central North Carolina, eastern and western Tennessee, Atlanta and nearby regions in Georgia, Birmingham Alabama, along the Ohio River and in northern Virginia, District of Columbia, Maryland and Delaware.

The 2009 projected 8-hour ozone DVFs using the MATS unmonitored area analysis are shown in Figure 4-19. Within the ASIP region, continued violations of the 0.08 ppm 8-hour ozone NAAQS in 2009 are estimated mainly in the Atlanta and northern Virginia areas. There appears to be isolated grid cells of 8-hour ozone exceedances in Charlotte, Memphis and along the Ohio River in the Louisville and Cincinnati regions. By 2012 the unmonitored area analysis estimates that all grid cells in the ASIP region would attain the 0.08 ppm 8-hour ozone NAAQS (Figure 4-20). And attainment of the 0.08 ppm 8-hour ozone NAAQS in the ASIP region is projected to continue into 2018 (Figure 4-21). Note that the MATS unmonitored area analysis estimates that violations of the 0.08 ppm ozone NAAQS would occur in the future years over several water bodies near current high ozone areas, such as Lake Michigan, Chesapeake Bay and the Gulf of Mexico. These high residual ozone projections are due in part to the MATS use of modeled ozone gradients to interpolate the DVCs and the model's tendency to estimate higher ozone in the stable atmosphere over water bodies. Although higher ozone values have been estimated over water than nearby land locations (e.g., as in the Lake Michigan Ozone Study), the model may be overstating the extent of this ozone increase.

Note that areas with no shading in the unmonitored area DVF analysis in Figures 4-19 through 4-21 are grid cells where there were less than 5 days with ozone greater than 70 ppb so no ozone projection could be made.

EPA guidance stresses that the unmonitored area test has more uncertainties than the projections at the monitors and it should be treated separately from the monitor based attainment test (EPA, 2007a). EPA further notes that while it is expected that additional emission controls may be needed to eliminate predicted violations of the monitor based test, the same requirements may not be appropriate in unmonitored areas. In any event, EPA recommends that areas of predicted violations in the unmonitored area test be scrutinized and understood to determine whether they are likely to exist in the ambient air or whether they may be caused by an error or uncertainties in the modeling system. At a minimum, it may be appropriate to deploy additional ozone monitors to such areas. In this application the continued exceedances of the 0.08 ppm 8-hour ozone NAAQS over water bodies are believed to be due in part to modeling artifacts that produce too high ozone in these regions.

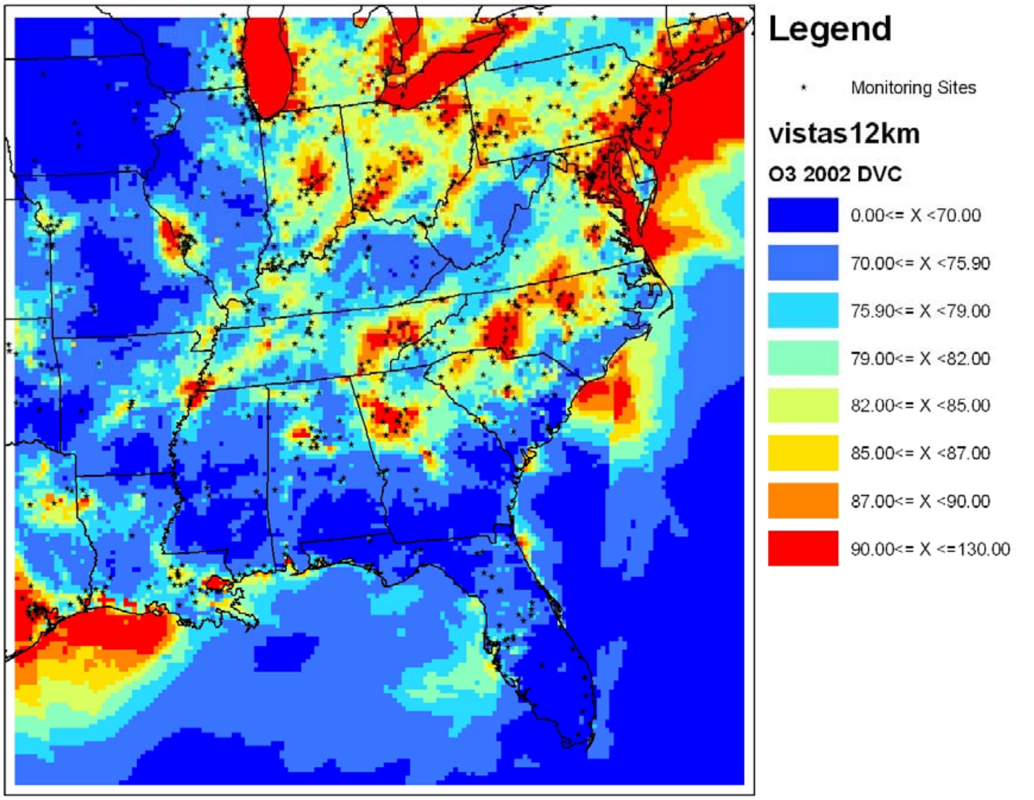

Figure 4-18. Current year interpolated 8-hour ozone Design Values (DVCs) using MATS.

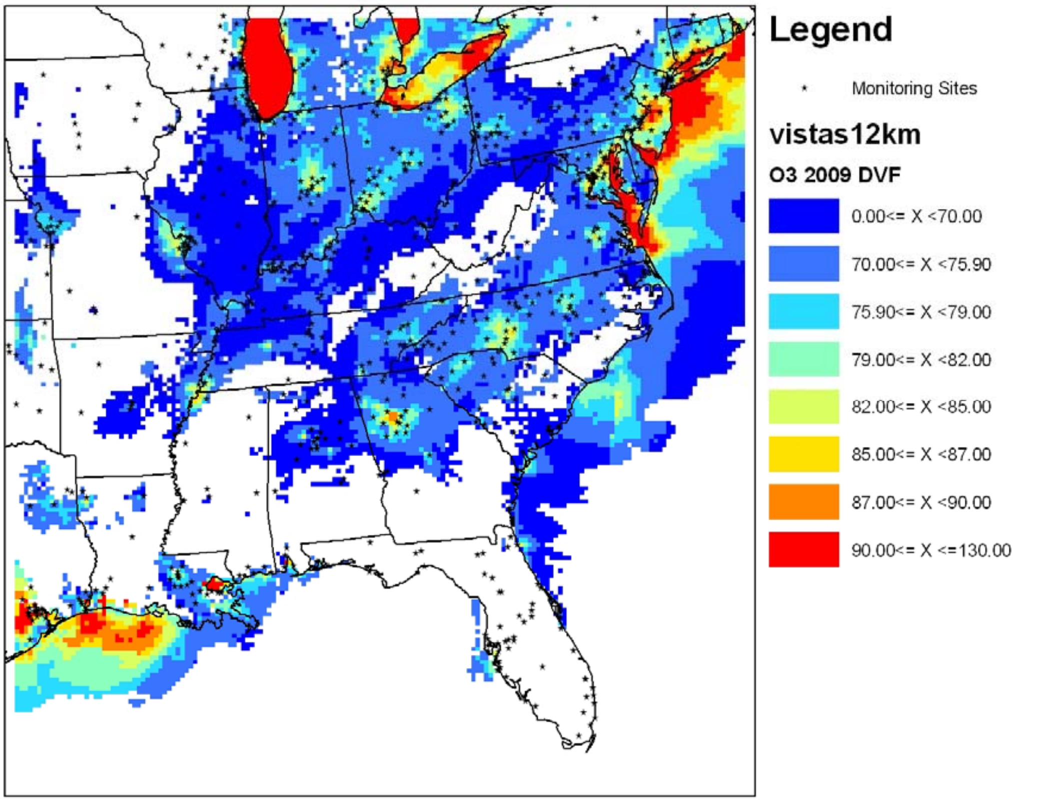

Figure 4-19. Projected 2009 8-hour ozone Design Values (DVFs) using MATS.

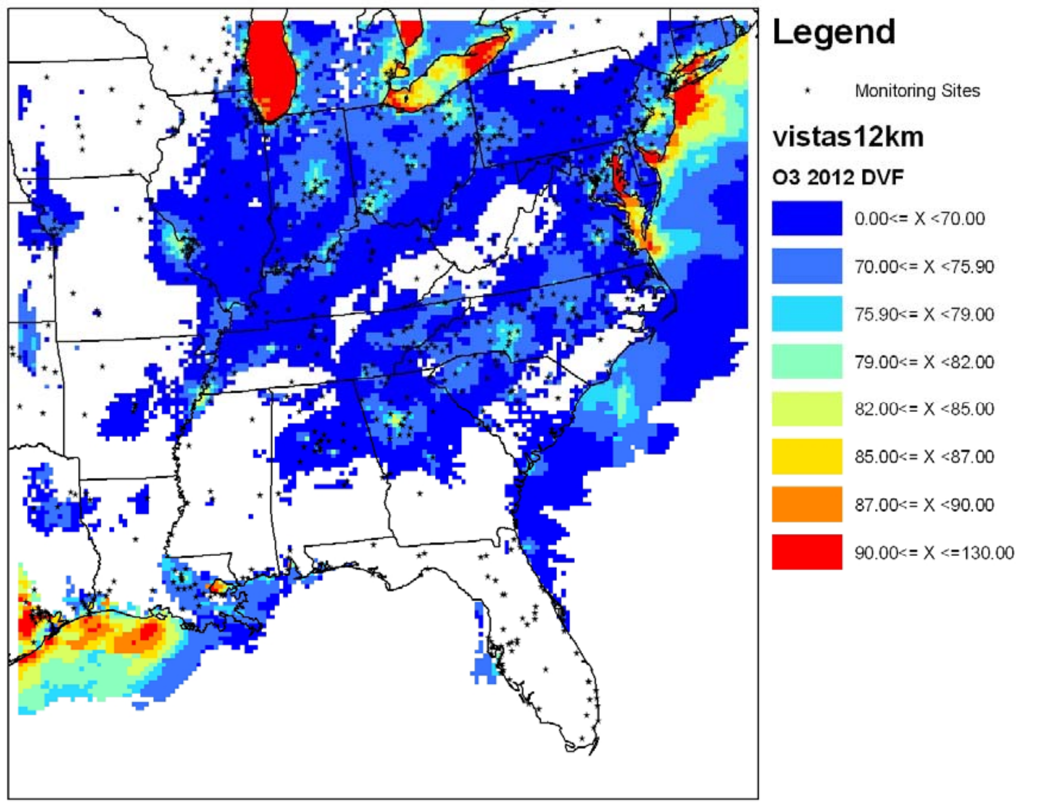

Figure 4-20. Projected 2012 8-hour ozone Design Values (DVFs) using MATS.

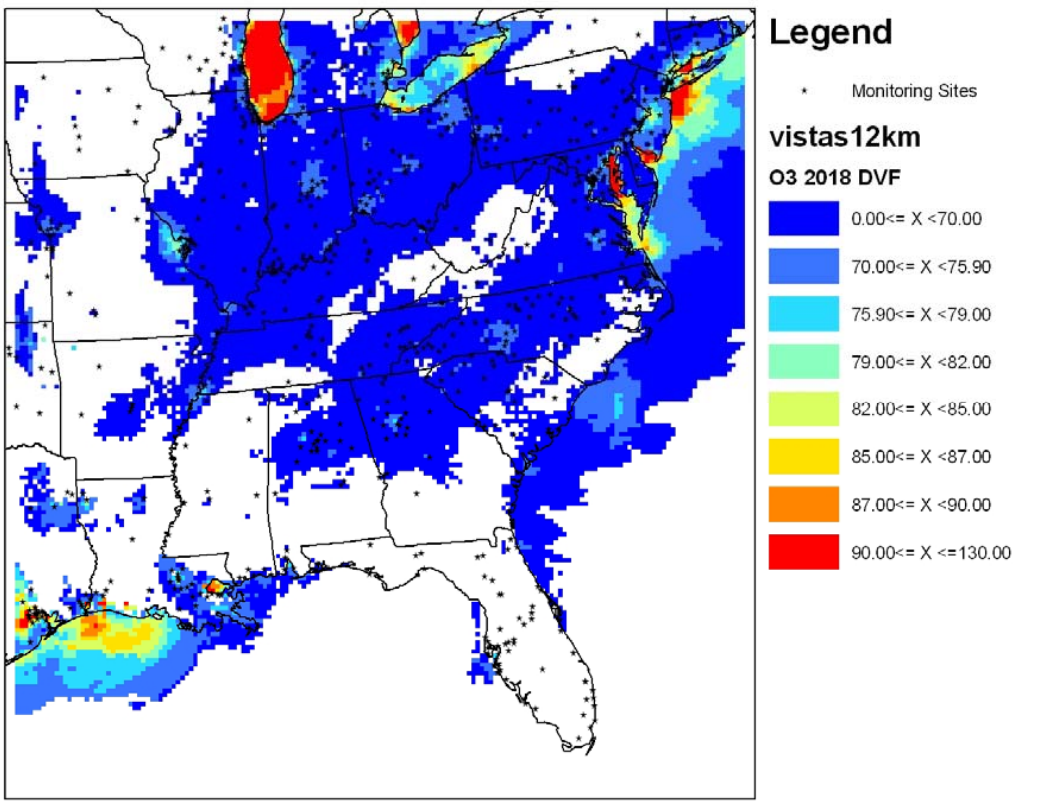

Figure 4-21. Projected 2018 8-hour ozone Design Values (DVFs) using MATS.

Table 4-17. Current (DVC) and future (DVF) year 8-hour ozone Design Values for all monitoring sites in the ASIP 12 km modeling domain.

5.0 ADDITIONAL SUPPORTING $PM_{2.5}$ ANALYSIS

This Chapter presents additional supporting analysis to the modeled future-year $PM_{2.5}$ projections presented in Chapter 4. These analyses may be used, along with additional state-specific analysis, as part of a weight of evidence (WOE) $PM_{2.5}$ attainment demonstration determination. The additional analysis includes the following:

- 2009 $PM_{2.5}$ projections using alternative projection software to EPA's Modeled Attainment Test Software (MATS) with the 2002 Base G2 and 2009 Base G4 CMAQ modeling results;
- 2009 $PM_{2.5}$ projections using an alternative model to CMAQ, the Comprehensive Air-quality Model with extensions (CAMx; ENVIRON, 2008); and
- PM Source Apportionment Technology (PSAT) modeling to estimate the contributions of specific nearby point sources to 2009 $PM_{2.5}$ concentrations in Kentucky, Tennessee, West Virginia and adjacent areas.

5.1 2009 $PM_{2.5}$ PROJECTIONS USING ALTERNATIVE PROJECTION SOFTWARE

EPA has developed a PC-based software tool entitled the Modeled Attainment Test Software (MATS) that includes the FRM $PM_{2.5}$ mass and STN/IMPROVE speciated $PM_{2.5}$ concentrations processed by the SANDWICH method. The Speciated Model Attainment Test (SMAT) presented in EPA's modeling guidance (EPA, 2007a) is codified in MATS. Several beta versions of MATS have been released with the annual $PM_{2.5}$ projection SMAT method first becoming available with the January 2008 release of MATS (Version 1.1.2). For the ASIP modeling performed in the 2006-2007 timeframe, the MATS tool with a $PM_{2.5}$ projection capability was not available. Thus, ASIP developed a $PM_{2.5}$ projection tool. The ASIP $PM_{2.5}$ projection tool is based on 2002 STN PM speciation data that were processed using the SANDWICH procedure (see Chapter 4) and are assigned to nearby FRM sites with the SMAT projection procedure performed using Excel spreadsheets to obtain future-year $PM_{2.5}$ Design Value projections.

Conceptually, the biggest difference between the MATS and ASIP Excel $PM_{2.5}$ projection approaches is how the SANDWICH PM speciation data are mapped to the FRM monitors. As noted above, the ASIP approach assigns SANDWICH STN PM speciation data from a nearby STN monitor to a FRM site so that SMAT can be applied. MATS, on the other hand, interpolates the SANDWICH speciated PM data and the Degree of Neutralization (DON) from the STN and IMPROVE sites to the FRM site to speciate the FRM $PM_{2.5}$ mass. Although how the FRM $PM_{2.5}$ mass is speciated is the biggest conceptual difference between the ASIP spreadsheet and MATS $PM_{2.5}$ projection approaches, in practice we have found several other differences in the two approaches as follows:

- Different methods for assigning SANDWICH PM speciation to FRM sites.
- Differences in the current-year (2000-2004) $PM_{2.5}$ Design Values that serve as the starting point for the projections.

- Differences in the STN SANDWICH speciation data used, including use of STN/IMPROVE data from different years in the ASIP spreadsheet (2002) and MATS (2002-2004) methods.
- Inclusion of Sea Salt in the MATS SANDWICH $PM_{2.5}$ speciation.

Sea Salt was included in the original SANDWICH paper (Frank, 2006a), however it was not included in the SANDWICH discussion in EPA's modeling guidance (EPA, 2007a). As the ASIP spreadsheet projection approach was based on EPA's final modeling guidance, Sea Salt was not included.

Below we compare the 2009 $PM_{2.5}$ Design Value projections using the 2002 Base G2 and 2009 Base G4 12 km CMAQ modeling results and the ASIP spreadsheet and EPA MATS projection tools. These comparisons are made using Version 1.2.1 (January 2008) of MATS, as compared to the latest Version 2.01 version of MATS that was used to make the future-year $PM_{2.5}$ Design Value projections presented in Chapter 4. Although the release notes for the latest publicly released version of MATS only mention updates to the 8-hour ozone and visibility projections, we did notice two changes in the $PM_{2.5}$ projections:

- Some minor changes to the rounding conventions used; and
- The treatment of two $PM_{2.5}$ monitoring sites in Birmingham, Alabama.

Regarding this latter difference, the North Birmingham and Wylam monitoring sites in Birmingham used to be treated as Community Monitoring Zone (CMZ) monitors whereby their $PM_{2.5}$ Design Values would be averaged, which is the way they were treated in MATS v1.2.1. However, this is no longer the case so the latest versions of MATS v1.5.1 was updated to treat them as separate monitoring sites.

5.1.1 Overview Comparison of MATS and ASIP Spreadsheet 2009 $PM_{2.5}$ Projections

Figure 5-1 displays a scatter plot of the 2009 projected $PM_{2.5}$ Design Values (DVFs) at FRM monitors in and nearby the ASIP region using the ASIP Excel spreadsheet and MATS projections methods. In general, there is good agreement between the projected DVFs using the two projection methods (r^2 = 0.982). However, there are some differences in the two methods' DVF projections, with the ASIP method sometimes estimating higher and sometimes lower DVFs than MATS; although it appears the MATS method is usually estimating lower DVFs than the ASIP Excel method. At most sites, the results of the two methods are within 0.1 $\mu g/m^3$ of each other. There are also some outliers with the largest two being sites where the ASIP Excel method estimates ~17.5 and ~14 $\mu g/m^3$ DVFs, whereas the MATS tool estimates ~16.5 and ~12 $\mu g/m^3$ DVFs, respectively.

One reason for the differences in projected DVFs is because the two methods are starting with different current year $PM_{2.5}$ Design Values (DVCs). Figure 5-2 displays a scatter plot of the DVCs in the ASIP Excel and MATS projection tools. Again there is good agreement between the two methods (r^2 = 0.986), but there are differences. It appears that the biggest reason for the differences in the two projected DVFs outliers given in the above paragraph is due to the starting point DVCs. With the exception of a few outliers most of the DVCs in the two methods agree to within a tenth of a $\mu g/m^3$.

Figure 5-3 displays the differences in the 2009 projected minus the current year $PM_{2.5}$ Design Values using the two methods. These differences will be mostly independent of the current year Design Values differences, so provide insight into the implementation of the SMAT and SANDWICH PM speciation in the ASIP Excel and MATS projection methods. Generally, the changes in Design Values (DVF-DVC) using the two methods agree within a few tenths of $\mu g/m^3$. But again, there are some differences.

Finally, to understand the effects in the different SANDWICH speciation data and the effects of the MATS interpolation of the STN/IMPROVE $PM_{2.5}$ speciation to the FRM monitoring site versus the ASIP method to assign an STN speciation, Figure 5-4 displays a comparison of the projected $PM_{2.5}$ Design Values using the two methods at FRM sites with co-located STN monitors. Note that the ASIP Excel spreadsheet tool relies on just 2002 STN data, whereas the MATS tool SANDWICH speciation was developed using three years (2002-2004) of STN and IMPROVE data. The agreement of the DVFs using the two methods at FRM sites with co-located STN data is extremely good and any differences are explained by the starting DVCs. Thus, Figure 5-4 demonstrates that the development of the modeled RRFs from the CMAQ output and the application of the SMAT in the ASIP Excel and MATS tools are the same and any differences in the projections can be completely explained by the differences in SANDWICH $PM_{2.5}$ speciation data and how they are assigned/interpolated to the FRM monitor site and the starting DVCs. It is unclear whether it is more appropriate to assign or interpolate $PM_{2.5}$ speciation data to FRM monitors without STN data and which approach is more valid would have to be evaluated on a case-by-case basis.

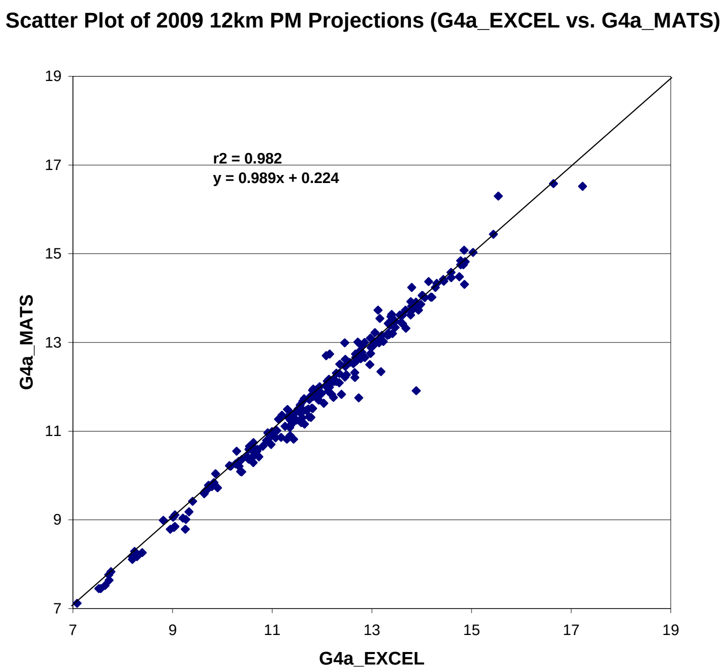

Figure 5-1. Comparison of ASIP Excel versus MATS projected 2009 $PM_{2.5}$ Design Values (DVFs) using the CMAQ 2002 Base G2 and 2009 Base G4 12 km modeling results.

5.1.2 Site-by-Site Comparison of MATS and ASIP Excel DVFs

Table 5-2 displays a tabular summary of the DVCs and DVFs using the ASIP Excel and MATS projection tools and their differences. One of the biggest differences in the two sets of DVFs is at the Birmingham Alabama NBHM (01-073-0023) and WYLM (01-073-2003) FRM monitoring sites; the ASIP approach has DVCs of 18.38 and 17.07 $\mu g/m^3$, respectively, whereas MATS has identical DVCs of 17.71 $\mu g/m^3$ for the two sites. As noted above, this is left over from when these two sites were considered Community Monitoring Zone (CMZ) sites whose results were averaged in the attainment demonstration. However, EPA revoked the CMZ status of these two monitors in 2007. MATS has been updated to treat each of these monitors individually.

Although there are differences in the DVCs and DVFs using these two methods, they are fairly consistent on which areas would attain the $PM_{2.5}$ NAAQS by 2009. The three nonattainment areas projected to continue to violate the $PM_{2.5}$ NAAQS in 2009 using the MATS discussed in Chapter 4 (Birmingham, Atlanta and Cincinnati NAAs), are also projected to be in continued nonattainment in 2009 using the ASIP Excel spreadsheet method. However, there is one site in the Atlanta area (Site No. 13-063-0091 in Clayton County, GA) that was projected to attain (i.e., < 15.05 $\mu g/m^3$) the $PM_{2.5}$ NAAQS using the ASIP Excel spreadsheet method (14.90 $\mu g/m^3$) but is projected to exceed the $PM_{2.5}$ NAAQS using MATS (15.08 $\mu g/m^3$). But the differences between the two projections is very small (0.18 $\mu g/m^3$).

In conclusion, all nonattainment areas (NAAs) that were projected to attain the $PM_{2.5}$ NAAQS by 2009 using the ASIP Excel spreadsheet method were also projected to attain the $PM_{2.5}$ NAAQS using the MATS tool. Conversely, all NAAS that were projected to continue to violate the $PM_{2.5}$ NAAQS in 2009 using the ASIP Excel method were also projected to violate the $PM_{2.5}$ NAAQS using MATS. Thus, despite the small differences in the ASIP Excel and MATS $PM_{2.5}$ projections, they are wholly consistent with each other on which areas are projected to attain and which areas are projected to not attain the $PM_{2.5}$ NAAQS by 2009.

Table 5-1. Comparison of ASIP Excel Spreadsheet and MATS v1.2.1 projection approach current year DVCs and 2009 projected DVFs using the CMAQ 2002 Base G2 and 2009 Base G4 12 km modeling results.

5.2 2009 $PM_{2.5}$ PROJECTIONS USING AN ALTERNATIVE MODEL

ASIP applied the CAMx model for the 2002 annual period using a 12/4 km grid focusing on a portion of the ASIP region. The primary purpose of the ASIP CAMx application was to use its PM Source Apportionment Technology (PSAT) to obtain contributions of specific local sources to the 2009 $PM_{2.5}$ concentrations at nearby $PM_{2.5}$ monitors in and near several northern ASIP States (i.e., KY, TN and WV). In performing the 2002 and 2009 CAMx simulations to analyze local source contributions, projected 2009 $PM_{2.5}$ Design Values were also generated that can be compared with those obtained using the CMAQ modeling discussed in Chapter 4. Thus, below we compare the 2009 $PM_{2.5}$ Design Values projected by CMAQ and CAMx using the 2002 Base G2 and 2009 Base G4 emission scenarios. We also discuss the contributions of the local sources to 2009 $PM_{2.5}$ concentrations. As these two discussions share a common CAMx application, the CAMx application approach is described first.

5.2.1 CAMx Model Application Methodology

The CAMx model was run with a 12/4 km grid configuration (Figure 5-5) for the 2002 annual period and the 2002 Base G2 and 2009 Base G4 emission scenarios. The CAMx 12 km grid covered the upper portion of the ASIP region and adjacent areas. Four 4 km nested-grids were embedded in the 12 km grid domain that covered the following Nonattainment Areas (NAAs) and nearby regions (See Figure 5-5):

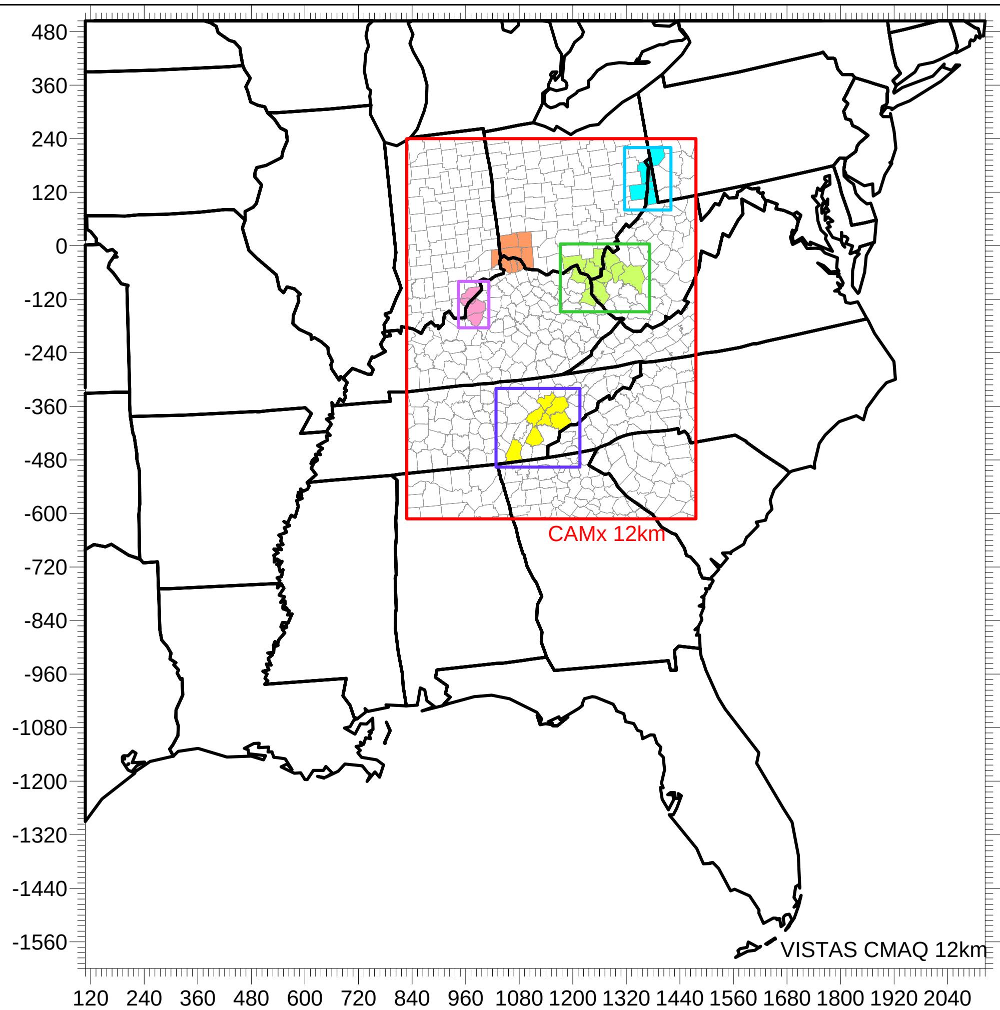
- Knoxville and Chattanooga, TN NAAs;
- Charleston, Ashland and Huntington, WV-OH-KY NAAs;
- Wheeling-Weirton-Steubenville, WV-OH-PA NAAs; and
- Louisville, KY-OH NAA.

The 12 km meteorological inputs were generated using the MM5CAMx processor and the VISTAS 2002 12 km MM5 simulation output (Olerud and Sims, 2004). The meteorological inputs for the 4 km nested grids were obtained using the CAMx flexi-nest feature. That is, the CAMx model internally interpolates the 12 km MM5 meteorological data to the 4 km grids. The CAMx 12/4 km nested-grid structure was run using two-way interactive grid nesting. That is concentrations can transfer both ways between the 12 km and 4 km domain boundaries. This is in contrast to the CMAQ 36/12 km modeling that uses one-way grid nesting where the CMAQ model is run first for the 36 km grid whose results are processed to obtain boundary conditions (BCs) for the 12 km grid domains. Thus, in one-way nesting mass can transfer from the 36 km grid into the 12 km grid but can not transfer from the 12 km grid to the 36 km grid.

The SMOKE emissions model was used to process the 2002 Base G2 emissions inputs to generate a CAMx-style point source stack input file on the CAMx 12 km grid domain. One major difference between the CAMx and CMAQ inputs is for point source emissions; in CMAQ point source plume rise is calculated external to the model and three-dimensional emission inputs are provided (note that the latest version of CMAQ released in fall 2008 has an option of calculating plume rise internal to the model). However, in CAMx, the emission inputs consist of a two-dimensional input of surface emissions (e.g., biogenics, mobile, area, etc.) that are emitted directly into the lowest layer of the model and a stack point source file that includes the stack coordinates, parameters and emissions. In CAMx, plume rise is calculated internal to the model and emissions from the point source are injected into the proper vertical layer. The CAMx two-dimensional low-level emissions were generated using the CMAQ 2002 Base G2 emissions and the CMAQ2CAMx converter. Point source fire emissions were also processed using the CMAQ2CAMx converter. The CAMx model was then run for the 2002 Base G2 emissions scenario on the 12/4 km nested-grid shown in Figure 5-5. Boundary conditions (BCs) for the CAMx 12 km grid were generated by processing the output from the CMAQ 2002 Base G2 12 km model simulation (i.e., one-way grid nesting between the CMAQ 12 km and CAMx 12 km grid domains). The CAMx 12/4 km 2002 Base G2 modeling results were evaluated against available measurements and its model performance compared against CMAQ. The CAMx 2002 model performance evaluation and comparison against the CMAQ performance is presented in Appendix D, with highlights provided in Section 5.2.2 below.

Similarly, the SMOKE emissions model was used to simulate the 2009 Base G4 point sources to generate a CAMx-ready point source stack input file. The remainder of the CAMx emissions inputs for the 2009 Base G4 emissions scenario were generated using the CMAQ2CAMx converter. There were two major update made to the 2009 Base G4 emissions for the CAMx simulation that was different than the CMAQ 2009 Base G4 simulation. The first was an addition of 65,000 tons per year of SO2 at the W. H. Sammis EGU in northern West Virginia. EGU emissions for the 2009 Base G4 emissions scenario were based on a 2010 Integrated Planning Model (IPM) EGU emissions forecast model. As the Sammis plant plans are to install a scrubber for SO2 emissions control between 2009 and 2010, the 2010 SO2 emissions are much lower than they should be in 2009. This difference was determined after the CMAQ 2009 Base G4 base case simulation had been completed. The second major change was the inclusion of SO2 and primary PM emissions for Jefferson County, Kentucky (Louisville) in the CAMx 2002 and 2009 modeling. As discussed in Chapter 2, these emissions were inadvertently left out of the CMAQ 2002 and 2009 modeling because when updated Jefferson County emissions were provided it only included ozone precursor emissions. The CAMx 2009 Base G4 simulation was also configured to apply the PM Source Apportionment Technology (PSAT) to generate separate PM contributions due to 31 individual facilities, which is discussed in Section 5.4.

The CAMx model was applied to the updated 2009 Base G4 emissions scenario to generate the standard model and PSAT source apportionment modeling output. The 2009 Base G4 and 2002 Base G2 CAMx standard model output were processed using the ASIP Excel projection tool to generate projected 2009 $PM_{2.5}$ Design Values that are compared to those generated by the ASIP Excel projections tool using the CMAQ 2002 Base G2 and 2009 Base G4 12 km modeling results.



VISTAS CMAQ 12 km: 168 x 177 (108, -1620) to (2124, 504)
CAMx 12km: 54 x 71 (828, -612) to (1476, 240)

5.2.2 Summary Model Performance Evaluation

The model performance of the CAMx 12/4 km 2002 Base G2 model simulation was compared with CMAQ 12 km modeling results using observational data from the CAMx 12 km modeling domain. Note that the CMAQ 2002 Base G2 base case simulation used actual emissions for EGUs and fires, whereas the CAMx 12/4 km Base G2 base case used typical emissions. The CAMx and CMAQ models were evaluated using the same databases and procedures discussed in Chapter 3 and Appendices B and C, only limited to observations within the CAMx 12 km domain (see Figure 5-5).

Appendix D contains the complete evaluation of the CAMx and CMAQ models and compares their model performance over the CAMx 12 km domain. Below we summarize their model performance for the key species of sulfate (SO4) and $PM_{2.5}$ mass using Bugle Plots. SO4 is a key species because most of the $PM_{2.5}$ reductions between 2002 and 2009 are due to reductions in SO2 emissions, so the SO4 performance is critically important.

Figure 5-6 displays a Bugle Plot of monthly SO4 fractional bias and fractional gross error across sites for the CMAQ and CAMx 2002 base case simulations within the CAMx 12 km modeling domain. The SO4 model performance for both models achieves the model performance goal with CMAQ having a slight underestimation and CAMx having a slight overestimation bias.

The Bugle Plots for total $PM_{2.5}$ mass for the CMAQ and CAMx 2002 base case simulations are shown in Figure 5-7. Again, CAMx estimates slightly higher $PM_{2.5}$ concentrations than CMAQ; however both models achieve the model performance goal for $PM_{2.5}$ across most months and networks and always achieve the model performance criteria. For example, across the IMPROVE network during the winter when lower $PM_{2.5}$ concentrations occur both CMAQ and CAMx overpredict with the CAMx overprediction severe enough to fall between the model performance goal and criteria. However, in the summer, when there are higher $PM_{2.5}$ concentrations, the CMAQ model underprediction tendency falls between the model performance goal and criteria, whereas CAMx achieves the performance goal.

Even with these differences, the model performance for the two models is comparable with both models achieving the model performance goals most of the time.

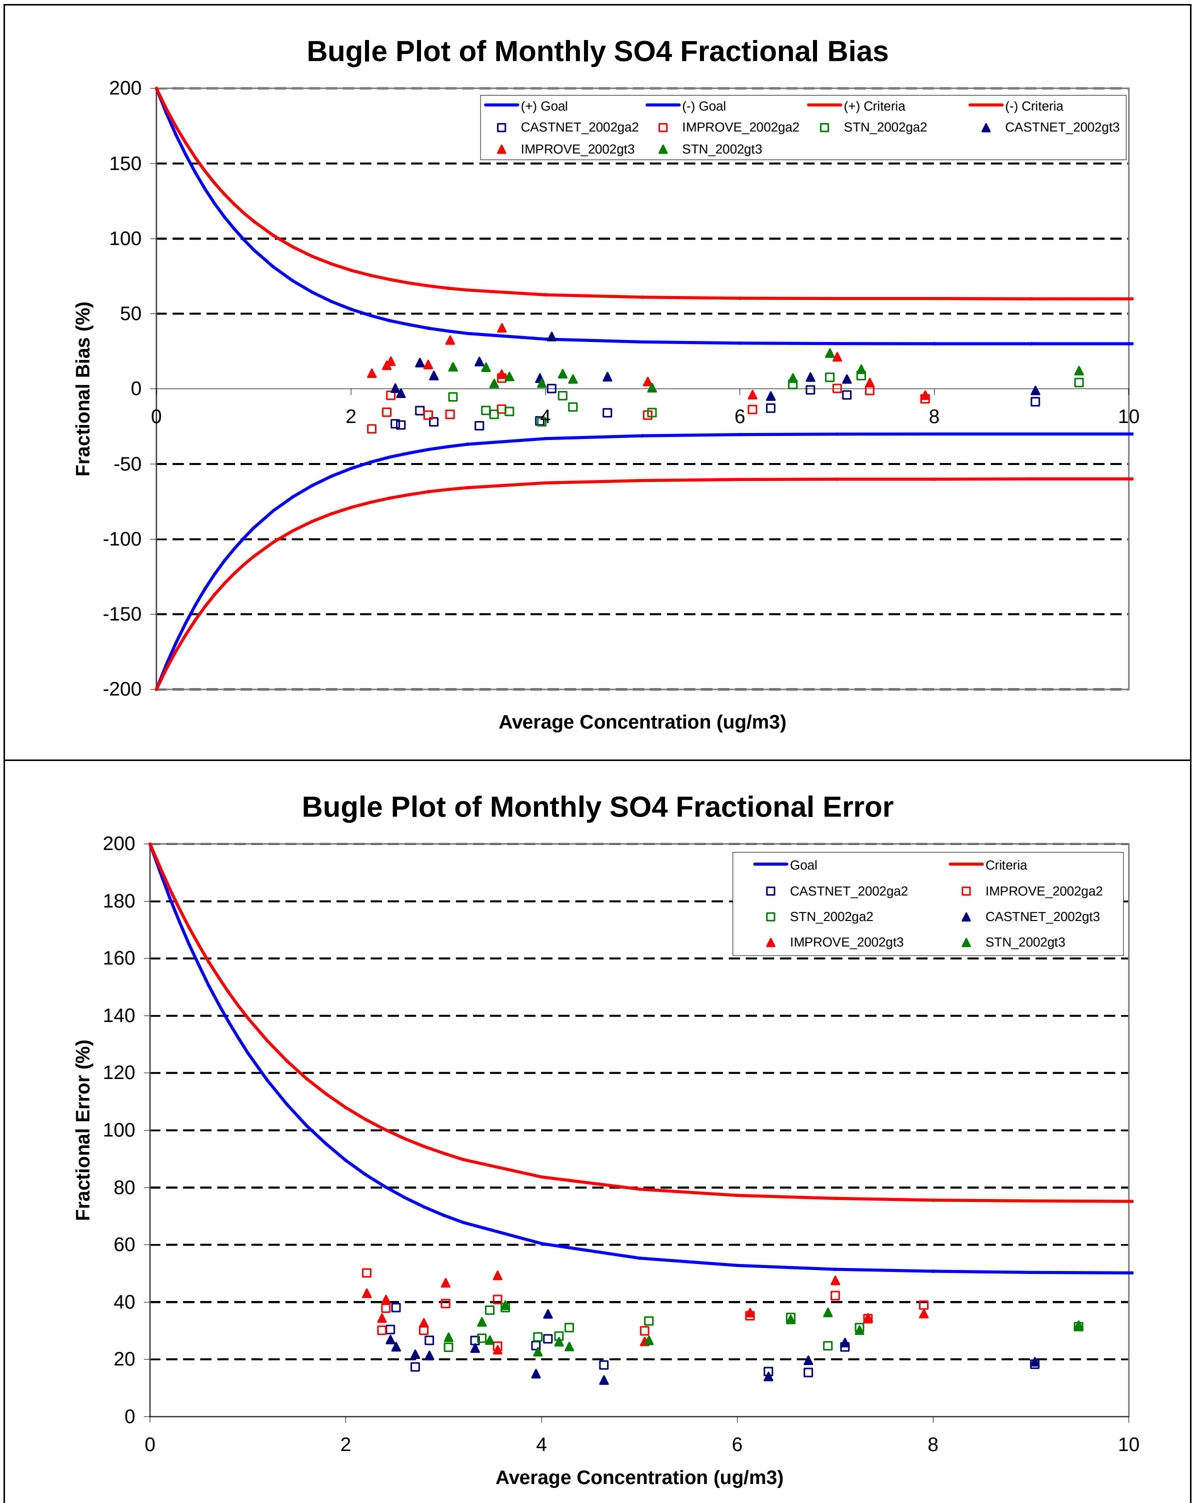

Figure 5-6. Bugle Plots of monthly fractional bias (top) and fractional error (bottom) for SO4 and comparison with model performance goals and criteria for the 2002 CMAQ Base.G2 Actual (open symbols) and CAMx Base G2 Typical (filled symbols) base case simulation.

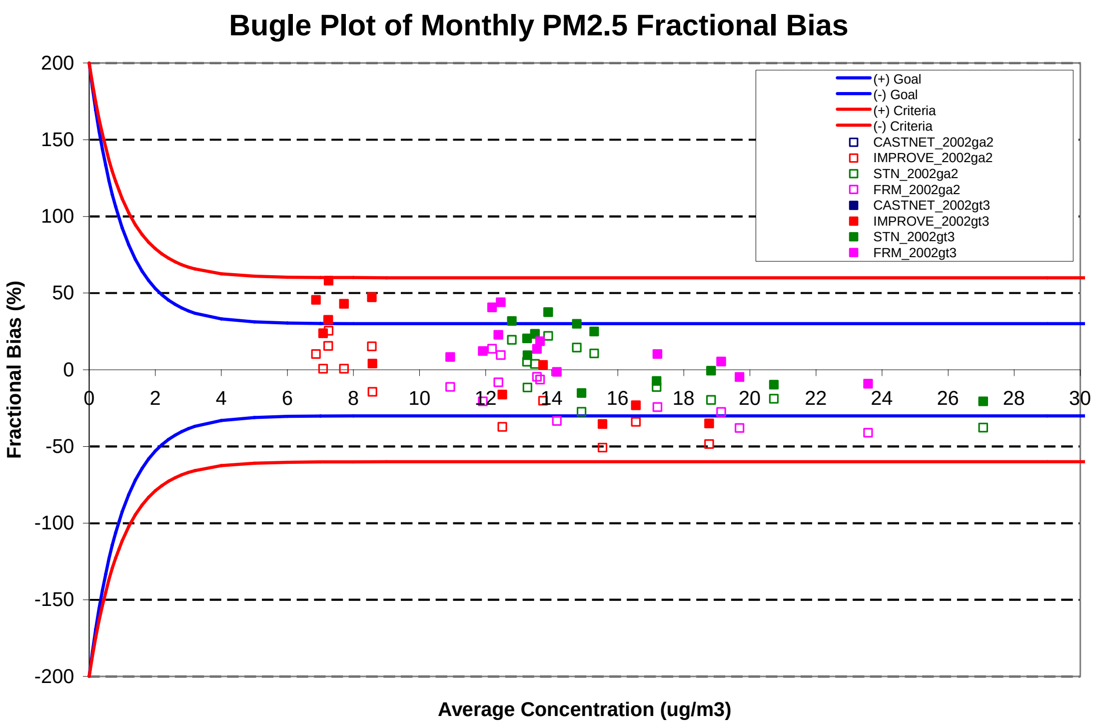

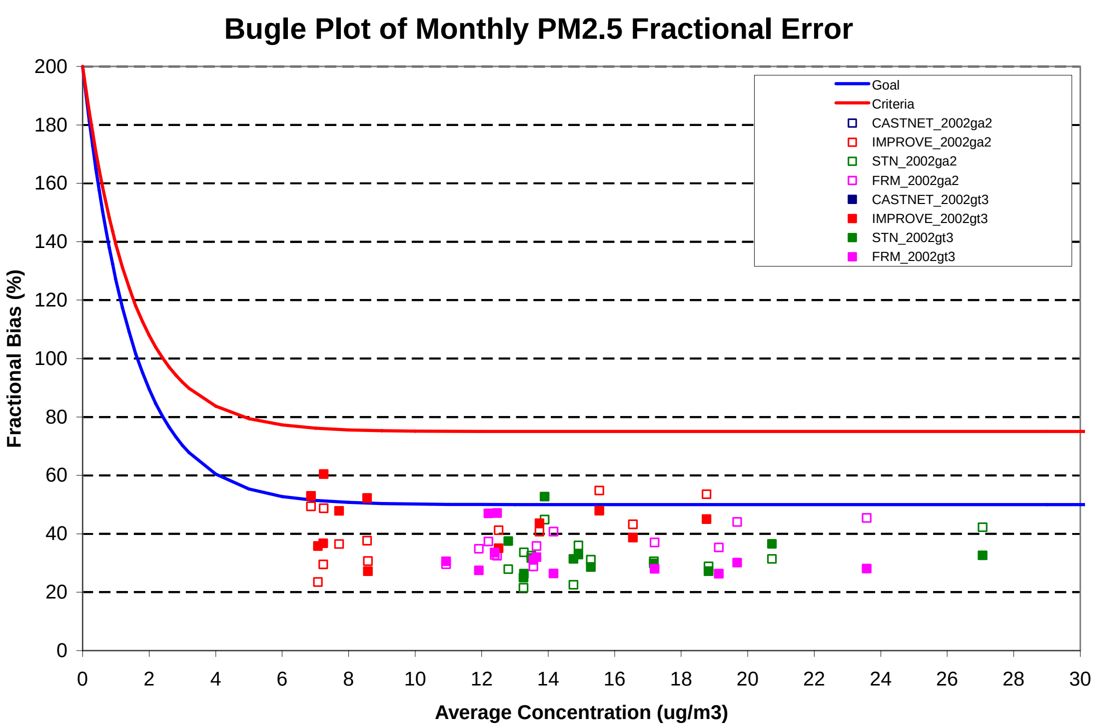

Figure 5-7. Bugle Plots of monthly fractional bias (top) and fractional error (bottom) for $PM_{2.5}$ mass and compared with model performance goals and criteria for the 2002 CMAQ Base.G2 Actual (open symbols) and CAMx Base G2 Typical (filled symbols) base case simulation.

Comparison of CMAQ and CAMx Projected 2009 $PM_{2.5}$ Design Values

Figure 5-8 and Table 5-2 compare the projected 2009 $PM_{2.5}$ Design Values using the CMAQ and CAMx 12 km modeling results for FRM sites within the CAMx 12 km grid domain (Figure 5-5). In general, CAMx estimates slightly higher projected 2009 $PM_{2.5}$ Design Values than CMAQ (i.e., there are less $PM_{2.5}$ reduction). In fact, there are five FRM sites that are estimated to attain the $PM_{2.5}$ NAAQS using the CMAQ modeling results that are above the NAAQS using the CAMx results, two in the Cincinnati NAA (in addition to the FRM site that both models estimate violate the annual $PM_{2.5}$ NAAQS in 2009) and three in the Louisville NAA. Although these differences have not been studied in detail, there are several reasons why the CAMx 2009 $PM_{2.5}$ projections are higher than CMAQ:

- The CAMx 2009 Base G4 run had an additional 65,000 tons per year of SO2 emissions from the Sammis EGU than the CMAQ 2009 Base G4 simulation;
- The CAMx 2002 and 2009 base case simulations included area source SO2 and PM emissions for Jefferson County Kentucky that were left out of the CMAQ modeling.
- The CAMx produces more SOA due to biogenic sources so that the changes in OCM between 2002 and 2009 in response to changes in anthropogenic OC emissions are less responsive in CAMx;
- The RRFs for almost all PM species appear to be higher in CAMx that CMAQ;
- CAMx was run on 12/4 km domains using two-way grid nesting where CMAQ was just run on a 12 km domain; and
- There are numerous model formulation issues in the two models including plume rise, transport, deposition, chemistry, etc.

The higher (i.e., closer to 1.0) RRFs in CAMx for most species is extremely small and likely not significant. The exception to this appears to be the SO4 and OCM RRFs, which is likely related in part to the higher SO2 emissions in the CAMx run and more biogenic SOA in CAMx than in the CMAQ 2009 Base G4 simulations.

With the exception of the Louisville NAA, the CAMx and CMAQ agree on which NAAs would attain and which NAAs are projected to continue to violate the annual $PM_{2.5}$ NAAQs in 2009. For the Louisville NAA, CAMx estimates projected 2009 $PM_{2.5}$ DVFs that are ~ 0.3 $\mu g/m^3$ higher than CMAQ so that they are >15.05 $\mu g/m^3$. As noted above, this is likely partly due to the inclusion of area source SO2 and PM emissions from Jefferson County, Kentucky in the CAMx runs that are projected to increase from 2002 to 2009. The Bar Charts of Jefferson County, Kentucky 2009 DVFs in Figure 5-8a indicate that the higher CAMx DVFs is mainly due to higher OCM contributions. Whether this higher OCM contribution is due to the inclusion of area source OCM emissions in Jefferson County or higher OCM contributions from biogenic VOCs is unclear. In any event, the projected $PM_{2.5}$ DVFs in the Louisville NAA by both the CMAQ and CAMx models are within the range where EPA guidance requires additional supporting WOE analysis based on both model projections.

The closeness of the projected 2009 $PM_{2.5}$ Design Values generated by the CMAQ and CAMx models and the agreement on which NAAs are projected to achieve $PM_{2.5}$ attainment in 2009 provides more confidence in the reliability of the 2009 $PM_{2.5}$ projections based on the CMAQ modeling presented in Chapter 4.

Table 5-2. Comparison of CMAQ and CAMx projected 2009 $PM_{2.5}$ Design Values at common FRM monitoring sites in the CAMx 12 km domain using CAMx and CMAQ 12 km modeling results and 2009 Base G4 emissions.

5.3 PSAT PM SOURCE APPORTIONMENT MODELING

As noted in Section 5.2.1, CAMx was used with its PSAT PM source apportionment option to generate the separate contributions of 31 facilities to projected 2009 $PM_{2.5}$ Design Values in the CAMx 12/4 km domain (Figure 5-5). PSAT was configured to obtain the separate SO4 and primary PM contributions of 31 different facilities in the CAMx 12/4 km modeling domain. The NO3/NH4 and SOA components of the PSAT PM source apportionment approach were not used because NO3 is an extremely small component of annual $PM_{2.5}$ levels in the ASIP region and SOA is dominated by biogenic emission sources; the facilities selected also have very small VOC emissions and consequently insignificant contribution to SOA. The formulation of the PSAT and testing and evaluation can be found in the CAMx user's guide (ENVIRON, 2008) and technical papers that are available on the CAMx website (www.camx.com). The emissions for these 31 facilities are given in Table 5-3. These 31 facilities totaled approximately 425,000 tons per year of SO2 emissions and 18,000 tons per year of $PM_{2.5}$ emissions. PSAT was used to estimate the contributions of the 31 PSAT facilities to the projected 2009 $PM_{2.5}$ Design Values at FRM monitors within each of the 4 km domains. The PSAT results are presented for each group of FRM monitoring sites within each of the four 4 km modeling domains (Figure 5-5).

Table 5-3. 31 separate facilities that PSAT SO4 and Primary PM source apportion were modeled using the CAMx model.

5.3.1 Charleston-Huntington-Ashland, WV-KY-OH 4 km Domain

Figure 5-9 displays the Charleston-Huntington-Ashland 4 km modeling domain, the locations of the facilities treated by PSAT and the locations of the FRM monitoring sites in the region. Figure 5-10 displays the contribution of SO2 and primary PM emissions from the 31 PSAT facilities (Table 5-3), the remainder sources in the CAMx 12/4 km domain (Figure 5-5) and BCs on the CAMx 12 km domain to the SO4 plus primary PM components of the projected 2009 $PM_{2.5}$ Design Values in the Charleston - Huntington - Ashland domain. The contributions of the BCs and other sources in the CAMx modeling domain dominate the 2009 PM contributions. Thus, in Figure 5-11 we display stacked bar charts that focuses on the contributions of the 31 PSAT sources to the SO4 and primary PM components of the 2009 $PM_{2.5}$ Design Values projected for the FRM monitors in the 4 km domain. The top panel in Figure 5-11 displays each facilities contribution to the total SO4 plus primary PM emissions component of the projected 2009 $PM_{2.5}$ Design Values, whereas the bottom two panels show the separate contributions for SO4 and primary PM components. Also shown in the top panel of Figure 5-11 are the CAMx projected $PM_{2.5}$ Design Values using the 4 km CAMx results at the top of each stacked bar. These CAMx 4 km projections may be slightly different that the projections using the CAMx 12 km results that were compared to the CMAQ 12 km projections given in Table 5-2. The total contribution due to all of the 31 PSAT sources to the 2009 $PM_{2.5}$ Design Values in the Charleston - Huntington - Ashland 4 km domain ranged from 0.5 to 2.5 µg/m^3.

The largest single facility contribution was 2.1 µg/m^3 from the Ak Steel facility for the FRM monitor in Lawrence County, Ohio. The 2.1 µg/m^3 contribution from Ak Steel to the Lawrence County monitor is about evenly split between primary PM (52%) and SO2 (48%) precursors. However, care should be taken in the interpretation of the Ak Steel facility's impact on the OH Lawrence County monitor because it appears to be located in the same 4 km grid cell as the monitor (see Figure 5-9). Emissions from a source that is located in the same grid cell as a monitor would impact the monitor even if the monitor was upwind of the facility, since when emissions injected in a grid cell they are instantly diffused across the grid cell. More refined analysis using a higher resolution grid or local-scale model may be needed to simulate the impacts of sources that this close to the monitoring site.

The next highest single facility contributor to the projected 2009 $PM_{2.5}$ Design Value at any monitor in the Charleston-Huntington-Ashland 4 km domain is the Swva, Inc. facility that contributes 0.6 µg/m^3 to the Cabell County, West Virginia FRM monitor. Again the contribution due to primary PM and SO4 is about the same. The next two highest facility contributors are the Ak Steel and Union Carbide (Dow) sources that contribute ~0.17 µg/m^3 to the Boyd County, Kentucky and Kanawha County, West Virginia FRM monitors, respectively.

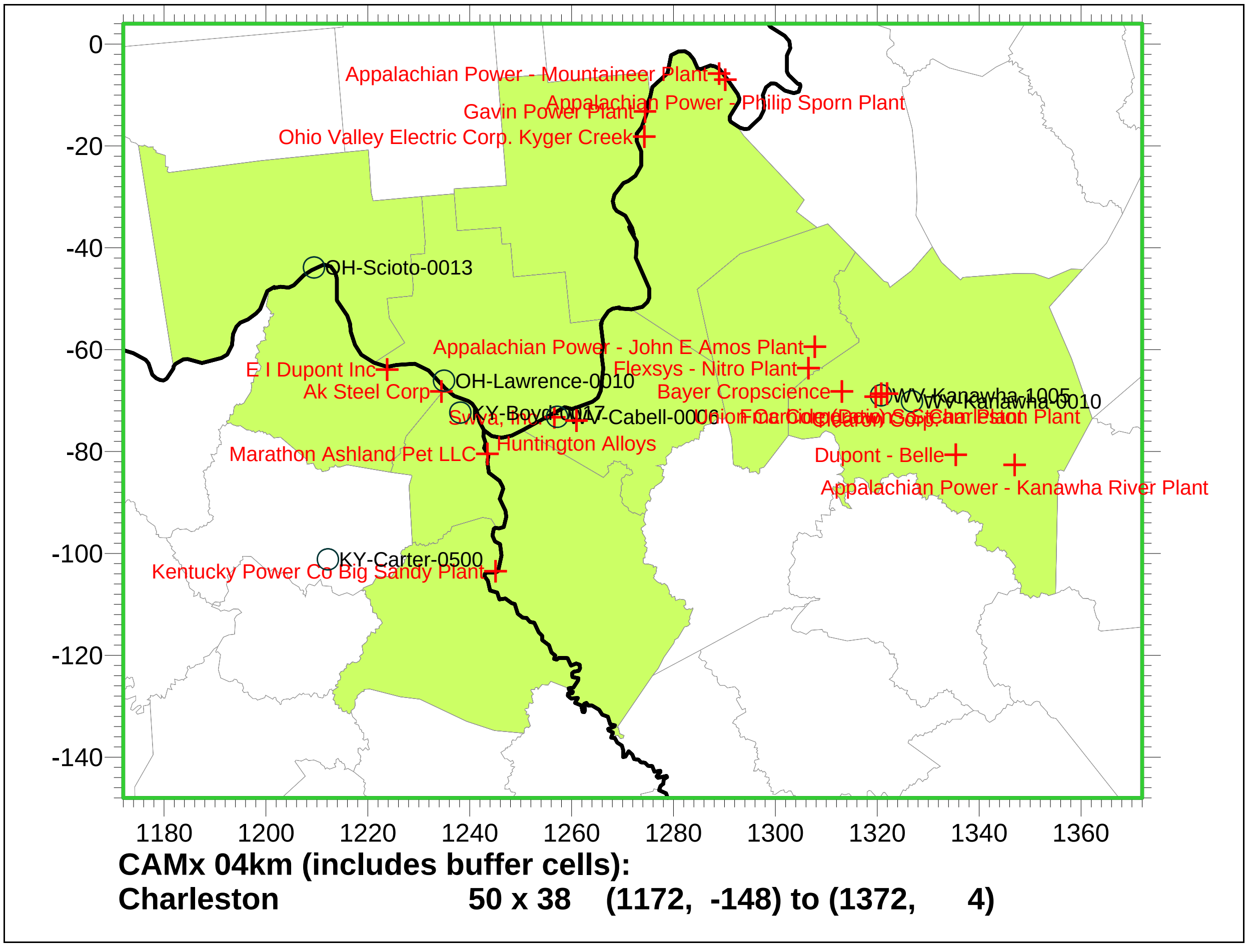

Figure 5-9. Charleston-Huntington-Ashland 4 km domain and locations of FRM monitors (black circles) and facilities treated by PSAT PM source apportionment (red crosses).

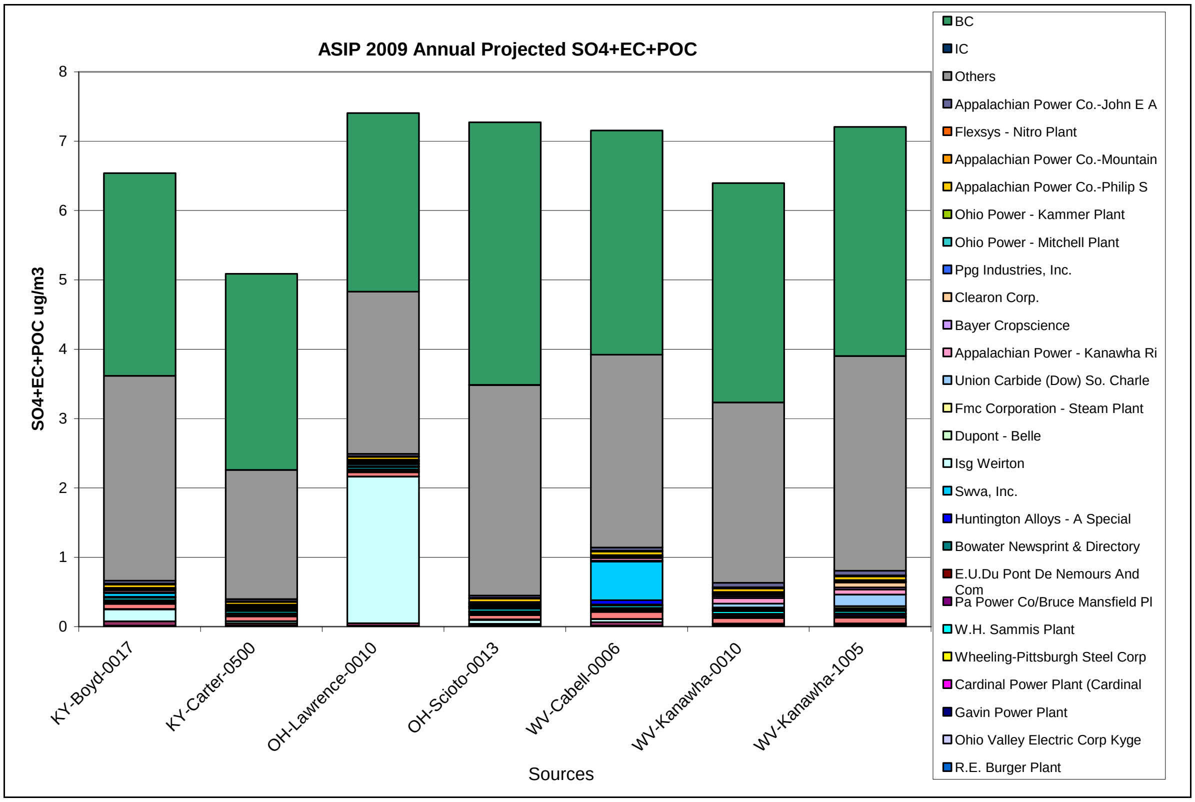

Figure 5-10. PSAT annual 2009 $PM_{2.5}$ source apportionment from 31 PSAT facilities plus all other sources in CAMx 12/4 km domain and BCs for the Charleston-Huntington-Ashland 4 km domain and total $PM_{2.5}$ mass due to SO4 and primary PM emissions.

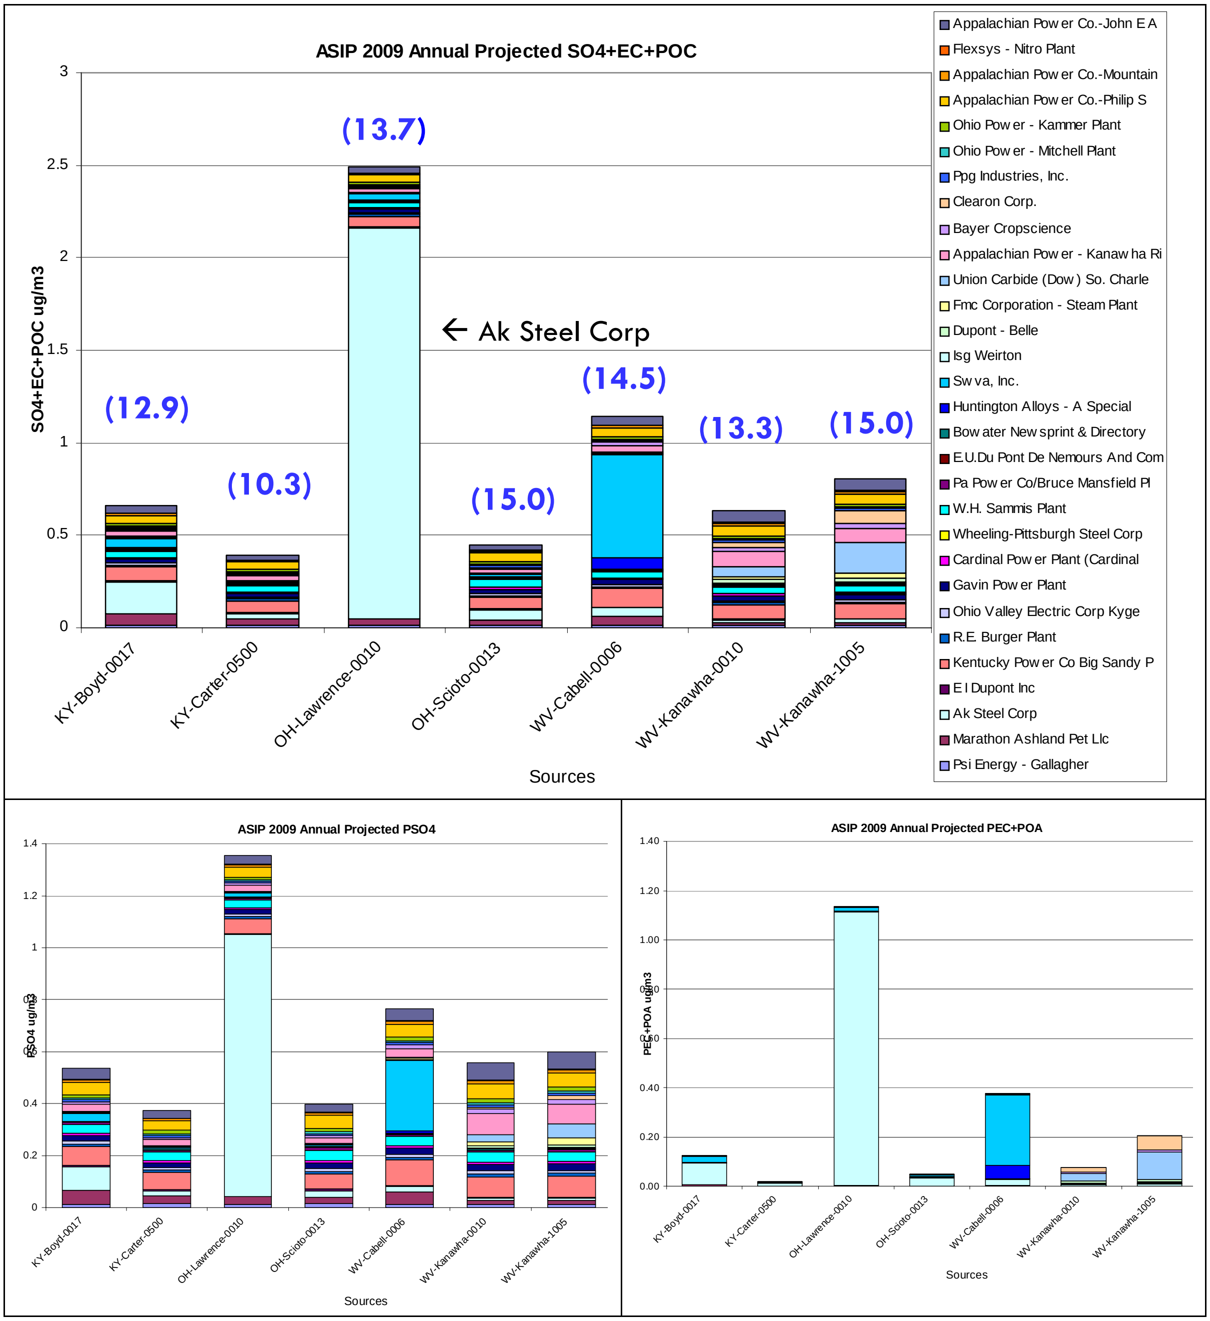

Figure 5-11. PSAT annual 2009 $PM_{2.5}$ source apportionment from 31 PSAT facilities for the Charleston-Huntington-Ashland 4 km domain and total $PM_{2.5}$ mass due to SO4 and primary PM emissions (top) and separately by SO4 (bottom left) and primary PM (bottom right).

5.3.2 Wheeling-Weirton-Steubenville 4 km Domain

Figure 5-12 displays the locations of the PSAT facilities and FRM monitors in the Wheeling-Weirton-Steubenville 4 km domain. The $PM_{2.5}$ contributions to the projected 2009 $PM_{2.5}$ Design Values from the 31 PSAT facilities are shown in Figure 5-13. The Isg Weirton source has the largest contribution of any facility in this 4 km domain contributing 1.4 and 1.1 µg/m^3 to the projected 2009 $PM_{2.5}$ Design Values at the, respectively, Hancock County, West Virginia FRM monitoring sites numbered 1004 and 0011. A vast majority of this contribution (80-90%) is due to primary PM emissions from the Isg Weirton facility (Figure 5-13, bottom right). The next largest contributing source in this domain is the Wheeling Pittsburgh Steel facility that contributes 0.7 µg/m^3 to the Brooke County, West Virginia FRM monitoring site, as well as 0.20-0.24 µg/m^3 to the two Hancock County, West Virginia monitoring sites. The $PM_{2.5}$ contributions from the Wheeling-Pittsburgh Steel facility are more evenly split between primary PM and SO4 (60% due to primary PM). Both of these facilities are in close proximity to the monitors where they have the highest contributions. Given that these facilities have modest emissions compared to many of the other 31 PSAT facilities (see Table 5-3), clearly a source's proximity to an FRM monitor is as important a factor to its contribution as its emissions strength.

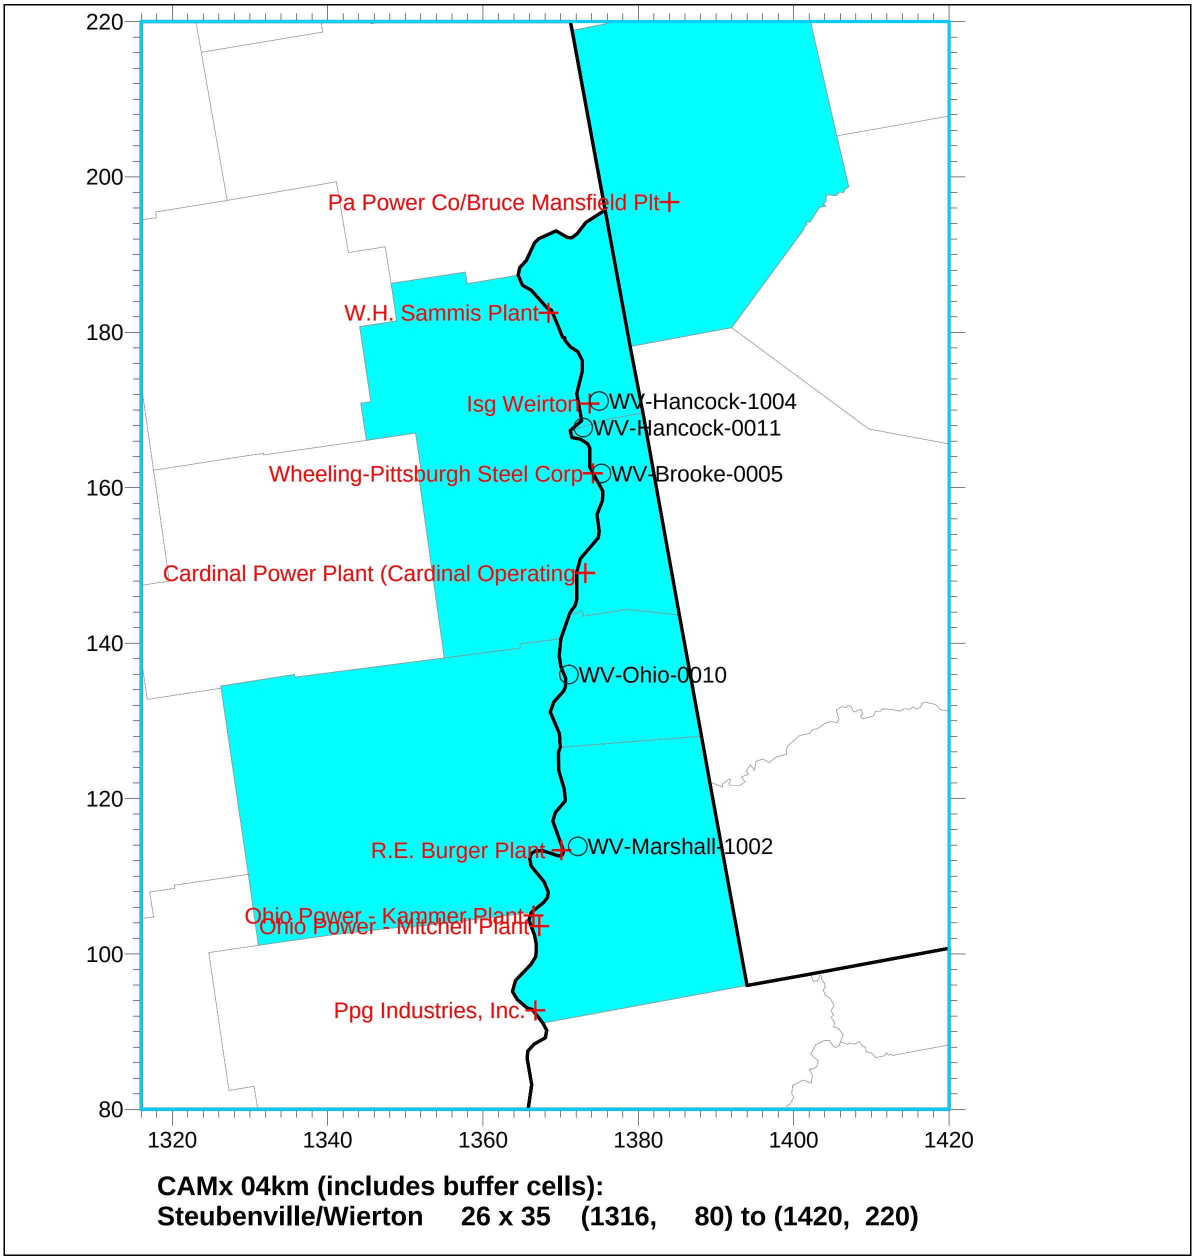

Figure 5-12. Wheeling-Weirton-Steubenville 4 km domain and locations of FRM monitors (black circles) and facilities treated by PSAT PM source apportionment (red crosses).

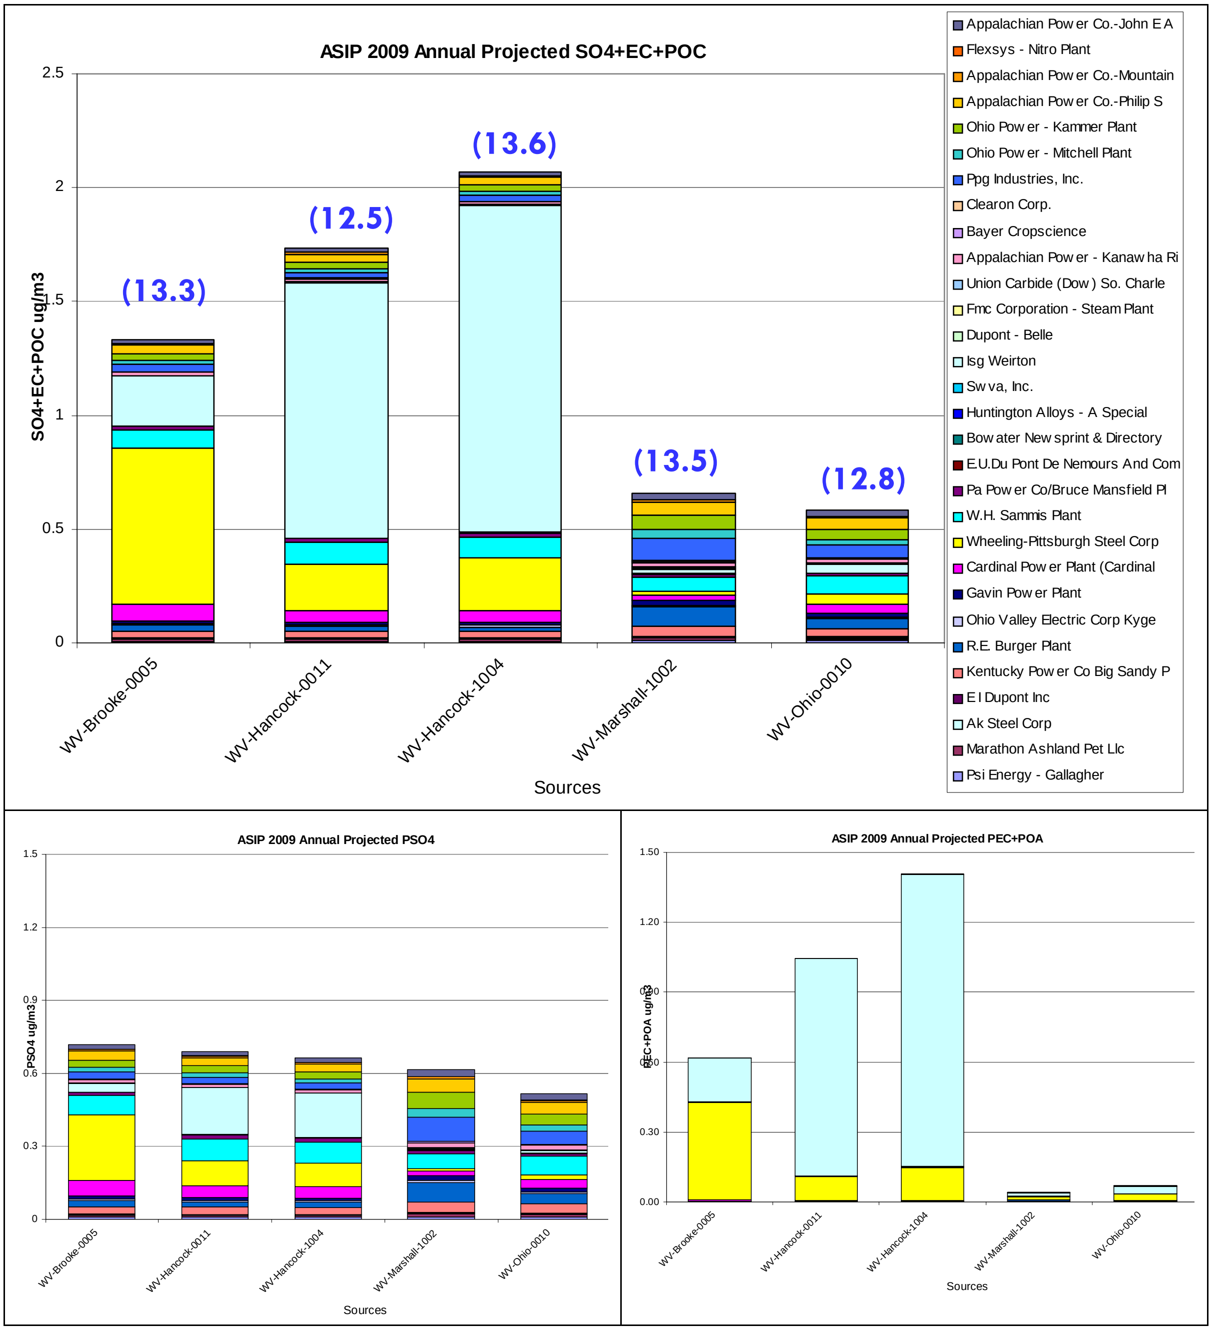

Figure 5-13. PSAT annual 2009 $PM_{2.5}$ source apportionment from 31 PSAT facilities for the Wheeling-Weirton-Steubenville 4 km domain and total $PM_{2.5}$ mass due to SO4 and primary PM emissions (top) and separately by SO4 (bottom left) and primary PM (bottom right).

5.3.3 Louisville 4 km Domain

Figure 5-14 displays the Louisville 4 km domain, the FRM monitors and the single source modeled by PSAT in the domain. The contributions of the 31 PSAT facilities to the projected 2009 $PM_{2.5}$ Design Values are shown in Figure 5-15. Note that the scale of the 31 PSAT source $PM_{2.5}$ contributions for the Louisville 4 km domain in Figure 5-15 is an order of magnitude lower than used for the Charleston-Huntington-Ashland (Figure 5-11) and Wheeling-Weirton-Steubenville (Figure 5-13) 31 source PSAT contributions reflecting the fact that, with the exception of PSI Energy Gallagher EGU, the remainder of the 31 PSAT facilities are farther away from the Louisville NAA. Given that it is the only one of the 31 facilities located in the Louisville 4 km domain it is not surprising that the PSI Gallagher facility is the largest contributor with $PM_{2.5}$ contributions of 0.05 to 0.20 $\mu g/m^3$ to the projected 2009 $PM_{2.5}$ Design Values at FRM monitors in the Louisville NAA. Because of the scale used in Figure 5-15, it appears some of the other sources may be contributing substantial amounts to the projected $PM_{2.5}$ Design Values at the Louisville monitors, but in reality their contributions are quite small. For example, the Kentucky Power Big Sandy EGU contribution (red stacked bar in Figure 5-15) is only 0.01 to 0.02 $\mu g/m^3$.

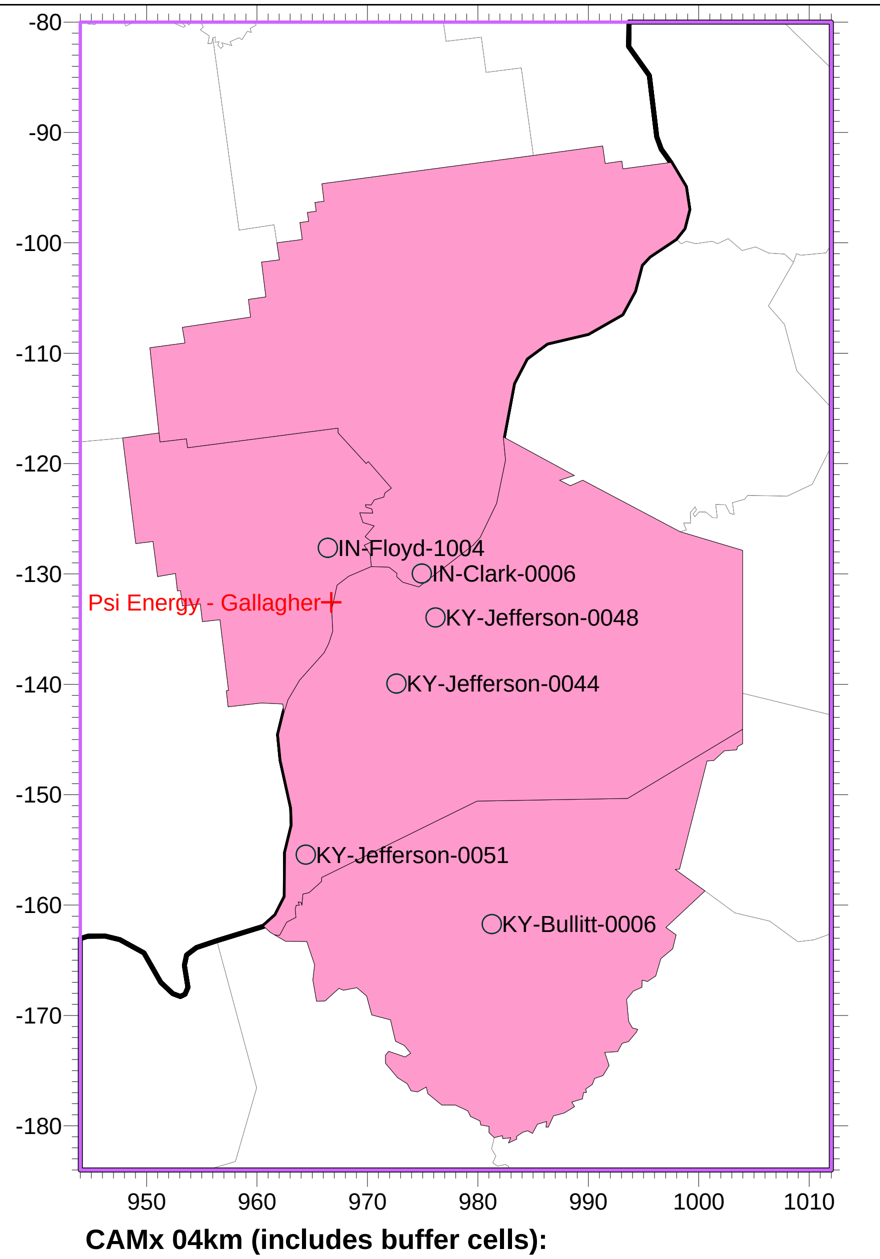

Figure 5-14. Louisville 4 km domain and locations of FRM monitors (black circles) and facilities treated by PSAT PM source apportionment (red crosses).

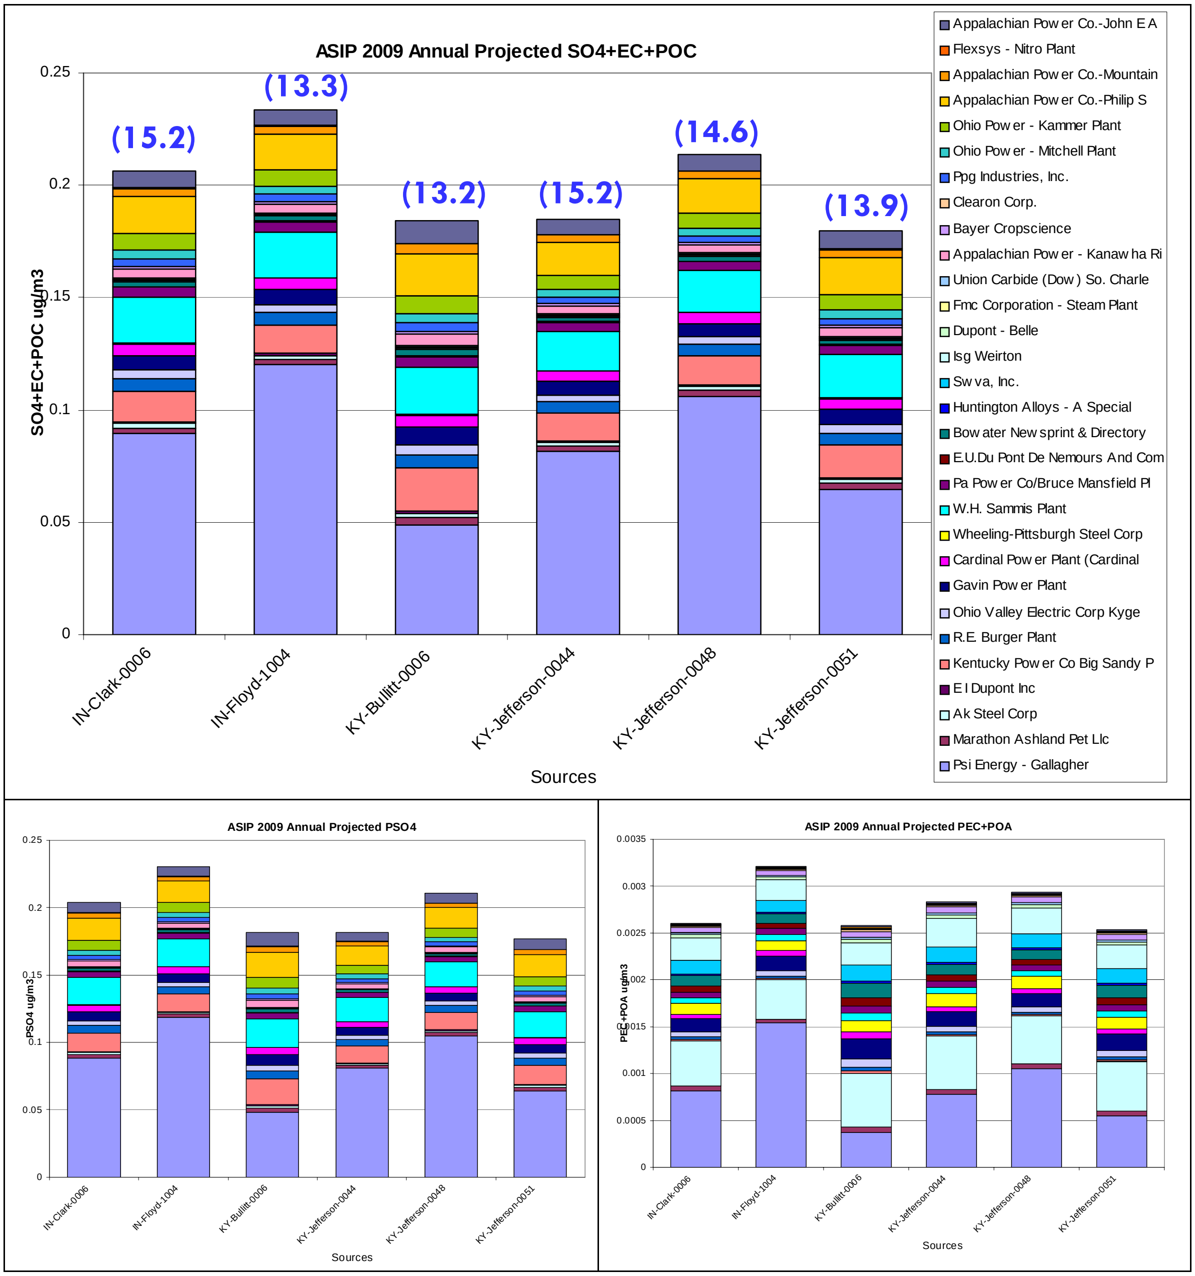

Figure 5-15. PSAT annual 2009 $PM_{2.5}$ source apportionment from 31 PSAT facilities for the Louisville 4 km domain and total $PM_{2.5}$ mass due to SO4 and primary PM emissions (top) and separately by SO4 (bottom left) and primary PM (bottom right).

5.3.4 Knoxville-Chattanooga 4 km Domain

Figure 5-16 displays the Knoxville-Chattanooga 4 km domain along with the FRM monitors therein and the two PSAT sources in the domain: Bowater and E. I. Du Pont. The largest contribution of any facility is 0.08 µg/m^3 that is due to the Bowater facility at the McMinn County, Tennessee FRM monitor (Figure 5-17). The next highest contributing facility is the E.I du Pont plant that contributes 0.05 µg/m^3 to the projected 2009 $PM_{2.5}$ Design Value at the Hamilton County, Tennessee 1011 monitoring site. Despite the fact that it is located fairly far away in the Charleston - Huntington - Ashland 4 km domain, the Kentucky Power Big Sandy EGU also has a relatively higher contribution (0.02-0.03 µg/m^3) to FRM monitors in the Knoxville 4 km domain, however, this contribution is small. This is undoubtedly due to its high SO2 emissions (~50,000 TPY) that are a factor of 10 greater than any of the local sources. As discussed for the Louisville 31 PSAT source contributions, the scale in the Knoxville-Chattanooga 4 km domain 31 PSAT source contributions is approximately an order magnitude lower than used for the Charleston-Huntington-Ashland and Wheeling-Weirton-Steubenville 4 km domain contributions.

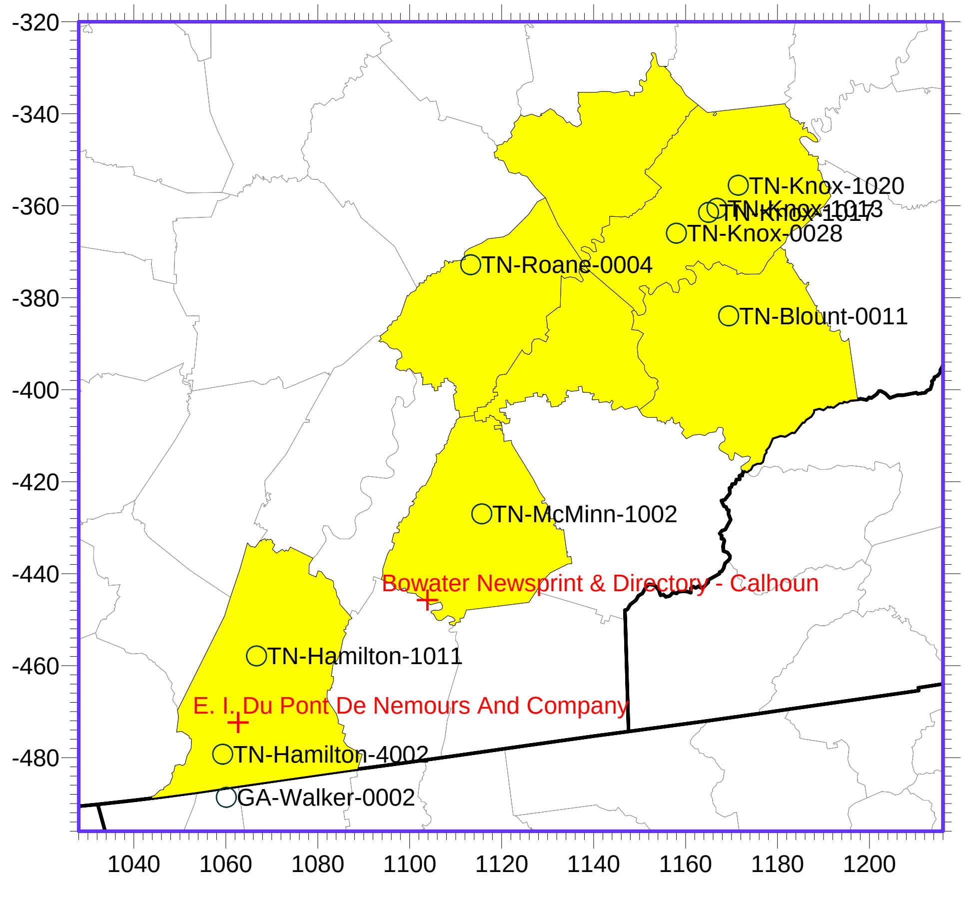

Figure 5-16. Knoxville-Chattanooga 4 km domain and locations of FRM monitors (black circles) and facilities treated by PSAT PM source apportionment (red crosses).

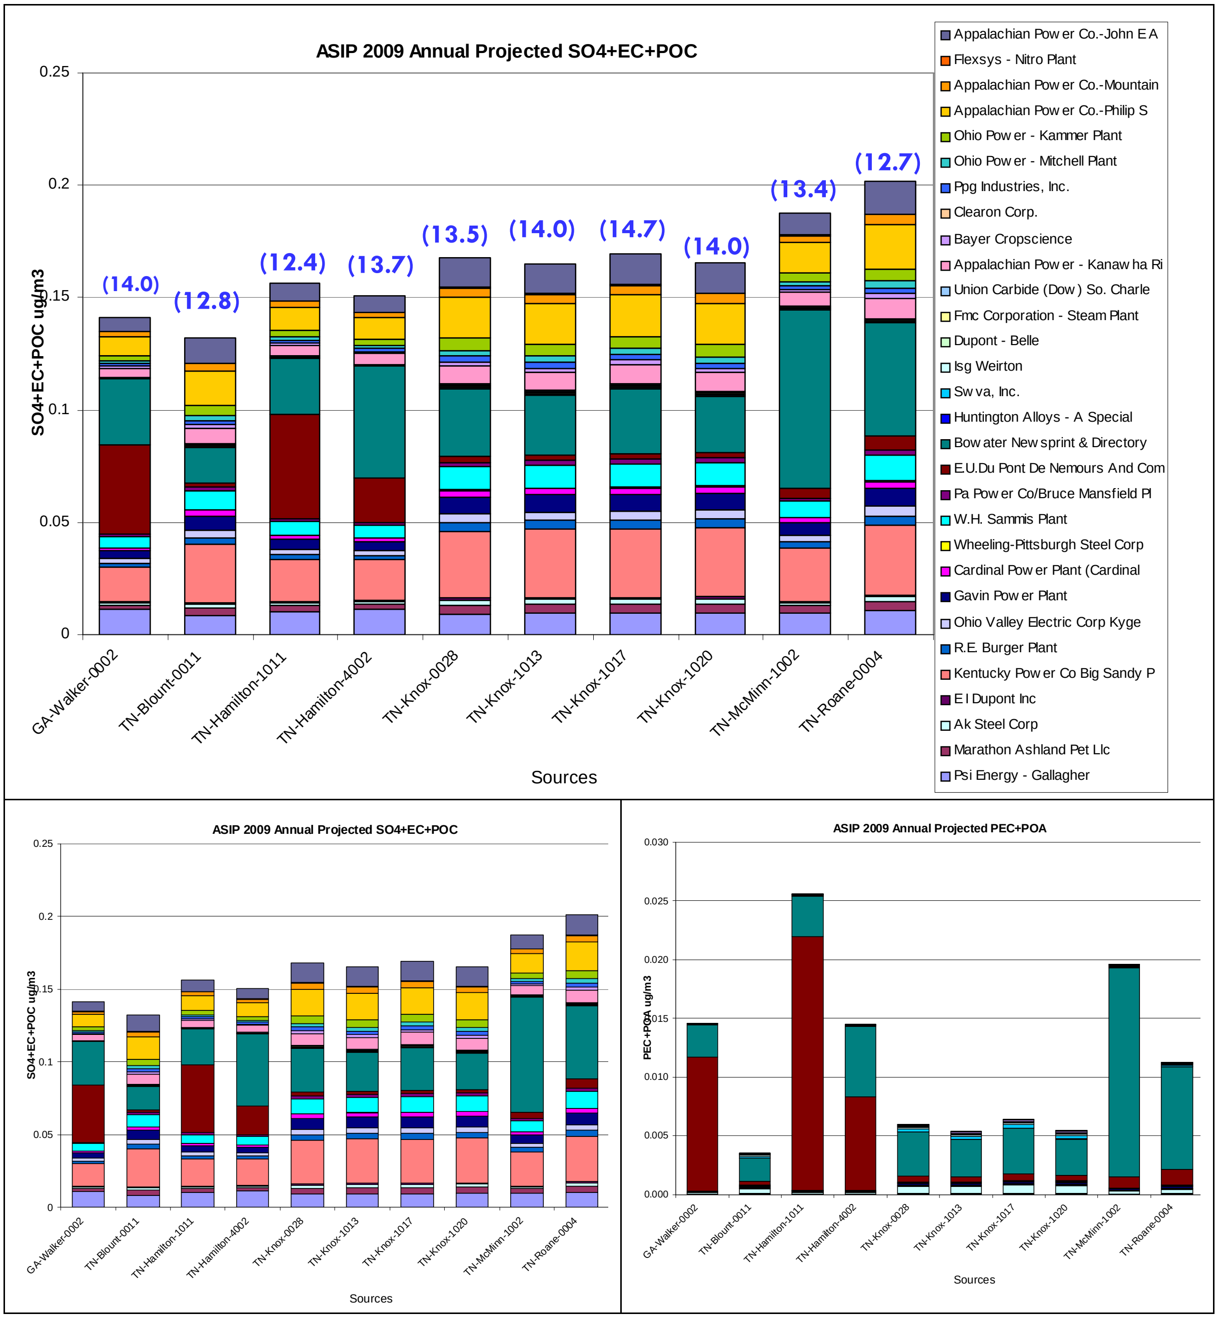

Figure 5-17. PSAT annual 2009 $PM_{2.5}$ source apportionment from 31 PSAT facilities for the Knoxville-Chattanooga 4 km domain and total $PM_{2.5}$ mass due to SO4 and primary PM emissions (top) and separately by SO4 (bottom left) and primary PM (bottom right).

5.3.5 Summary of PSAT Source Apportionment Modeling

Table 5-4 summaries the contribution from the 31 PSAT sources to projected 2009 $PM_{2.5}$ Design Values in the four 4 km nested-grid domains. The contributions of the 31 PSAT sources in the Charleston-Huntington-Ashland and Wheeling-Weirton-Steubenville 4 km domains is approximately a factor of 10 higher than seen for the Louisville and Knoxville-Chattanooga domains, which is due to the identification of many more PSAT sources in these two 4 km domains than the Louisville and Knoxville-Chattanooga 4 km domains, the close proximity of some of the PSAT sources to some of the FRM monitors in the Charleston-Huntington-Ashland and Wheeling-Weirton-Steubenville 4 km domains, and higher total emissions from all PSAT sources in the these two 4 km domains.

In some of the highest facility contribution cases in the Charleston-Huntington-Ashland and Wheeling-Weirton-Steubenville 4 km domains, the PSAT source is located very close to the FRM monitor that is impacted. Although the CAMx modeling used a finer grid (4 km) than the standard ASIP CMAQ modeling (12 km), the CAMx modeling is still using 12 km meteorology and did not attempt to simulate refined local-scale source-receptor relationships. However, the results do suggest that the close proximity of a source to an FRM monitor is as important a factor in its impact as the strength of its emissions. This is especially true for primary PM emission impacts.

Table 5-4. Summary of PSAT contributions to projected 2009 $PM_{2.5}$ Design Values at FRM monitors in each of the four 4 km domains.

4 km Domain	31 PSAT Source Contribution (µg/m^3)		Largest Single Facility Contribution (µg/m^3)
	Minimum	Maximum	
Charleston - Huntington - Ashland	0.4	2.5	2.1
Wheeling-Weirton-Steubenville	0.6	2.1	1.4
Louisville	0.18	0.23	0.20
Knoxville-Chattanooga	0.13	0.20	0.08

5.4 SUMMARY OF ADDITIONAL ANALYSIS

Alternative 2009 $PM_{2.5}$ Design Value projection methods (ASIP Excel spreadsheet method) corroborate the 2009 $PM_{2.5}$ Design Value projections presented in Chapter 4 using EPA's Modeled Attainment test Software (MATS). Although there were some small differences performing 2009 $PM_{2.5}$ Design Value projections using alternative procedures and models, they agreed on which NAAs would have 2009 $PM_{2.5}$ Design Values above and below the 15 µg/m^3 annual $PM_{2.5}$ NAAQS.

An alternative model to CMAQ (CAMx) also corroborates the CMAQ projected $PM_{2.5}$ Design Values. In general, CAMx projected slightly higher (0.1 to 0.3 µg/m^3) $PM_{2.5}$ Design Values than CMAQ. This appears to be primarily due to less reductions between 2002 and 2009 in SO4 and OCM in CAMx than CMAQ. The CAMx 2009 Base G4 emissions scenario did include more SO2 emissions than the CMAQ 2009 Base G4 scenario, which assumed that the W.H. Sammis EGU would have a scrubber and inadvertently neglected area source SO2 and PM emissions in Jefferson County, Kentucky. However, the differences in 2009 SO2 emissions does not explain the CAMx lower SO4 reductions between 2002 and 2009 for all monitors. The lower OCM reductions may be explained in part due to higher biogenic contributions in the CAMx OCM than CMAQ making the OCM RRFs less responsive to reductions in anthropogenic OCM emissions.

PM source apportionment was used to assess the contributions of 31 facilities to the projected 2009 $PM_{2.5}$ Design Values at FRM monitors in four 4 km modeling domains that covered portions of the KY, TN and WV ASIP and adjacent states. For the 31 facilities selected, there were higher contributions in the Charleston-Huntington-Ashland and Wheeling-Weirton-Steubenville 4 km domains than the Louisville and Knoxville-Chattanooga 4 km domains and the proximity of a source to an FRM monitor is as important a factor as its strength of emissions.

Table A.3 – ASIP BaseG4 2009 Point Source Emissions Summary – Example Hourly SCC Level Emission Totals.

```
Processed as Point sources
Base inventory year      2009
No gridding matrix applied
No speciation matrix applied
Temporal factors applied for episode from
     Thursday July 18, 2002  at 000000 to
     Friday July 19, 2002  at 000000
Annual total data basis in report
```

APPENDIX B

Air Quality Model Performance Evaluation: State-by-State and Key Monitoring Site $PM_{2.5}$ Model Evaluation

B.1 OVERVIEW

The discussion of model performance evaluation in this Appendix focuses on the evaluation of the 2002 Base G2 Actual base case modeling results from the Community Multiscale Air Quality (CMAQ) modeling system Version 4.5 with SOAmods enhancement across each VISTAS state and at key $PM_{2.5}$ monitors within the VISTAS states. The CMAQ results are compared with observational data from the **S**peciated **T**rends **N**etwork (STN)[1], **F**ederal **R**eference **M**ethod (FRM) $PM_{2.5}$ mass and **S**outh **E**ast **A**erosol **R**esearch and **CH**aracterization (SEARCH) study monitoring networks. The evaluation focuses primarily on the air quality model's performance with respect to individual components of fine particulate matter ($PM_{2.5}$) and total fine particulate matter ($PM_{2.5}$) mass within $PM_{2.5}$ nonattainment areas (NAAs) in the ASIP region. Consequently, the focus is on the STN and FRM monitoring sites that are located within the $PM_{2.5}$ NAAs, although SEARCH also includes two sites in NAAs (Atlanta and Birmingham). Previously we have presented an evaluation of the CMAQ 2002 Base G2 Actual base case simulation focusing primarily on PM and visibility as part of the Visibility Improvements for States and Tribal Associations in the Southeast (VISTAS) that focused on the regional model performance and performance at Class I areas (Morris et al., 2009).

B.2 CMAQ EVALUATION METHODOLOGY

EPA's integrated ozone, $PM_{2.5}$ and regional haze modeling guidance calls for a comprehensive, multi-layered approach to model performance testing, consisting of the four major components: operational, diagnostic, mechanistic (or scientific) and probabilistic (EPA, 2007a).

B.2.1 Evaluation Approach

The CMAQ model performance evaluation effort focused on the first two components, namely:

- <u>Operational Evaluation:</u> Tests the ability of the model to estimate $PM_{2.5}$ concentrations and the components of $PM_{2.5}$ (i.e., sulfate, nitrate, ammonium, organic carbon, elemental carbon and other $PM_{2.5}$) within the $PM_{2.5}$ nonattainment areas. This evaluation examines whether the measurements are properly represented by the model predictions but does not necessarily ensure that the model is getting "the right answer for the right reason"; and
- <u>Diagnostic Evaluation:</u> Tests the ability of the model to predict PM chemical composition including PM precursors (e.g., SOx, NOx, and NH_3) and associated oxidants (e.g., ozone and nitric acid); PM size distribution; temporal variation; spatial variation; mass fluxes; and components of light extinction (i.e., scattering and absorption).

The diagnostic evaluation can also include the performance of diagnostic tests to better understand model performance and identify potential flaws in the modeling system that can be corrected. The diagnostic evaluation may also includes the use of "probing tools" to understand why the model obtains a given prediction; probing tools include Process Analysis (PA), decoupled direct method (DDM) and source apportionment (SA).

[1] The Speciated Trends Network (STN) is now referred to as the Chemical Speciation Network (CSN)

In this final model performance evaluation for the ASIP 2002 Actual Base G2 CMAQ 36/12 km base case simulation, the operational evaluation for $PM_{2.5}$ has been given the greatest attention since this is the primarily thrust of EPA's modeling guidance. However, we have also examined certain diagnostic features dealing with the model's ability to simulate sub-regional and monthly/diurnal gas phase and aerosol concentration distributions. In the course of the ASIP and VISTAS studies, numerous diagnostic sensitivity tests were performed to investigate and improve model performance. Key diagnostic tests performed are discussed and the results for the rest are available on the projects modeling website: http://pah.cert.ucr.edu/vistas/vistas2/.

B.2.2 Particulate Matter and Component Species

Fine particulate matter can be composed of varying amounts of several different species. The main components of $PM_{2.5}$ are as follows:

- Sulfate (SO4)
- Nitrate (NO3)
- Ammonium (NH4)
- Organic Carbon Matter (OCM)
- Elemental Carbon (EC)
- Soil (also known as crustal material, fine soil, major metal oxides, inorganic particulates, or other PM)
- Sea Salt (NaCl)
- Particle Bound Water (PBW)

B.2.3 Ambient Air Quality Data for ASIP Model Evaluation

A ground-level model evaluation database for 2002 was compiled by the modeling team using several routine and research-grade databases. The focus of the evaluation of the CMAQ model for use in simulating $PM_{2.5}$ mass concentrations in urban areas and NAAs. The primary monitoring networks available to evaluate this component of the CMAQ are: (a) EPA Federal Reference Method $PM_{2.5}$ and PM_{10} Mass Networks (EPA-FRM); (b) EPA Speciation Trends Network (STN) of $PM_{2.5}$ component species; and (c) two sites from the Southeastern Aerosol Research and Characterization (SEARCH). These PM monitoring networks may also provide ozone and other gas phase precursors and product species, and visibility measurements at some sites. There are also gas-phase criteria pollutant measurements in NAAs from the EPA's Air Quality System (AQS) that are available for use. In addition, there are several more monitoring networks that collect PM or PM related species that are more rural in nature, such as IMPROVE, CASTNet and NADP. The VISTAS model performance evaluation focused more on model performance at these more rural networks to perform a regional evaluation of the CMAQ 2002 Base G2 base case that is more relevant for regional haze modeling at Class I areas and is presented elsewhere (Morris et al., 2009). The study team has performed a detailed evaluation of the CMAQ 2002 base case simulation using the AQS that is available on the modeling website: http://pah.cert.ucr.edu/vistas/vistas2/mpe2.shtml. Table B-1 and Figure B-1 summarizes the species collected and locations of the monitoring sites for the FRM, STN and SEARCH monitoring networks use in the ASIP $PM_{2.5}$ model evaluation.

Table B-1a. Ambient $PM_{2.5}$ monitoring data available in $PM_{2.5}$ nonattainment areas in the ASIP region during 2002.

Monitoring Network	Chemical Species Measured	Sampling Frequency; Duration
SEARCH	24-hr PM_{25} (FRM Mass, OC, BC, SO_4, NO_3, NH_4, Elem.); 24-hr PM coarse (SO_4, NO_3, NH_4, elements); Hourly $PM_{2.5}$ (Mass, SO_4, NO_3, NH_4, EC, TC); and Hourly gases (O_3, NO, NO_2, NO_y, HNO_3, SO_2, CO)	Daily, Hourly;
EPA-FRM	Only total fine mass ($PM_{2.5}$)	1 in 3 days; 24 hr
EPA-STN	Speciated $PM_{2.5}$	Varies; Varies

B.3 MODEL PERFORMANCE STATISTICS

To quantify $PM_{2.5}$ model performance, several statistical measures were calculated and evaluated for all the monitors within each ASIP state with a NAA and at individual monitors within the NAAs. The statistical measures selected were based on the recommendations outlined in section 18.4.1 of the USEPA's *Guidance on the Use of Models and Other Analyses for Demonstrating Attainment of Air Quality Goals for Ozone, PM2.5, and Regional Haze* (EPA, 2007a). VISTAS/ASIP has established model performance goals and criteria for $PM_{2.5}$ and components of fine particle mass based on previous model performance for ozone and fine particles that are shown in Table B-1b. EPA modeling guidance for fine particulate matter at the time noted that PM models might not be able to achieve the same level of performance as ozone models.

Table B-1b. Model performance goals and criteria for components of fine particle mass.

Fractional Bias	Fractional Error	Comment
$\leq$15%	$\leq$35%	Goal for PM model performance based on ozone model performance, considered excellent performance
$\leq$30%	$\leq$50%	Goal for PM model performance, considered good performance
$\leq$60%	$\leq$75%	Criteria for PM model performance, considered average performance. Exceeding this level of performance indicates fundamental concerns with the modeling system and triggers diagnostic evaluation.

B.4 $PM_{2.5}$ MODELING PERFORMANCE ACROSS THE ASIP STATES

In the following discussions we use selected monthly scatter plots, time series plots, soccer plots, bugle plots and model performance statistical measures from the UCR Analysis Tool application to the 2002 CMAQ Base G2 Actual base case simulation in an operational evaluation of the model for $PM_{2.5}$ mass and components of $PM_{2.5}$ within each ASIP state. These results represent just a small subset of the model performance evaluation products of the CMAQ 2002 36/12 km Base G2 base case simulation. Complete model evaluation products are available on the project website:

http://pah.cert.ucr.edu/vistas/vistas2/mpe2.shtml

The focus of the model performance evaluation in this Appendix is on $PM_{2.5}$ and $PM_{2.5}$ components within $PM_{2.5}$ nonattainment areas (NAAs) and urban areas in the ASIP region. The regional performance evaluation of the model for PM and visibility has been documented in the VISTAS Regional Haze SIP Technical Support Document (TSD; Morris et al., 2009), which in addition to the products available on the website includes:

- Regional operational and diagnostic model performance evaluation for PM and visibility across the VISTAS/ASIP region in the southeastern U.S. (Appendix B of VISTAS TSD);
- Model performance for PM and visibility at Class I areas in the VISTAS region. (Appendix C of VISTAS TSD); and
- Spatial model performance for PM components across the VISTAS/ASIP 12 km grid. (Appendix D of VISTAS TSD).

The performance of the ASIP/VISTAS CMAQ 2002 36/12 km Base G2 base case simulation for ozone has also been evaluated with the results discussed at the end of Chapter 3 with more details available at:

http://pah.cert.ucr.edu/vistas/vistas2/evaluation_results/2002ga2a.mpe/

B.4.1 Alabama

Figures B-2a-f contain scatter plots and model performance statistics for $PM_{2.5}$ component species at STN sites located in Alabama, the four quarters of 2002, Q1 (Jan-Mar), Q2 (Apr-Jun), Q3 (Jul-Sep) and Q4 (Oct-Dec) and the CMAQ 2002 36/12 km Base G2 base case simulation. Performance for SO4 is quite good with the scatter plots clustered tightly around the 1:1 line of perfect agreement (Figure B-2a) and fractional bias and error performance metrics mostly achieve the most stringent <±15% and < 35% performance goal for bias and error (Table B-1b). Performance for NO3 exhibits an underprediction tendency with fractional bias values of approximately -20% in Q1, -140% in Q2, -160% in Q4 and -30% in Q4 (Figure B-2b). The large summer NO3 underprediction bias occurs when both the model and measured NO3 values are extremely low with the modeled values near zero and with the STN NO3 observed values < 1 $\mu g/m^3$. Note that under these summer conditions, the NO3 will almost completely volatilize off the FRM filter so the FRM would measure insignificant $PM_{2.5}$ mass due to NO3. Thus, these large summer NO3 underpredictions are not a concern as NO3 is not an important component of $PM_{2.5}$ mass. Performance for NH4 is also fairly good achieving the <±30%/50% fractional bias/error goal for PM species (Figure B-2c), which is not surprising given its strong link to SO4.

With the exception of a few outliers, performance for organic carbon mass (OCM or OC) in Alabama is characterized by an underestimation bias that ranges from -40% to -70% (Figure B-2d). The reasons for the OCM underprediction includes measurement artifacts including the fact that the STN OC measurements are not blank corrected and have high uncertainties (see SANDWICH discussion in Chapter 4) and there are also large uncertainties in the OC emissions and the form of OC emissions as particles or semi-volatile organic gases. EC model performance at STN sites in Alabama is also fairly good, mostly achieving the PM model performance goal, albeit with an underestimation tendency in Q2, Q3 and Q4 (Figure B-2e).

The CMAQ performance for $PM_{2.5}$ mass at 3 STN and ~20 FRM monitoring sites in Alabama are shown in Figures B-2f and B-2g, respectively. Performance for $PM_{2.5}$ mass is generally good achieving the most stringent ozone performance goal in Q1 and Q4 and the PM goal all year round.

Time series of predicted (CMAQ 12 km results) and observed 24-hour $PM_{2.5}$ components and model performance statistics at the key North Birmingham STN site are shown in Figure B-3. As discussed in Chapter 4, this is the site with the highest projected 2009 $PM_{2.5}$ Design Value in the ASIP region. SO4 performance is quite good with annual fractional bias and errors of 6% and 29% achieving the most stringent ozone performance goal (Figure B-3a, top). The fractional bias for NO3 of -110% indicates a large underprediction bias that is driven by near zero modeled NO3 concentrations in the summer when the observed values are < 1 ug/m^3 (Figure B-3a, bottom). However, the NO3 performance in the winter, when observed values are above 1 ug/m^3 is much better. The EC and OCM performance at the North Birmingham STN site is characterized by an underprediction with fractional bias of -30% and -49%, respectively (Figure B-3b). This underprediction is due in part to uncertainties in the STN carbon measurements as well as the contributions of nearby industrial sources whose impacts are diluted across the 12 km CMAQ grid used. Performance for NH4 and $PM_{2.5}$ mass at the North Birmingham STN site are also quite good with fractional bias/error values of -5%/33% and 11%/29% achieving the more stringent ozone performance goal. The good performance of NH4 and $PM_{2.5}$ mass is not surprising given that they are closely tied to SO4 that exhibits good model performance.

Figure B-4 contains time series of predicted and observed PM components and performance statistics for the SEARCH BHM monitoring site also located at North Birmingham. Performance at the SEARCH BHM site is similar to the STN site at the same location with generally good performance for SO4, NH4 and $PM_{2.5}$ mass and an underprediction bias for EC and OCM. The SEARCH BHM site also includes performance for the "Soil" species that is greatly overestimated with annual fractional bias values of +164% (Figure B-4d, top)

Figure B-5 displays a soccer plot of monthly fractional bias versus gross error for $PM_{2.5}$ mass performance across ~20 FRM sites in Alabama and compares them with the three levels of bias/error performance goals in Table B-1b. $PM_{2.5}$ model performance is best in the winter months when the most stringent ozone < ±15%/35% bias/error goal is achieved. In the summer months the model tends to underestimate the FRM observed $PM_{2.5}$ mass by -15% to -25%, but still achieves the <±30%/50% PM model performance goal. The Bugle Plots of monthly $PM_{2.5}$ bias and error in Figure B-6 also confirm that the bias and error performance goals for PM are achieved across FRM sites in Alabama.

The $PM_{2.5}$ model performance products on the project website also include a day-by-day evaluation of the $PM_{2.5}$ model performance at STN sites. This is done with side-by-side stacked bar charts of $PM_{2.5}$ components for each sampling day in 2002 and each STN site in Alabama. These model performance displays can be found at:

B.4.2 Florida

Figure B-7 summarizes the CMAQ $PM_{2.5}$ species model performance across the ~4 STN sites in Florida and Q1, Q2, Q3 and Q4 2002. SO4 is underestimated at the Florida STN sites (Figure B-7a) with fractional bias values that are closer to zero in the winter than summer (e.g., -6% in Q4 versus -23% in Q3 for the 12 km CMAQ results) with the 12 km results exhibiting better performance than the 36 km results. Even with this underestimation bias SO4 performance at the Florida STN sites is fairly good. NO3 performance, on the other hand, exhibits a large underprediction bias with fractional bias values that range from -70% in Q4 to -170% in Q3 (Figure B-7b). NH4 performance at the Florida STN sites is fairly good always achieving the <±30%/50% PM performance goal and sometimes even achieving the more stringent <±15%/35% ozone performance goal (Figure B-7c). It is interesting that in Q1 and Q4 when both SO4 and NO3 exhibit an underprediction bias, NH4 exhibits a slight overprediction bias. Given the linked relationship between these species this is somewhat surprising and may be due to artifacts in the measurements, or the modeled SO4 being more fully neutralized by NH4 than in the measurements. The OCM and EC performance is characterized by underprediction tendency with the OCM fractional bias ranging from -75% to -110% with the CMAQ 36 km and 12 km producing nearly identical performance metrics (Figure B-7d). The EC performance is better with fractional bias values ranging from -2% to -53% with the 12 km modeling results producing significantly better EC performance metrics than the 36 km modeling results (Figure B-7e).

The $PM_{2.5}$ mass performance in Florida is summarizes across ~4 STN sites and 28 FRM sites in Figures B-7f and B-7g, respectively. Across the STN sites, the $PM_{2.5}$ fractional bias ranges from -27% to -75% for the four months examined, whereas across the FRM network the bias values are lower ranging from+2% to -69%. Given the underprediction tendency of SO4, NO3 and carbon the general underprediction of total $PM_{2.5}$ mass is not unexpected. Why the underprediction bias is greater across the STN network than the FRM network is unclear but is likely related to the locations of the 3 STN and 28 FRM monitoring networks and the measurement artifacts of the two sampling techniques (e.g., FRM will loose more of the volatile material).

An example predicted and observed time series and annual model performance metrics for 24-hour PM components at an STN site in Miami-Dade County Florida is shown in Figure B-8. The summer sulfate underprediction tendency results in an annual fractional bias of -30% with error of 44% just barely achieving the PM model performance goals (Figure B-8a, top). NO3 performance at this Miami site is very poor with a -180% fractional bias with modeled NO3 on most days near zero, compared to around 0.5 $\mu g/m^3$ measured values during the summer. OCM and EC are also underpredicted at the Miami site with fractional bias values of, respectively, -123% and -84% (Figure B-8b). Ammonium performance is fairly good meeting the most stringent ozone performance goal, whereas total $PM_{2.5}$ is underpredicted due to the underprediction of most of the PM components as discussed above (Figure B-8c).

The soccer plot of monthly $PM_{2.5}$ bias and error performance for FRM sites in Florida is shown in Figure B-9, with the Bugle Plots shown in Figure B-10. For the winter months of Nov, Dec, Jan and Feb the $PM_{2.5}$ performance statistics are quite good with bias/error values meeting the <±15%/35% ozone performance goal. The spring and fall months either achieve the <±30%/50% or <±50%/125% performance goal and criteria. The May-Jul summer months are at or exceed the -50% performance criteria levels (note that in the Soccer Plots if the symbol would be plotted outside of the range of the plot then it is plotted on the axis, such as the May and July -50% values in Figure B-9).

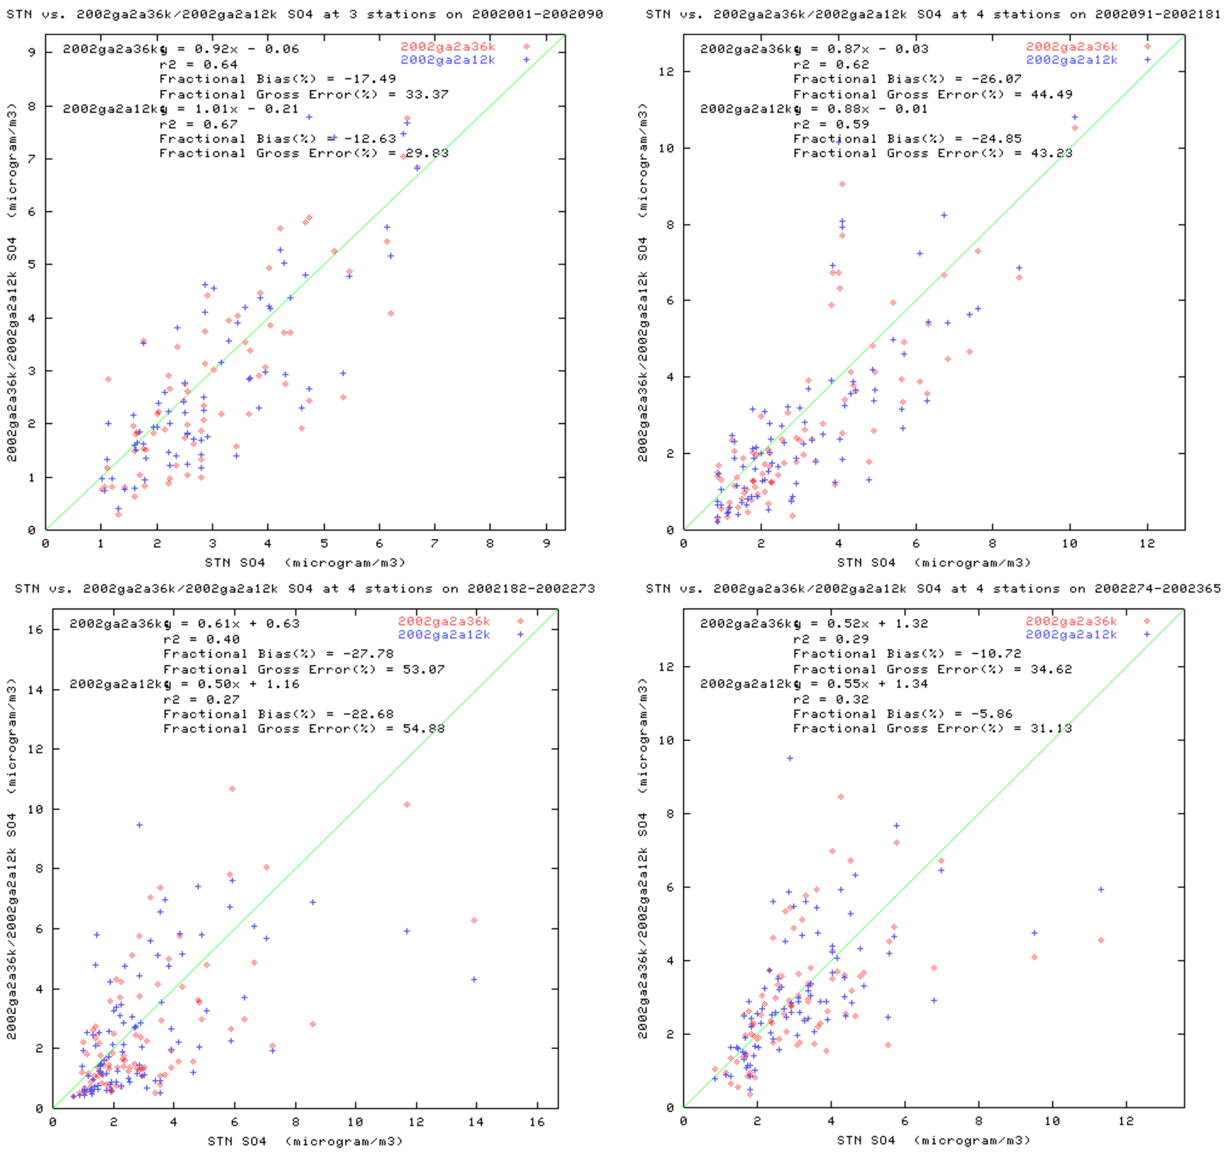

Figure B-7a. Scatter plots of predicted and observed sulfate (SO4) concentrations for Q1, Q2, Q3 and Q4 2002, STN sites in Florida and the CMAQ 2002 36 and 12 km Base G2 Actual base case simulation.

B.4.3 Georgia

There appears to be valid data capture issues in the 2002 STN MPE database for Georgia with several sites starting up during Q1 resulting in less comparisons than the other quarters. The CMAQ SO4 performance in Georgia is generally pretty good with bias/error frequently achieving the <±15%/35% ozone performance goal and always achieving the PM goal (Figure B-11a). The STN sites also have the summer nitrate underprediction performance issue as seen in the other states (Figure B-11b). The NH4 model performance falls between the SO4 and NO3 performance and achieves the <±30%/50% PM performance goal for all four quarters (Figure B-11c).

The carbon performance in Georgia appears to be slightly better than the other states, although still with an underestimation tendency ranging from -40% to -70%. The OCM model performance fails to achieve the PM performance goal, but does achieve the PM performance criteria (Figure B-11d). EC performance is variable with generally low bias but lots of scatter producing higher gross errors (Figure B-11e).

The performance of total $PM_{2.5}$ mass across the STN (Figure B-11f) and FRM (Figure B-11g) monitoring sites in Georgia is generally fairly good. Q3 exhibits an underprediction tendency with fractional bias values of approximately -25% (STN) and -18% (FRM) that is likely caused by the underestimation of SO4 and especially OCM. But in general the $PM_{2.5}$ performance statistics mostly achieve the most stringent ozone performance goal and always achieve the PM performance goal.

Example time series of predicted and observed PM concentrations and annual statistics for a site in the Atlanta Georgia (DeKalb County) is shown in Figure B-12. The model tracks the observed SO4 concentrations at this site extremely well producing low fractional bias (-5%) and gross error (27%). NO3 performance exhibits the underprediction tendency seen in the other states, but is not as severe with a -16% fractional bias and 77% error. The CMAQ 12 km results reproduces the OCM concentrations at this site surprisingly well with low bias (-14%) and error (31%). EC is overestimated (bias of 28%) at this Atlanta site with fairly high error (44%) but still achieves the PM performance goal. NH4 is overstated at this site on average (29% error) but also achieves the PM performance goal. Finally, the performance for $PM_{2.5}$ mass at the DeKalb County STN site is extremely good with very low bias (2%) and error (25%).

Figure B-13 displays another example of predicted and observed PM species, time series and annual statistics for a site in Atlanta, only this time for the SEARCH Jefferson Street (JST) site. Unlike the STN 1:3 sampling frequency, the SEARCH JST site collects 24-hour samples everyday so has a richer model evaluation database. The performance at the SEARCH JST Atlanta is similar to the STN DeKalb County site with good performance for SO4 that achieves the ozone performance goal, and NO3 performance that has an overall annual underestimation tendency (bias of -16%) and high error (80%). It appears the summer NO3 underestimation bias is being compensated by a winter NO3 overestimation bias that can be quite large (Figure B-13a, bottom). The SEARCH JST site had some data capture problems for OCM so the performance is not very meaningful, but does suggest and underprediction tendency as seen at other sites. Unlike the DeKalb County STN site that suggests an EC overestimation bias (28%), at the SEARCH JST site the CMAQ 12 km modeling results exhibits a zero bias and fractional gross error of 37% (Figure B-13b, bottom). The STN and SEARCH sites use different sampling techniques for carbon which may help explain these differences. The observed NH4 at the JST site is reproduced well (Figure B-13c, top) with a fractional bias of -5% and error of 37%. The

Soil term measures at the JST site is greatly overestimated with fractional bias of 136% (Figure B-13d). The Soil performance issue is discussed extensively in the VISTAS regional haze TSD (Morris et al., 2009) and two potential reasons for its poor performance are: (1) incompatibilities between the measured Soil that is built up from measured elements and the "Soil" in the modeling which is the other $PM_{2.5}$ that consists of $PM_{2.5}$ that is not explicitly speciated as SO4, NO3, OCM or EC; and (2) impacts of local fugitive dust sources at the monitor that are subgrid-scale to the CMAQ 36/12 km modeling so is not captured by the modeling. Performance for total $PM_{2.5}$ mass at the JST site is excellent (Figure B-13d, bottom) with a low bias (-3%) and error (24%).

Figure B-14 and B-15 displays Soccer and Bugle Plots, respectively, of monthly fractional bias and error across the 26 FRM sites in Georgia. All months achieve the PM performance goal and 8 of the 12 months even achieve the more stringent ozone performance goal. The months that the $PM_{2.5}$ mass performance doesn't achieve the ozone performance goal are due to an overestimation bias in January and underestimation bias in May-July.

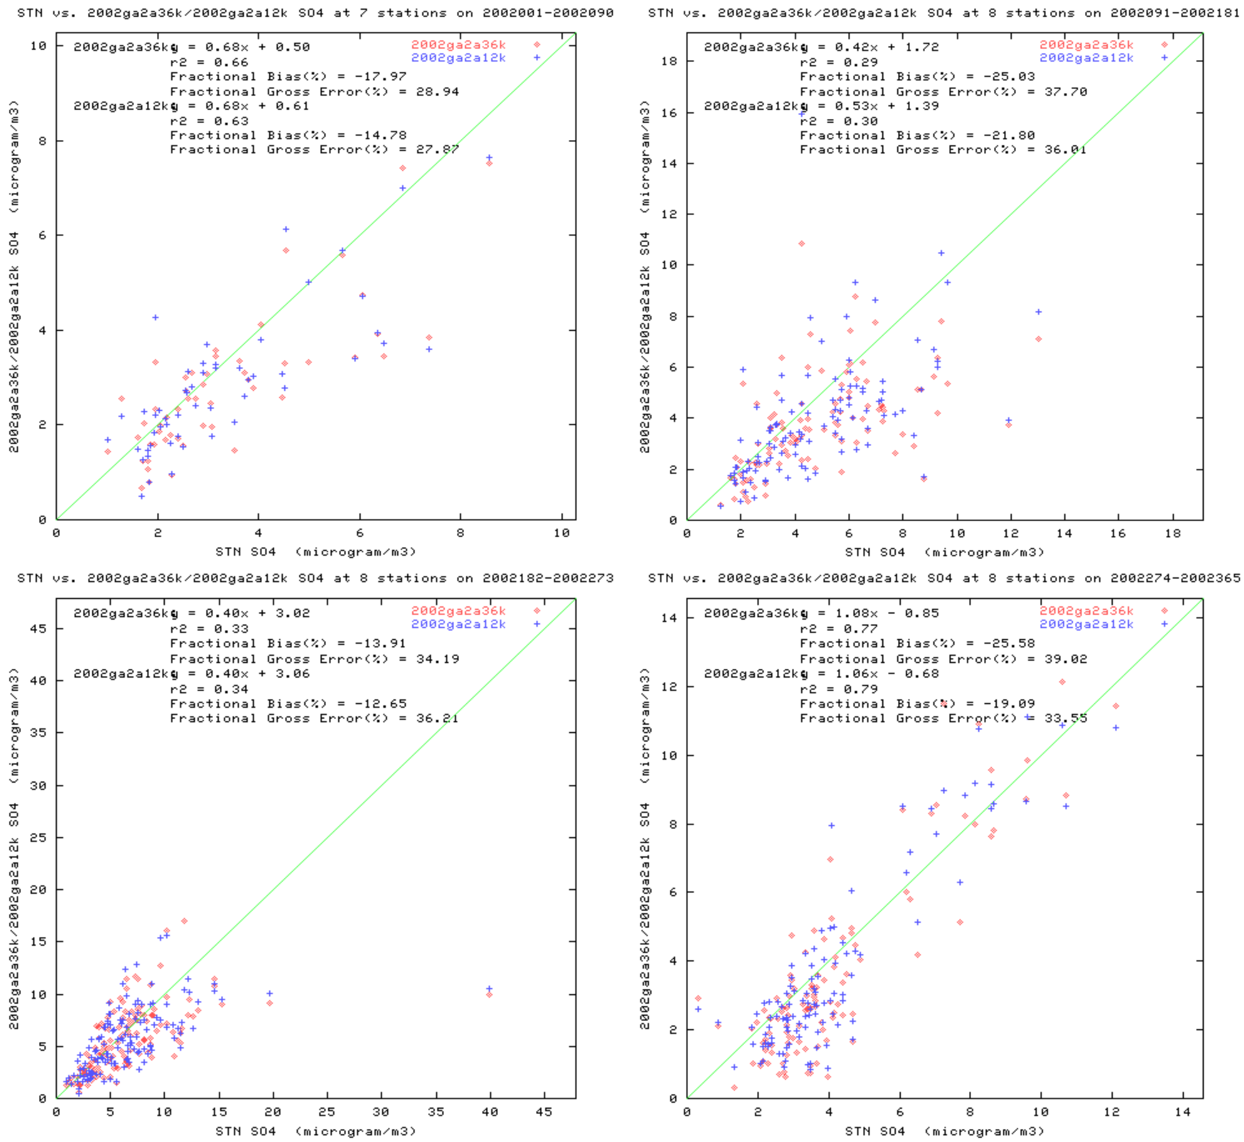

Figure B-11a. Scatter plots of predicted and observed sulfate (SO4) concentrations for Q1, Q2, Q3 and Q4 2002, STN sites in Georgia and the CMAQ 2002 36 and 12 km Base G2 Actual base case simulation.

B.4.4 Kentucky

The quarterly scatter plots and performance statistics for PM species and sites in Kentucky are shown in Figure B-16. The performance for SO4 in Q1 is mixed, with a group of points clustered around the 1:1 line and another further to the right resulting in a net underprediction bias of approximately -25%. An examination of the more detailed perform plots on the website reveals that this dichotomy in Q1 SO4 model performance in Kentucky is due to temporal rather than spatial differences in performance. The CMAQ 12 km SO4 performance in Q2 and Q3 achieve the most stringent ozone performance goal. Like Q1, Kentucky SO4 performance in Q4 has an underprediction bias of approximately -30% so is right at the PM performance goal.

As seen in the other states, NO3 performance in Kentucky is characterized by underprediction bias during the warmer months that is largest in Q2 (-98% to -105%) and Q3 (-115% and -125%) (Figure B-16b). During the cooler periods of the year, the NO3 fractional bias is low with values of -6% in Q2 and 8% in Q4, although the error is too large to achieve the ozone performance goal (~60%).

Like SO4, NH4 performance is fairly good albeit with an underprediction bias that is largest in Q2 and Q3 (-20% to -30%) (Figure B-16c). As seen for the other states, OCM in Kentucky is underpredicted with the bias ranging from -80% to -105% (Figure B-16d). The OCM errors are the opposite sign but the same magnitude as the bias suggesting that the OCM underprediction bias is almost systematic. The CMAQ 36 km and 12 km modeling results exhibit different EC performance in Kentucky. The CMAQ 12 km results have bias that is much closer to zero than the 36 km results, whose EC performance is characterized by an underprediction bias (Figure B-16e). In fact, the CMAQ 36 km EC fractional bias is approximately 30 percentage points lower than the CMAQ 12 km modeling results. This is likely due to the 36 km grid cells over dispersing the urban EC emissions. Both the CMAQ 36 km and 12 km results exhibit a lot of variability producing a lot of scatter and high error metrics.

The performance of total $PM_{2.5}$ mass concentrations in Kentucky is evaluated across 10 STN (Figure B-16f) and 23 FRM sites (Figure B-16g). Given the underprediction of most of the PM component species it is not surprising that total $PM_{2.5}$ mass is underpredicted across the STN sites by approximately -20%, -30%, -20% and 0% for Q1, Q2, Q3 and Q4. Across the FRM sites in Kentucky, however, the CMAQ model for $PM_{2.5}$ mass bias that is generally closer to zero with values of from approximately +10% to -20% for the four quarters of 2002. The FRM $PM_{2.5}$ mass performance always achieves the PM performance goal and sometimes even achieves the ozone model performance goal.

An example PM model performance for a single STN site in Lexington (Fayette County) Kentucky is shown in Figure B-17. The model reproduces the temporal variations in SO4 quite well (Figure B-17a, top) at this site resulting in low bias (-10%) and error (33%). Although the model shows some skill in reproducing the observed higher NO3 values in the winter, especially in the first part of the year, the near zero modeled NO3 during the summer results in a fractional bias value of -62% with 87% error, so does not achieve the PM performance goal (Figure B-17a, bottom).

OCM is underpredicted with fractional bias values of -52% and an error of 58% just at the PM performance goal (Figure B-17b, top). EC exhibits much better performance at the Lexington, Kentucky site with a bias near zero (-4%) and error of 36% so almost achieves the ozone performance goal.

The performance for NH4 and $PM_{2.5}$ mass is quite good, which is not surprising given the good SO4 performance and the strong link between SO4 and these two species in Kentucky. The fractional bias for NH4 and $PM_{2.5}$ are both approximately -10% with NH4 having an error of 36% and $PM_{2.5}$ an error of 28% thereby achieving the ozone performance goal.

Figure B-18 displays another example time series performance for PM components at an STN site in Kenton County, Kentucky that lies in the Cincinnati NAA. The performance at the Cincinnati NAA STN site is similar to that at Lexington STN site with very good SO4 performance that produces bias/error values of -12%/30% that achieves the ozone performance goal and NO3 with a net underestimation with bias/error of -47%/75% that is right at the PM performance criteria (Figure B-18a). OCM exhibits a large underprediction bias (-57%), whereas performance for EC is better with bias (14%) and error (36%) that is right at the ozone performance goal (Figure B-18b). NH4 (-4%/37%) and $PM_{2.5}$ (-7%/31%) also exhibit low bias/error and good performance, which again is not surprising given their relationship with SO4 (Figure B-18c).

Figure B-19 and B-20 summarized the Kentucky $PM_{2.5}$ mass model performance using Soccer and Bugle Plots of monthly bias and error. With the exception of July, whose fractional bias falls slightly below -30%, $PM_{2.5}$ performance in the other 11 months achieves the PM bias/error performance goal of <-30%/75%. In fact 5 months that occur mainly in the winter even achieve the more stringent ozone model performance goal.

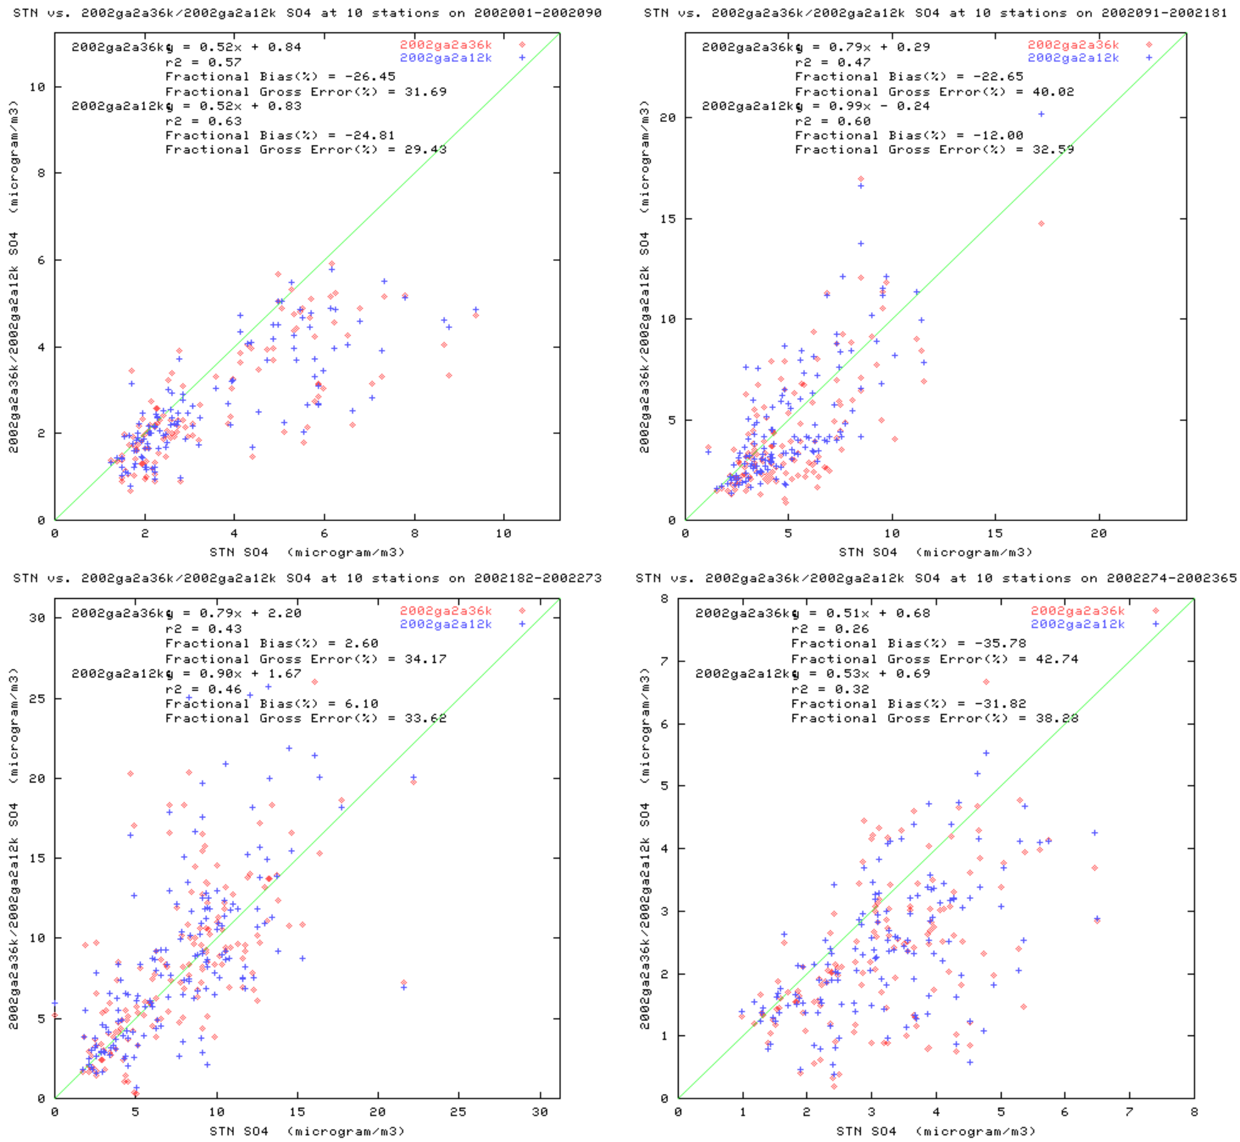

Figure B-16a. Scatter plots of predicted and observed sulfate (SO4) concentrations for Q1, Q2, Q3 and Q4 2002, STN sites in Kentucky and the CMAQ 2002 36 and 12 km Base G2 Actual base case simulation.

B.4.5 Mississippi

Performance of PM species across sites in Mississippi is shown in Figure B-21. SO4 is generally underpredicted with fractional bias values ranging from -18% to -41%. Although the PM performance goal is achieved in Q2 and Q3, because the underprediction bias in Q1 and Q4 exceeds -30% the PM performance goal is not achieved. NO3 performance metrics are poor with fractional bias values of -50% to -60% in Q1, -110% in Q2, -150% in Q3 and -14% to -28% in Q4.

NH4 performance is characterized by lots of scatter and little correlation so that even though the ozone bias performance goal is achieved in Q1, Q2 and Q4, the error goal is not (Figure B-21c). OCM is underpredicted at sites in Mississippi with fractional bias values of approximately -70% to -90% (Figure B-21d). Performance for EC is better, albeit still with an underprediction bias ranging from -10% to -60%. Again as seen for other states, the CMAQ 12 km modeling results produces much lower bias that is closer to zero than the 36 km modeling results (Figure B-21e).

$PM_{2.5}$ performance in Mississippi across the STN and FRM networks are shown in Figures B-21f and B-21g, respectively. Across the STN network, $PM_{2.5}$ is underestimated by approximately -20% in Q4 rising to -47% in Q3 with Q1 and Q2 in between. Across the FRM network, the $PM_{2.5}$ underprediction bias is lower, at -2% in Q4 and -30% for Q3 with again Q1 and Q2 being in between. The 12 km CMAQ modeling results for FRM $PM_{2.5}$ achieves the PM performance goal across all four quarters and even the ozone performance goal in Q4.

Figure B-22 displays an example model performance time series analysis at an STN site in Jones County in southeastern Mississippi (Hattiesburg). SO4 performance is worse than seen in the other ASIP states with a -36% fractional bias and 44% error. NO_3 performance exhibits similar characteristics as the other ASIP states with a summer underestimation bias that produces an annual fractional bias value of -40%. Like the other states, OCM is underestimated by -43% on average, but unlike the other states the underprediction fractional bias for EC exhibits an underprediction (-60%) that is even greater than seen for OCM. Performance statistics for NH4 are reasonable with a near zero bias and 42% error, the near zero bias is due to a few days of large overprediction compensated for a general underprediction. Given the fact that almost all of the PM components are underestimated, the underprediction of total $PM_{2.5}$ mass is not a surprise with a fractional bias value of -35%.

The Soccer Plot (Figure B-23) and Bugle Plot (Figure B-24) for $PM_{2.5}$ mass performance confirm that $PM_{2.5}$ performance in Mississippi is worse than seen for the other ASIP states. Only two months achieve the ozone model performance goal and only 8 months achieve the PM model performance goal. The underprediction bias in March through July 2002 produces fractional bias that do not achieve the $<\pm50\%$ PM performance goal.

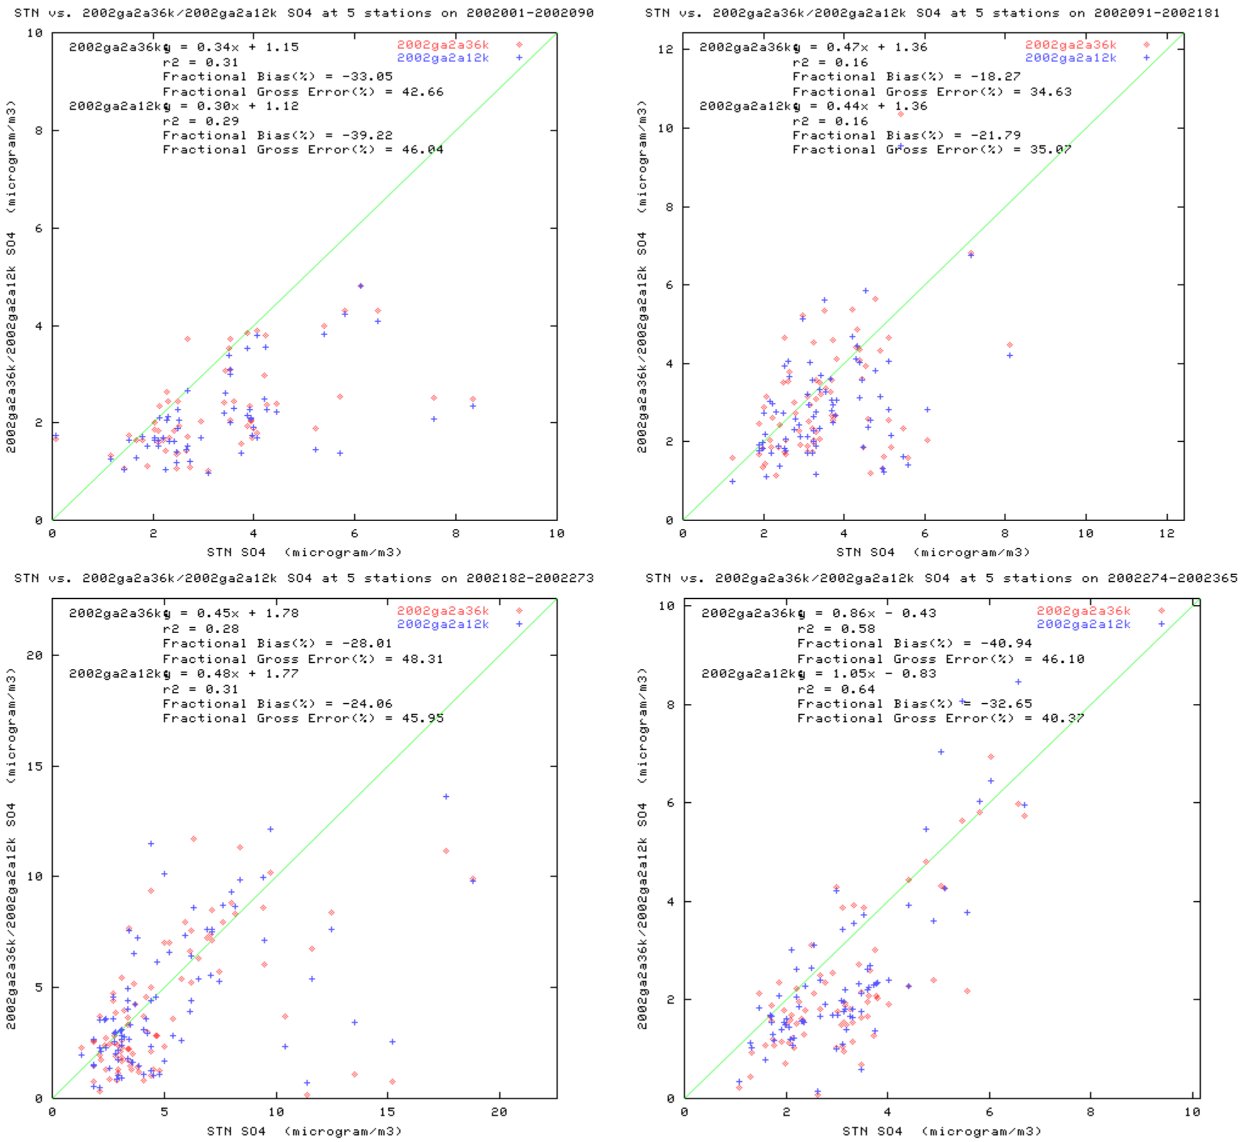

Figure B-21a. Scatter plots of predicted and observed sulfate (SO4) concentrations for Q1, Q2, Q3 and Q4 2002, STN sites in Mississippi and the CMAQ 2002 36 and 12 km Base G2 Actual base case simulation.

B.4.6 North Carolina

SO4 performance across 9 STN monitoring sites in North Carolina and four quarters from 2002 is shown in Figure B-25a. SO4 performance achieves the PM performance goal with fractional bias values that range from -13% to -30%. Although NO3 is still greatly underestimated in North Carolina during the summer (Q3 bias of -90% to -118%), during Q1 and Q4 NO3 exhibits a slight overestimation bias of 10% to 30% (Figure B-25b). This is likely due to overstated ammonia emissions during the winter and adjacent periods which is somewhat verified by the overstated ammonium during Q1 and Q4 that have fractional bias values in the +20% to +30% range (Figure B-25c)

OCM is characterized by an underprediction bias ranging from -70% to -90% failing to achieve even the PM performance criteria (Figure B-25d). EC, on the other hand, achieves the PM performance goal in Q1 and Q4 but has lots of scatter in the other two months exceeding the PM performance goal for bias in Q2 (-36% and -41%) and for error in Q3 (~62%).

$PM_{2.5}$ mass performance across the 9 STN sites in North Carolina exhibits an underprediction bias of -20% to -30% for Q1-Q3 that achieves the PM performance goal and near zero bias in Q4 that achieves the ozone performance goal (Figure B-25f). The model exhibits lower bias across the FRM $PM_{2.5}$ mass network in North Carolina that ranges from +10% to – 26% and achieves the PM performance goal throughout the year (Figure B-25g). FRM $PM_{2.5}$ is overpredicted in 4 (10% to 18%) and underpredicted in Q2 (-21% and -26%) and Q3 (-21% to -22%). The STN $PM_{2.5}$ performance is similar except because the STN measurements tend to be higher the underprediction bias is greater and the overprediction bias is less.

Figures B-26 and B-27 displays time series performance analysis at two STN sites in North Carolina, one on Charlotte (Mecklenburg County) and the other in Raleigh (Wake County). So4 performance is good at both sites, albeit with an underprediction bias of -14% for Charlotte and -19% for Raleigh with both sites having low error (31% and 32%). Although both sites have a net annual NO3 underprediction bias (-19% and -38%) due to the summer underprediction tendency discussed previously, during the winter there are some days when the CMAQ model overpredicts the observed NO3 by a factor of 2-3. OCM is underpredicted by a far margin at the two sites (-34% and -50%). At the Charlotte site EC is overpredicted by 45% which occurs year round, whereas at the Raleigh site EC is predicted well with a zero bias and 34% error. NH4 is predicted reasonably well with bias/error values that achieve or nearly achieve the ozone performance goal. $PM_{2.5}$ is predicted well at the Charlotte site with low bias (-8%) and error (29%), but underestimated at the Raleigh site with a bias of -28%.

The Soccer and Bugle Plots summary of FRM $PM_{2.5}$ mass model performance in North Carolina are shown in Figures B-28 and B-29. With the exception of the large summer underprediction bias in June and July, the other 10 months $PM_{2.5}$ performance achieves the <±30%/50% PM performance goal and four of the months even achieve the more stringent ozone performance with four additional months right at the ozone goal.

Figure B-29. Bugle plots of monthly fractional bias (top) and gross error (bottom) for FRM sites in North Carolina and thee CMAQ 12 km 2002 Base G2 Actual base case simulation.

B.4.7 South Carolina

The CMAQ performance for SO4 across the 4 STN sites in South Carolina generally has an underprediction bias but is reasonably good always achieving the PM performance goal (Figure B-30a). NO3 performance is poor with an underprediction bias generally from -23% to -166% that is largest in the summer (Q3) when NO3 is lowest and not an important component of the $PM_{2.5}$ (Figure B-30b). NH4 performance is variable frequently achieving the PM performance goal with the worst performance in the summer with a large underprediction tendency. OCM is underestimated with bias of -76% to -87%. EC performance also has an underestimation tendency, although not is bad as seen for OCM. The CMAQ 12 km results also exhibits much better EC performance than the CMAQ 36 km modeling results with the 12 km EC model performance almost always achieving the PM performance goal, whereas the CMAQ 36 km EC results never achieves the PM performance goal although Q1 is right at the PM performance goal (Figure B-30e).

$PM_{2.5}$ model performance across STN and FRM networks in South Carolina are shown in Figures B-30f and B-30g, respectively. $PM_{2.5}$ mass is usually underpredicted across both networks, with the fractional bias across the STN network is worse and approximately 20 percentage points worse underprediction than the FRM network. In fact, the bias and error for $PM_{2.5}$ across the FRM network achieves or almost achieves the PM performance goal for all four quarters and even the ozone performance goal for Q1 and Q4.

An example time series of predicted and observed PM concentrations and model performance metrics at the Greenville, South Carolina STN site is given in Figure B-31. All PM components are underestimated on average with fractional bias values for SO4, NO3, NH4, OCM, EC and $PM_{2.5}$ of, respectively, -23%, -97%, -19%, -46%, -11% and -30%. Although the model does show some skill in reproducing the temporal and seasonal variability in the observed PM concentrations.

The summary fractional bias and gross error Soccer and Bugle Plots for total $PM_{2.5}$ mass across the FRM network in South Carolina are shown in Figures B-32 and B-33. During the fall and winter months of Aug, Sep, Nov, Dec, Jan and Feb the monthly bias and error statistics achieve the ozone model performance goal. The three additional months of Mar, Apr and Oct achieve the PM performance goal. Whereas the summer months of May, Jun and Jul fail to achieve the PM performance goal due to large underprediction bias that is due to the underprediction of each of the PM component species.

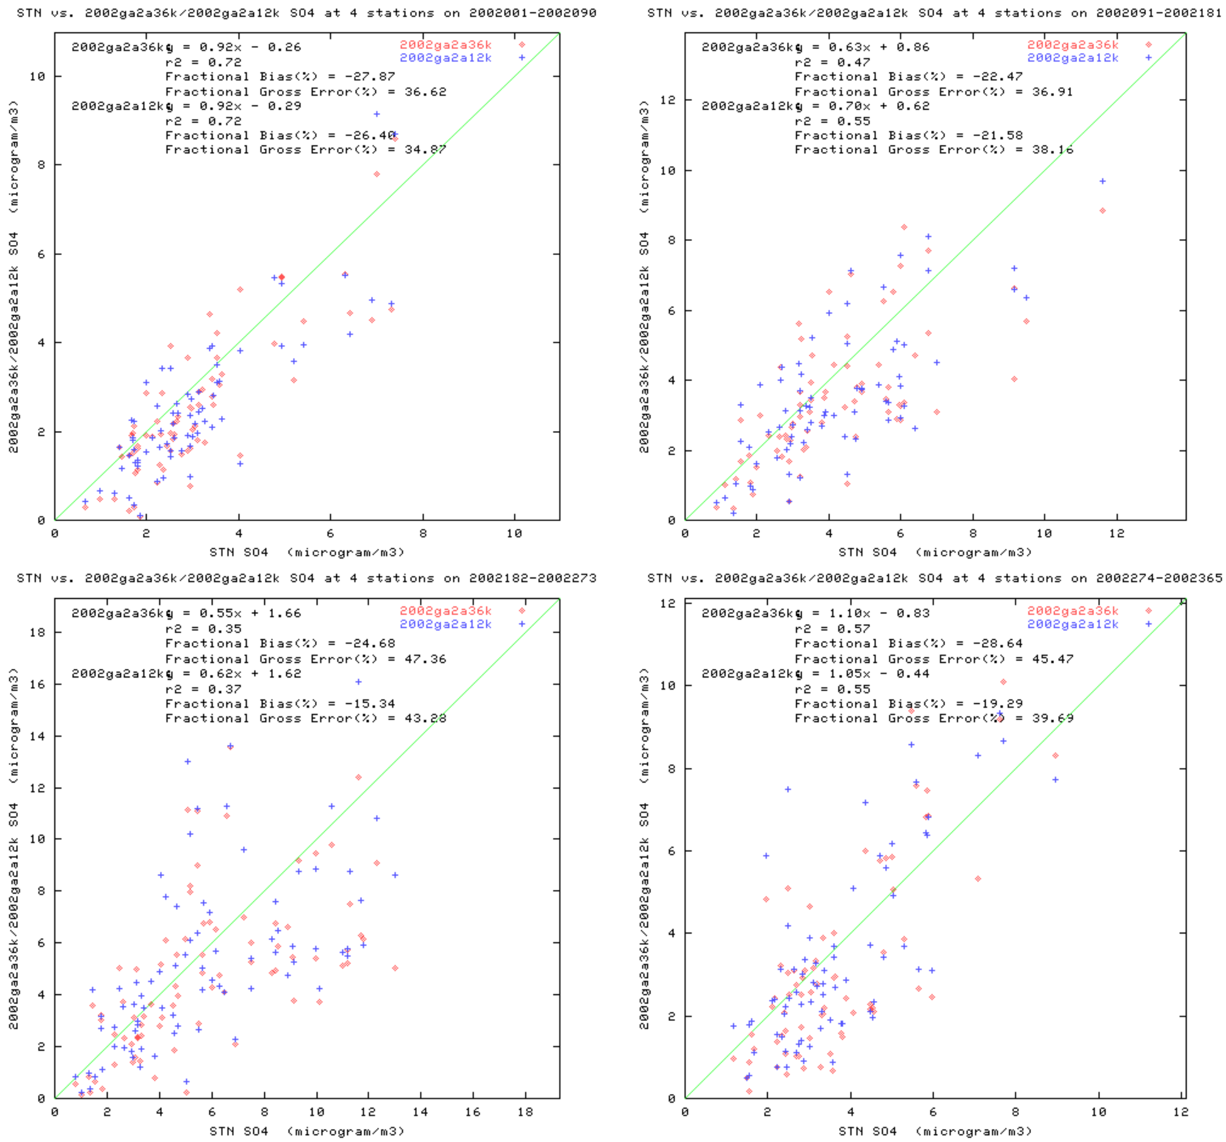

Figure B-30a. Scatter plots of predicted and observed sulfate (SO4) concentrations for Q1, Q2, Q3 and Q4 2002, STN sites in South Carolina and the CMAQ 2002 36 and 12 km Base G2 Actual base case simulation.

Figure B-33. Bugle plots of monthly fractional bias (top) and gross error (bottom) for FRM sites in South Carolina and thee CMAQ 12 km 2002 Base G2 Actual base case simulation.

B.4.8 Tennessee

The CMAQ does a good job predicting the observed SO4 concentrations in Tennessee with bias and error values that either achieve the most stringent ozone performance goal (Q2 and Q3) or falls slightly out of the ozone goal (Figure B-34a). The CMAQ 12 km results are slightly better than the 36 km predictions and, unlike the other states, where Q3 had the largest underprediction bias in Tennessee the SO4 performance in Q3 is quite good with the 12 km results producing a 8% bias and 36% error.

The model exhibits little skill in its NO3 predictions (Figure B-34b) with the usual large underprediction bias in the summer (e.g., -150% in Q3). Although the bias is low in Q1 and Q4 (<±10%), the error is large (60% to 80%). NH4 performance is generally reasonably good with low bias and error in Q1 and Q2l, but a slight underprediction bias in Q3 (-7% and -18%) and an overprediction bias in Q4 (15%).

As seen in the other states, OCM exhibits a large underprediction bias that generally ranges from -65% to -90% (Figure B-34d). EC performance is fairly good with the 12 km results always achieving the PM performance goal (Figure B-34f).

Tennessee $PM_{2.5}$ mass performance across the STN and FRM networks are shown in Figures B-34f and B-34g. Across the STN networks performance for $PM_{2.5}$ achieves the ozone goal in Q1 and almost in Q4, but exhibits an underprediction bias in Q2 and Q3 with the 12 km modeling results achieving the PM performance goal. Across the FRM network the model performs better for $PM_{2.5}$ achieving the ozone performance goal in Q1 and Q4, but with an underprediction bias in Q2 (-17%) and Q3 (-18%) that just barely falls out of the ozone performance goal.

Example time series comparisons and annual model statistics are presented for two sites in Tennessee, one in Chattanooga, Hamilton County (Figure B-35) and one in Knoxville, Knox County (Figure B-36). The model reproduces the daily variations in the SO4 at these two sites fairly well with an annual underprediction bias of -17% and -9%. NO3 is underpredicted in the summer resulting in an annual underprediction bias in Chattanooga and Knoxville of -86% and -74%, respectively. OCM is underpredicted at both sites with bias values of -56% and -44%. EC is underestimated on average in Chattanooga (-23%) and overestimated in Knoxville (21%). The underprediction of the two main PM components at the two sites (SO4 and OCM) results in a net underprediction bias of $PM_{2.5}$ mass of -51% and -22%.

The monthly fractional bias and error Soccer and Bugle Plots for FRM $PM_{2.5}$ performance in Tennessee show that all months of the year achieve the PM model performance goal and that 5 of the months even achieve or are right at the ozone model performance goal. The months that do not achieve the ozone performance goal are due to a summer underprediction bias for May-July and a fall/winter overprediction bias for October and November and a too high error for December.

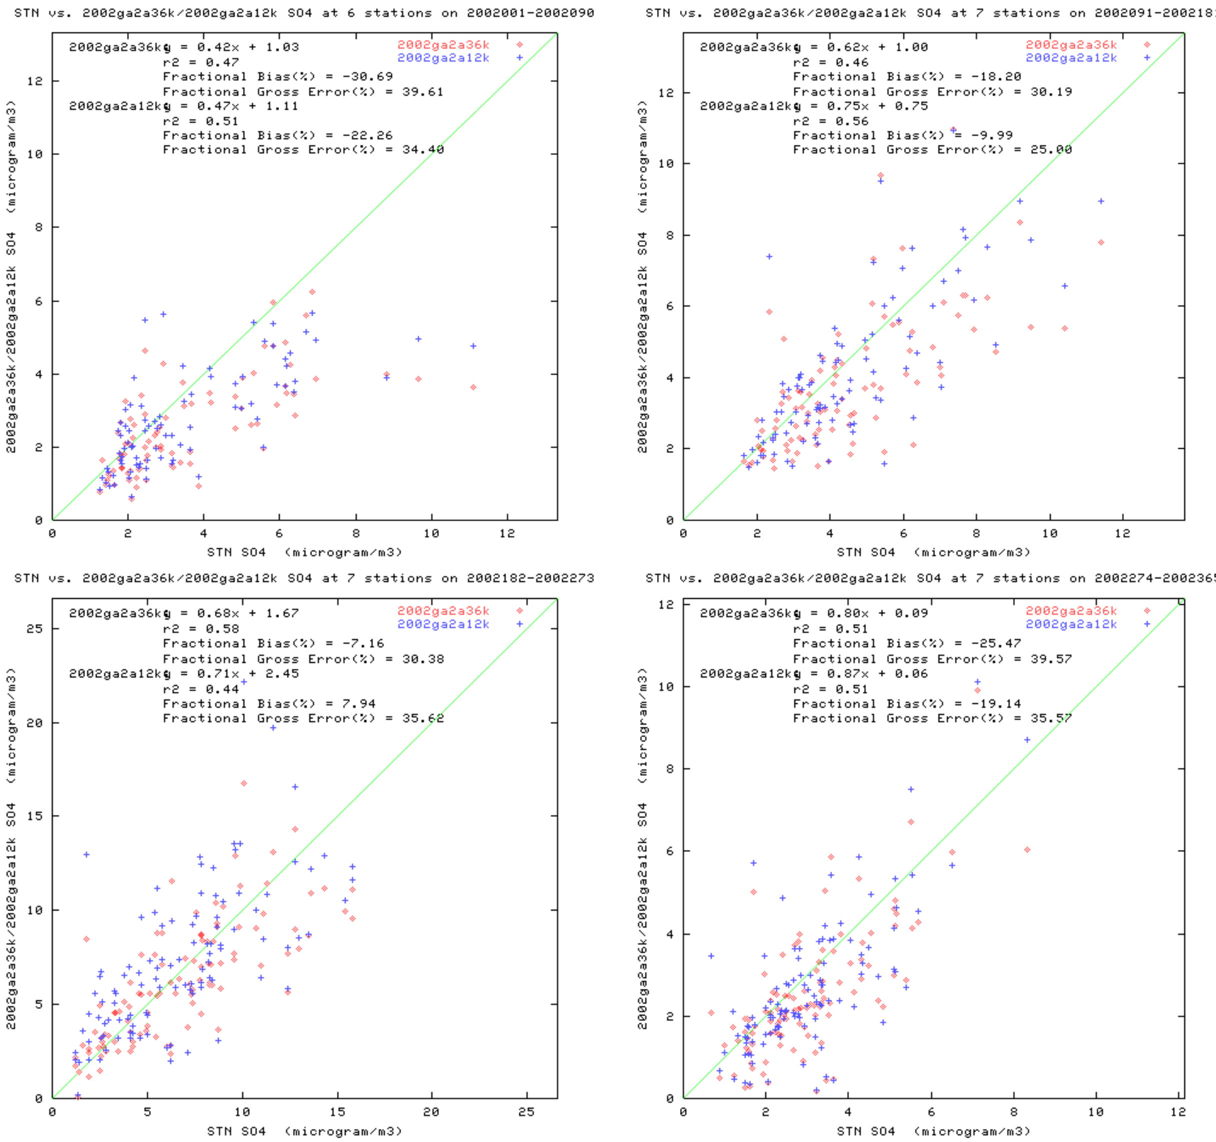

Figure B-34a. Scatter plots of predicted and observed sulfate (SO4) concentrations for Q1, Q2, Q3 and Q4 2002, STN sites in Tennessee and the CMAQ 2002 36 and 12 km Base G2 Actual base case simulation.

B.4.9 Virginia

SO4 performance is fairly good in Virginia with low bias and error in Q2 and Q3 that achieves the <±15%/35% ozone bias/error performance goal (Figure B-39a). Although SO4 performance in Q1 and Q4 exhibit a -17% to -21% underprediction bias, it still achieves the PM performance goal. As seen for the other states, NO3 performance is poor and characterized by an underprediction bias that is greatest in the summer (-150%) when CMAQ estimates near zero NO3 predictions. NH4 performance achieves the ozone performance goal in Q1 and Q2 and PM performance goal the other two quarters (Figure B-39c).

OCM performance is characterized by an underprediction bias of from -65% to -91% with error of opposite sign and similar magnitude (Figure B-39d). The fractional bias for EC is about 20-30 percentage points higher using CMAQ with a 12 km grid than 36 km grid resulting in the 12 km results always achieving the PM performance goal but the 36 km results underprediction bias in Q2 and Q4 is approximately -40% range so does not achieve the PM performance goal, but does achieve the PM performance criteria.

The $PM_{2.5}$ mass performance across the FRM sites is fairly good achieving (Q1, Q3 and Q4) or nearly achieving (Q2) the ozone performance goal (Figure B-39g). Across the STN sites, the PM performance goal is also achieved for all four quarters by the CMAQ 12 km modeling.

Figure B-40 displays an example annual time series model performance evaluation for a site in Richmond County, Virginia. SO4 performance at this Richmond County STN site is extremely good as the model follows the day-to-day variations quite well resulting in low annual fractional bias (-11%) and gross error (30%). NO3 performance, on the other hand, is characterized by a winter overprediction and summer underprediction bias with an annual bias and gross error of -46% and 91%, respectively. OCM at the Richmond site has an underprediction bias that occurs throughout the year resulting in an annual fractional bias of -46%. Better performance is seen for EC with bias (24%) and error (42%) that achieves the PM performance goal. $PM_{2.5}$ performance is also fairly good with bias (-10%) and error (28%) that achieves the most stringent ozone performance goal.

Another example time series model performance analysis is given in Figure B-41 for a site in Roanoke County, Virginia. Similarly good SO4 and poor NO3 performance is seen at the Roanoke County site. OCM is almost systematically underpredicted through the year with a -50% bias and 51% error. Whereas better performance is seen for EC that achieves the ozone performance goal. $PM_{2.5}$ performance is generally characterized by an underestimation tendency resulting in a -33% fractional bias.

Figures B-42 and B-43 summarize the $PM_{2.5}$ model performance across 19 FRM sites in Virginia using, respectively, Soccer and Bugle Plots. Monthly fractional bias and gross error for $PM_{2.5}$ mass achieves the PM performance goal for every month in 2002, with six of the months achieving the ozone performance goal and another two just at the ozone goal. As seen in the other states, the three summer months of May, June and July have an underprediction bias that exceeds the ozone performance goal, but still meets the PM performance goal.

B.4.10 West Virginia

There were no speciated $PM_{2.5}$ STN monitoring sites within West Virginia during the 2002 modeling year, so the $PM_{2.5}$ model evaluation is limited to the 16 FRM $PM_{2.5}$ mass monitoring sites. In Q1, Q2 and Q3, CMAQ underestimates $PM_{2.5}$ mass across the FRM sites in West Virginia by approximately -23%, -37% and -27%, respectively, and achieves the PM performance goal in (Figure B-44). In Q4 the model has near zero bias and 32% error so achieves the ozone model performance goal. The Soccer and Bugle Plots in Figures B-45 and B-46 summarizes the FRM $PM_{2.5}$ mass performance in West Virginia in each month. Nine of the months achieve the PM performance goal with the winter months even achieving or nearly achieving the ozone model performance goal. As seen for the other states, the underprediction bias during the May-July summer months results in the bias falling outside of the PM performance goal, but within the PM performance criteria.

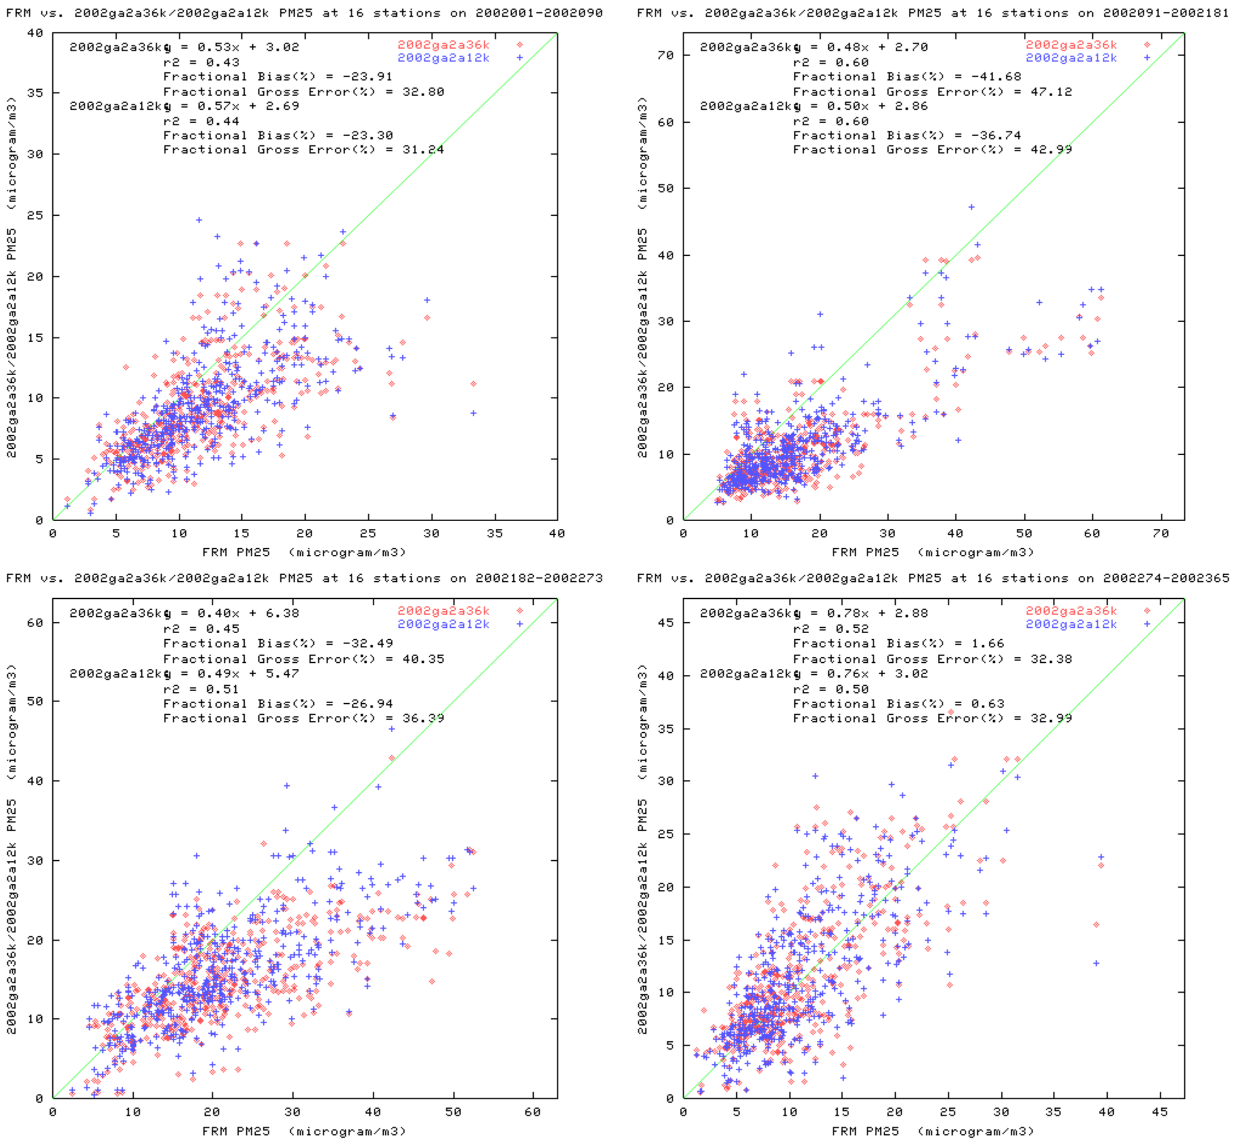

Figure B-44. Scatter plots of predicted and observed fine particulate mass ($PM_{2.5}$) concentrations for Q1, Q2, Q3 and Q4 2002, FRM sites in West Virginia and the CMAQ 2002 36 and 12 km Base G2 Actual base case simulation.

B.5 CONCLUSIONS STATE-BY-STATE MODEL EVALUATION

The state-by-state model performance evaluation for P.$M_{2.5}$ mass and component species reveals several model performance tendencies of the CMAQ 2002 Base G2 actual base case. SO_4 performance is by far constantly the best performing PM species frequently achieving the most stringent ozone performance goal. Although the SO_4 performance in some of the most southern states degraded some (e.g., Florida and Mississippi). NO_3 performance, on the other hand, was consistently poor with a large summer underprediction bias. OCM was routinely underpredicted, with the underprediction bias most severe in the summer months (May – July). EC performance is usually fairly good frequently achieving the most stringent ozone model performance goal with the CMAQ 12 km modeling results exhibiting much superior EC performance to the 36 km modeling results. Performance for NH4 and total $PM_{2.5}$ mass is also good most of the time. This is not surprising since the SO_4 performance is usually quite good and SO_4 dominates the $PM_{2.5}$ mass and drives the NH4 performance in the Southeast U.S.

APPENDIX C

Spatial Maps of Quarterly Average $PM_{2.5}$ Components and Total Mass Concentrations with Superimposed Observations for the CMAQ 2002 12 km Base G2 Actual Base Case Simulation

C.1 OVERVIEW OF SPATIAL MODEL PERFORMANCE

The discussion in this appendix provides a general qualitative overview of the 2002 Base G2 Actual base case model performance of the Community Multiscale Air Quality (CMAQ) modeling system Version 4.5 with SOAmods enhancement across the ASIP 12 km domain, with emphasis on temporal (seasonal) and spatial patterns within the domain. The evaluation is carried out for each of the major $PM_{2.5}$ components separately (sulfate, nitrate, ammonium, organic carbon material, elemental carbon, soil $PM_{2.5}$, sea-salt $PM_{2.5}$), as well as for total $PM_{2.5}$ mass. For each species, two sets of figures are provided, one comparing model predictions to observations at the STN sites, the other to observations at the IMPROVE network sites (soil and sea-salt are available at the IMPROVE network only). Total $PM_{2.5}$ mass estimates are also compared to observations at the FRM network, in addition to the STN and IMPROVE networks. Four figures are provided for each set corresponding to the average concentrations during the four quarters of the year (Q1: Jan-Mar; Q2: Apr-Jun; Q3: Jul-Sep; Q4: Oct-Dec).

This evaluation allows for a general understanding of model performance and key issues. A more detailed and quantitative performance evaluation at key VISTAS states sites is provided in Appendix B and summarized in Chapter 3.

The observed quarterly average $PM_{2.5}$ mass and $PM_{2.5}$ species concentrations were obtained by averaging all 24-hour measurements at a site that occurred during each three month quarter. The modeled quarterly average spatial maps were obtained by averaging the daily average concentrations for each day in the three month quarter and each grid cell. No attempt was made to match the modeled daily average concentrations with the 1:3 day sampling frequency used by the monitoring networks. In fact, obtaining modeled quarterly average concentrations trying to match the measurement days is problematic since not all sites collect valid samples on every 1:3 day sampling day. In the case of the STN network, this results in a bias in the Q1 quarterly average predicted and observed comparisons since many of the STN sites started up in 2002 and have samples near the end of Q1 but not during the beginning. For species like SO4 that has a strong seasonal trend, basing observed Q1 averages on samples in March and modeled values averaged across January-February-March introduces a seemingly underprediction bias that is artificial and an artifact of the network sampling periods. We know this is occurring at some STN sites, for example see discussion for Georgia in Section 3.5.3.

C.2 SPATIAL MODEL PERFORMANCE EVALUATION

C.2.1 Sulfate (SO4)

Modeled sulfate concentrations show a very strong seasonal pattern (Figures C-1a,b), with peak concentrations occurring during summer months (Quarters 2 and 3), when photochemistry is highest. A spatial pattern is also evident, with higher concentrations in the northeast, Ohio River valley, and southeast, compared to the upper Midwest and Florida, caused mainly by the higher and denser SO_2 emissions in those regions compared to the latter two. In Florida, the impacts of individual major sources of SO_2 are evident (such as in the Tampa and Jacksonville areas), as their emissions remain relatively unmixed with emissions from other regions, being surrounded by ocean. However, in most of the domain, a "regional" sulfate field is observed as a result of mixing of emissions from various regions, especially for the long averaging time presented here (three months).

Overall, the model seems to accurately simulate sulfate levels over the domain, and captures both the temporal and spatial patterns exhibited in the observations, both from the STN (Figure C-1a) and IMPROVE (Figure C-1b) networks. The exception is Quarter 1 for the STN network, in which the observed concentrations seem higher than the modeled ones, and there is not much agreement in the spatial pattern between the two. This is mainly due to an artifact in the way the observations are presented here discussed above. Since some of the STN sites were not in operation during the first few months of 2002, observed Quarter 1 averages might in fact be driven by observations during the latter (and warmer) part of Quarter 1 (e.g., March samples), and therefore are biased high.

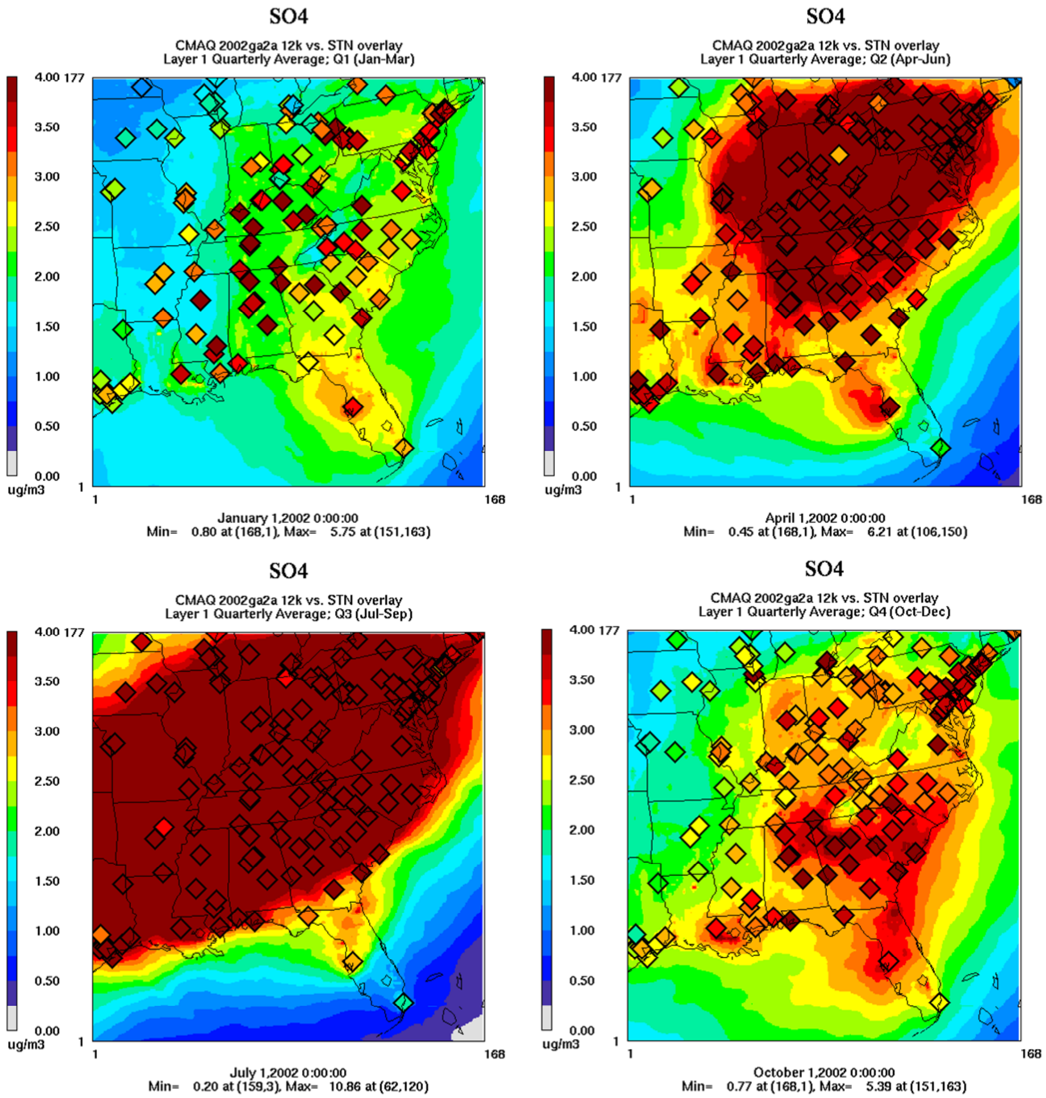

Figure C-1a. 2002 Quarterly averages of CMAQ simulated and STN observed (diamonds) sulfate (SO4) concentrations over the VISTAS 12 km domain.

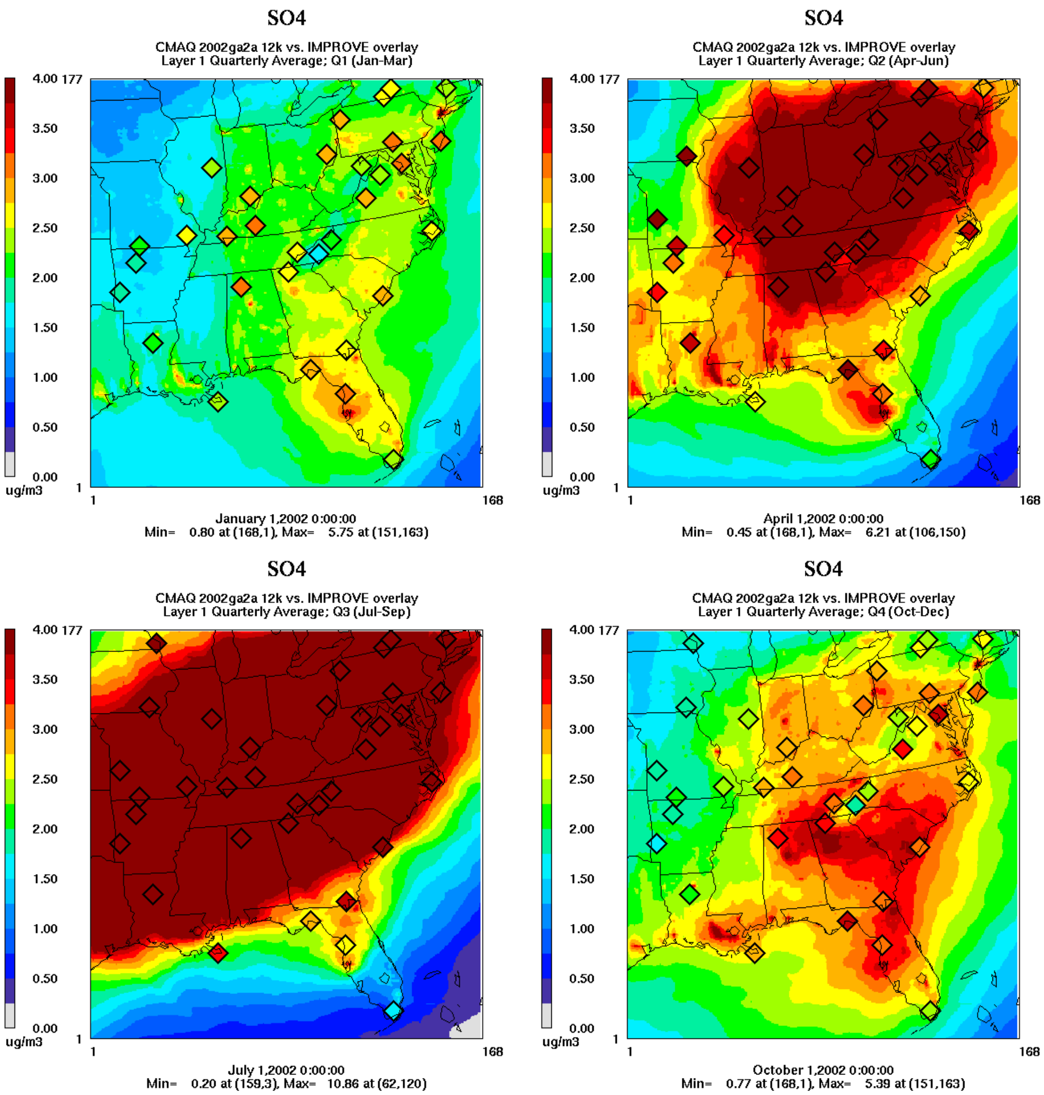

Figure C-1b. 2002 Quarterly averages of CMAQ simulated and IMPROVE observed (diamonds) sulfate (SO4) concentrations over the VISTAS 12 km domain.

C.2.2 Nitrate (NO3)

Nitrate is in many ways the "mirror" image of sulfate, with peak concentrations occurring during wintertime, when the cooler temperatures are favorable for particulate nitrate formation and sulfate concentrations are lower making more ammonia available to bond with nitrate. The need for nitrate to be neutralized by a basic compound in order to be in the particulate state results in peak particulate nitrate concentrations occurring in areas of the domain where ammonia emissions are highest, such as the Midwest.

While overall the model does capture the seasonal and spatial variability in particulate nitrate concentrations (Figures C-2a,b), it does seem to overestimate concentrations during wintertime, especially over urban centers, such as in part of the Northeast and over Atlanta and Birmingham. Winter overestimations are also evident over much of North Carolina. While it is impossible to infer from these data alone on the cause for these overpredictions, they are related to either one or a combination of the model nitrate partitioning between gaseous and particulate phase, and the availability of gaseous ammonia, as reflected by the emissions inventory. The latter can be the common denominator between the overpredictions over the urban centers and over North Carolina, as ammonia emissions in these areas, though originating from different sources (mobile sources in the urban centers; agricultural ammonia emissions in North-Carolina), might be overestimated, making more ammonia available for particulate formation compared to the observations.

In the summer, the model estimates near zero (< 0.25 $\mu g/m^3$) particulate nitrate concentrations, whereas the observed values are typically in the 0.25-0.75 $\mu g/m^3$ range. In any event, both the modeled and observed summer NO3 values suggest that it is not an important component of the total $PM_{2.5}$ mass concentrations in the southeastern U.S. during the summer.

Fairly similar trends are observed when comparing the model to either the STN (Figure C-2a) or the IMPROVE (Figure C-2b) networks, however a more detailed analysis is provided based on the STN, given its size and density.

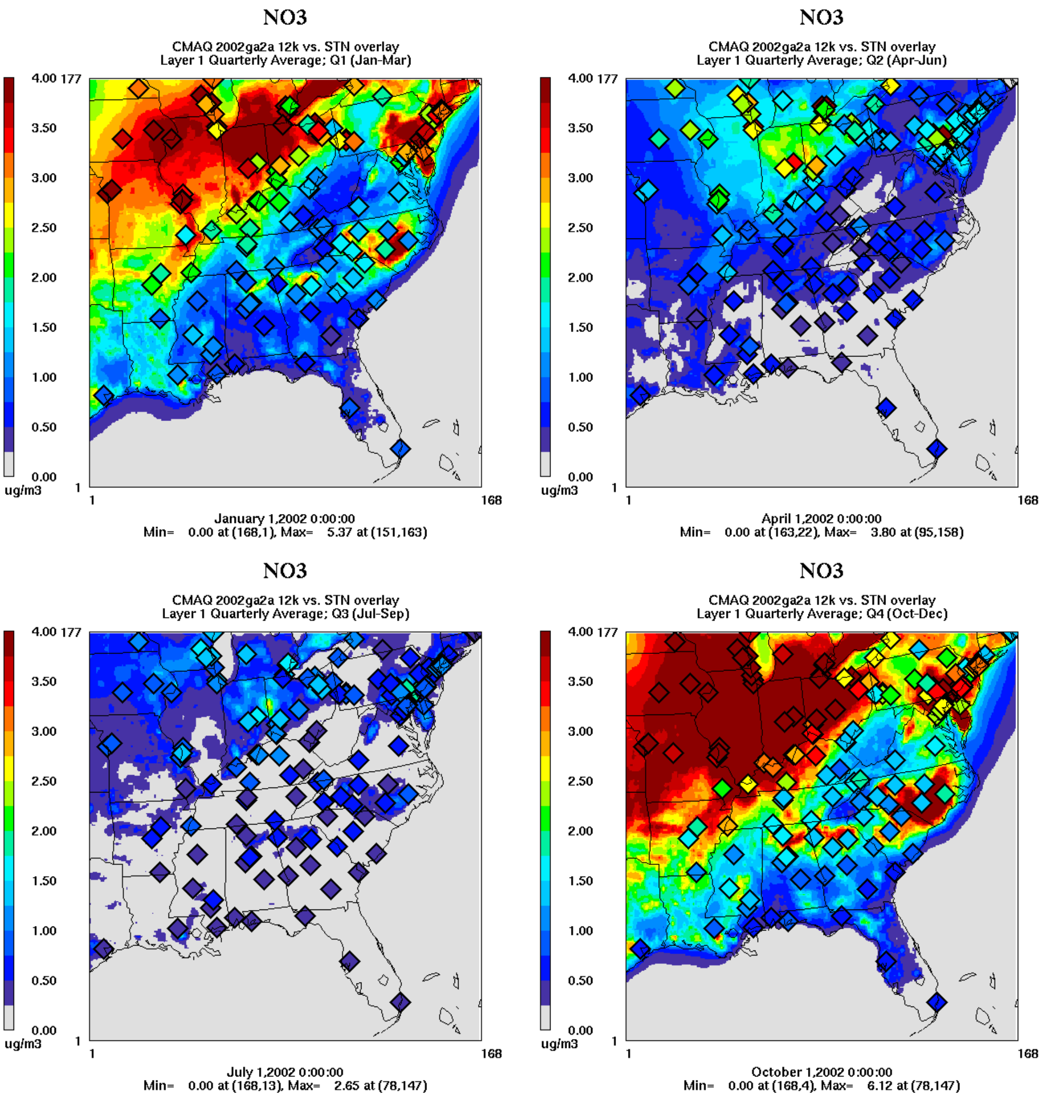

Figure C-2a. 2002 Quarterly averages of CMAQ simulated and STN observed (diamonds) nitrate (NO3) concentrations over the VISTAS 12 km domain.

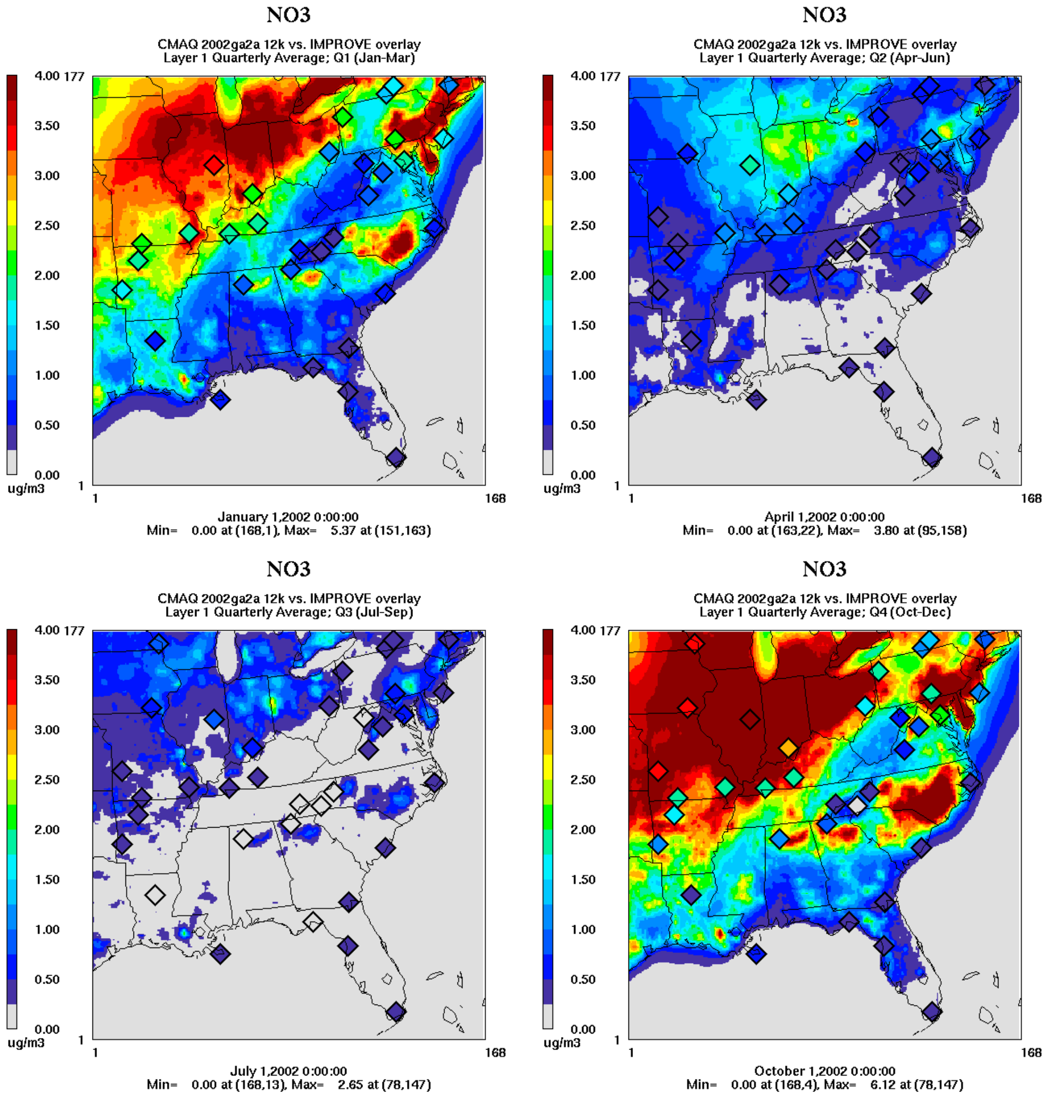

Figure C-2b. 2002 Quarterly averages of CMAQ simulated and IMPROVE observed (diamonds) nitrate (NO3) concentrations over the VISTAS 12 km domain.

C.2.3 Ammonium (NH4)

Ammonium concentrations depend, to a large degree, on the availability of sulfate and nitrate. Therefore, ammonium levels do not exhibit as strong seasonal pattern, due to the seasonal tradeoff between sulfate and nitrate, to which it bonds.

Model performance, when compared to the STN data (Figure C-3a), seems to be better during summertime (Quarters 2 and 3), when the ammonium is mainly associated with sulfate. During wintertime (Quarters 1 and 4), most of the issues observed with nitrate overpredictions are also evident in the ammonium plots, especially over North-Carolina and the urban centers of the Southeast.

Ammonium is not directly measured by IMPROVE, rather it is derived by assuming it completely neutralizes the measured sulfate and nitrate. Assuming that nitrate is completely neutralized by ammonium is most of the time a valid assumption, however the same may not be true for sulfate, especially in the summer months. Hence the observed ammonium comparison in the IMPROVE case (Figure C-3b) is likely overstated during the summer months when sulfate is less likely to be fully neutralized and the seemingly underpredicted observed ammonium concentrations across the Appalachian Mountain IMPROVE monitoring sites in Quarter 3 in Figure C-3b are in part due to using derived observed ammonium.

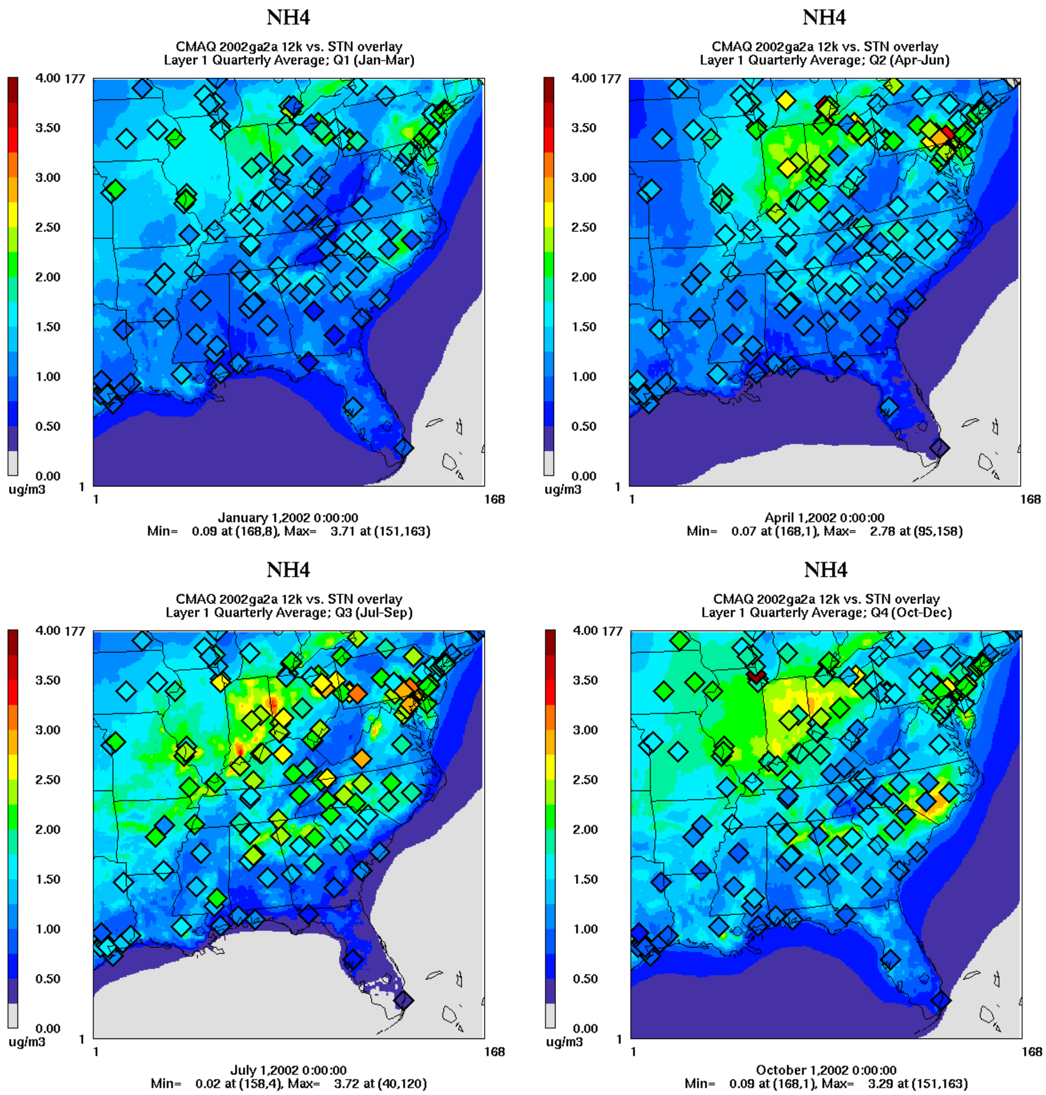

Figure C-3a. 2002 Quarterly averages of CMAQ simulated and STN observed (diamonds) ammonium (NH4) concentrations over the VISTAS 12 km domain.

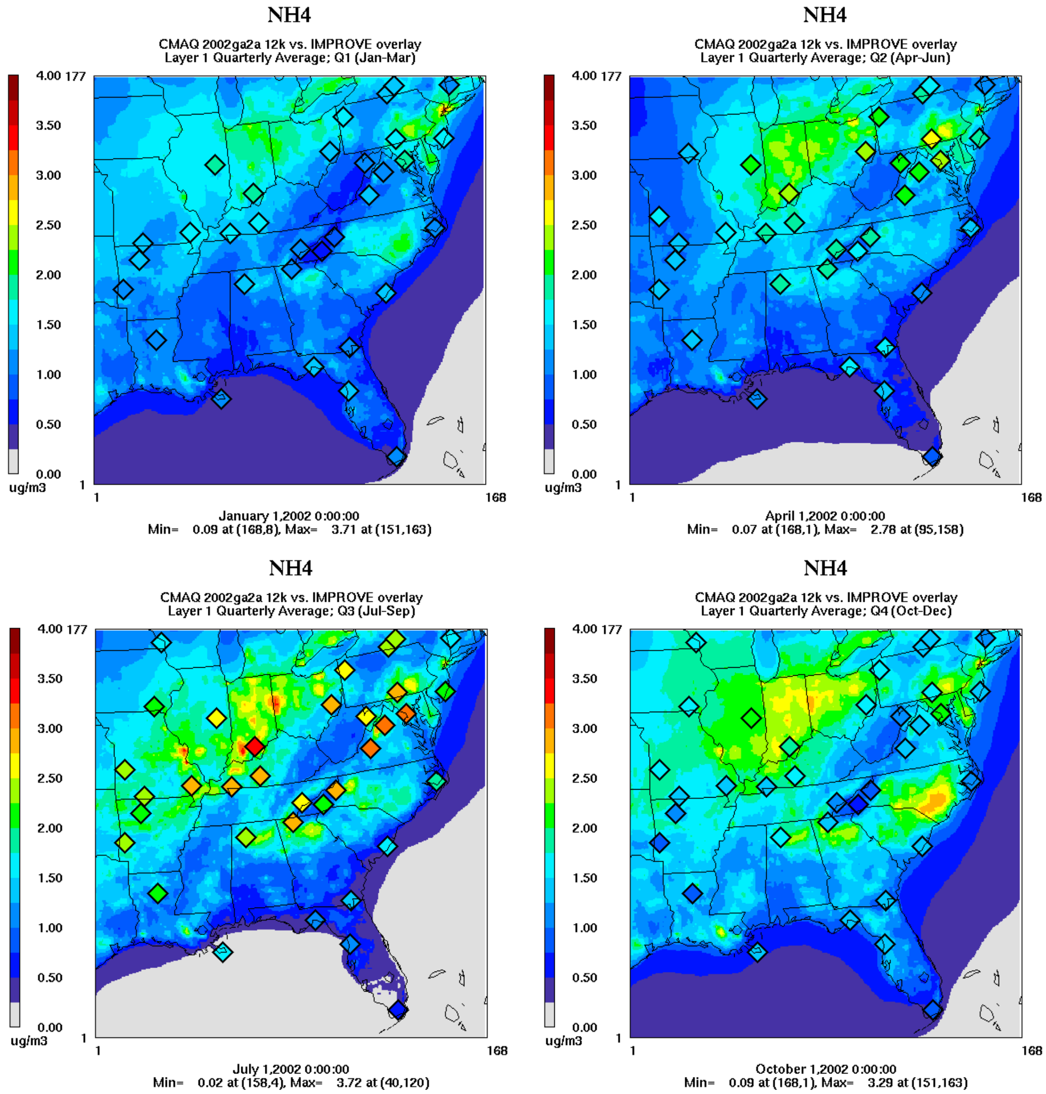

Figure C-3b. 2002 Quarterly averages of CMAQ simulated and IMPROVE derived (diamonds) ammonium (NH4) concentrations over the VISTAS 12 km domain.

C.2.4 Organic Carbon Material (OCM)

Evaluating model performance for OCM is complicated due to its dual primary/secondary nature and anthropogenic/biogenic precursor sources. As a result, the evaluation is dependant on a combination of very different emissions and formation processes. In addition, there is a fair amount of uncertainty associated with OC measurements, with a major limitation being the inability to directly measure OCM. Instead, only OC is measured, and OCM is estimated (and compared to model results) by multiplying OC by an OCM/OC ratio factor. Such OCM/OC ratio factors typically range from 1.2 to 2.2 depending on whether the OCM is fresh or aged, where we have used an OCM/OC factor of 1.4. In addition, different analysis methods are used in the STN (NIOSH) and IMPROVE networks that introduce additional measurement artifacts.

The seasonal pattern of OCM concentrations would depend on the relative contributions from secondary OCM (peak concentrations during summertime) and primary OCM. The seasonal pattern of primary OCM would depend on the seasonality of activity and emissions from sources such as biomass burning and transportation. Given a flat activity/emissions profile, primary OCM is would typically be higher in wintertime, due to reduced atmospheric mixing.

Comparing model OCM predictions to STN observations (Figure C-4a), both exhibit a fairly flat seasonal pattern. Overall, the modeled concentrations are lower compared to observations. The model seems to exhibit a much stronger spatial pattern, with peak concentrations occurring in the Southeast. This is likely associated with biomass burning in the winter months, and biogenic secondary OCM formation in the summer months. The increased modeled-concentrations of secondary OCM are evident in Quarter 3, especially over the Northeast. When comparing simulated concentrations to IMPROVE observations (Figure C-4b), better agreement is observed. Given that most IMPROVE sites are located in rural areas, this may be an indication that OCM is underpredicted mainly at urban sites (STN, Figure C-4a), possibly due to local spatial gradients and the comparison of diffused 12 km grid-cell volume average concentrations to point measurements at urban sites. It is also partly due to measurement artifacts where the STN OC observations are not "blank corrected" so are biased high.

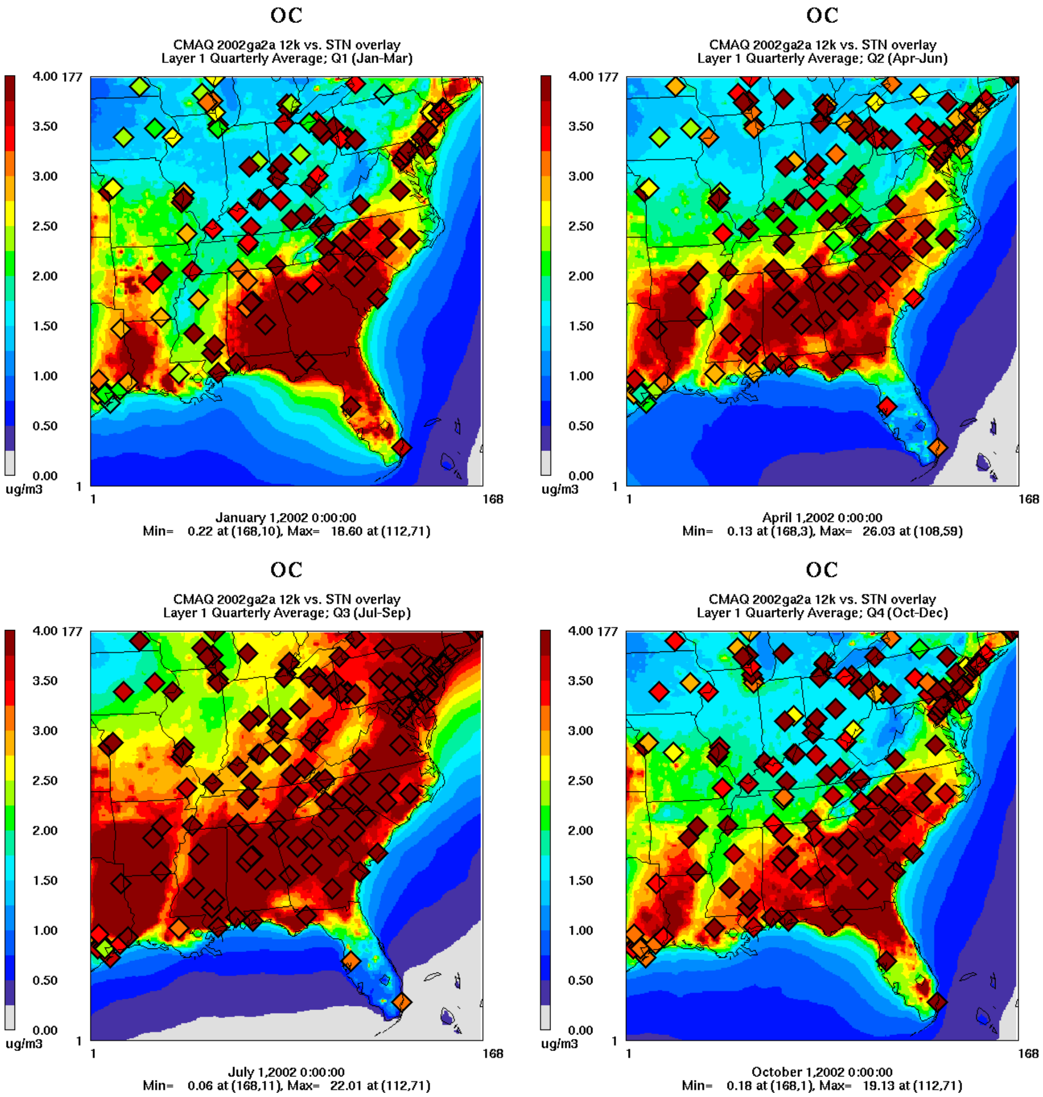

Figure C-4a. 2002 Quarterly averages of CMAQ simulated and STN observed (diamonds) organic carbon material (OCM) concentrations over the VISTAS 12 km domain.

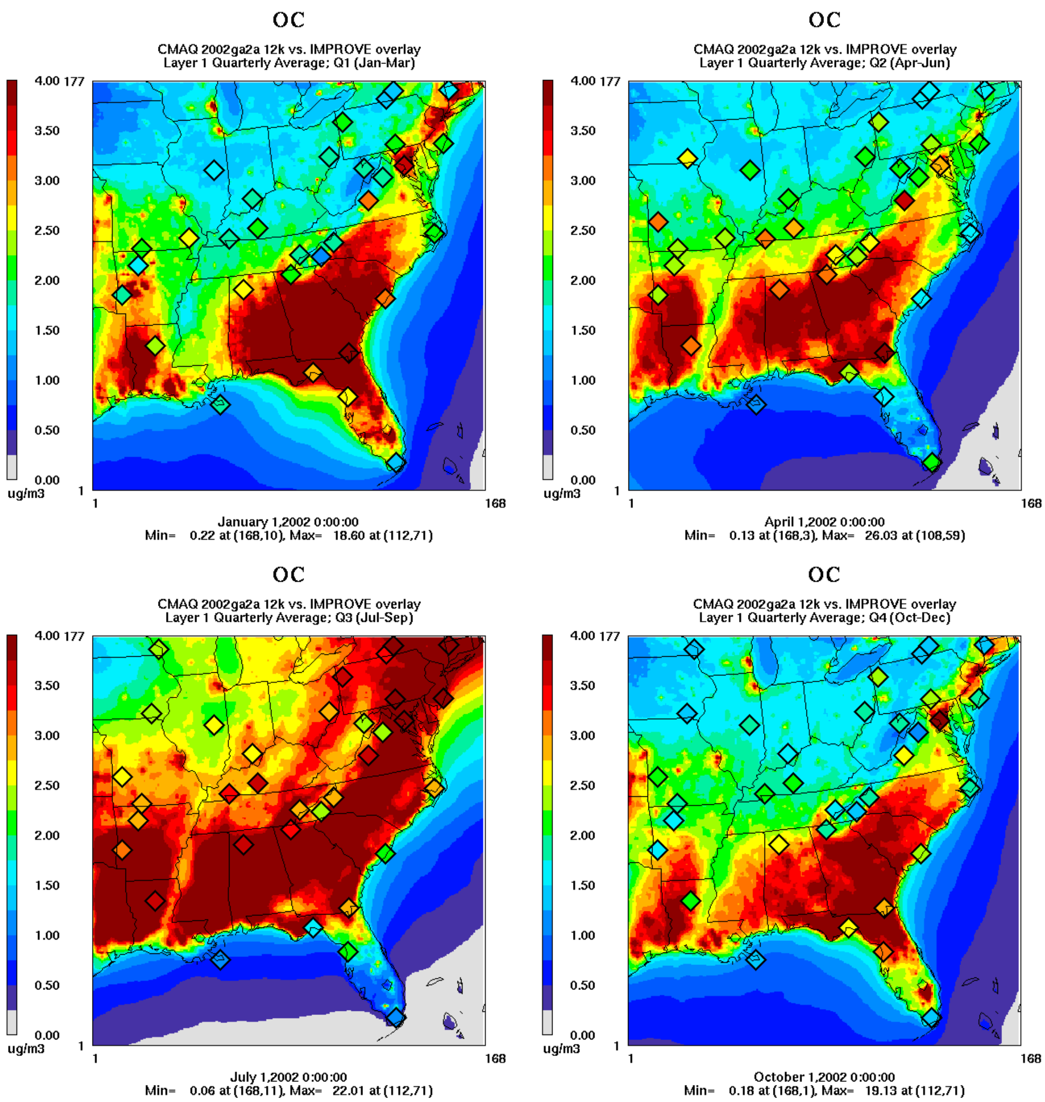

Figure C-4b. 2002 Quarterly averages of CMAQ simulated and IMPROVE observed (diamonds) organic carbon material (OCM) concentrations over the VISTAS 12 km domain.

C.2.5 Elemental Carbon (EC)

Evaluating model performance for EC, the model tends to underpredict concentrations when compared to the STN network (Figure C-5a), while better agreement is observed with the IMPROVE network (Figure C-5b). This follows the same conclusion as for OCM and may be reflecting the differences between grid-cell volume average concentrations and point measurements. These differences are expected to be more pronounced at urban sites (STN) compared to rural ones (IMPROVE), as at urban locations there are likely stronger local spatial gradients in EC concentrations. The STN and IMPROVE networks also use different methods for measuring EC that may also be contributing to the differences in EC model performance using the two networks. In Chapter 3 and Appendix B we noted that the CMAQ 12 km modeling results exhibited superior EC model performance to the CMAQ 36 km modeling results across the urban STN network so the dilution of the urban EC emissions across the coarse 12 km grid cell is surely contributing to the EC underprediction tendency.

Both the modeled values and observations (at both networks) exhibit higher concentrations in wintertime (Quarters 1 and 4) that is likely due to reduced atmospheric mixing compared to summertime. However, the seasonal pattern is much stronger in the model results compared to the observations.

Another interesting finding has to do with relatively high modeled EC concentrations in the western part of the Georgia-Florida border, especially in Quarter 1. This is due to modeled emissions from biomass burning activities. However, nearby measurements at both the STN and IMPROVE networks do not exhibit the same trend.

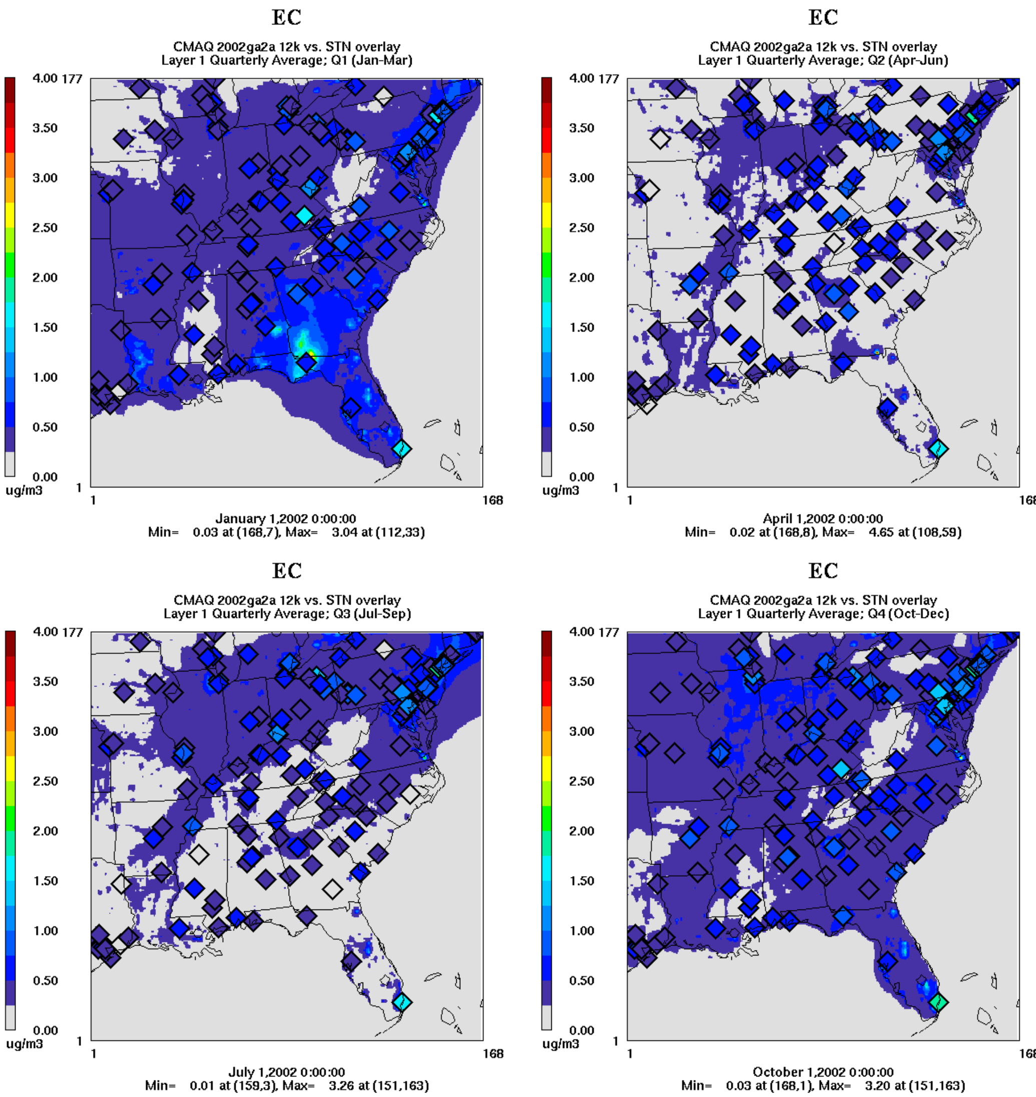

Figure C-5a. 2002 Quarterly averages of CMAQ simulated and STN observed (diamonds) elemental carbon (EC) concentrations over the VISTAS 12 km domain.

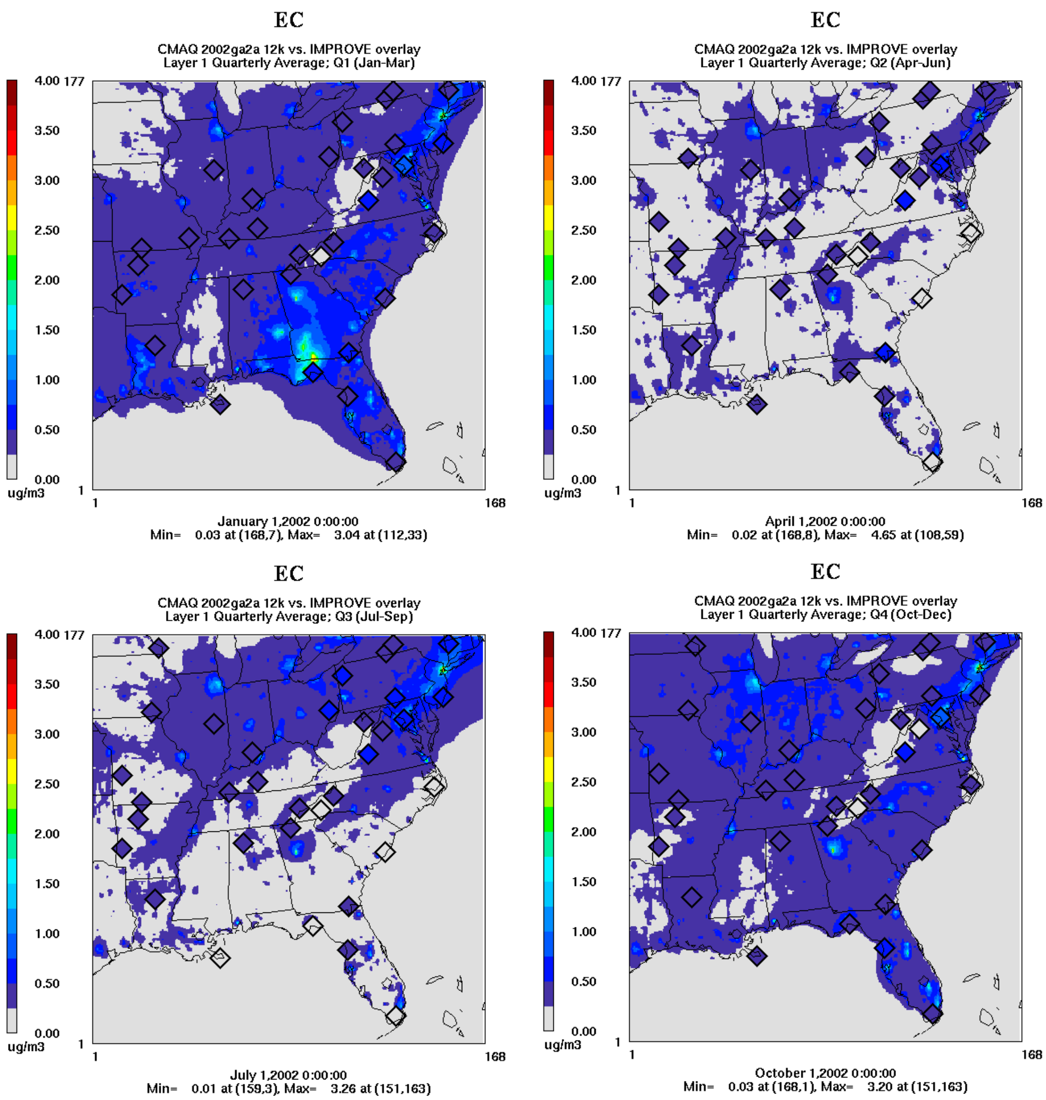

Figure C-5b. 2002 Quarterly averages of CMAQ simulated and IMPROVE observed (diamonds) elemental carbon (EC) concentrations over the VISTAS 12 km domain.

C.2.6 Soil $PM_{2.5}$ (SOIL)

Soil $PM_{2.5}$ is measured/calculated/derived at the IMPROVE sites only (Figure C-6). In general, soil $PM_{2.5}$ is overpredicted compared to the observations. This is a common issue in grid-based models, where resuspended fugitive dust is assumed to be mixed uniformly in the first layer of the model, whereas in practice most of it is removed locally by impaction onto surfaces such as cars, buildings and vegetation. Higher concentrations are especially evident in urban centers, due to the way the model calculates the emission and dispersion of resuspended road dust. However, this is not very evident in this comparison, since most IMPROVE sites are located in rural areas. The ASIP/VISTAS modeling did apply fugitive dust transport factors (FDTF) to fugitive dust emission source categories to account for dust that is deposited locally and not transported.

Another issues associated with the Soil evaluation is the mismatch between how Soil is defined in the measured versus modeled values. The measured Soil values are derived by building it up from the elements, whereas the modeled values are obtained from the emission speciation profiles that assign all $PM_{2.5}$ that is not explicitly speciated as SO4, NO3, EC or OCM to the other $PM_{2.5}$ category that is interpreted as Soil in the model performance evaluation.

Also evident in the figures are the higher modeled concentrations in the western side of the domain. This could be originating for various reasons, such as possibly higher emissions in that region, transport into the domain from the west, or differences in methodologies used to calculate crustal emissions between the various Regional Planning Organizations (RPOs). The latter is likely the case, since a sharp spatial gradient is observed between the Midwest RPO states (and west of Mississippi, in the portions of the CENRAP states) and the MANE-VU (northeast) and VISTAS (southeast) states (see Figure 1-1 for definition of the RPO states).

Regardless of actual model performance, in the context of $PM_{2.5}$ State Implementation Plan (SIP) development and future attainment tests, modeled levels of soil components are of relatively little importance, since they are normalized according to observations, and little to no controls are being applied to fugitive dust sources (so the Relative Reduction Factor would be equal or close to unity).

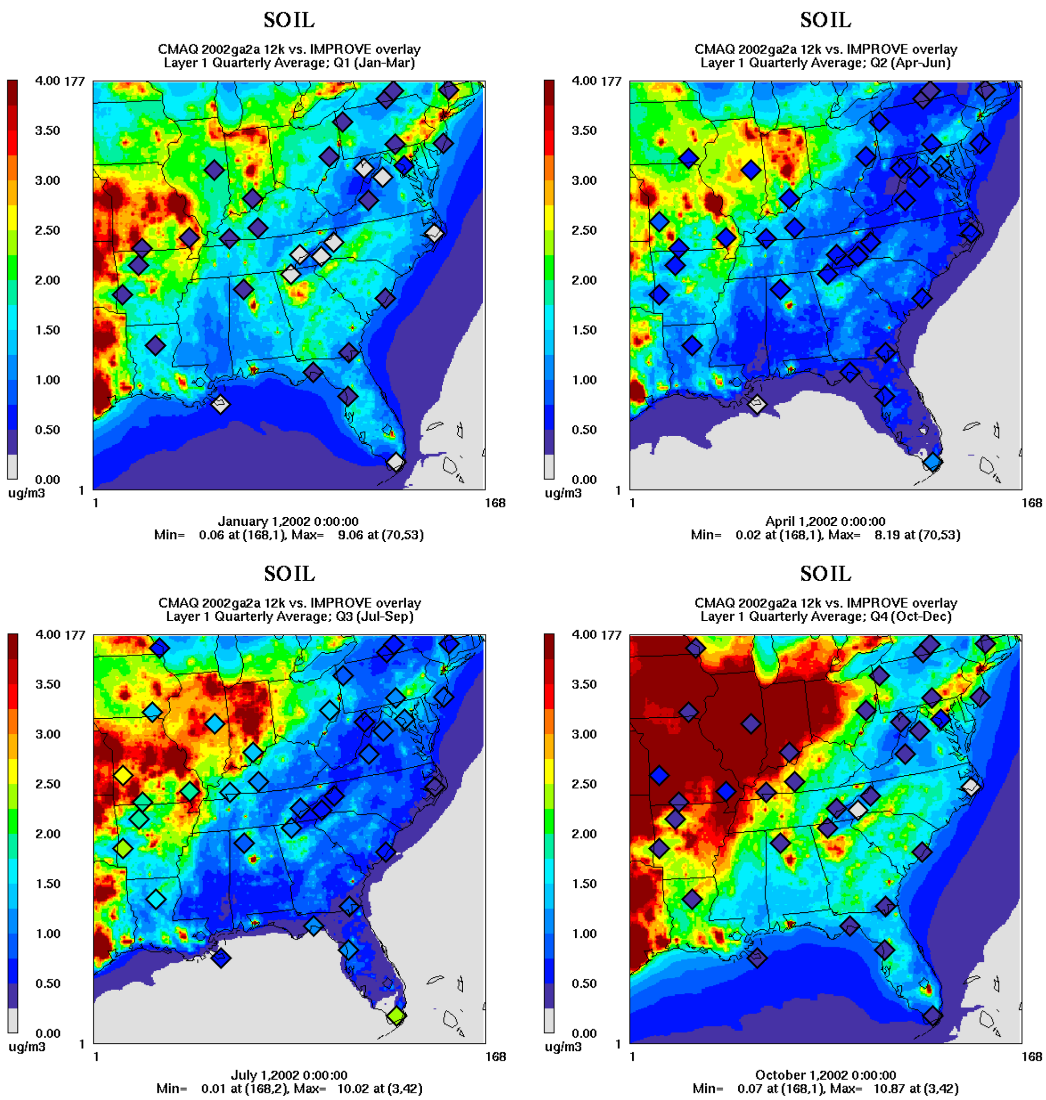

Figure C-6. 2002 Quarterly averages of CMAQ simulated and IMPROVE observed (diamonds) soil $PM_{2.5}$ (SOIL) concentrations over the VISTAS 12 km domain.

C.2.7 Sea-Salt $PM_{2.5}$ (SeaSalt)

Sea-salt $PM_{2.5}$ is measured/calculated at some of the IMPROVE sites only (Figure C-7). As expected, higher concentrations are measured at sites along the coastline. This spatial pattern is captured by the model as well; however, concentrations along the coastline are underpredicted compared to the measurements.

Since sea-salt $PM_{2.5}$ is not used for future attainment tests as part of the SIP development process, model performance in this case is of relatively little importance.

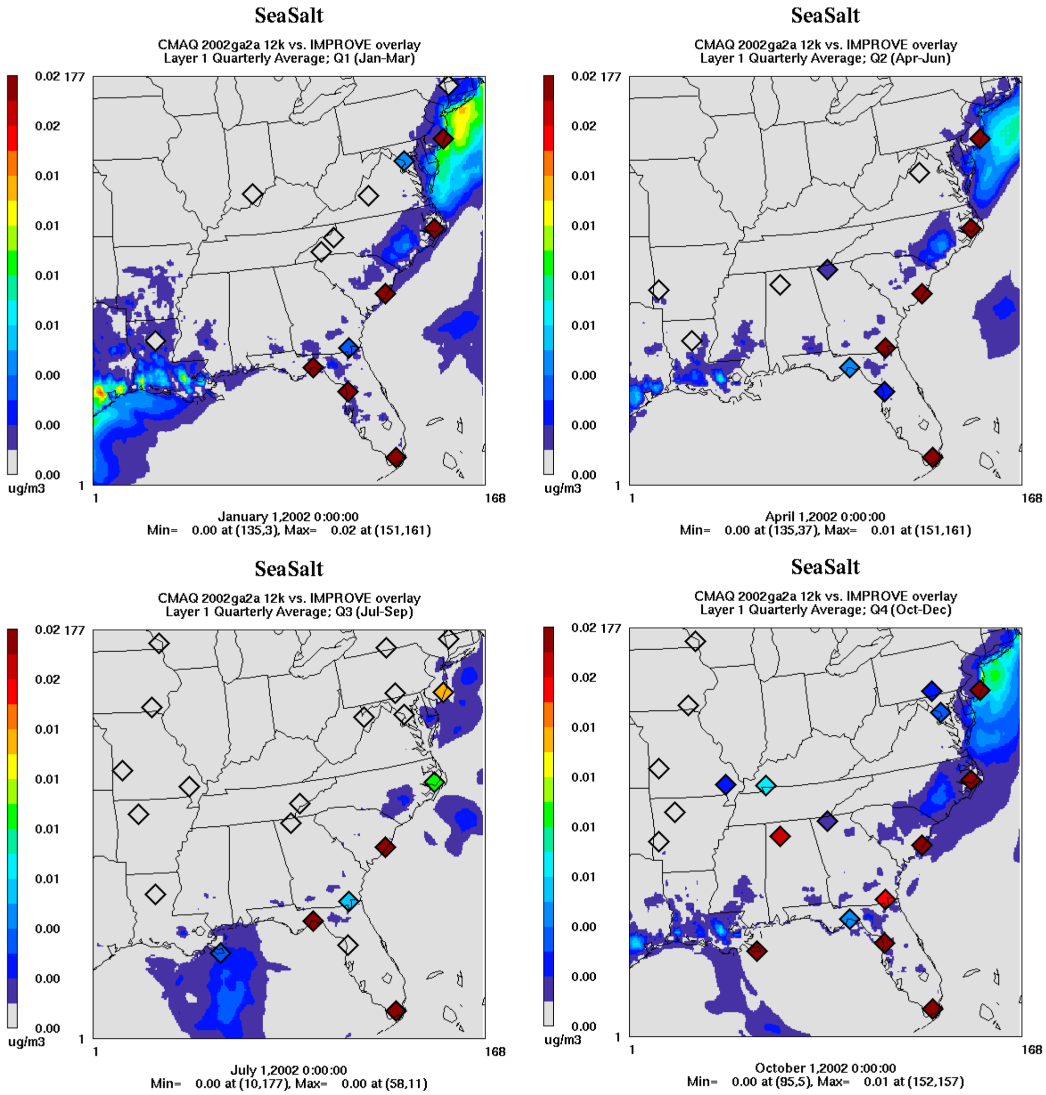

Figure C-7. 2002 Quarterly averages of CMAQ simulated and IMPROVE observed (diamonds) sea-salt $PM_{2.5}$ (SeaSalt) concentrations over the VISTAS 12 km domain.

C.2.8 Total $PM_{2.5}$ Mass ($PM_{2.5}$)

A comparison of the modeled spatial distribution of quarterly average total $PM_{2.5}$ mass concentrations with observations from the FRM, STN and IMPROVE network are provided in Figure C-8. The conclusions on the model performance for total $PM_{2.5}$ mass vary by which network is examined. For Q1, there are elevated PM $_{2.5}$ concentrations in the major urban areas (e.g., Chicago-Gary, St. Louis, Atlanta, Northeast Corridor, etc.) and the western part of the Georgia-Florida border, the latter is due to biomass burning. The mainly rural IMPROVE monitors fail to capture any of these elevated areas, but does confirm the relative clean conditions in the Appalachian Mountains (Figure C-8c, top left). The IMPROVE St. Marks measured $PM_{2.5}$ levels appears to refute the elevated $PM_{2.5}$ in Q1 along the western Florida-Georgia border. However, the STN (Figure C-8b) and FRM (Figure C-8a) spatial plots confirm that elevated $PM_{2.5}$ levels occur in this area during Q1; the lack of elevated $PM_{2.5}$ at St. Marks is likely due to its coastal location.

During Q2 the model predicts elevated total $PM_{2.5}$ mass levels from St. Louis across the Midwest into Ohio with highest values centered on Indianapolis, in southeastern Pennsylvania and up the Northeast Corridor, and in the Birmingham and Atlanta urban areas in the southeast. The IMPROVE monitors suggest that the model is capturing the rural aspect of the spatial distribution of the total $PM_{2.5}$ mass patterns, albeit with an underprediction bias (Figure C-8c, top right). However, the FRM (Figures 3-26 and C-8a) and STN (Figure C-8b) plots indicates that the model is underestimating the spatial coverage of the elevated total $PM_{2.5}$ mass levels.

The highest seasonal $PM_{2.5}$ levels occur in the Q3 summer period when SO4 is the highest. The observations indicate that the entire interior portion of the ASIP/VISTAS 12 km grid domain is covered by elevated $PM_{2.5}$ levels, which is reproduced reasonably well by the model. However, the model is estimating slight lower values and relatively cleaner areas over the Appalachian Mountains that are not supported by the observations. In addition, the observed $PM_{2.5}$ concentration gradient from high to low occurs further south than predicted by the model. However, in general the model is doing a good job in reproducing the spatial distribution of $PM_{2.5}$ in Q3.

In Q3 the model estimates elevated PM levels across the upper Midwest (MO-IL-OH) and southwest (Northern AL and GA, SC and NC) that is split by the Appalachian Mountains and elevated levels in the Northeast Corridor. The IMPROVE network plots confirm the relative cleaner area in the Appalachian Mountains (Figure C-8c) and the STN network plot confirms the three areas of high $PM_{2.5}$ (Figure C-8b).

Model performance evaluation for total $PM_{2.5}$ mass depends heavily on the performance for the individual components. As such, it is less meaningful than the performance evaluation for the individual components. In addition, modeled total $PM_{2.5}$ is not used for future attainment tests as part of the SIP development process that uses the Speciated Modeled Attainment Test (SMAT) that is based on the modeled $PM_{2.5}$ component species. The FRM network spatial map (Figure 3-26 and C-8a) confirms the three areas of elevated $PM_{2.5}$ concentrations, but suggests the southeast area is not as high as the others and that the $PM_{2.5}$ distribution should be spottier.

In conclusion, the model appears to do a good job in reproducing the spatial and temporal variations in $PM_{2.5}$ concentrations across the ASIP/VISTAS 12 km grid, albeit with an underprediction bias. The spatial distribution of the modeled $PM_{2.5}$ concentrations is smoother and less spotty than the observed distributions, which is due in part to the coarse 12 km grid spacing used in the modeling.

APPENDIX D

Comparative Model Performance Evaluation of the CMAQ and CAMx Models

D.1 OVERVIEW

In this Appendix we present a comparison of the PM model performance evaluation between the CMAQ 2002 12 km Base G2 Actual base case and the CAMx 12/4 km Base G2 Typical base case simulations. In Chapter 3 and Appendices B and C, as well as in the VISTAS regional haze modeling TSD (Morris et al., 2009), we presented a detailed model performance evaluation of the 2002 CMAQ 36/12 km Base G2 Actual base case simulation. The basic features of model performance between the two modeling systems are similar. So just a summary model performance comparison is presented in this section. We first present a broad brush evaluation of the two models across the CAMx 12 km modeling domain, and then present a more detailed evaluation of model performance within each of the four 4 km modeling domains (see Figure D-1).

Although the basic meteorological, emissions and initial and boundary conditions used in the CMAQ and CAMx 2002 base case simulations were similar, there were several updates to the 2002 Base G2 emissions used in the CAMx modeling. Because the CAMx 2002 base case simulation was performed more recently than the CMAQ base case, we were able to implement several emission corrections to the 2002 Base G2 emissions. The following is a list of the major differences in the CMAQ and CAMx 2002 base case simulations:

- Addition of 65,000 tons per year SO2 emissions at the W.H. Sammis EGU in northern West Virginia.
- Addition of SO2 and PM emissions in Jefferson County, Kentucky (Louisville) that were inadvertently left out of the CMAQ 2002 Base G2 emissions scenario when only ozone precursor emissions were provided in the emissions update.
- The treatment of SOA from biogenic VOCs is different in the two models.
- The used of 4 km resolution over the four 4 km domains and two-way grid nesting in CAMx between the 12/4 km grids versus CMAQ 12 km domain.
- The CMAQ base case used Actual and the CAMx Typical emissions for EGUs and fires.
- Other differences related to model formulation.

D.2 EVALUATION ACROSS THE CAMx 12 KM DOMAIN

Numerous statistical performance measures and graphical displays of model performance were generated comparing the CMAQ 12 km Base G2 Actual and CAMx 12/4 km Base G2 Typical base case simulations. Below we evaluate the performance for each of the major components of $PM_{2.5}$ as well as for total $PM_{2.5}$ mass using PM measurements across the CAMx 12 km domain (Figure D-1) and observations from the IMPROVE, STN[1], CASTNet and FRM monitoring networks.

D.2.1 SO4 Model Performance Across the CAMx 12 km Domain

Bugle Plots and Time Series Plots of monthly fractional bias and error for sulfate (SO4) concentrations and the CMAQ and CAMx models using observed SO4 concentrations across the CAMx 12 km domain and the IMPROVE, STN and CASTNet monitoring networks are shown in Figures D-2 and D-3, respectively. In the Bugle Plots in Figure D-2, the filled symbols are for the CAMx 2002gt3 base case, whereas the unfilled symbols are for the CMAQ 2002ga2 base case simulations. The two models SO4 performance measures are quite good with both models almost always achieving the PM performance goal (bias/error ≤±30%/50%) and frequently achieving the more stringent ozone performance goal (bias/error ≤±15%/35%) for many months. Although both models achieve performance goals for SO4, there are differences in the two models' performance. CMAQ tends to underestimate the observed SO4 concentrations, whereas CAMx has an overestimation tendency. This is clearly seen in the monthly fractional bias bar charts in Figure D-3. Which model is performing better for SO4 depends on the month and monitoring network examined.

Across the IMPROVE network, the two models have similar SO4 performance that is very good from January to August, albeit with the CMAQ underestimation and CAMx overestimation tendency mentioned previously. In September and October, the CAMx overestimation tendency becomes greater with the October fractional bias (40%) exceeding the PM performance goal (≤ ±30%). However, for the last two months of the year the CAMx bias is lower than CMAQ.

Across the STN monitoring network the two models SO4 performance is quite good achieving the most stringent ozone model performance goal for most months, again with CMAQ exhibiting and underestimation and CAMx an overestimation tendency; the degradation of the CAMx fractional bias in September and October that was seen across the IMPROVE network is not present across the STN network.

For the first half of 2002, the CAMx exhibits near zero SO4 fractional bias across the CASTNet network that is much lower than CMAQ. During the summer (June-September) both models have near zero fractional bias and error that achieves the PM performance goal. The CAMx October SO4 overestimation bias seen in the IMPROVE network is also present in the CASTNet network resulting in degraded model performance for that month.

The bottom right monthly bar chart in Figure D-3 displays model performance for ammonium (NH4) across the STN network. During the non-summer months, both models exhibit an overestimation bias for NH4, with the CAMx overestimation bias greater than CMAQ. During the summer months the bias is lower with the CAMx performance slightly better than CMAQ.

[1] Note that the Speciated Trends Network (STN) is now called the Chemical Speciation Network (CSN)

Figure D-4 displays scatter plots of predicted and observed 24-hour SO4 (IMPROVE and STN) and weekly SO4 (CASTNet) SO4 concentrations and 24-hour STN NH4 concentrations for January, April, July and October, 2002. In January (Figure D-4a), the SO4 performance of the two models is similar with both models always achieving the PM performance goals and both models achieving the more stringent ozone performance goal across the STN network, with the CAMx model also achieving it across the CASTNet network.

The CMAQ and CAMx SO4 performance is also very good in April with both models achieving the ozone model performance goal across all three monitoring networks. Similarly, in July the model performance of both models is very good and, with the exception of fractional error across the IMPROVE network, achieves the most stringent ozone performance goal; the CMAQ and CAMx fractional error values across the IMPROVE network were 36% and 39% that just barely exceeds the ozone performance goal (≤35%).

In October, the CAMx increase in SO4 overestimation tendency results in degraded SO4 model performance across the IMPROVE and CASTNet networks, although SO4 performance of both models using the STN network is quite good. The reason for the CAMx degraded SO4 model performance in October is unclear, but it appears to be an isolated occurrence to this month for the more rural IMPROVE and CASTNet monitors.

In conclusion, based on the fractional bias and error statistical performance measures the performance of both the CMAQ and CAMx models for simulating SO4 concentrations across the CAMx 12 km KY/TN/WV modeling domain can be characterized as being very good. The CMAQ model tends to have an underestimation tendency, whereas the CAMx model tends to have an overestimation tendency. For most months the two models achieve the most stringent ozone performance goal and, except for the CAMx October performance, always achieve the PM performance goal.

D.2.2 NO3 Model Performance Across the CAMX 12 km Domain

The monthly Bugle, Time Series and Scatter Plots of model performance for particulate nitrate (NO3) are shown in, respectively, Figures D-5, D-6 and D-7. As seen for the CMAQ performance discussed in Chapter 3 and Appendices B and C, the NO3 performance is not as good as seen for SO4. Both models exhibit a general winter overestimation and summer underestimation bias. This results in the NO3 performance for both models exceeding the PM performance goal, and even the PM performance criteria on occasion (Figure D-5). Although the summer underestimation bias is greater in magnitude than the winter overestimation bias, it occurs when the observed NO3 concentrations are very low so is not as big of a concern (Figure D-5).

The Scatter Plots in Figure D-7 display the predicted and observed NO3 comparisons for four months and across the IMPROVE, STN and CASTNet networks, as well as a Scatter Plot for total nitrate (NO3+HNO3) across the CASTNet network (bottom right in Figure D-7). An examination of the performance for total nitrate allows an assessment of whether any NO3 model performance issues may be due to an incorrect characterization of the oxidation of NOx to nitric acid and/or an incorrect thermodynamic partitioning between gaseous HNO3 and particulate NO3. For January, April and July, the CMAQ and CAMx model performance for total nitrate is quite good suggesting that the model's NO3 performance issues for these months may be more due to the partitioning of total nitrate. Errors in meteorology, such as temperature and relative humidity, ammonia emissions, and sulfate all affect this partitioning. In October, both models overestimate total nitrate across the CASTNet network, as well as overestimating particulate NO3. For October, this suggests too much oxidation of NOx to nitric acid is also occurring; overstated photochemical activity in October is also consistent with the CAMx SO4 overestimation bias for that month.

In summary, NO3 performance by both models is characterized by a summer underprediction and winter overprediction bias, with the summer underprediction bias being more severe. However, the summer underprediction bias is not that important as it occurs when the observed NO3 is very low ($< 1\ \mu g/m^3$). When NO3 concentrations are higher in the winter and adjacent months, the model performance is better usually achieving the PM model performance goal and almost always achieving the PM model criteria. This is illustrated in the Bugle Plot in Figure D-5 where the high fractional bias and error values occur under low NO3 concentrations so are plotted in the flared area of the performance goal and criteria thereby achieving the PM performance goal and criteria.

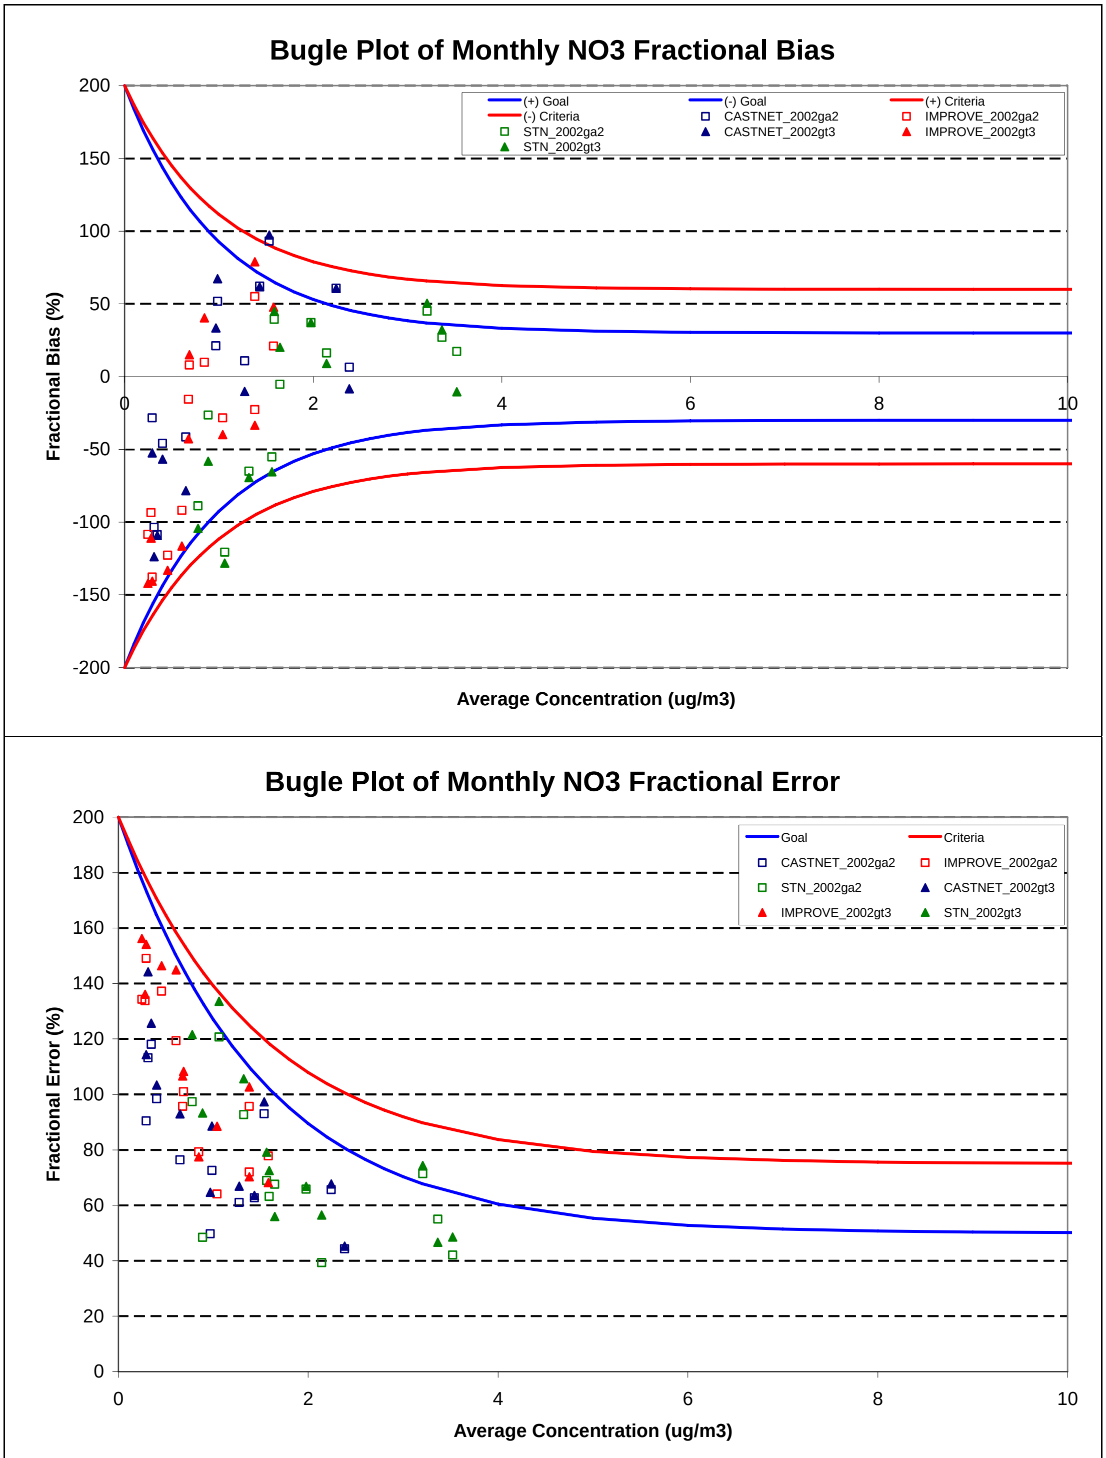

Figure D-5. Bugle Plot of monthly Fractional Bias (top) and Error (bottom) for CMAQ and CAMx estimated nitrate (NO3) concentrations across the CAMx 12 km domain.

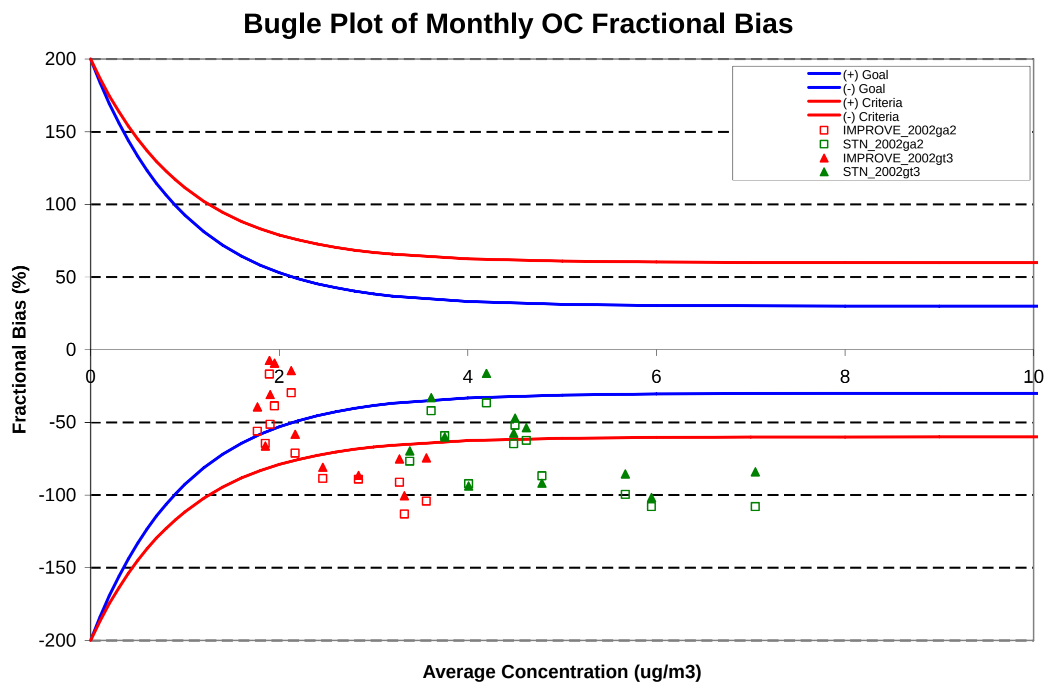
D.2.3 Particulate Carbon Model Performance Across the CAMx 12 km Domain

The performance of the CMAQ and CAMx models for Organic Carbon Mass (OCM) and Elemental Carbon (EC) using the IMPROVE and STN observations is given in Figures D-8, D-9 and D-10. OCM is usually one of the two most important components of $PM_{2.5}$ mass in the ASIP region. It is made up of numerous components, including primary OCM from combustion, biomass burning, meat cooking and vegetation detritus and secondary organic aerosols (SOA) from biogenic and anthropogenic VOC emissions. Consequently, numerous emissions and atmospheric processes need to be simulated correctly to achieve good OCM performance and since routine OCM measurements do not distinguish between these different forms of OCM, there is the potential for introducing compensatory errors with one component of OCM compensating for an overestimation or underestimation of another. An added complication to the OCM evaluation is that the observations measure just the Organic Carbon (OC) portion of OCM and the additional components of OCM (e.g., oxygen) must be accounted for through a scaling factor. In this evaluation we used an OCM/OC scaling factor of 1.4. The OCM/OC ratio generally varies from 1.2 to 2.2 with lower values for fresh OCM emissions (e.g., urban areas) and larger ratios for more aged air masses that have been photochemical processed (e.g., rural areas). Thus, the 1.4 OCM/OC ratio is probably appropriate for the urban STN monitors, but is likely too low for the more rural IMPROVE monitors. In fact, the new IMPROVE equation uses an OCM/OC ratio of 1.8.

Given the above uncertainties, the OCM evaluation is less certain than other PM components. However, it is clear that both the CMAQ and CAMx models underestimate OCM concentrations across the CAMx 12 km domain at both the more rural IMPROVE as well as more urban STN monitoring sites. This underprediction tendency is greatest in the summer with the CMAQ model exhibiting a slightly more severe underestimation bias than CAMx. The summer period is when OCM and SOA is the highest so such underpredictions could suggest insufficient SOA formation. The summer OCM underprediction is severe enough that both the CMAQ and CAMx models fail to achieve PM performance criteria (Figure D-8a).

The two models' performance for EC is generally characterized by a summer underestimation bias across the more rural IMPROVE and a winter and adjacent months overestimation bias across the more urban STN network. CAMx tends to estimate higher EC concentrations than CMAQ so the summer EC underestimation bias is not as severe as seen for CMAQ. On the other hand, the CAMx EC overestimate bias across the STN network is more severe than seen for CMAQ. These results are also seen in the Scatter plots in Figure D-10.



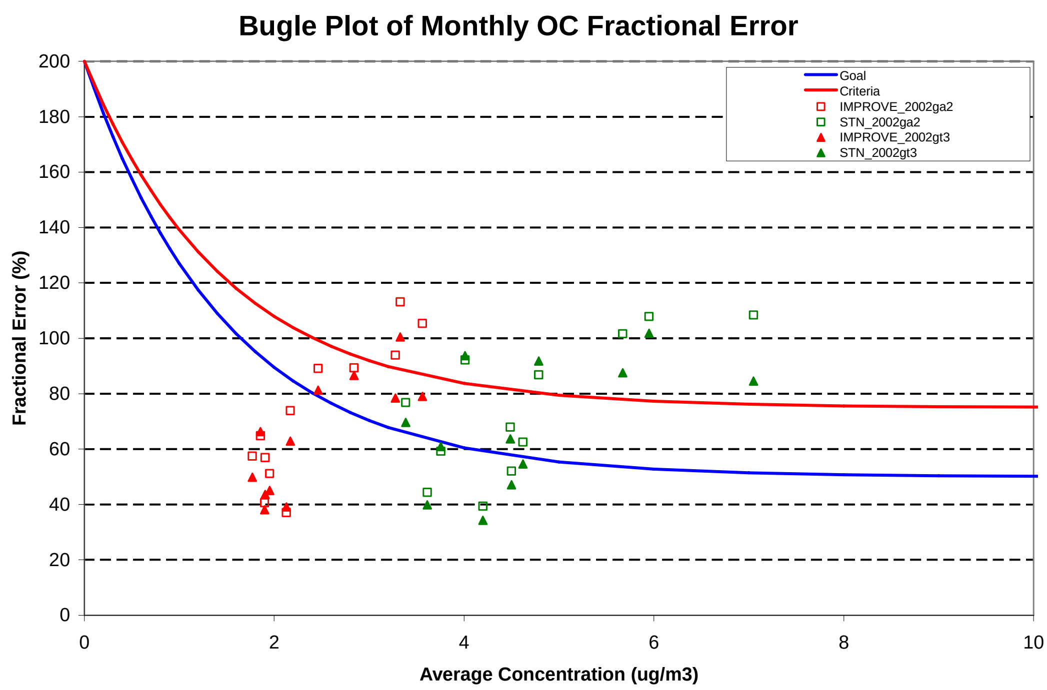


Figure D-8a. Bugle Plot of monthly Fractional Bias (top) and Error (bottom) for CMAQ and CAMx estimated Organic Carbon Mass (OCM) concentrations across the CAMx 12 km domain.

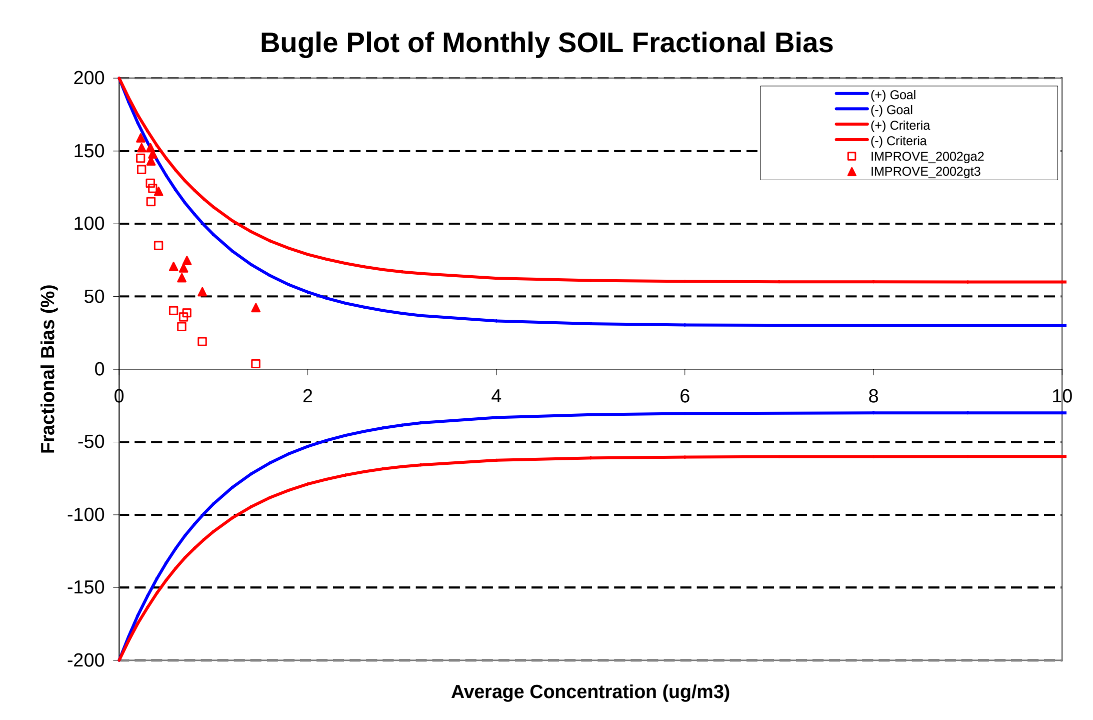
D.2.4 Soil Model Performance Across the CAMx 12 km Domain

The Soil model performance is just presented for the IMPROVE network using Bugle and Time Series Plots of monthly fractional bias and error that are given in Figures D-11 and D-12, respectively. Both models appear to systematically overestimate the IMPROVE Soil observations with CAMx estimating higher values so has a more severe Soil overestimation tendency. As noted previously, there are incommensurability problems between the measured and modeled Soil. The IMPROVE measured Soil is constructed from measurements of key elemental components of Soil, whereas the modeled Soil is other $PM_{2.5}$, the left over component of the $PM_{2.5}$ emissions inventory that is not explicitly speciated as SO4, NO3, OCM or EC. The fact that the Soil overprediction bias is greater in the winter than summer suggests that the seasonal variations of the Soil emissions in the model may overstate Soil emissions in the winter. One potential cause could be a failure to fully account for the effects of a wetted surface that suppresses Soil emissions when rain or dew occurs (e.g., road dust, wind blown dust, etc.). In any event, despite the large Soil overestimation bias of both models for Soil, because Soil is such a small component of $PM_{2.5}$ in the ASIP region and has low concentrations, the CMAQ and CAMx models achieves the PM model performance goal as indicated in the Bugle Plot (Figure D-11).



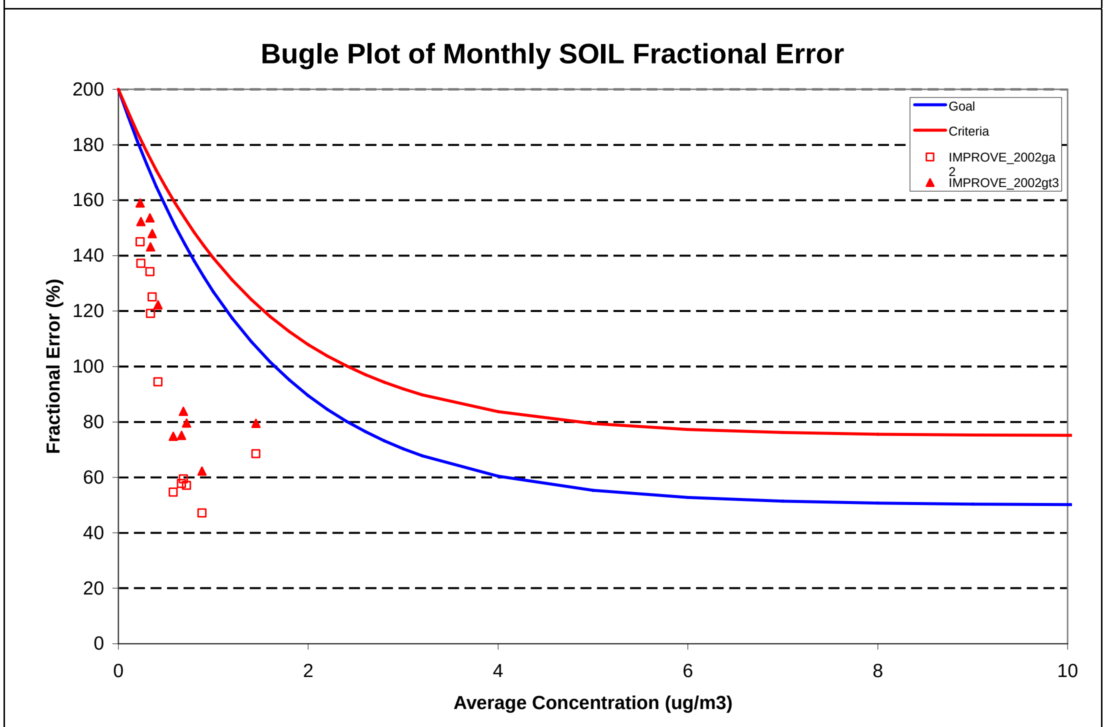


Figure D-11. Bugle Plot of monthly Fractional Bias (top) and Error (bottom) for CMAQ and CAMx estimated Soil $PM_{2.5}$ concentrations across the CAMx 12 km domain.

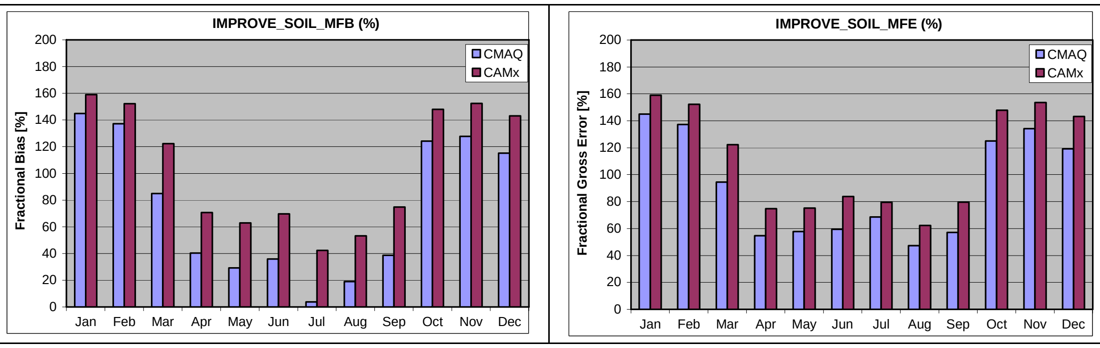

Figure D-12. Monthly Fractional Bias (left) and Error (right) across the 12 km CAMx domain for the CMAQ 12 km domain and CAMx 12/4 km 2002 Base G2 base case simulations Soil concentrations using the IMPROVE monitoring network.

D.2.5 Total $PM_{2.5}$ Mass Model Performance Across the CAMx 12 km Domain

The model performance statistics for the two models and total $PM_{2.5}$ mass across the CAMx 12 km domain using data from the IMPROVE, CASTNet and FRM monitoring networks are shown in Figures D-13, D-14 and D-15. The two models $PM_{2.5}$ performance usually achieves the PM model performance goal and always achieves the PM performance criteria. The CMAQ model fails to achieve the PM model performance goal during the summer due to an underprediction bias, whereas when the CAMx fails to achieve the PM performance goal it is in the fall due to an overprediction bias.

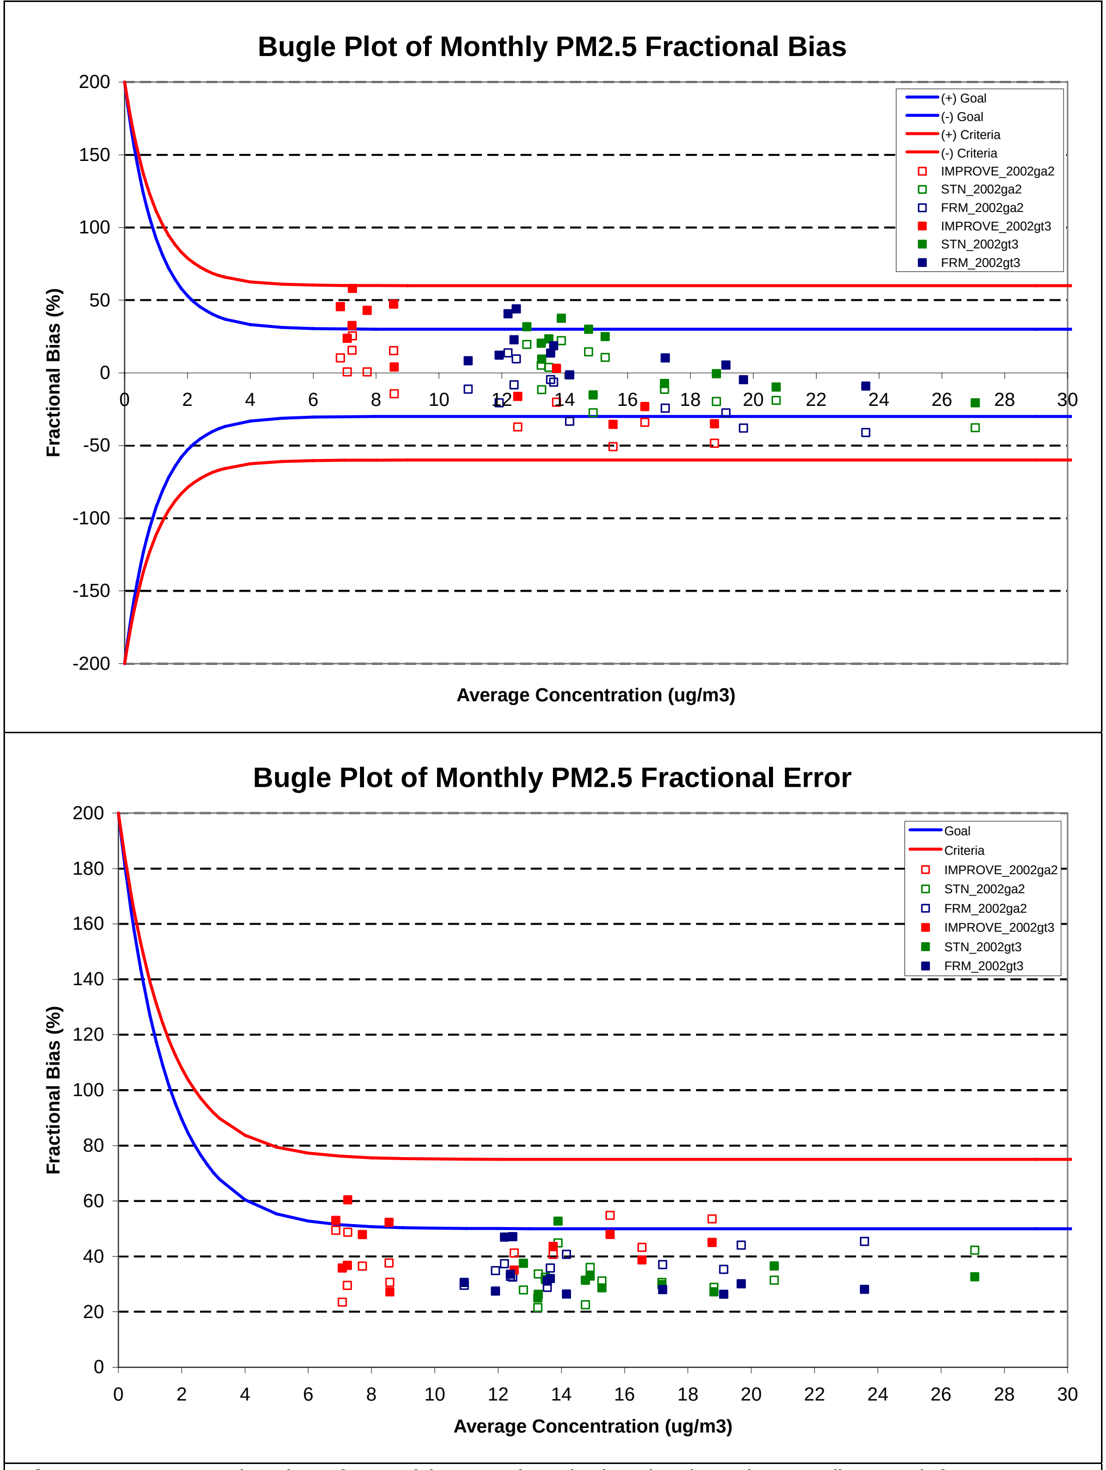

Figure D-13. Bugle Plot of monthly Fractional Bias (top) and Error (bottom) for CMAQ and CAMx estimated total $PM_{2.5}$ mass concentrations across the CAMx 12 km domain.

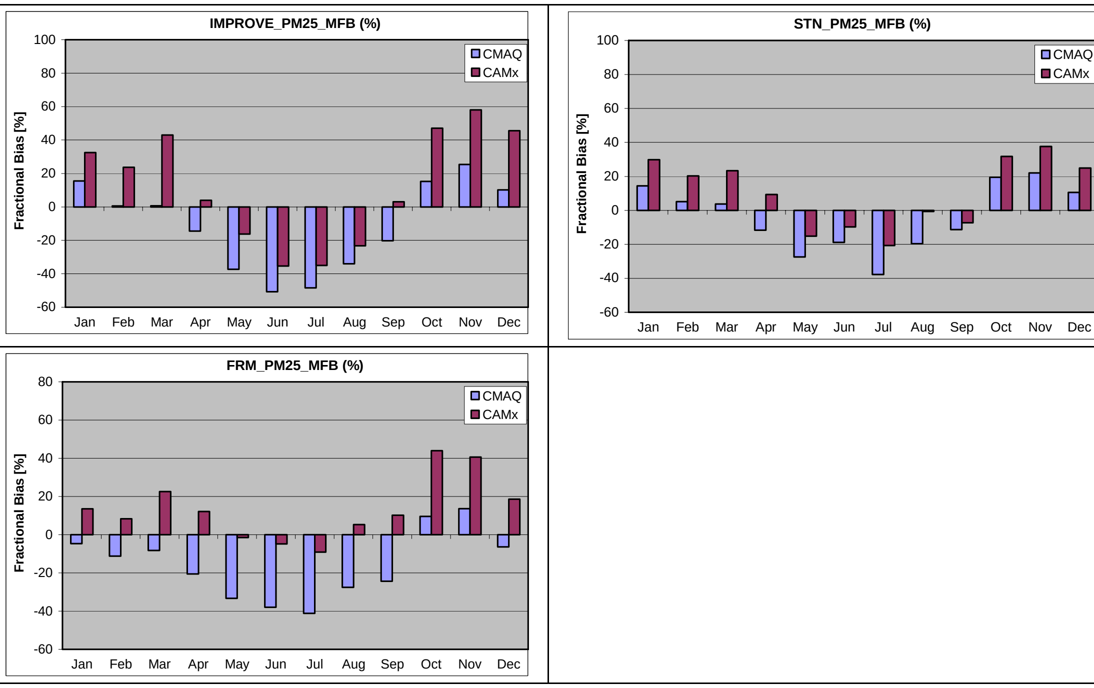

Figure D-14a. Monthly Fractional Bias across the 12 km CAMx domain for the CMAQ 12 km domain and CAMx 12/4 km 2002 Base G2 base case simulations total $PM_{2.5}$ mass concentrations suing the IMPROVE (top left), STN (top right) and FRM (bottom left) monitoring networks.

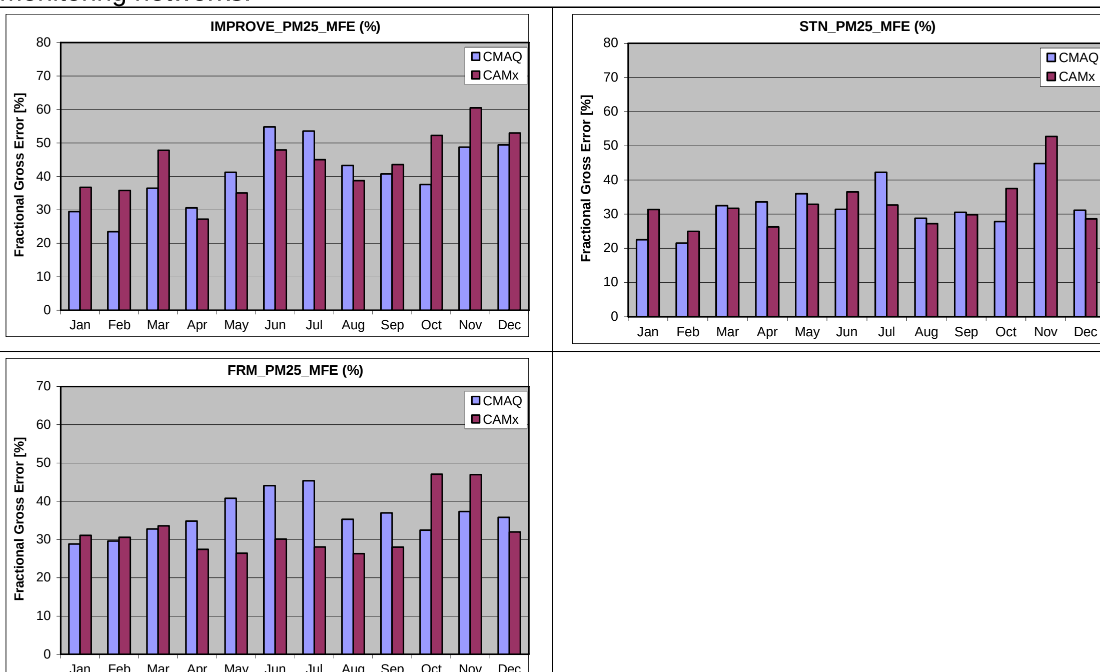

Figure D-14b. Monthly Fractional Error across the 12 km CAMx domain for the CMAQ 12 km domain and CAMx 12/4 km 2002 Base G2 base case simulations total $PM_{2.5}$ mass concentrations suing the IMPROVE (top left), STN (top right) and FRM (bottom left) monitoring networks.

Figure D-15d. Scatter plots of predicted and observed total $PM_{2.5}$ mass concentrations across the CAMx 12 km domain using IMPROVE PM2.5 (top left), STN PM2.5 (top right), FRM $PM_{2.5}$ (bottom left) and IMPROVE RCFM (bottom right) data during October 2002 and the CAMx 2002gt3 and CMAQ 2002ga2a modeling results.

D.3 SUBREGIONAL $PM_{2.5}$ MODEL PERFORMANCE EVALUATION

The purpose of the CAMx 2002 12/4 km modeling was to use the PM Source Apportionment Technology (PSAT) to assess the separate contributions of 31 point source facilities to 2009 $PM_{2.5}$ concentrations at FRM monitors in four 4 km subregional modeling subdomains (see Section 5.3):

- Charleston-Huntington-Ashland WV-KY-OH
- Knoxville-Chattanooga TN-NC-GA
- Louisville KY-IN
- Wheeling-Weirton-Steubenville WV-OH-PA

In the sections below we evaluate the $PM_{2.5}$ model performance of the CAMx 2002 4 km Base G2 Typical and CMAQ 2002 12 km Base G2 Actual in each of these subdomains.

D.3.1 Charleston-Huntington-Ashland WV-KY-OH

Figure D-16 reproduces Figure 5-7 from Chapter 5 and displays the locations of FRM monitoring sites within the Charleston subdomain, as well as the locations of the PSAT facilities whose separate $PM_{2.5}$ contributions were assess in Section 5.3. Scatter plots of predicted and observed 24-hour total $PM_{2.5}$ mass for the seven FRM sites located in the Charleston subdomain by Quarter of 2002 are shown in Figure D-17. Also given in Figure D-17 is the Quarterly fractional bias and error performance statistics for FRM $PM_{2.5}$ mass and the CMAQ and CAMx models.

The CMAQ model $PM_{2.5}$ performance in the Charleston subdomain is characterized by an underprediction tendency. This underprediction is sufficient that CMAQ does not achieve the ≤±30% PM performance goal for fractional bias during the first three Quarters of the year, and CMAQ's fractional error even exceeds the ≤50% PM performance goal for Quarter 2. Much better CMAQ $PM_{2.5}$ performance is seen for Quarter 4 where the fraction bias (-1%) achieves the most stringent ozone performance goal (≤±15%) and its error (37%) almost achieves the ozone goal (≤35%).

The CAMx total $PM_{2.5}$ mass model performance is quite different than CMAQ. The CAMx fractional bias/error performance statistics for Quarters 1 and 3 of 2002 (-8%/29% and -6%/24%) achieves the most stringent ozone bias/error performance goal (≤±15%/≤35%) and the PM performance goal (≤±30%/≤50%) is achieved for the first three Quarters of 2002. However, in Quarter 4 the CAMx overprediction bias results in the fractional bias (32%) falling just outside of the PM performance goal (≤±30%), although the CAMx fractional error does achieve the PM performance goal in Quarter 4.

Time series of predicted and observed 24-hour $PM_{2.5}$ concentrations at the seven FRM sites in the Charleston subdomain are shown by Quarter in Figure D-18. The CMAQ and CAMx $PM_{2.5}$ concentrations track each other well, with the CAMx estimating higher values that better match the observed values through the first three Quarters of the year. The observed day-to-day variations in the 24-hour $PM_{2.5}$ concentrations are frequently well matched by the two models. However, the models, and especially CMAQ, fail to capture the magnitude of the observed high concentrations $PM_{2.5}$ spikes on some of the days during 2002.

D.3.2 Knoxville-Chattanooga TN-NC-GA

Figure D-19 displays the Knoxville-Chattanooga 4 km subdomain, along with the FRM and PSAT point source locations. Figure D-20 displays scatter plots and performance statistics for 24-hour $PM_{2.5}$ concentrations across FRM monitors in the Knoxville subdomain and each Quarter of 2002. As seen for the Charleston subdomain, the CAMx exhibits much better $PM_{2.5}$ model performance than CMAQ for the first three Quarters of 2002, but for the last Quarter the reverse is true. For the first three Quarters of 2002, CAMx $PM_{2.5}$ performance achieves the most stringent ozone performance goal, whereas CMAQ does not exhibiting a large underprediction tendency that even fails to achieve the PM performance goal for Quarters 2 and 3. However, in Quarter 4 it is CMAQ that nearly achieves the ozone model performance goal and CAMx that fails to achieve the PM performance goal for fractional bias.

Example $PM_{2.5}$ time series comparisons for two sites in the Knoxville subdomain and each Quarter of 2002 are given in Figure D-21. There is a lot of day-to-day variation in the observed 24-hour $PM_{2.5}$ concentrations. The model reproduces much of the temporal variability in the observations. CAMx is doing a much better job in reproducing the observed $PM_{2.5}$ concentrations during the first three Quarters of the year. During Quarter 4 it appears that much of the CAMx overprediction bias is due to a few days of very high modeled $PM_{2.5}$ concentrations.

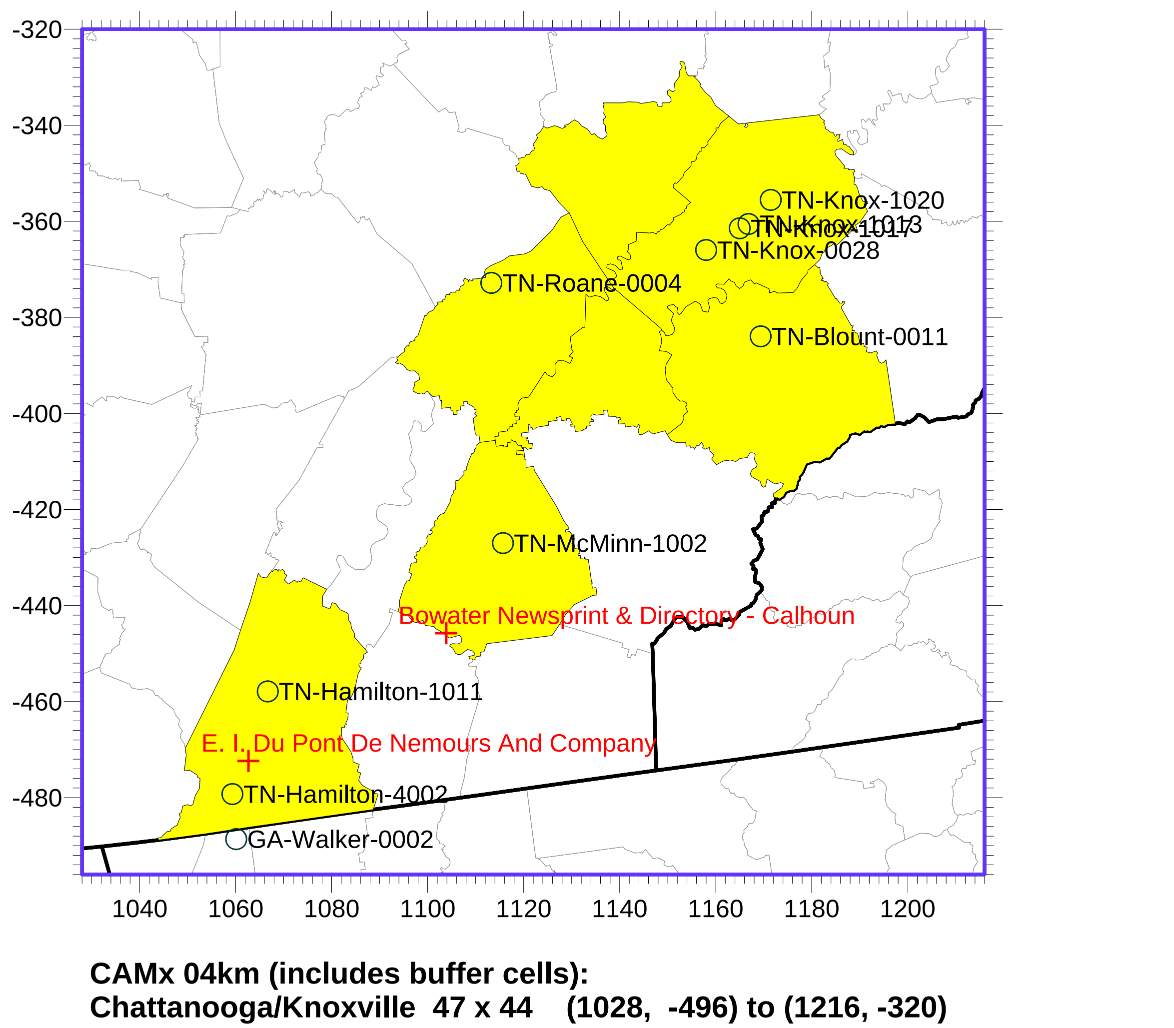

Figure D-19. Knoxville-Chattanooga TN-NC-GA 4 km domain and locations of FRM monitors (black circles) and facilities treated by PSAT PM source apportionment (red crosses).

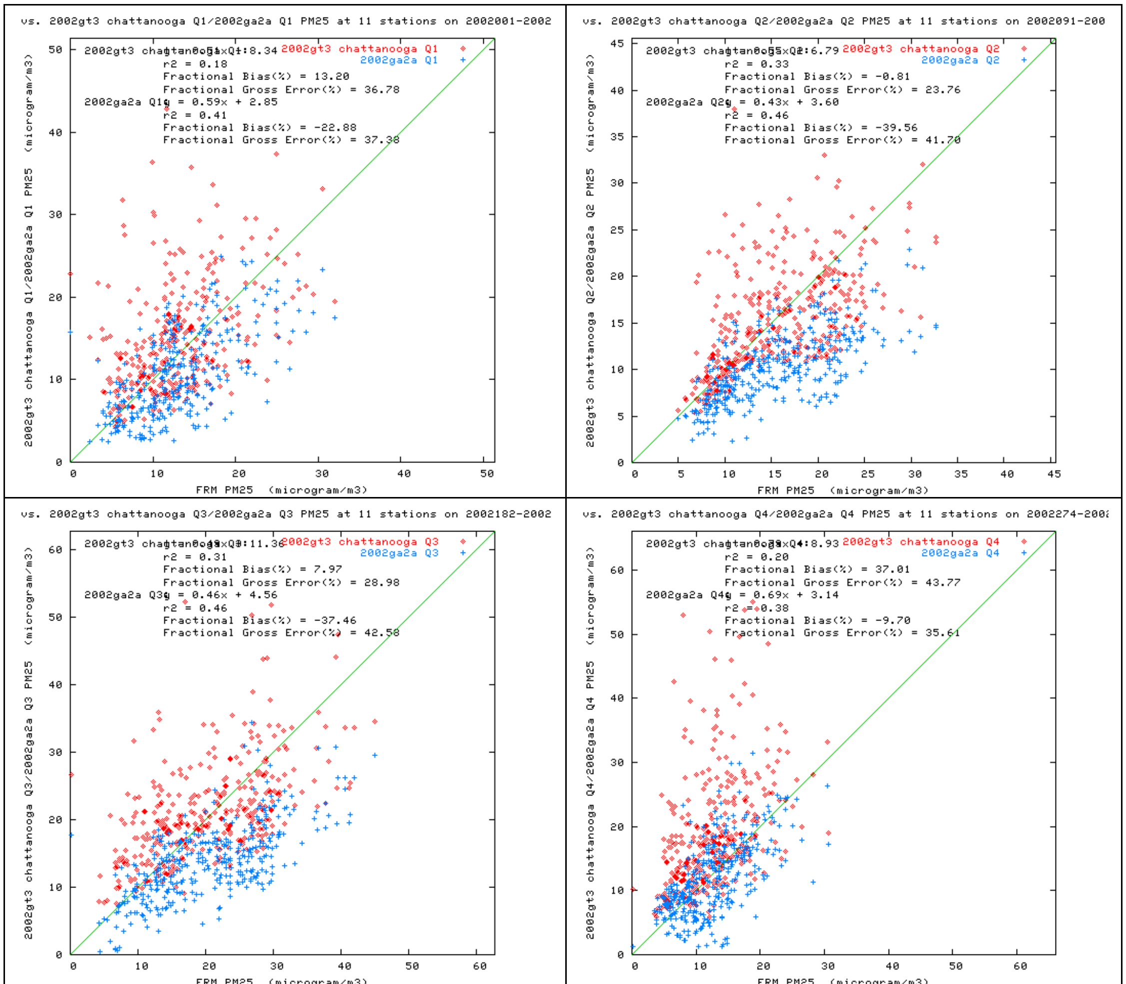

Figure D-20. Scatter Plots and performance statistics for predicted and observed 24-hour FRM $PM_{2.5}$ concentrations by Quarter during 2002, the CAMx 2002gt3 4 km and CMAQ 2002aga2 12 km base case simulations and the Knoxville subdomain.

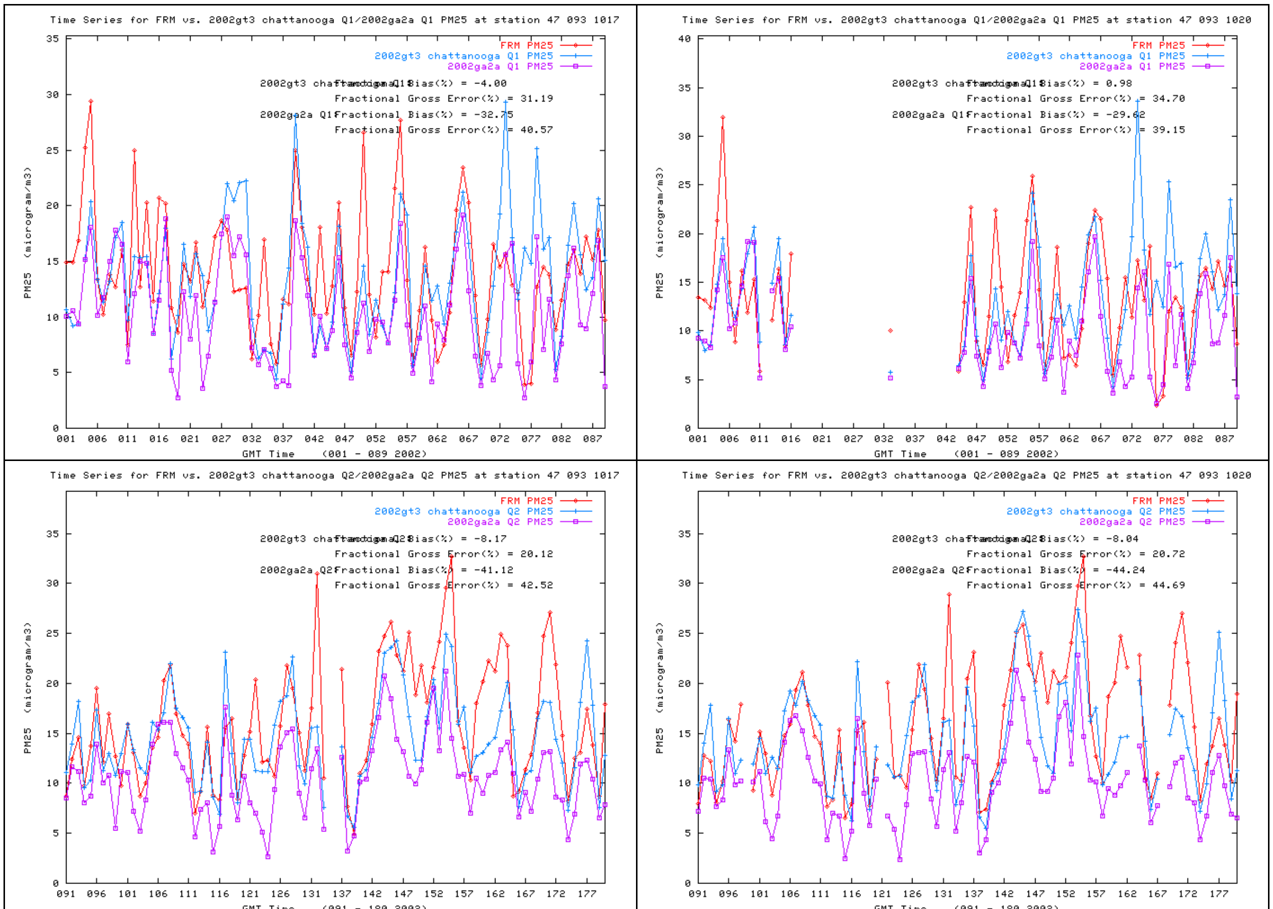

Figure D-21. Time Series of predicted and observed 24-hour $PM_{2.5}$ concentrations for two FRM sites in the Knoxville subdomain, Quarter 1 (top), 2, 3 and 4 (bottom) and the CAMx 2002gt3 and CMAQ 2020aga2 base case simulations.

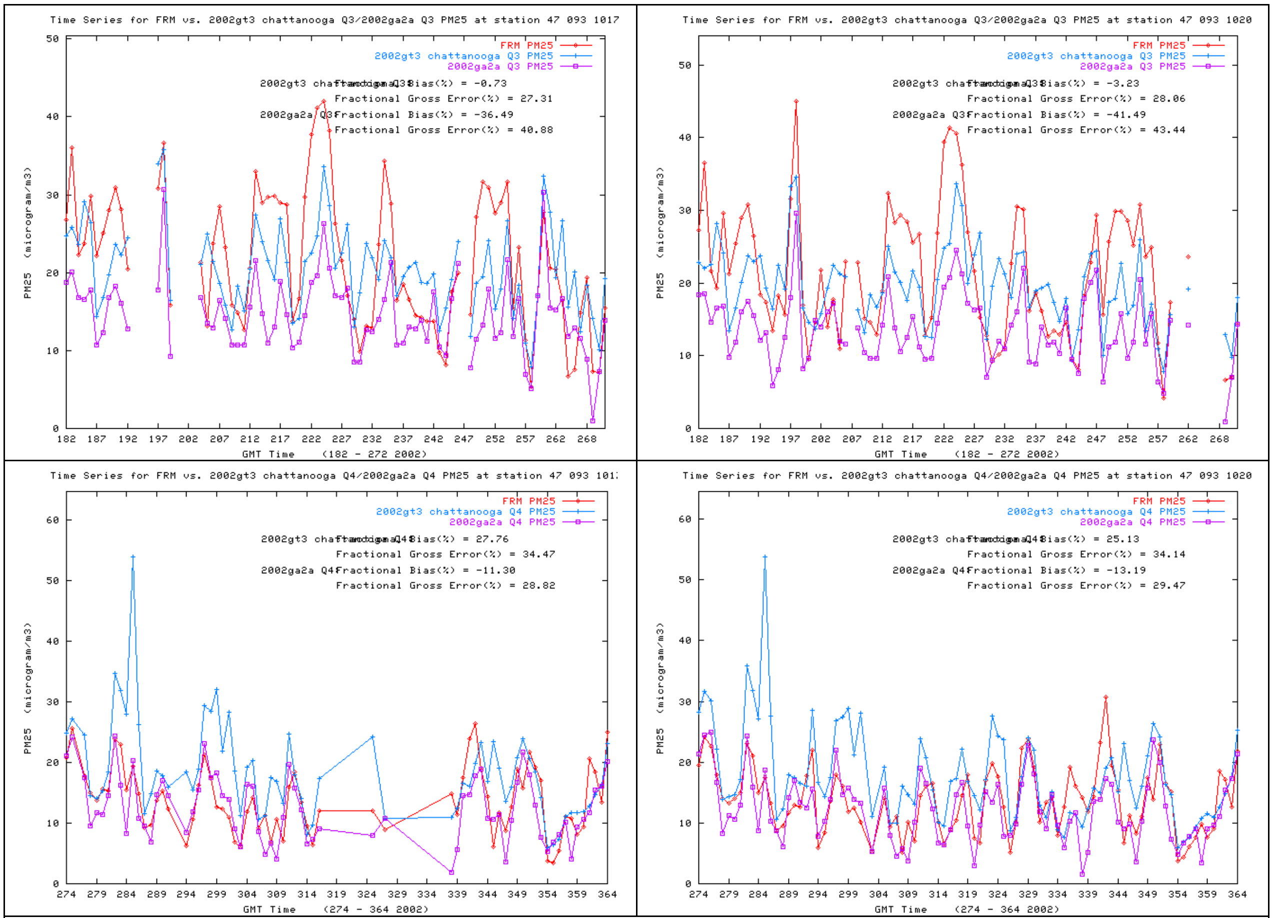

Figure D-21. (continued) Time Series of predicted and observed 24-hour $PM_{2.5}$ concentrations for two FRM sites in the Knoxville subdomain, Quarter 1 (top), 2, 3 and 4 (bottom) and the CAMx 2002gt3 and CMAQ 2020aga2 base case simulations.

D.3.3 Louisville KY-IN

$PM_{2.5}$ model performance across the Louisville subdomain is not as good as seen for the other subdomains. The CMAQ $PM_{2.5}$ performance in Louisville achieves the ozone performance goal in the first Quarter and achieves or nearly achieves the PM performance goal in all four Quarters. However, the CAMx $PM_{2.5}$ overprediction tendency exceeds the PM performance goal for Quarter 1 and 4, but for Quarter 2 is achieving the more stringent ozone goal. These findings are also seen in the time series comparisons for two example FRM monitoring sites in Figure D-24.

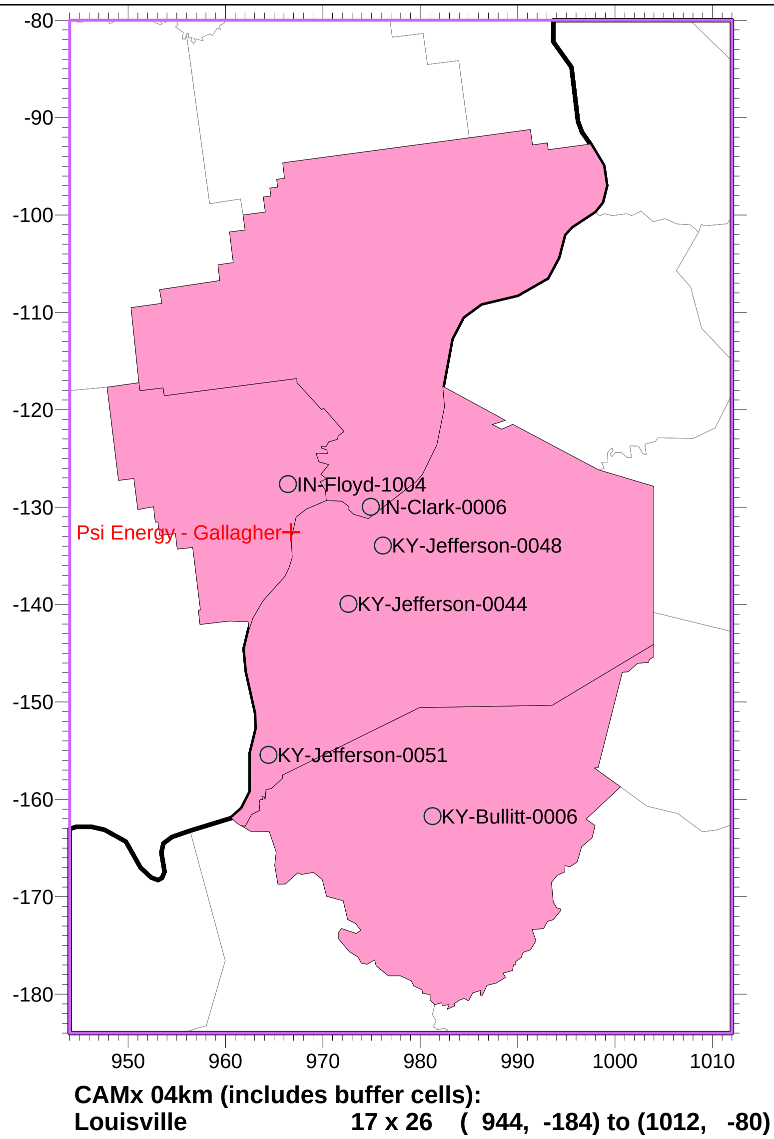

Figure D-22. Louisville KY-IN 4 km domain and locations of FRM monitors (black circles) and facilities treated by PSAT PM source apportionment (red crosses).

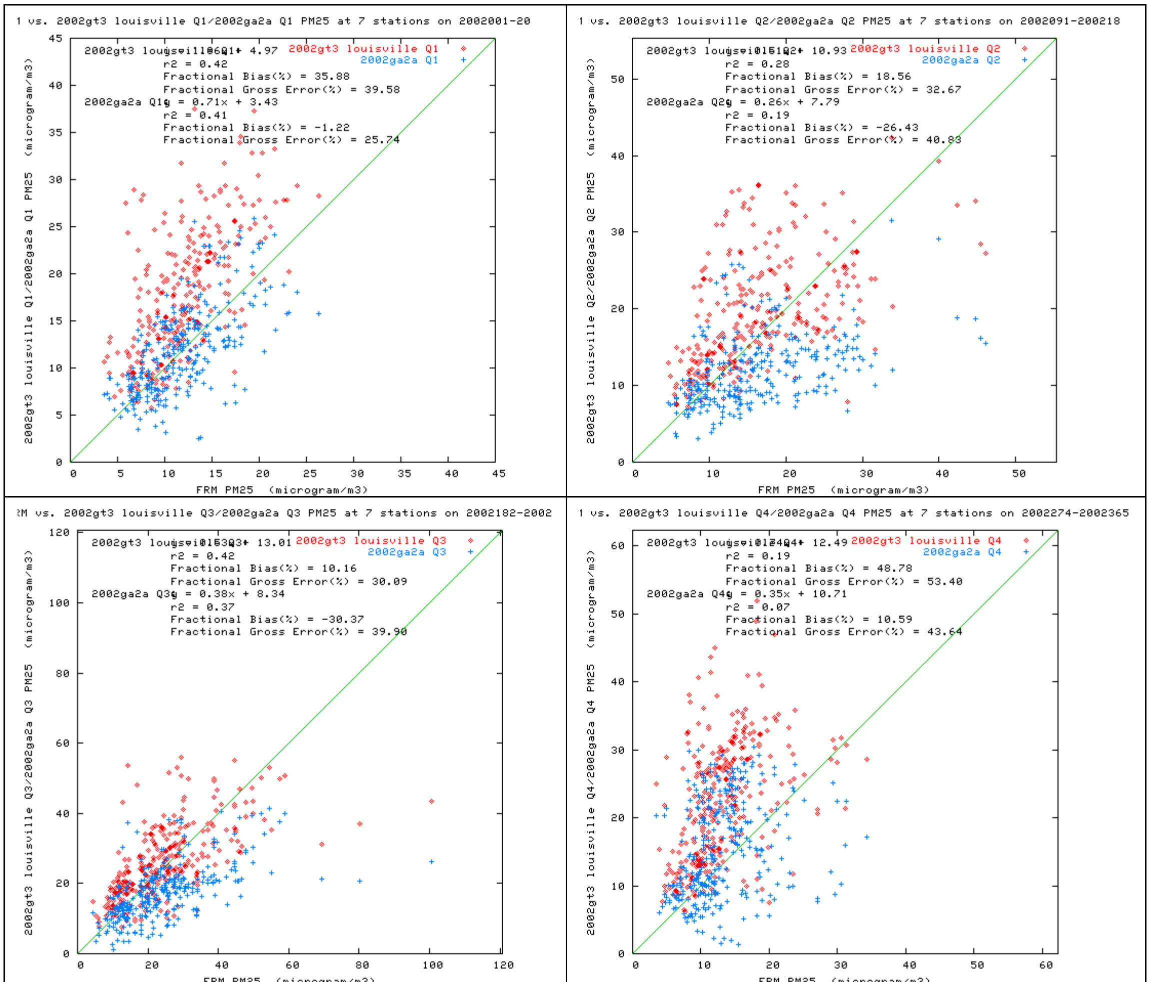

Figure D-23. Scatter Plots and performance statistics for predicted and observed 24-hour FRM $PM_{2.5}$ concentrations by Quarter during 2002, the CAMx 2002gt3 4 km and CMAQ 2002aga2 12 km base case simulations and the Louisville subdomain.

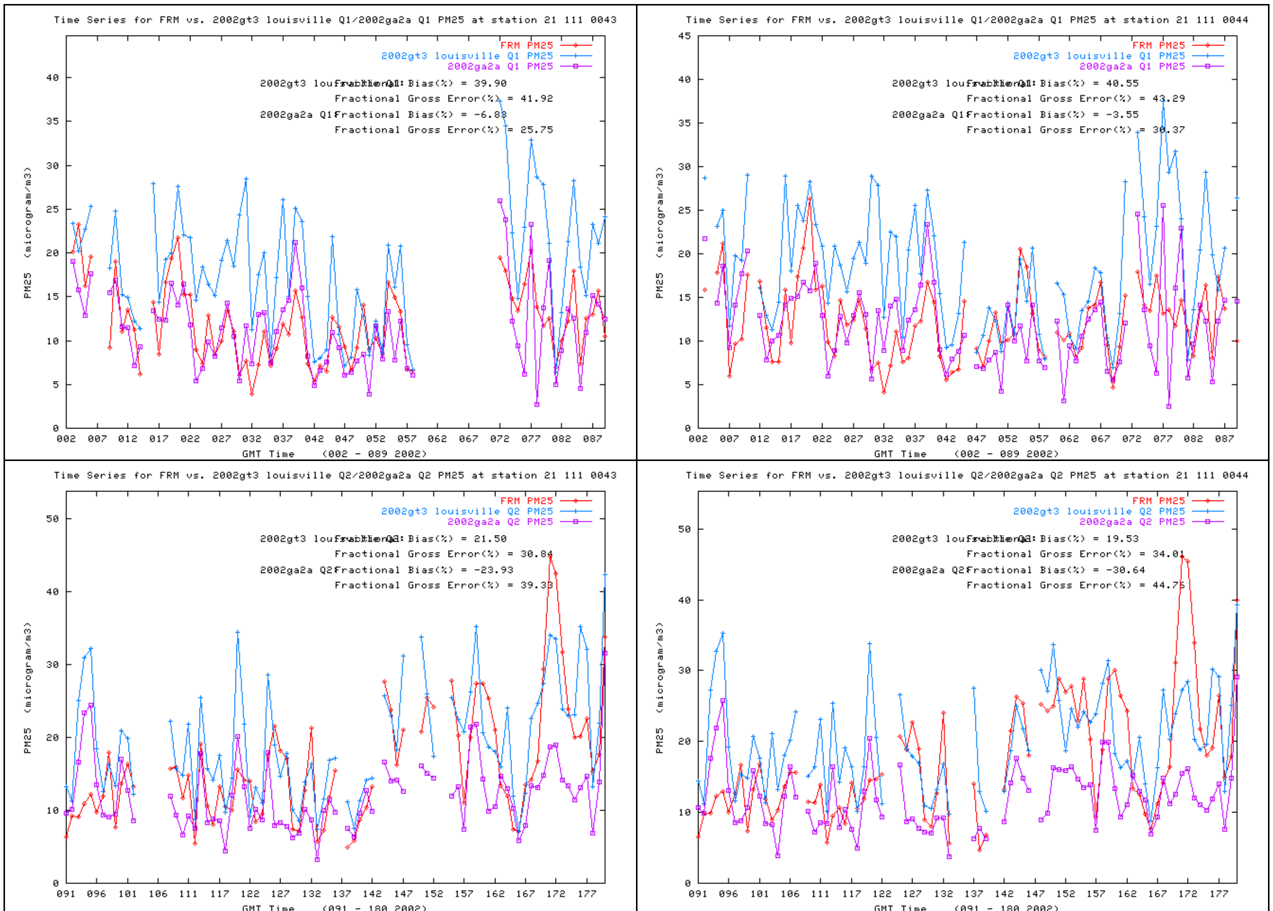

Figure D-24. Time Series of predicted and observed 24-hour $PM_{2.5}$ concentrations for two FRM sites in the Louisville subdomain, Quarter 1 (top), 2, 3 and 4 (bottom) and the CAMx 2002gt3 and CMAQ 2020aga2 base case simulations.

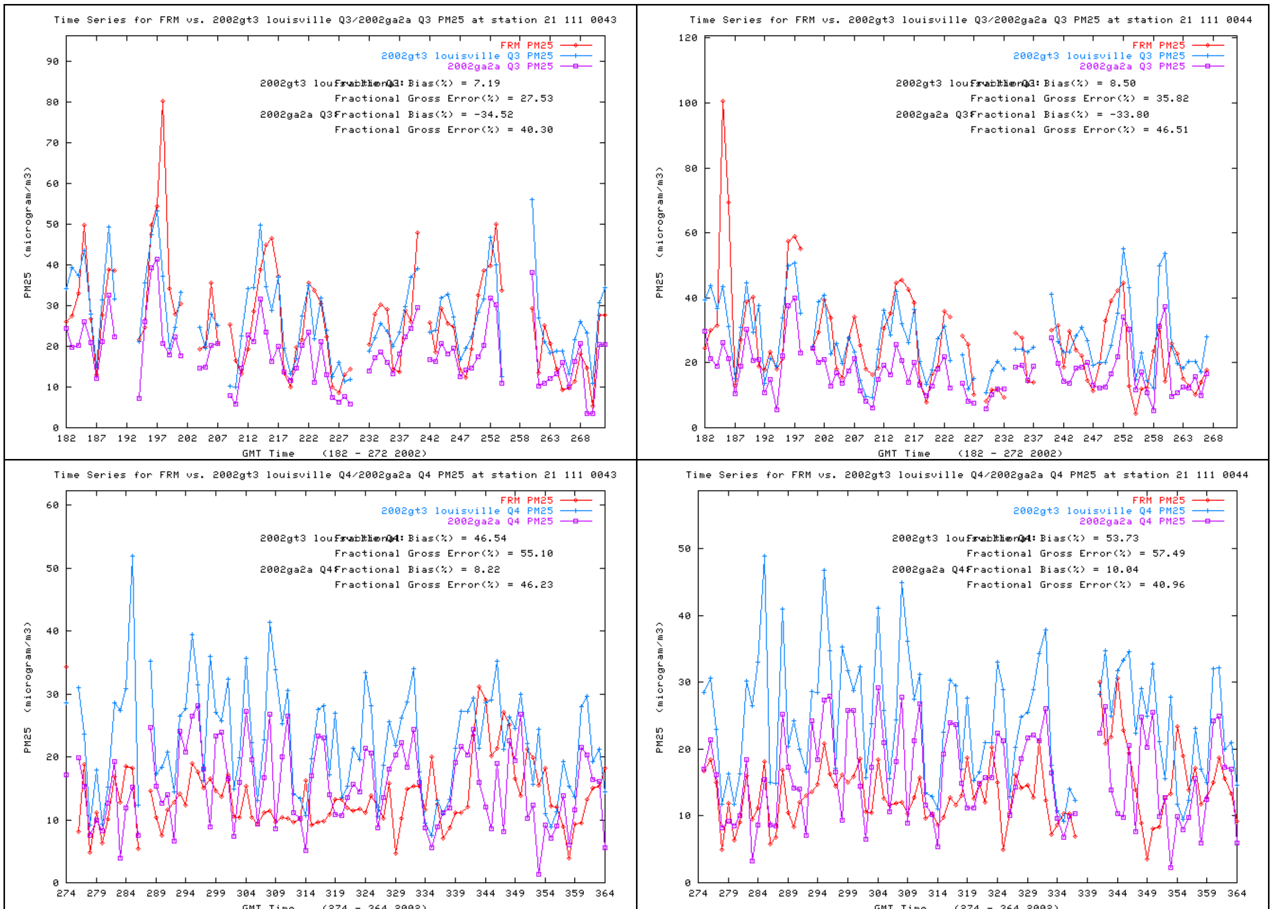

Figure D-24. (continued) Time Series of predicted and observed 24-hour $PM_{2.5}$ concentrations for two FRM sites in the Louisville subdomain, Quarter 1 (top), 2, 3 and 4 (bottom) and the CAMx 2002gt3 and CMAQ 2020aga2 base case simulations.

D.3.4 Wheeling-Weirton-Steubenville WV-OH-PA

The Wheeling subdomain and the $PM_{2.5}$ model performance results are shown in Figures D-25, D-26 and D-27. For the first three Quarters of 2002, CAMx is exhibiting better $PM_{2.5}$ performance than CMAQ with CAMx achieving the ozone model performance goal in Quarters 1, 2 and 3. Although CMAQ also achieves the ozone goal in Quarter 1, the underprediction bias in Quarters 2 and 3 (~-25%) exceeds the ozone performance goal, but does achieve the PM model performance goal. In fact, the PM model performance goals is achieved by both models for all four Quarters of 2002.

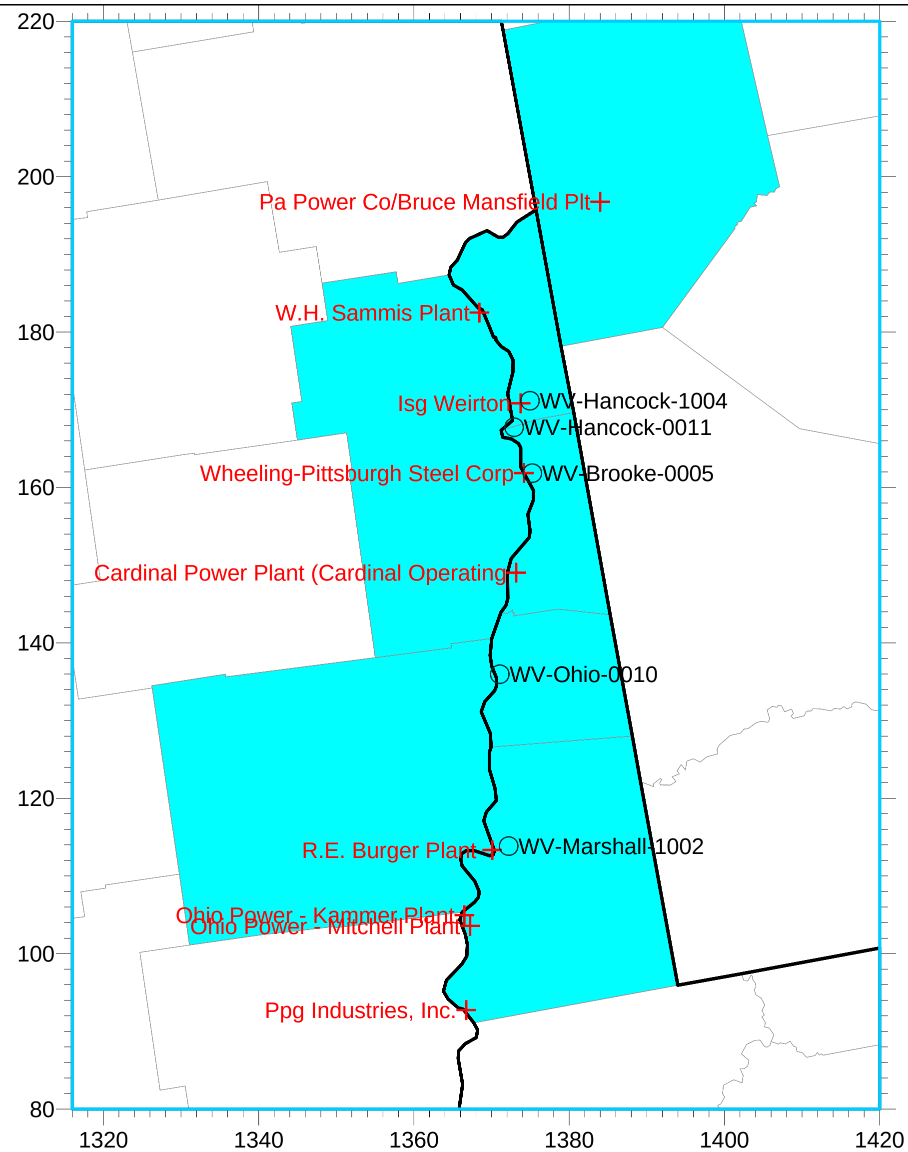

Figure D-25. Wheeling-Weirton-Steubenville WV-OH-PA 4 km domain and locations of FRM monitors (black circles) and facilities treated by PSAT PM source apportionment (red crosses).

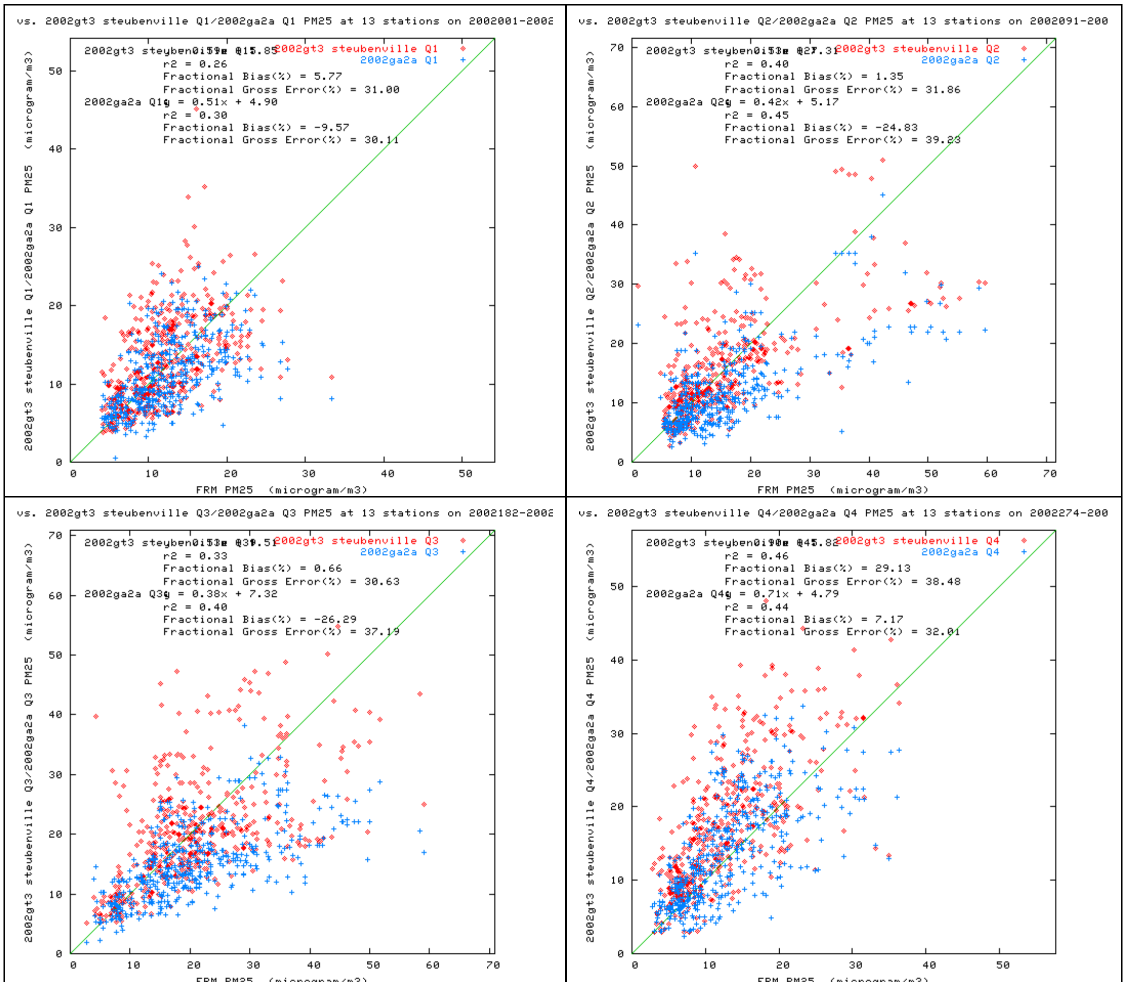

Figure D-26. Scatter Plots and performance statistics for predicted and observed 24-hour FRM $PM_{2.5}$ concentrations by Quarter during 2002, the CAMx 2002gt3 4 km and CMAQ 2002aga2 12 km base case simulations and the Wheeling subdomain.

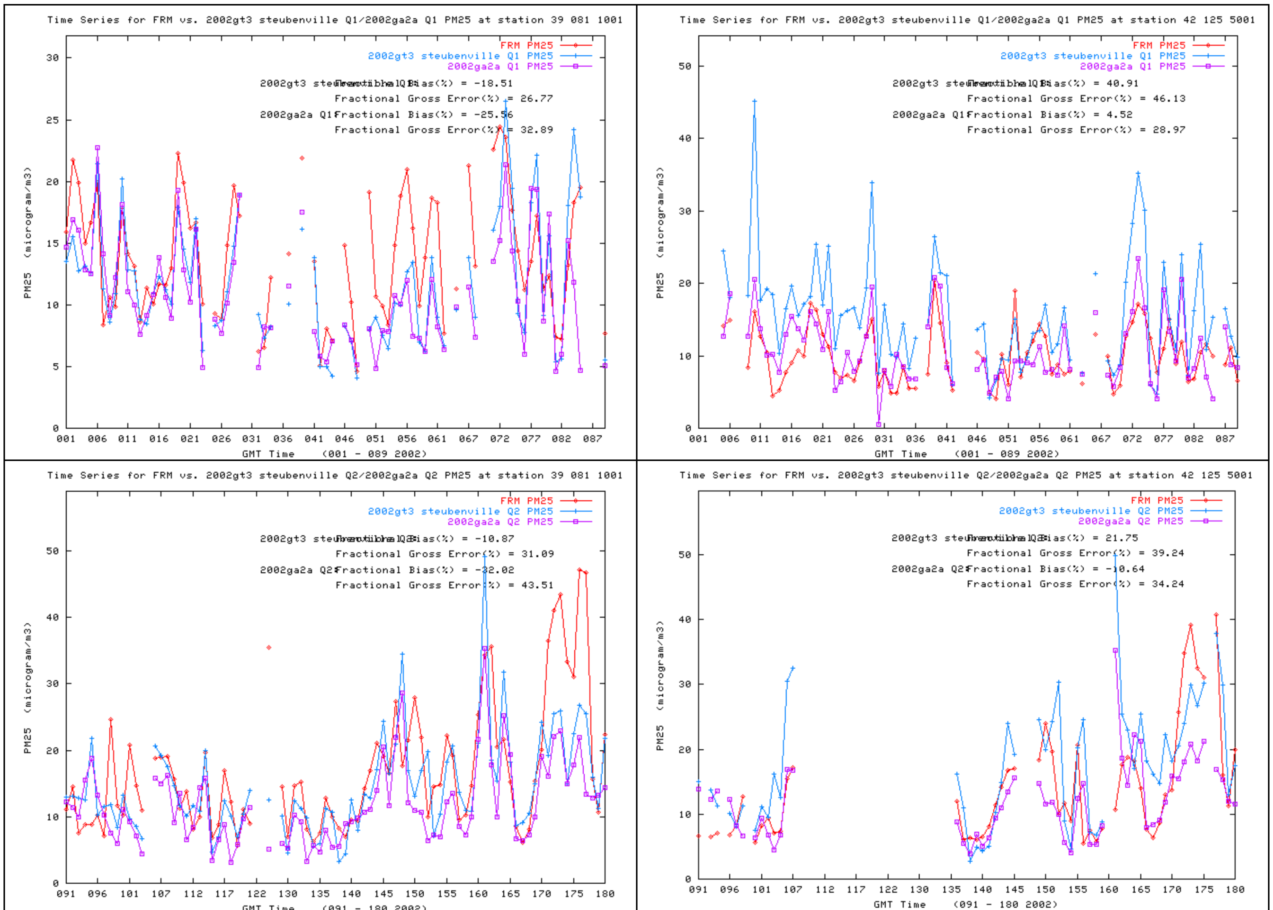

Figure D-27. Time Series of predicted and observed 24-hour $PM_{2.5}$ concentrations for FRM sites in the Wheeling subdomain, Quarter 1 (top), 2, 3 and 4 (bottom) and the CAMx 2002gt3 and CMAQ 2020aga2 base case simulations.

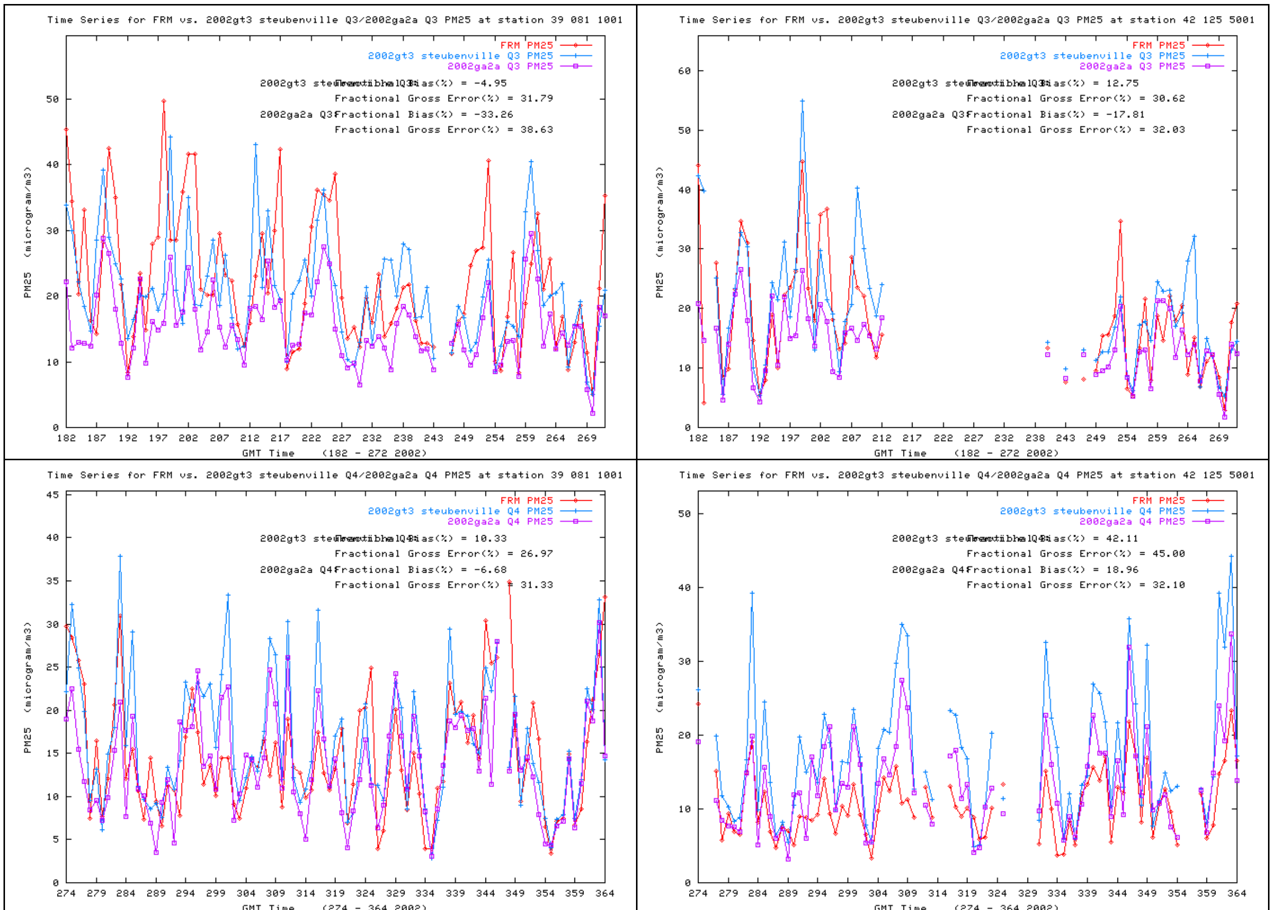

Figure D-27. (continued) Time Series of predicted and observed 24-hour $PM_{2.5}$ concentrations for FRM sites in the Wheeling subdomain, Quarter 1 (top), 2, 3 and 4 (bottom) and the CAMx 2002gt3 and CMAQ 2020aga2 base case simulations.

D.4 CONCLUSIONS

In general, the CMAQ and CAMx models are exhibiting similar model performance for $PM_{2.5}$, although CAMx usually has an overestimation and CMAQ usually has an underestimation tendency. Exceptions to this are for OCM, which both models underestimate during the summer, and Soil, which both models overestimate. The CMAQ and CAMx model performance usually meets the PM model performance goal for most months and PM species. The best model performance is achieved for SO4 and total $PM_{2.5}$ mass concentrations, with the models' frequently achieving the more stringent ozone model performance goal.

SUMMARY OF METEOROLOGICAL CONDITIONS AND CART RESULTS FOR IMPROVE SITES IN NC

Prepared by
Sharon Douglas and Belle Hudischewskyj
ICF International

Characterizing Meteorology

- Objectives:
  - Characterize relationship between meteorology, PM2.5, visibility, for IMPROVE, STN, and SEARCH sites
  - Evaluate how well meteorological and visibility conditions of the 2002 modeling year represents the 2000-2004 baseline period

Classifying Days using Visibility, Meteorology, and PM2.5

- Classification and Regression Tree (CART) analyses
  - Classify days based on extinction coefficient
  - 5 extinction classes defined for each site
    - 20th, 50th, 80th, and 95th percentiles
  - 2000-2004 data
  - 21 IMPROVE, 8 SEARCH, 16 STN sites

Classifying Days Using Visibility, Meteorology, and PM2.5

- Classification and Regression Tree (CART) methods
  - Use meteorological parameters at (or near) the site
  - Use PM2.5 on previous days at regional/upwind sites
  - CART decision tree sorts days using most influential parameters first
  - Assign days to “bins” of days with similar meteorology
  - Several bins assigned to same class
    - different combinations of meteorological conditions can lead to same extinction

CART Results for Visibility at IMPROVE sites

- Using only meteorological inputs, 65 to 80% of days are accurately classified
- Adding PM2.5 on previous day at upwind sites improves accuracy of classifying days for visibility to 73-88%
- Optimal CART decision tree has 25-35 bins
- Key parameters vary across sites and classes

CART Visibility Analyses – IMPROVE

- In general, poor visibility days are associated with
  - High temperatures
  - High relative humidity
  - High PM2.5 on the previous day at upwind sites
  - Low wind speeds near the surface and aloft
  - Stable morning conditions
  - Predominant surface wind direction is site specific
- PM2.5 composition on poor visibility days varies by site
- Greater variability in conditions leading to good visibility

NOTES ON SUMMARIES OF RESULTS FOR VISIBILITY

- Classification accuracy for visibility combines Categories 2 & 3, so emphasis is on Category 1 (Best) and 4 & 5 (Worst) days
- References to high, low etc… are used mostly in a relative and site specific sense, rather than an absolute sense, to compare and distinguish the characteristics of the poor visibility categories (more detailed descriptions are included in the project report)

DOCUMENTATION AND EVALUATION OF THE GEOS-CHEM SIMULATION FOR 2002 PROVIDED TO THE VISTAS GROUP

Final Report

Principal Investigator: Daniel J. Jacob, Harvard University
(djacob@fas.harvard.edu)
Co-Investigators: Rokjin Park and Jennifer A. Logan, Harvard University

June 24, 2005

TABLE OF CONTENTS

1. PROJECT OBJECTIVE AND PRODUCTS DELIVERED

The objective of this project was to provide chemical boundary conditions with synoptic-scale resolution from the GEOS-Chem global chemical transport model (CTM) to serve as continental-scale CMAQ regional simulations for 2002 conducted by the VISTAS group. The GEOS-Chem simulations were to include a detailed representation of ozone-NO_x-VOC-PM chemistry as described by Park et al. [2003, 2004] (appended to this report). They were to replicate the Park et al. [2003, 2004] simulations but with coarser resolution (4^ox5^o horizontal resolution vs. 2^ox2.5^o), updated anthropogenic emissions from the EPA NEI 1999, and 2002-specific biomass burning emissions. They were also to include preliminary simulations of soil dust and sea salt. We conducted three full-year simulations for 2002:

1. A *baseline* simulation with best estimates of 2002 emissions;
2. A *background* simulation modified from the baseline by shutting off U.S. anthropogenic[1] emissions;
3. A *natural* simulation modified from the baseline by shutting off anthropogenic emissions worldwide.

3-D concentration fields with 3-hour temporal resolution were archived from each simulation to serve as boundary conditions for CMAQ. A model performance evaluation (MPE) was conducted through comparisons of the baseline simulation to IMPROVE and CASTNET observations in the United States, using the same metrics as in Park et al. [2003, 2004].

2. DESCRIPTION OF GEOS-CHEM SIMULATIONS FOR VISTAS

2.1. The GEOS-Chem model

The GEOS-Chem model (http://www-as.harvard.edu/chemistry/trop/geos) is a cooperative global CTM used by 21 institutions in North America and Europe, and centrally managed by Daniel Jacob's group at Harvard. It is driven by assimilated meteorological observations from the Global Earth Observation System (GEOS) of the NASA Global Modeling and Assimilation Office (GMAO). It is presently being applied to a wide range of atmospheric composition problems including greenhouse gases, oxidants, PM, mercury, and other species. The coupled ozone-NO_x-VOC-PM version of GEOS-Chem is described in Park et al. [2004] (appendix B). The GEOS-Chem model is documented in over 100 papers in the refereed literature (see above web site for the

[1] "Anthropogenic" here includes all fuel, industrial, and agricultural sources; it does not include biomass burning. See Park et al. [2004] for detail on source specifications.

publication list). Evaluations of the global PM simulation are presented in Park et al. [2003, 2004, 2005ab], Li et al. [2005], Alexander et al. [2005], and Heald et al. [2005].

2.2. Model configuration used for VISTAS

The GEOS-Chem simulations for VISTAS used GEOS meteorological observations for the year 2002. These were obtained from GMAO as a 6-hourly archive (3-hour for surface quantities such as mixing depths). The data through August 2002 are from the GEOS-3 assimilation, with horizontal resolution of $1^o x1^o$ and 55 vertical layers. The data after August 2002 are from the updated GEOS-4 assimilation, with horizontal resolution of $1^o x1.25^o$ and 48 vertical layers.

GEOS-Chem simulations can be conducted either with the native resolution of the GEOS meteorological data, or with degraded horizontal resolution to reduce computational expense. The Park et al. [2003, 2004] simulations used a $2^o x2.5^o$ horizontal resolution. Continental-scale simulations for North America have been conducted with the native $1^o x1^o$ resolution of the GEOS-3 data [Li et al., 2005; Park et al., 2005b]. The VISTAS simulations used a coarser horizontal resolution of 4^o latitude x 5^o longitude, as this was considered sufficient to provide boundary conditions outside of North America for use in continental-scale CMAQ simulations. In Fiore et al. [2003], we previously compared ozone simulations for North America using GEOS-Chem with $4^o x5^o$ and $2^o x2.5^o$ resolution, and the MAQSIP regional model with 36x36 km^2 resolution. We found that using the $4^o x5^o$ resolution of GEOS-Chem significantly degraded the ability of the model to reproduce the observed variability of concentrations over North America, but still maintained the synoptic-scale structure and did not incur a significant continental-scale mean bias.

Significant modifications to the representation of PM sources were made in the VISTAS simulations relative to the work of Park et al. [2003, 2004] and are described in more detail below. They include (1) use of U.S. anthropogenic emissions from the EPA NEI 1999 inventory; (2) use of forest fire information specific to 2002; (3) inclusion of the secondary organic aerosol (SOA) formation mechanism from Chung and Seinfeld [2002]; (4) inclusion of prototype soil dust and sea salt simulations. An additional modification was the application of surface emissions and dry deposition to the GEOS-diagnosed mixed layer column rather than to the surface layer of the model. This was introduced to correct for the effect of 1-hour operator splitting between transport and chemistry (including emissions and dry deposition) in the model, when dealing with a very shallow surface layer (only 10-m deep in GEOS-3). The effect is significant for fast-depositing gases such as HNO_3 and NH_3; correcting it is an objective model improvement that has since been implemented in the standard version of GEOS-Chem.

Other aspects of the simulation (transport, chemistry, deposition) are as described in Park et al. [2004]. Briefly, transport uses the advection scheme of Lin and Rood [1998], with instantaneous vertical mixing through the local mixing depth, and convective transport computed from GEOS-3 archived convective mass fluxes by replicating the convection algorithm of the parent GEOS general circulation model

(GCM). Natural sources are calculated within the GEOS-Chem simulation as a function of local values of meteorological variables (temperature, insolation, soil moisture, precipitation, wind speed, convective cloud tops). The description of ozone-NO_x-VOC-PM chemistry includes ~100 chemical species and ~400 chemical reactions. A full documentation of this mechanism is posted as a pdf document on the GEOS-Chem web site (http://www.env.leeds.ac.uk/%7Emat/GEOS-CHEM/geoschem_mech.pdf). Coupling of PM with ozone-NO_x-VOC oxidant chemistry takes place through sulfate, nitrate, and SOA formation and thermodynamics, aerosol effects on UV actinic fluxes, and heterogeneous radical chemistry. Wet deposition of soluble gases and PM follows the scheme of Liu et al. [2001] and includes contributions from scavenging in convective updrafts, rainout and washout in convective and large-scale precipitation, and partial or total release during re-evaporation below cloud base. Dry deposition is computed with a standard resistance-in-series scheme [Wang et al., 1998].

All simulations were conducted from September 1, 2001 to December 31, 2002. The first four months were used to achieve proper initialization. Results delivered to VISTAS are from the 12-month 2002 simulation.

2.3. PM sources used in VISTAS simulations

We describe here briefly the PM sources used in the VISTAS simulations. Description of the biomass burning emission inventory for 2002 is presented in section 2.4.

2.3.1. Sulfate-nitrate-ammonium

Global GEOS-Chem budgets of sulfate, nitrate, and ammonium aerosols, including breakdown by source types of emissions for sulfur, NO_x, and ammonia, are given by Park et al. [2004]. Anthropogenic emissions are from the Global Emission Inventory Activity (GEIA) with 1^ox1^o spatial resolution and seasonal temporal resolution, and are scaled for individual countries to the year 1998 on the basis of national emission inventories and fuel use statistics. Park et al. [2004] give global totals for non-U.S. anthropogenic emissions computed in this manner. They used the same procedure also for U.S. emissions. For the VISTAS baseline simulation, we used monthly mean anthropogenic U.S. emissions from the NEI 1999 inventory produced by EPA. An archive of monthly mean NEI 1999 emissions from that inventory with 0.25^ox0.25^o horizontal resolution was generated for us by Alice Gilliland of EPA/ORD, and was re-gridded to 4^ox5^o for application to VISTAS. The U.S. emission of ammonia in the NEI99 inventory (3.6 Tg N yr^{-1}) is known to be too high [Gilliland et al., 2004]. Therefore we retained for that species the U.S. emission inventory of Park et al. [2004] (2.2 Tg N yr^{-1})

Natural emissions except for biomass burning are as given by Park et al. [2004]. Volcanic sulfur emissions are from the GEIA climatology. Emission of dimethylsulfide (DMS) by phytoplankton uses a global distribution of DMS seawater concentrations from Kettle et al. [1999] and a standard sea-air exchange parameterization driven by the local wind. Soil emissions of NO_x are from GEIA and are function of local temperature and precipitation history. Lightning emissions of NO_x are computed globally with a standard algorithm based on convective cloud tops [Wang et al., 1998] and are scaled to yield a global source of 6 Tg N yr^{-1} [Martin et al., 2002]. Emissions of ammonia from soils and oceans are from GEIA.

2.3.2. Carbonaceous aerosols

Detailed discussion of the EC and OC emission source processes in the model is given in Park et al. [2003] (appendix A). Anthropogenic emissions of EC and OC outside the U.S. are from the Cooke et al. [1999] inventory. For the VISTAS baseline simulation we used U.S. anthropogenic emissions from Park et al. [2003], who optimized EC and OC sources using monthly IMPROVE observations for 1998. Both EC and OC have major sources from biomass burning; emission factors are from Andreae and Merlet [2001] and are applied to the 2002 biomass burning inventory described in section 2.4. Secondary organic aerosol (SOA) formation from biogenic hydrocarbons follows the scheme of Chung and Seinfeld [2002] developed for application in global models (the Park et al. [2003] simulations simply scaled the SOA source to 10% of monoterpene emission). The Chung and Seinfeld [2002] describes SOA formation from oxidation of several classes of biogenic hydrocarbons through gas-aerosol partitioning of the semi-volatile products as a function of local temperature and pre-existing OC mass concentration.

2.3.3. Soil dust

We included in the VISTAS simulations a preliminary representation of soil dust using the global dust mobilization scheme of Zender et al. [2003]. Dust particles in four different size classes were transported as separate tracers with different source and settling properties, thus allowing in particular some segregation of $PM_{2.5}$ and $PM_{10-2.5}$. A global evaluation of this preliminary dust simulation in GEOS-Chem was presented by Fairlie [2004]. Asian and African dust sources are simulated without obvious bias. There is a large overestimate at many IMPROVE sites in fall due to spurious local dust generation from seasonally dry and vegetation-deprived prairie ecosystems.

2.3.4. Sea salt

The sea salt concentrations in the VISTAS simulations are from a new GEOS-Chem capability developed by Alexander et al. [2005]. The simulation uses the standard source scheme of Monahan [1986] which is function of surface wind speed over the oceans, and transports sea salt PM in two size classes (0.1-1 and 1-10 μm). The resulting global source of sea salt in GEOS-Chem is 5400 Tg yr^{-1}, consistent with earlier literature (3500-7600 Tg yr^{-1}). Alexander et al. [2005] present further discussion of the global sea salt budget and distributions in GEOS-Chem, including comparisons to observations and previous global models.

2.4. Biomass burning emission inventory for 2002

2.4.1. The United States and Canada

We developed an inventory for emissions from fires in the United States using data for areas burned that are reported by several federal agencies, by regional interagency coordination centers such as the Pacific Northwest, Western Great Basin, Eastern Great Basin, and Southwest (www.or.blm.gov/nwcc/, www.nv.blm.gov/wgbcc/, www.blm.gov/utah/egbcc/, www.fs.fed.us/r3/fire/) and by various states. We also obtained a data base of fires in the southeastern United States from G. Stella of Alpine Geophysics. In the western half of the U.S. and Alaska, most of the land is federally owned, so the fire information is thought to be comprehensive. Reports from the Bureau of Indian Affairs, Bureau of Land Management (BLM), National Park Service, Fish and Wildlife Service, and U.S. Forest Service are available on-line (http://famweb.nwcg.gov/weatherfirecd). These reports give the fire name, start and end date, their location (latitude and longitude), and area burned. We analyzed these data to spatially and temporally allocate the fires. A simple concatenation of data was not possible as different agencies sometimes reported the same fires, so we ensured that duplicate reports for the same fire were eliminated. The Daily Incident Management Reports (www.cidi.org/wildfire) of the National Interagency Coordination Center (NICC) were consulted to corroborate incidence, location and sizes of major fires, and to determine whether these fires were surface or crown fires.

Our database of all fires with areas larger than 100 acres gives a total of 1626 fires, of which 338 are located in the southeastern states. These fires consumed 2.65 x 10^6 ha in the United States in 2002. The data provided by Alpine Geophysics for the southeast gave a total area of 0.044 x 10^6 ha. Six states accounted for over 80% of the national area burned, namely Alaska, Oregon, Colorado, California, New Mexico, and Arizona. Alaska accounted for one third of the area burned in the United States, and the seven largest fires in Alaska contributed 55% of the area burned for the state. For the entire United States, the largest 20 fires accounted for half the area burned nationally.

The area burned in the United States in 2002 was the second highest for the previous ten years. To put the area burned in a larger context, the area burned in Canada was similar to that in the United States, 2.76 x 10^6 ha, while 2.8 x 10^6 ha burned in Kazakhstan, and 11 x 10^6 ha in Asiatic Russia. It was also a very high fire year in Russia.

For our initial estimate of the amount of dry matter burned (used in the GEOS-CHEM simulations) we adopted a loading 2.6 kg DM/m^2 for Alaskan fires, and 1.8 kg DM/m^2 for the lower states. We found that 47 Tg of dry matter was consumed by fires in the United States, producing CO emissions of 5 Tg in about 3 months. We developed preliminary maps of dry matter burned on a 1^ox1^o grid by month by assuming that each fire burned at the same rate during each day of the burn period.

For Canada, we relied on a product provided by David Lavoue (Environment Canada). He is developing an inventory for Canada using a detailed data-base on the location of the size and position of the fires; that data-base is not yet publicly available. He gave us an interim product that consists of monthly totals of fuel consumed on a map with resolution of 1°x1° latitude by longitude. Lavoue estimates that 58 Tg of dry matter was consumed by fires in 2002, which gives rise to CO emissions of 7 Tg..

2.4.2. Russia and Kazakhstan

The most detailed fire information was available for eastern Russia. The IFFN report (http://www.fire.uni-freiburg.de/iffn/iffn_28/Russia-1.pdf) gives estimates by province of the total areas burned in Asian Russia for the fire season of 2002. The total area burned was 11 x 10^6 ha. The Fire Laboratory of the Sukachev Institute of Forest, Krasnoyarsk, provides maps showing the locations of large fires for 10-day periods derived from NOAA AVHRR data (http://www.fire.uni-freiburg.de/current/ archive/archive.htm). We used these maps to spatially and temporally apportion the area burned in each province among all of the fires logged for the province; burn scars at the end of the fire season were approximated as rectangles. The areas burned were put on a grid of 1°x1° (lat. x long.) for each 10 day period. The Kamchatka Peninsula was not included on the burning maps for eastern Russia. Areas burned there were confined to June and July (IFFN report). Maps of ATSR fire counts were used to locate the fires.

Most of the burning in Russia was in July-August in the northern province of Yakutia. There was a smaller peak in the burning in May, primarily in the provinces of southern Siberia. We relied on a detailed vegetation map of Russia to determine the dominant vegetation type in each gridbox, and applied appropriate fuel loads to determine the amount of biomass burned.

Table 1. Loadings used for fires in Russia, in kg dry matter (DM) m^{-2}

Vegetation Type	kg DM m^{-2}
Tundra	1.8
Wooded Tundra	2.0
Taiga	2.5
Boreal Forest	3.0
Grasslands	0.3
Steppe	0.3
Desert	0.3
Farmlands	0.3

Recent work indicates the importance of including the burning of peat as a component of boreal fires. We track peat burning separately from burning of other forest fuels as it has a higher moisture content, hence less efficient combustion, and higher emission factors for CO. The construction of peatland map is in progress for Russia (L. Pozdnyakova, personal communication), there is not one currently available. As a surrogate, we used maps of wetlands and soil drainage to give the distribution of boggy or poorly drained soils, as advised by S. Conard and M. Turetsky. The locations of individual fires given by the remote sensing data were superimposed on this map; burning of peat was confined to the area defined by the perimeter of the fires. Few experiments have been reported which describe measurements of fuel consumed and emissions from peat fires in boreal forests. We assumed that 2.2 kg C m^{-2} was burned.

For western Russia, wildfires other than peat bog fires were not reported in sufficient detail to ascertain their whereabouts. Qualitative descriptions of major peat bog fires in July to September around Moscow, St. Petersburg, Nizhny Novgorod, and other cities were abundant, but few estimates of areas burned and depth of peat burned were found. From the IFFN news and CNN reports, we used quantitative and qualitative information to approximate the areas burned in the peat bogs around four of the major cities. We distributed the burning homogeneously in the oblast (province) that contained each city and applied a fuel consumption estimate for peat burning as above.

Maps of fires for each month and the annual amount burned (2.8 x 10^6 ha) were available for Kazakhstan. Here also, ATSR fire counts were used to locate the fires on a monthly basis. We used a vegetation map for Kazakhstan [http://www.fire.unifreiburg.de/iffn/country/ kz/kz_2_1b.gif] and an agricultural map of the CIS (Major World Crop Areas and Climatic Profiles) to determine the fuel loads to use. Based on these maps, we postulated that the fires in the southern regions were burning of agricultural residues, for which we adopted a loading of 1.2 kg DM m^{-2}; for the pine forests in the north, we adopted a loading recommended for Kazakhstan's pine forests, 2 kg DM m^{-2}.

2.4.3. Summary

We find that 409 Tg dry matter was consumed in Russia, 52 Tg in Kazakhstan, and 47 Tg in the United States. For Canada, Lavoue's estimate of 58 Tg of dry matter consumed in 2002 is low in comparison to our estimate for Russia, given the ratio of areas. Lavoue did not include burning of peat in Canada as he believes it in not an important component of the Canadian fires (personal communication). These estimates were used in the GEOS-CHEM simulations to provide monthly emissions from biomass burning. In other regions we replied on the work of Van der Werf et al. (Science, 2003), based on VIRS satellite data.

3. MODEL PERFORMANCE EVALUATION

Model performance evaluation (MPE) of the baseline VISTAS simulation focused on the annual and seasonal PM concentration statistics previously reported by Park et al. [2003, 2004] using observations from IMPROVE and CASTNET sites. The Park et al. simulations were conducted for 1998 and 2001, whereas the VISTAS simulation was for 2002. We use here observations from 145 IMPROVE sites and 84 CASTNET sites available for 2002.

The limitations of using U.S. concentration data to evaluate a global PM simulation with 4^ox5^o horizontal resolution should be stressed. Any variability on scales less than ~500 km cannot be resolved. This compromises the evaluation for individual sites, particularly in urban, industrial, and coastal regions. We focus therefore our evaluation on the large-scale spatial distribution and on seasonal statistics for the national ensemble of sites. The evaluation figures shown here reproduce similar figures presented by Park et al. [2003, 2004] for their 1998 and 2001 simulations with 2^ox2.5^o resolution. Direct comparison to these figures can therefore be made to assess the relative quality of the simulations. We use the slopes of the regression lines in the simulated vs. observed scatterplots to diagnose mean biases in the model. Regression lines are computed with the reduced major axis method [Hirsch and Gilroy, 1984].

Figure 1 compares simulated and observed annual mean sulfate concentrations at the ensemble of IMPROVE and CASTNET sites for the year 2002, plotted on the 4^ox5^o model grid. Values are highest in the industrial midwest, in both model and observations, reflecting the distribution of anthropogenic emissions. Figure 2 shows scatterplots of simulated vs. observed annual and seasonal sulfate concentrations for the ensemble of (left) IMPROVE and (middle) CASTNET sites. The right column in Figure 2 compares simulated and observed sulfate precipitation data for 2002 at NADP sites. The correlation between model and observations is high for the annual mean values (R^2 = 0.82 for the concentration data and 0.71 for the deposition data) and also for the seasonal means (R^2 = 0.63–0.87 for the concentration data). An exception is the deposition data in summer, for which correlation between model and observations is low (R^2 = 0.18). Overall, the correlations presented here are consistent with those presented by Park et al. [2004] for 2001 (see Figures 3 and 4 of appendix B) although that simulation was more successful in capturing the variance in summer deposition.

Figure 3 compares simulated and observed annual mean concentrations of ammonium at CASTNET sites. Observed concentrations are higher in the east than in the west and are highest in the midwest, reflecting agricultural operations. The model reproduces this spatial distribution. Scatterplots of simulated vs. observed annual and seasonal ammonium concentrations are shown in Figure 4 for the ensemble of sites. The model reproduces the variability of observed ammonium concentrations, both in an annual mean sense (R^2 = 0.81) and in different seasons (R^2 = 0.72-0.81). The R^2 values are slightly lower than the values from the Park et al. [2004] simulation (Figure 6 of appendix B). That simulation showed a factor of 2 high bias in fall due to too high seasonal ammonia emission. Despite the same ammonia emission, the VISTAS simulation shows much reduced bias (50% for ammonium concentration in fall). This reflects in part the increase in the effective ammonia deposition velocity resulting from application of the dry deposition sink throughout the mixed layer column, as described in section 2.2.

Figure 5 compares simulated and observed annual mean nitrate concentrations at the IMPROVE and CASTNET sites. Maximum concentrations are in the Midwest, reflecting the limitation of ammonium nitrate formation by the availability of ammonia. The model captures the observed spatial distribution of nitrate concentrations but tends to be high on an annual mean basis (slope = 1.41-1.80 in Figure 4). This is however also an improvement over Park et al. [2004], which found a factor of 2 high bias (slope = 1.87 – 2.43 in Figure 6 of appendix B), and reflects the improved treatment of HNO_3 dry deposition. The high bias in the VISTAS simulation is mainly driven by the fall months, when the model appears to produce too much ammonium nitrate due to too high ammonia emission [Park et al., 2004].

Figure 6 compares simulated and observed annual mean concentrations of EC at IMPROVE sites, and the scatterplots of Figure 7 compare seasonal mean concentrations. The model reproduces about half of the observed spatial variability in different seasons (R^2 = 0.42-0.58) except in summer (R^2 = 0.18). Simulated concentrations tend to be higher than observed (slope = 1.58-1.74) except in summer (slope = 0.76). The high bias is mostly driven by IMPROVE sites in the northeastern corridor.

Figure 8 compares simulated and observed annual mean concentrations of organic carbon mass (OMC) at IMPROVE sites, and Figure 9 shows the seasonal scatterplots. Although the ability of the model to reproduce variability in the observations is poor, particularly in summer, the simulated seasonal mean concentrations are generally within a factor of two of observations. The simulation is significantly worse than that described by Park et al. [2003]; this reflects the use of the Chung and Seinfeld [2002] SOA parameterization, which appears to underestimate the source from vegetation.

Overall, the MPE conducted for the VISTAS simulation for the U.S. shows the level of agreement that can be expected considering the state of the science in large-scale aerosol modeling and the intrinsic limitations of a simulation with 4^ox5^o horizontal resolution. Simulated concentrations are mainly within a factor of 2 of observations on regional and seasonal scales, and can generally account (except for OC) for most of the observed variability on those scales.

Abstract. We use a global 3-D model (GEOS-CHEM) to better quantify the sources of elemental carbon (EC) and organic carbon (OC) aerosols in the United States through simulation of year-round observations for 1998 at a network of 45 sites (IMPROVE). Simulation with our best *a priori* understanding of sources, including global satellite data to constrain fire emissions, captures most of the variance in the observations (R^2 = 0.84 for EC, 0.67 for OC) with a low bias of 15% for EC and 26% for OC. Multiple linear regression to fit the IMPROVE data yields best estimates of 1998 U.S. sources of 0.60 Tg yr^{-1} EC and 0.52 Tg yr^{-1} OC from fossil fuel; 0.07 Tg yr^{-1} EC and 0.89 Tg yr^{-1} OC from biofuel; 0.08 Tg yr^{-1} EC and 0.60 Tg yr^{-1} OC from wildfires; and 1.10 Tg yr^{-1} OC from vegetation. We find that fires in Mexico and Canada contributed 40-70% of annual mean natural EC in the United States for 1998, and 20-30% of annual mean natural OC. Transpacific transport from Asian pollution sources amounted to less than 10% of the natural EC and less than 2% of the natural OC; in contrast to ozone, we find that intercontinental transport of anthropogenic carbonaceous aerosols does not enhance significantly the natural background. IMPROVE observations and model simulations for the summer of 1995 show that Canadian fire emissions can produce large events of elevated EC and OC in the southeastern United States. Our best estimates of mean natural concentrations of EC and OC in the United States, using a model simulation with climatological monthly mean fire emissions, are 2-3 times higher than the default values recommended by the U.S. Environmental Protection Agency (EPA) for visibility calculations, except for OC in the eastern United States (16% lower).

1. Introduction

Carbonaceous aerosol is one of the least understood components of fine particulate matter (PM). It is usually divided in two fractions, elemental carbon (EC) and organic carbon (OC). OC is the second most abundant component of the aerosol in the United States after sulfate, and the dominant component of the natural continental aerosol [*Malm et al.*, 2000]. EC is the dominant component of the light-absorbing aerosol. Carbonaceous aerosol is presently the subject of intense scrutiny because of its impact on human health, visibility, and climate.

We present here an assessment of the sources of EC and OC in the United States by using a global 3-D model (GEOS-CHEM) simulation of observations from the Interagency Monitoring of Protected Visual Environments (IMPROVE) network. Our focus is on quantifying the anthropogenic and natural sources of these aerosols, the role of transboundary transport, and the implications for visibility. The U.S. Environmental Protection Agency Regional Haze Rule [*U.S. EPA*, 2001] mandates a schedule of increasing emission controls to achieve "natural visibility conditions" in national parks and other wilderness areas by 2064. The ambiguity in defining "natural visibility conditions" requires better information on natural PM concentrations and the perturbing effects from fires and from sources outside the United States.

Elemental carbon is emitted to the atmosphere by combustion. Major sources in the United States include coal burning and diesel engines. Organic carbon is emitted directly to the atmosphere (primary OC) and formed *in situ* by condensation of low-volatility products of the photooxidation of hydrocarbons (secondary OC). Primary sources of OC in the United States are wood fuel, coal burning, and wild fires [*Seinfeld and Pandis*, 1998; *Cabada et al.*, 2002]. Secondary OC includes an anthropogenic component from oxidation of aromatic hydrocarbons, and a biogenic component from oxidation of terpenes [*Griffin et al.*, 1999].

Our approach is to conduct a 3-D model simulation of EC and OC concentrations in the United States for 1998, with best *a priori* sources, compare results with observations from the IMPROVE network, and use the constraints from the comparison to optimize our treatment of sources by multiple linear regression. Our treatment of fire emissions accounts for year-to-year variability through satellite observations; 1998 was a particularly active fire year, thus offering good constraints on emissions from that source. We also present a case study for the summer of 1995 to demonstrate the large-scale enhancements of EC and OC concentrations in the United States that can arise from Canadian fires. We go on to quantify mean natural EC and OC concentrations in the United States for different seasons and regions, using climatological fire emissions and sources from vegetation, and to assess the enhancement of EC and OC background concentrations resulting from transpacific transport of Asian pollution.

2. Model Description

2.1 General

We use the GEOS-CHEM global 3-D model of tropospheric chemistry [*Bey et al.*, 2001] to simulate EC and OC aerosols for 1998 (1 year) and 1995 (summer). The model (version 4.23, http://www-as.harvard.edu/chemistry/trop/geos/index.html) uses assimilated meteorological data from the NASA Goddard Earth Observing System (GEOS) including winds, convective mass fluxes, mixed layer depths, temperature, precipitation, and surface properties. Meteorological data for 1995 and 1998 are available with 6-hour temporal resolution (3-hour for surface variables and mixing depths), 2^{o} latitude by 2.5^{o} longitude horizontal resolution, and 20 (GEOS1 for 1995) or 48 (GEOS3 for 1998) sigma vertical layers. We retain this spatial resolution in the GEOS-CHEM simulation. The lowest model levels are centered at approximately 50, 250, 600, 1100, and 1750 m above the local surface in GEOS1 and 10, 50, 100, 200, 400, 600, 900, 1200, and 1700 m in GEOS3.

The simulation of carbonaceous aerosols in GEOS-CHEM follows that of the Georgia Tech/Goddard Global Ozone Chemistry Aerosol Radiation and Transport (GOCART) model [*Chin et al.*, 2002], with a number of modifications described below. The model resolves EC and OC, with a hydrophobic and a hydrophilic fraction for each (i.e., four aerosol types). Combustion sources emit hydrophobic aerosols that then become hydrophilic with an e-folding time of 1.2 days following *Cooke et al.* [1999] and *Chin et al.* [2002]. We assume that 80% of EC and 50% of OC emitted from all primary sources are hydrophobic [*Cooke et al.*, 1999; *Chin et al.*, 2002; *Chung and Seinfeld*, 2002]. All secondary OC is assumed to be hydrophilic. The four aerosol types in the model are further resolved into contributions from fossil fuel, biofuel, and biomass burning, plus an OC component of biogenic origin, resulting in a total of 13 tracers transported by the model.

Simulation of aerosol wet and dry deposition follows the schemes used by *Liu et al.* [2001] in previous GEOS-CHEM simulations of ^{210}Pb and ^{7}Be aerosol tracers. Wet deposition includes contributions from scavenging in convective updrafts, rainout from convective anvils, and rainout and washout from large-scale precipitation. Wet deposition is applied only to the hydrophilic component of the aerosol. Dry deposition of aerosols uses a resistance-in-series model [*Walcek et al.*, 1986] dependent on local surface type and meteorological conditions; it is small compared to wet deposition. *Liu et al.* [2001] found no systematic biases in their simulations of ^{210}Pb and ^{7}Be with GEOS-CHEM.

2.2 *A priori* sources of EC and OC

We use global anthropogenic emissions of EC (6.4 Tg yr^{-1}) and OC (10.5 Tg yr^{-1}) from the gridded *Cooke et al.* [1999] inventory for 1984. This inventory includes contributions from domestic, vehicular, and industrial combustion of various fuel types. In the GOCART simulation of *Chin et al.* [2002], the *Cooke et al.* [1999] inventory was used with no seasonal variation. However, the source from heating fuel should vary with season [*Cabada et al.*, 2002]. *Cooke et al.* [1999] do not resolve the contributions to EC and OC emissions from heating fuel. We assume these contributions to represent 8% (EC) and 35% (OC) of total anthropogenic emissions, based on data for the Pittsburgh area from *Cabada et al.* [2002] and apply local seasonal variations of emissions using the heating degree days approach [*EIA*, 1997; *Cabada et al.*, 2002]. In this manner we find that anthropogenic EC emission in the United States in winter is 15% higher than in summer. For OC the anthropogenic winter emission is twice that in summer.

The *Cooke et al.* [1999] inventory does not include biofuels, which provide however an important source of heating in rural households and are also used in agroindustrial factories. We use a global biofuel use inventory with $1^{o}x1^{o}$ spatial resolution from *Yevich and Logan* [2002] with emission factors of 1.0 g EC and 5 g OC per dry mass burned [*Street et al.*, 2001; *Dickerson et al.*, 2002]. For the United States and Canada, we supersede that inventory with data on wood fuel consumption for residential and industrial sectors available for individual states and provinces [*EIA*, 2001] and which we distribute on a rural population map. Emission factors for this North American wood fuel source are 0.2 g EC and 3.0 g OC per kg dry wood burned [*Cabada et al.*, 2002]. Seasonal variation in biofuel emissions is included for the United States only and is estimated according to the heating degree-days approach.

Biomass burning emissions of EC and OC are calculated using the global biomass burning inventory of *Duncan et al.* [2002]. This inventory uses a fire climatology compiled on a $1^{o}x1^{o}$ grid by *Lobert et al.* [1999], and applies monthly and interannual variability to that climatology from satellite observations. Emission factors are 2g EC and 14 g OC per kg dry mass burned [*Chin et al.*, 2002], higher than for biofuels because combustion is less efficient. For boreal forest fires, which are of particular interest here, emission factors reported in the literature range from 0.38 to 2.55 g EC per kg dry mass burned [*Lavoué et al.*, 2000, and references therein], consistent with the value assumed here. The OC/EC emission ratio of 7 is within the range of 6.9 to 8.2 used by *Liousse et al.* [1996]. Figure 1 shows the resulting annual OC emissions from biomass burning in North and Central America for 1997-2000 as well as the climatological mean. An ENSO-related drought resulted in catastrophic wildfires in the tropical forests of southern

Mexico and Central America in 1998 [*Peppler et al.*, 2000]. Canadian fire emissions were also unusually large in 1998. Fire emissions in the United States were 38% higher than the climatological mean.

Figure 2 shows the spatial and seasonal distribution of biomass burning OC emission from our model in 1998. Fires in Mexico and Central America were most intense in May [*Peppler et al.*, 2000, *Cheng and Lin*, 2001]. Canadian fires peaked in July-September. In the United States, most fires occurred in the northwest (Idaho, Montana) in summer; additional fires occurred in spring in Florida, due to the ENSO-induced drought.

Secondary formation of OC from oxidation of large hydrocarbons is an important source but uncertainties are large [*Griffin et al.*, 1999; *Kanakidou et al.*, 2000; *Chung and Seinfeld*, 2002]. *Chung and Seinfeld* [2002] find that biogenic terpenes are the main source of secondary OC aerosols. We assume a 10% carbon yield of OC from terpenes [*Chin et al.*, 2002], and apply this yield to a global terpene emission inventory dependent on vegetation type, monthly adjusted leaf area index, and temperature [*Guenther et al.*, 1995].

Table 1 shows a summary of *a priori* EC and OC emissions used in the GEOS-CHEM simulation for 1998. The most important global source for both is biomass burning. In the United States, EC is mostly emitted from the combustion of fossil fuel and OC originates mostly from vegetation (but with large seasonal variation, as discussed below).

3. Model evaluation

A global evaluation of the EC and OC aerosol simulation was done by *Chin et al.* [2002] as part of a more general evaluation of aerosol optical depth using ground and satellite observations. Our simulation of aerosol sources and meteorological processes is similar to that of *Chin et al.* [2002] and our global distributions of EC and OC concentrations are comparable. We focus here our model evaluation on the United States, using observations at the IMPROVE sampling sites. The IMPROVE monitoring program was initiated in 1987 in national parks and other protected environments to identify the contribution of different aerosol components to visibility degradation [*Malm et al.*, 1994]. The data for 1995 and 1998 consist of 24-h speciated aerosol concentrations measured twice a week. The EC and OC concentrations are determined using the Thermal Optical Reflectance (TOR) method, which is state of the science but is subject to uncertainties that are difficult to quantify [*Chow et al.*, 1993; *Malm et al.*, 1994]. In the present paper we take the data at face value. There are 45 IMPROVE sites with continuous measurements for 1998 (Figure 3).

Figure 4 compares simulated and observed annual mean EC and OC concentrations at the 45 IMPROVE sites for the year 1998. The IMPROVE measurements are plotted on the 2^o x 2.5^o model grid. The bottom panels show the differences (model bias). A general objection to evaluating model results with 24-hr averaged concentrations in continental surface air is the inability of models to resolve nighttime stratification [*Jacob et al.*, 1993]. This is not an issue in our case because of high vertical resolution of the model near the surface and because the IMPROVE sites are not in the vicinity of large sources. We verified that the 24-h average concentrations simulated by the model in layers 1 (0-10m), 2 (10-50m), and 3 (50-100m) are not significantly different.

Observed concentrations of EC and OC are generally higher in the eastern than the western United States, reflecting higher anthropogenic and vegetative (OC) emissions in the east. The OC maximum is shifted south relative to the EC maximum, and shows a secondary maximum along the west coast, reflecting the vegetative source. The model captures well this large-scale spatial distribution of EC and OC. Fires in the model also lead to high concentrations over Central America and western Canada.

Site-to-site comparisons reveal however some major discrepancies between model and observations, as shown in the bottom panel of Figure 4 and in the scatterplot of Figure 5. Some of these discrepancies appear to reflect inadequate spatial resolution in the model. Model overestimates at coastal sites with large local urban or fire sources (BRIG in New Jersey; OKEF in Georgia; REDW, PORE, and PINN in California) are due to the inability of the model to simulate steep subgrid land-to-sea gradients in mixing depth [*Fiore et al.*, 2002]. Model overestimates at SEQU (California) and GLAC (Montana) are due to local fire emissions (Figure 1) for which averaging over the grid scale may induce large errors in the simulation of local observations. We exclude these seven sites in further statistical data analysis.

The model overestimates OC concentrations at THSI (Oregon) and MORA (Washington) sites due to a particularly large vegetative source in the model in summer that is apparently not seen in the observations. The discrepancy is local in nature (it is not found at nearby sites). As discussed further below, our specification of the vegetative OC source appears inadequate to describe OC concentrations at these two sites, and therefore we exclude them from further statistical analysis.

Figure 5 shows that the model generally reproduces the annual mean EC and OC concentrations to within a factor of two and captures the spatial pattern well (R^2=0.84 for EC and R^2=0.67 for OC). However, the slope of the reduced major axis line [*Hirsch and Gilroy*, 1984] is 0.85±0.06 for EC and 0.74±0.08 for OC, reflecting a low bias in the model. We will correct for this model bias by adjusting the sources, as discussed below.

Figure 6 and Figure 7 compare seasonal variations of simulated and observed EC and OC concentrations at selected IMPROVE sites. Contributions from individual sources to the model concentrations are shown. Seasonal variations for EC differ considerably from site to site, and the model has significant success in capturing these differences. Fossil fuel is the dominant source for EC at most sites, but seasonal maxima in May-September over the western United States are due to forest fires. The OC concentrations are generally highest in summer and lowest in winter, both in the model and in the observations; this seasonal variation is mostly due to the biogenic source. Peaks in OC in May-September in the western United States are seen both in the model and in the observations and are due to wildfires, as for EC. Wintertime OC is higher in the eastern than the western United States, and includes contributions of comparable importance from biofuels and fossil fuels.

Rogers and Bowman [2001] used satellite measurements and air parcel trajectory calculations to illustrate the transport of the 1998 fire plumes from Central America to the central and southern United States. Our model successfully captures the corresponding peaks of EC and OC observed in May at the IMPROVE sites (e.g., BIBE in Texas, CHIR in Arizona, CANY in Utah, MOZI in Colorado, UPBU in Arkansas, GRSM in Tennessee). The enhancement in concentrations is much stronger for OC than for EC, both in the model and in the observations, reflecting high OC/EC fire emission ratios and the relatively large fossil fuel source of EC in the United States.

The model has also some success in reproducing the influences from fire emissions within the United States. For example, the high OC in April-June at CHAS in Florida is well captured in the model. Fires in the western United States result in peak EC and OC concentrations in September at several sites (MORA, Washington; THSI, Oregon; LAVO, California; JARB, Nevada).

Figure 8 compares simulated and observed monthly mean concentrations for the ensemble of IMPROVE sites and for separate seasons. The model simulation with *a priori* sources has success in reproducing the variability of observed EC and OC for winter and spring, as measured by the high R^2 (0.67-0.79) correlation between model and observations. The slope of the regression line (0.84-0.98) is close to one for both EC and OC. The R^2 is lower in summer and fall, particularly for OC (0.37-0.40) and the slope of the regression line is off from one (0.72-0.74 for EC and 0.74-1.06 for OC). The slope of the OC regression line in fall is close to one only because high model bias from wildfire sources at western sites offsets the low model bias at eastern sites.

4. Top-down emission estimates

The statistical model biases apparent in Figure 8 could reflect errors in the *a priori* sources. We examine what adjustments in the sources would be needed for least-squares minimization of the bias between simulated and observed monthly mean EC and OC concentrations. We identify for this purpose four source components: fossil fuel, biofuel, biomass burning, and vegetation (the latter for OC only). We use a multiple linear regression to fit the annual mean U.S. source for each component to the monthly mean IMPROVE observations. In order to give equal weight to EC and OC concentrations in the least-squares minimization, we normalize them by their respective annual mean concentrations for the ensemble of IMPROVE sites (0.29 $\mu g\ m^{-3}$ for EC, 1.23 $\mu g\ m^{-3}$ for OC).

We find in this manner that fossil fuel and biofuel emissions should be increased by 15% and 65% respectively from *a priori* levels, while biomass burning emissions should be decreased by 17% and the biogenic source for OC should be increased by 11%. We consider these adjustments to be well within the uncertainties on the *a priori* estimates. The *a posteriori* values of our adjusted sources are given in Table 1. The increase in the biofuel source is largely determined by the model underestimate of observed OC for the cold season.

Figure 9 presents annual mean surface air concentrations of EC and OC in the model using *a posteriori* sources. Relative to the simulation with *a priori* sources (Figure 4), there are 15-20% increases in EC and OC concentrations in the eastern United States. Changes in the western United States are smaller because the decrease in the biomass burning source offsets the increase in the biogenic OC source.

The effect of source adjustment on the ability of the model to fit observed EC and OC concentrations is shown by the scatterplots in Figure 8. Compared to the simulation with *a priori* sources, the R^2 correlation coefficients are slightly higher and the slopes of the regression lines are closer to unity. Figures 6 and 7 show the effect of the *a posteriori* sources on the simulation at individual sites. The adjustments are generally too small to correct site-specific discrepancies, which would require modifying the geographic distributions of the sources.

Figures 10 and 11 show the contributions of individual *a posteriori* sources to EC and OC for winter and summer. Fossil fuel is the most important source of EC everywhere in the United States, except in some areas in the west in summer where wildfires make a more important contribution. For OC, the anthropogenic sources (fossil and biofuel) dominate in winter, while the natural sources (fires and vegetation) are more important in summer. The fossil fuel OC is mostly concentrated in the northeastern corridor, the industrial Midwest and Southern California, whereas the biofuel OC is more widely distributed. Biogenic OC in summer is highest in the southeast and along the west coast. We previously discussed in the context of Figure 7 the large OC enhancements in the southern United States due to fires in Central America, but these enhancements are in spring (cf. Figure 2) and thus not apparent in Figure 11. Figure 11 shows a large enhancement in OC concentrations over the north-central United States due to Canadian fires, but the IMPROVE sites are not well situated to observe this enhancement (Figure 3). We present below a case study for summer 1995 demonstrating Canadian fire influence over the eastern United States.

5. Canadian fire influence: a case study for the summer of 1995

Previous studies [*Wotawa and Trainer*, 2000; *Fiore et al.*, 2002; *McKeen et al.*, 2002] have shown that major Canadian wildfires in June-July 1995 caused large enhancements of CO and smaller enhancements of ozone in the southeastern United States. The Canadian fire plumes were carried by northerly flows associated with high pressure systems on the back side of cold fronts. We use here a GEOS-CHEM simulation for the summer 1995 to demonstrate large aerosol EC and OC enhancements from these fires at IMPROVE sites in Arkansas (UPBU), Tennessee (GRSM) and Kentucky (MACA).

Our simulation of the 1995 Canadian wildfires uses daily, geographically resolved emission data estimated from the area burned in each province. Those data are given by *Wotawa and Trainer* [2000] for CO, and are scaled here to our climatological biomass burning emission inventory for CO [*Lobert et al.*, 1999] to derive corresponding EC and OC emissions. The resulting EC and OC emissions from the fires are 0.34 and 2.41 Tg, respectively, and are distributed in five areas (Northwest Territories, Alberta, Saskatchewan, Manitoba, and Ontario) for four burning periods from 17 June to 13 July.

Figure 12 shows the time series of simulated and observed EC and OC concentrations at three sites in the southeastern United States: UPBU in Arkansas, MACA in Kentucky, and GRSM in Tennessee. There are two large peaks in the observations, for July 1 and July 8, which are captured by the model and are due to the Canadian fires (compare solid and dashed lines in Figure 12). The timing of those peaks is consistent with those concurrently observed for CO at nearby sites [*McKeen et al.*, 2002]. Our simulation of the magnitude of the July 7-9 event is improved in a sensitivity simulation where we assume initial lifting of the fire emissions up to 4 km altitude (Figure 12, dotted line). Such lifting can be expected from buoyancy, particularly for large crown fires [*Liousse et al.*, 1996; 1997; *Lavoué et al.*, 2000].

Our model simulation allows us to assess the influence of Canadian fire emissions on seasonal aerosol concentrations in the United States for the summer of 1995. We find that the events associated with Canadian fire plumes persisted typically for 3-5 days. On a seasonal basis, they caused the mean June-August 1995 natural EC to increase by 80% (east) and 36% (west) and the mean OC to increase by 23% (east) and 16% (west), relative to a sensitivity simulation with no Canadian fires.

6. Implications for natural visibility in the United States

We use results from our model to estimate the role of natural carbonaceous aerosols in visibility reduction and compare to the default values recommended by *EPA* [2001] for application of the Regional Haze Rule. Our 1998 simulation with *a posteriori* sources yields annual average concentrations of natural EC and OC from fires and vegetation of 0.09 μg/m^3 and 1.09 μg/m^3, respectively, for the western United States (west of 95^{o}W) and 0.06 μg/m^3 and 0.95 μg/m^3, respectively, for the eastern United States. In order to compute the light extinction by OC we need to multiply the OC mass by 1.4 to obtain an Organic Carbon Mass (OMC) that accounts for the non-carbon additional mass attached to OC aerosols [*Malm et al.*, 1994]. The resulting annual average for natural OMC is 1.52 μg/m^3 and 1.33 μg/m^3 for the west and east, respectively. Except for OMC in the eastern United States, our best estimates of natural concentrations for EC and OMC are significantly higher than the default values recommended by *EPA* [2001] which are 0.02 μg/m^3 for EC, and 0.47 μg/m^3 (west) and 1.40 μg/m^3 (east) for OMC.

Several issues need to be addressed in this comparison to the EPA default values. First, 1998 had unusually high fire emissions, principally from Mexico and Canada, as shown in Figure 1. Second, it is important to quantify the contribution of transboundary transport to natural EC and OC concentrations in the United States. Third, there is ambiguity from a U.S. policy standpoint as to whether intercontinental transport of anthropogenic pollution (as from Asia) should be considered part of the "natural" background. To address these issues we conducted three sensitivity simulations, with sources modified from those in our standard 1998 simulation. The first includes no EC and OC sources in the United States to quantify the contributions from transboundary transport, mostly from Canada and Mexico. The second includes EC and OC sources from Asia only, to quantify the transpacific transport. The third uses climatological biomass burning emissions as shown in Figure 1 in order to derive mean default values of natural EC and OC concentrations in the United States. The results are summarized in Table 2.

We find that the transboundary transport of anthropogenic sources makes only a small contribution (less than 10%) to the total anthropogenic concentrations of EC and OC in the United States. However, the transboundary transport of natural sources, mostly from fires in Canada and Mexico, makes a large contribution to annual mean natural concentrations in the United States for 1998 (44% in the west and 67% in the east for EC; 28% in the west and 37% in the east for OC).

Transpacific transport from Asian sources is found to make little contribution to EC and OC concentrations in the United States, even in the context of the natural background. The concentrations generated in the simulation with anthropogenic and natural Asian sources only (Table 2) amount to less than 2% of the natural OC concentrations from the standard simulation, and less than 10% of the natural EC. The small role of intercontinental transport in contributing to background EC and OC concentrations over the United States reflects the short lifetime of these species against wet deposition, particularly considering that the lifting of air from the continental boundary layer to the free troposphere involves wet processes [*Stohl*, 2001]. This can be contrasted to ozone, for which transport from outside North America makes a large contribution to the U.S. background [*Fiore et al.*, 2002].

Our best estimates of mean natural EC and OC concentrations for comparison to the EPA default values are obtained from the simulation using mean climatological fire emissions. We find annual average concentrations of natural EC and OMC of 0.06 $\mu g/m^3$ and 1.25 $\mu g/m^3$, respectively, for the western United States and 0.04 $\mu g/m^3$ and 1.17 $\mu g/m^3$, respectively, for the eastern United States (Table 2). These are higher by a factor of 2-3 than the EPA default values except for OMC in the eastern United States which is lower by 16%.

The implications of our results for natural visibility estimates are substantial, particularly in the western United States. Our higher natural OMC component relative to EPA's default estimates results in lower natural visibility. For example, *EPA* [2001] uses its default natural PM concentrations to derive mean light extinctions of $15.60\times10^{-6}\ m^{-1}$ and $15.78\times10^{-6}\ m^{-1}$ at Bandelier National Monument (BAND, New Mexico) and at Yellowstone National Park (YELL, Wyoming). Applying the *EPA* [2001] visibility formula with our best estimates of natural EC and OMC (from the simulation with climatological mean fires), and using EPA default values for the other PM components, we find natural light extinctions of $19.13\times10^{-6}\ m^{-1}$ and $19.31\times10^{-6}\ m^{-1}$ at BAND and YELL, respectively, about 22% higher than EPA values.

7. Conclusions

We used the GEOS-CHEM global 3-D model to simulate observed concentrations of elemental carbon (EC) and organic carbon (OC) from a network of 45 sites in relatively remote regions of the United States (IMPROVE network). Our focus was to better quantify the anthropogenic and natural sources of EC and OC in the United States, and the role of transboundary and intercontinental transport, in the context of assessing the effect of these aerosols on visibility.

We conducted a 1-year simulation for 1998 using best *a priori* estimates of EC and OC sources, including global satellite observations of fires, and compared the results to observed concentrations at the IMPROVE sites. Wildfire emissions were from a gridded climatological inventory, scaled to monthly fire emissions for 1998 using satellite fire count data. The model reproduces well the spatial pattern in the observations ($R^2 = 0.84$ for EC, $R^2 = 0.67$ for OC) but is biased low by 15% for EC and 26% for OC. From a multiple linear regression fit we concluded that fossil fuel and biofuel emissions for EC and OC in the United States should be increased by 15%, and 65% respectively from *a priori* levels, while biomass burning emissions for both EC and OC should be decreased by 17% and the biogenic source for OC should be increased by 11%. Our best *a posteriori* estimates are given in Table 1.

Canadian fire influence on the United States in 1998 was largely confined to the upper Midwest, where no IMPROVE data are available. We conducted an additional simulation for the summer of 1995, for which large CO enhancements in the southeastern United States from Canadian fires had previously been reported [*Wotawa and Trainer*, 2000]. We find correspondingly large EC and OC enhancements in the IMPROVE observations for this region, which the model captures and diagnoses as being due to Canadian fire emissions. Model results indicate that Canadian fires in 1995 enhanced the mean June-August natural EC and OC concentrations in the eastern United States by 80% and 23%, respectively.

Our 1998 and 1995 simulations lead confidence in the representation of fire emissions of EC and OC in the model. We used a simulation with climatological monthly mean fire emissions, together with our best estimate of the biogenic OC source, to estimate natural concentrations of carbonaceous aerosols in the United States for purpose of natural visibility assessments and application of the EPA Regional Haze Rule [*EPA*, 2001]. Our best estimates of natural annual mean concentrations for EC are 0.06 μg/m^3 in the western United States (west of 95^{o}W) and 0.04 μg/m^3 in the east; for organic carbon mass (OMC = 1.4 OC, to account for the non-carbon contribution to OC aerosols), they are 1.25 μg/m^3 in the west and 1.17 μg/m^3 in the east. These values are 2-3 times higher than the default values recommended by *EPA* [2001] for application of the Regional Haze Rule, except for OMC in the east (16% lower). Our higher estimates of the natural OMC concentrations relative to EPA's default estimates result in higher natural light extinction (and hence lower natural visibility) by 22% in the western United States. We also find a large seasonal variability in natural light extinction from EC and OC, with highest values in summer due to sources from wildfires and vegetation.

We further investigated the contribution from transboundary transport to EC and OC concentrations in the United States. A sensitivity simulation with no EC and OC sources in the United States shows that fires in Mexico and Canada made a large contribution to annual mean natural concentrations of EC (40-70%) and OC (30-40%) in the United States in 1998. A sensitivity simulation with Asian sources only shows that transpacific transport contributes less than 10% of the natural background EC over the United States, and less than 2% of the natural background OC.

Acknowledgments. This research was supported by the Electric Power Research Institute (EPRI) and the U.S. Environmental Protection Agency (EPA). The authors are grateful to R. Yevich for providing her annual biofuel emission data.

Figures Captions

Figure 1. Yearly biomass burning OC emission in 1997-2000 for North and Central America, and climatological mean value (see text).

Figure 2. Annual biomass burning OC emission over North and Central America in 1998 (top) and seasonal variations for different regions (bottom).

Figure 3. IMPROVE sampling sites with continuous records for 1998.

Figure 4. Annual mean concentrations of EC (left) and OC (right) in surface air over the United States in 1998. The top panel shows results from the GEOS-CHEM model using a priori sources. The middle panel shows the IMPROVE observations plotted on the model $2^o \times 2.5^o$ grid. The bottom panel shows the difference between the two.

Figure 5. Scatterplot of simulated (GEOS-CHEM) vs. observed (IMPROVE) annual mean EC and OC concentrations for the data shown in Figure 4. The pluses and the circles indicate data in the western and eastern United States (separated at 95^oW), respectively. The asterisks with letter labels indicate sites discarded in the statistical analysis (see text): REDW(A), PORE(B), PINN(C), SEQU(D), GLAC(E), OKEF(F), and BRIG(G). The squares indicate OC data at MORA(H) and THSI(I) sites which were

discarded in statistical analysis for OC. The thin solid and dotted lines represent the y = x relation and a factor of 2 deviation. The thick solid line represents the reduced major-axis linear regression [*Hirsch and Gilroy*, 1984], excluding sites A-I. The Pearson correlation coefficients R^2 and regression equations are indicated.

Figure 6. Seasonal variation of monthly mean EC concentrations in 1998 at selected IMPROVE sites. Site locations are shown in Figure 1. Values are monthly means. Closed circles indicate the observations. Dashed and solid lines represent the model simulations with *a priori* and *a posteriori* sources, respectively. The *a priori* model components by source types are indicated as thin solid lines with symbols: asterisks (fossil fuel combustion), diamonds (biomass burning), and squares (biofuel use).

Figure 7. Same as in Figure 6 but for OC. The *a priori* model results by source types are represented as thin solid line with asterisks (fossil fuel), diamonds (biomass burning), squares (biofuel), and triangles (biogenic terpenes).

Figure 8. Scatterplots of monthly mean EC (left two columns) and OC (right two columns) simulated vs. observed concentrations with *a priori* (left) and *a posteriori* (right) sources, for the ensemble of IMPROVE sites and for individual seasons in 1998. Sites in the western and eastern United States (separated at 95^{o}W) are shown as pluses and open circles, respectively. Thin solid lines indicate a perfect match of the model results with observations, and dotted lines denote a factor of 2 departure. Thick solid lines represent the reduced major axis regression. The Pearson correlation coefficients R^2 are indicated.

Figure 9. Annual mean concentrations of EC (left) and OC (right) in surface air over the United States in 1998 from the GEOS-CHEM model using *a posteriori* sources.

Figure 10. Contribution from different sources types to EC concentrations (μg m^{-3}) in surface air for DJF and JJA. Values are model results for 1998 using a posteriori sources (Table 1).

Figure 11. Same as Figure 10 but for OC.

Figure 12. Concentrations of EC and OC at three southeastern U.S. sites (UPBU, MACA, and GRSM) in June-July 1995. Observations (24-h averages, twice a week) are shown as asterisks. The solid line shows results from the standard model simulation. Results from sensitivity simulations without Canadian fire emissions (dashed line) and with fire emissions initially mixed to 600 hPa (dotted line) are also shown.

Tables

Table 1. Carbonaceous aerosol sources in the GEOS-CHEM model (1998).

Aerosol	Source type	Global ($Tg\ yr^{-1}$)[a]	United States ($Tg\ yr^{-1}$) *A priori*	*A posteriori*
EC		22.0	0.66	0.75
	Fossil fuel	6.6	0.52	0.60
	Biofuel	1.4	0.04	0.07
	Biomass burning	14.0	0.10	0.08
OC		129.8	2.70	3.11
	Fossil fuel	10.6	0.45	0.52
	Biofuel	7.6	0.54	0.89
	Biomass burning	97.9	0.72	0.60
	Biogenic	13.7	0.99	1.10

[a] Including *a posteriori* emissions for the United States.

Table 2. Natural and anthropogenic EC and OC concentrations ($\mu g\ m^{-3}$) in the United States[a].

	Natural concentrations		Anthropogenic concentrations	
	West	East	West	East
EC				
1998 emissions (base)	0.09	0.06	0.21	0.62
No U.S. sources	0.04	0.04	0.02	0.02
Asian sources only	0.003	0.001	0.005	0.003
Climatological fire emissions	0.06	0.04	0.21	0.62
OMC[b]				
1998 emissions (base)	1.52	1.33	0.52	1.90
No U.S. sources	0.43	0.49	0.05	0.05
Asian sources only	0.022	0.013	0.013	0.007
Climatological fire emissions	1.25	1.17	0.52	1.90

[a]Values are annual means from the standard 1998 simulation (base) and from the sensitivity simulations described in section 5. Partition between West and East is at 95°W. The natural concentrations from the simulation with climatological fire emissions can be compared to the default estimates suggested by *EPA* [2001] for application of the Regional Haze Rule: 0.47 $\mu g\ m^{-3}$ (West) and 1.40 $\mu g\ m^{-3}$ (East) for OMC, and 0.02 $\mu g\ m^{-3}$ for EC.

[b]Organic carbon mass (OMC), defined as 1.4 times the OC mass to account for non-carbon contributions to the organic aerosol.

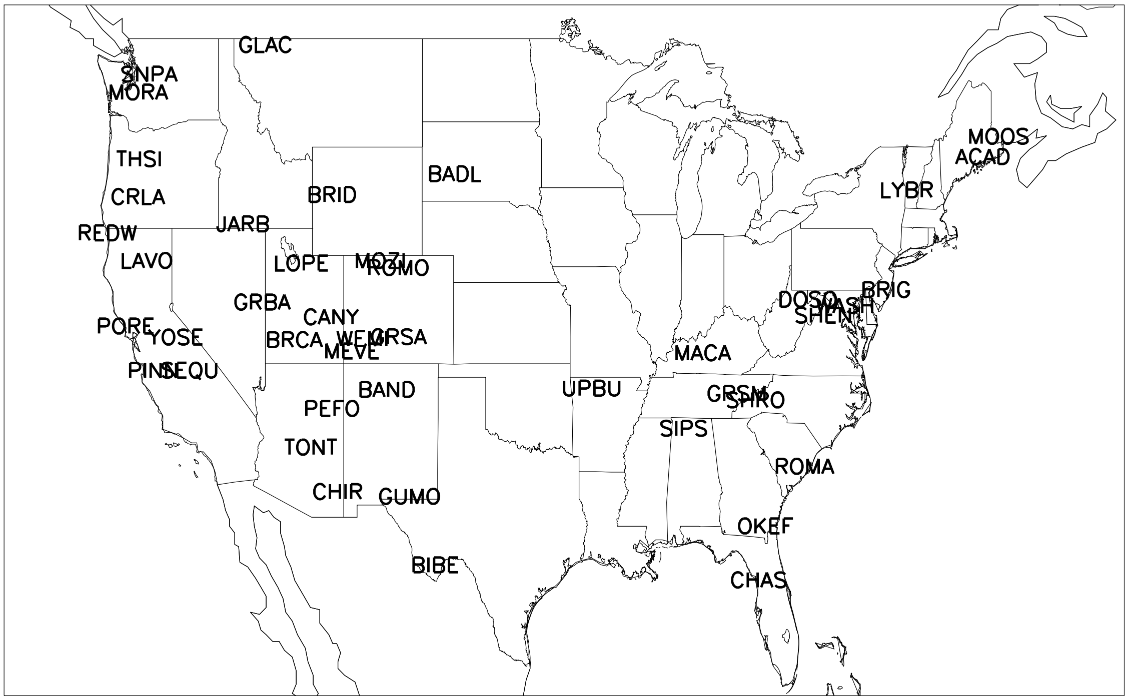

Figure 3. IMPROVE sampling sites with continuous records for 1998.

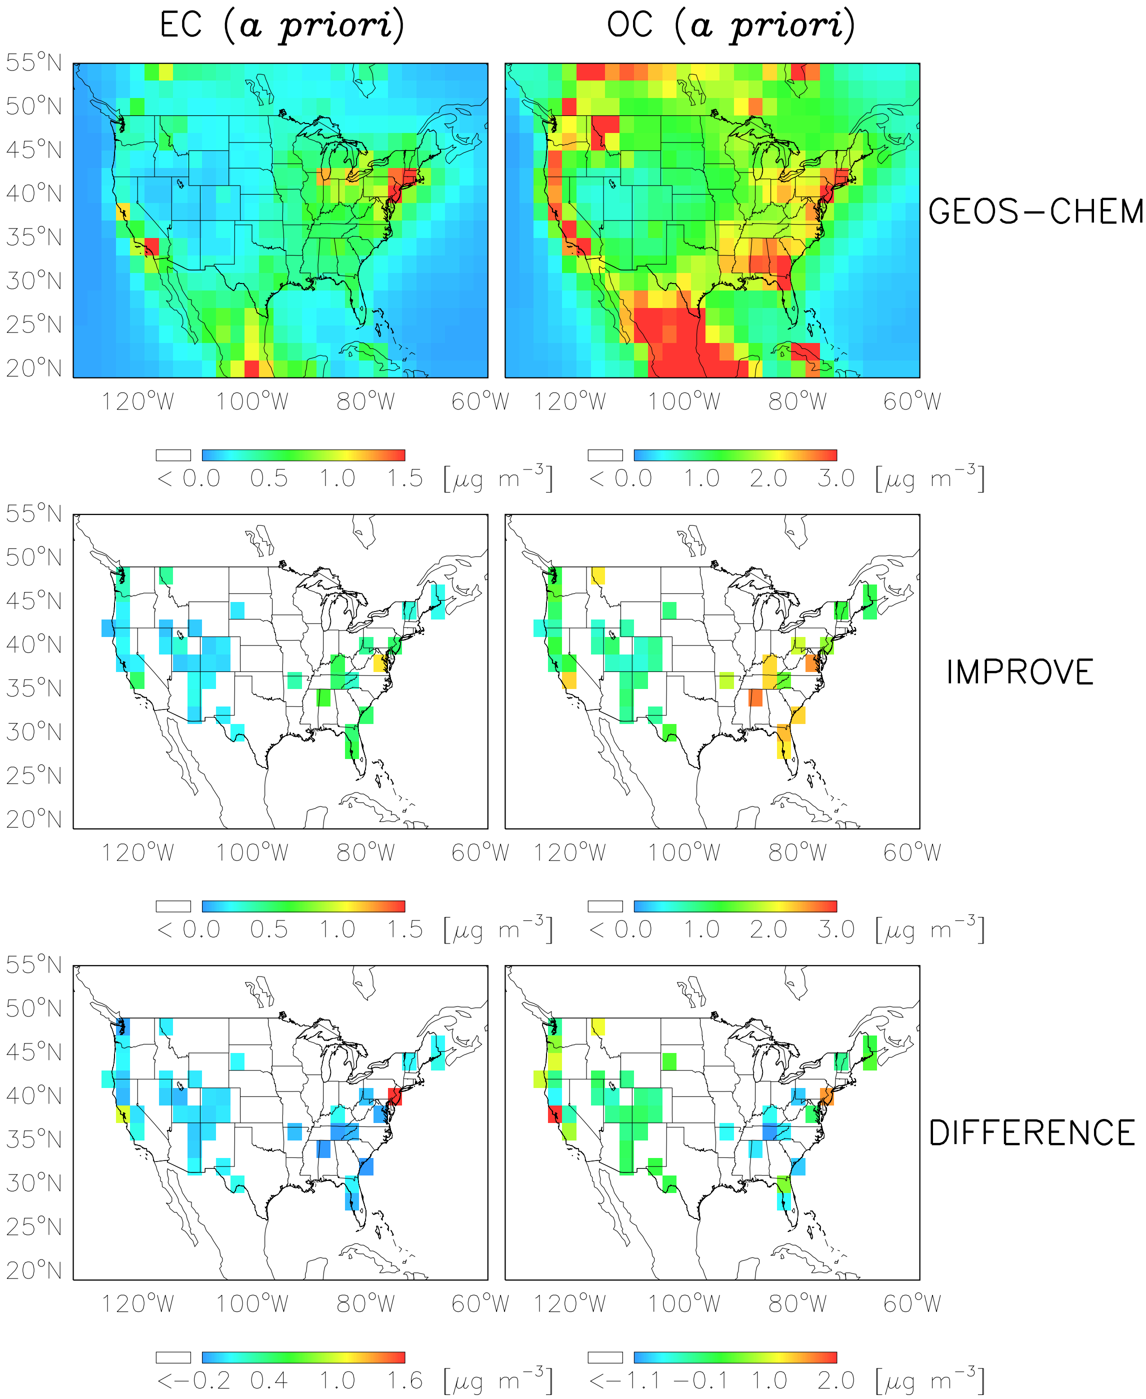

Figure 4. Annual mean concentrations of EC (left) and OC (right) in surface air over the United States in 1998. The top panel shows results from the GEOS-CHEM model using a priori sources. The middle panel shows the IMPROVE observations plotted on the model $2^o \times 2.5^o$ grid. The bottom panel shows the difference between the two.

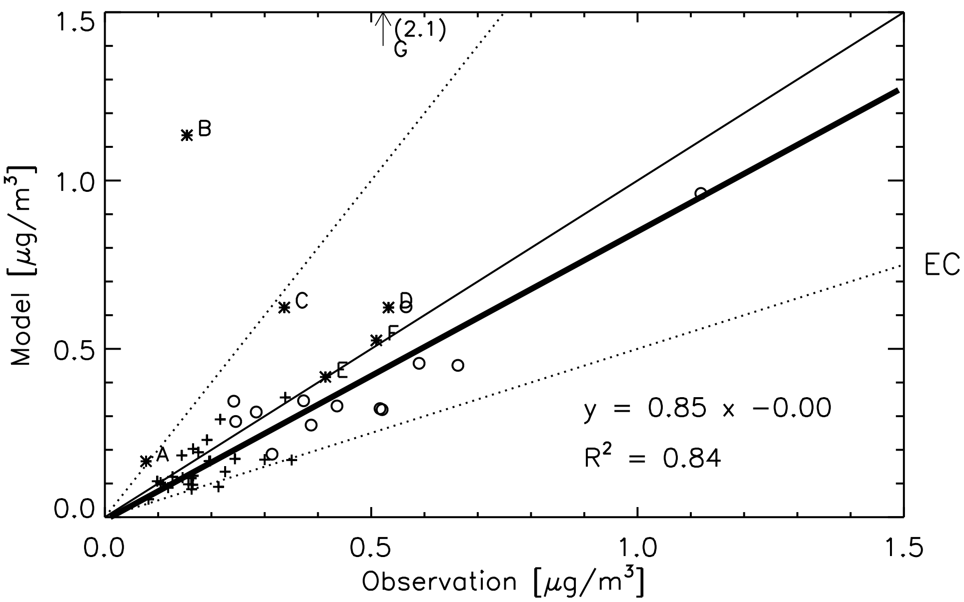

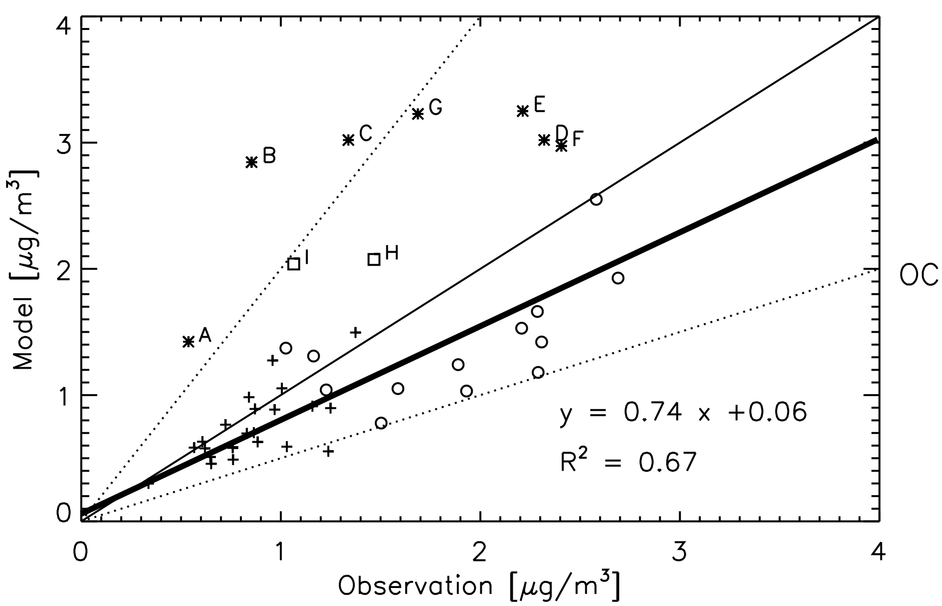

Figure 5. Scatterplot of simulated (GEOS-CHEM) vs. observed (IMPROVE) annual mean EC and OC concentrations for the data shown in Figure 4. The pluses and the circles indicate data in the western and eastern United States (separated at 95^{o}W), respectively. The asterisks with letter labels indicate sites discarded in the statistical analysis (see text): REDW(A), PORE(B), PINN(C), SEQU(D), GLAC(E), OKEF(F), and BRIG(G). The squares indicate OC data at MORA(H) and THSI(I) sites which were discarded in statistical analysis for OC. The thin solid and dotted lines represent the y = x relation and a factor of 2 deviation. The thick solid line represents the reduced major-axis linear regression [*Hirsch and Gilroy*, 1984], excluding sites A-I. The Pearson correlation coefficients R^2 and regression equations are indicated.

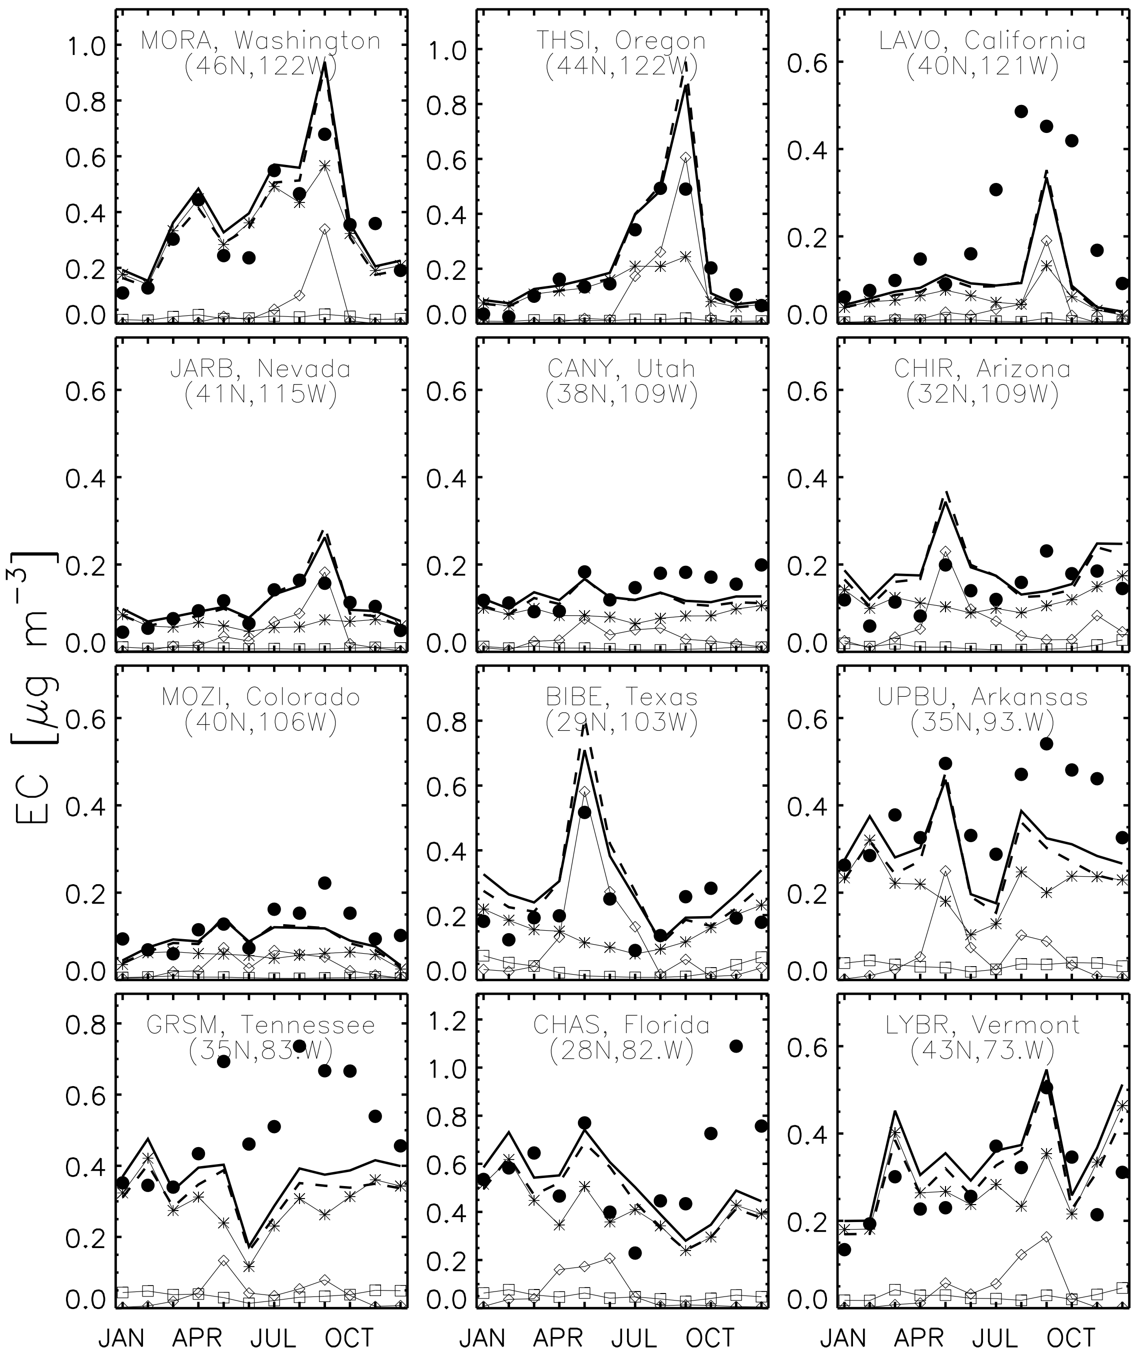

Figure 6. Seasonal variation of monthly mean EC concentrations in 1998 at selected IMPROVE sites. Site locations are shown in Figure 1. Values are monthly means. Closed circles indicate the observations. Dashed and solid lines represent the model simulations with *a priori* and *a posteriori* sources, respectively. The *a priori* model components by source types are indicated as thin solid lines with symbols: asterisks (fossil fuel combustion), diamonds (biomass burning), and squares (biofuel use).

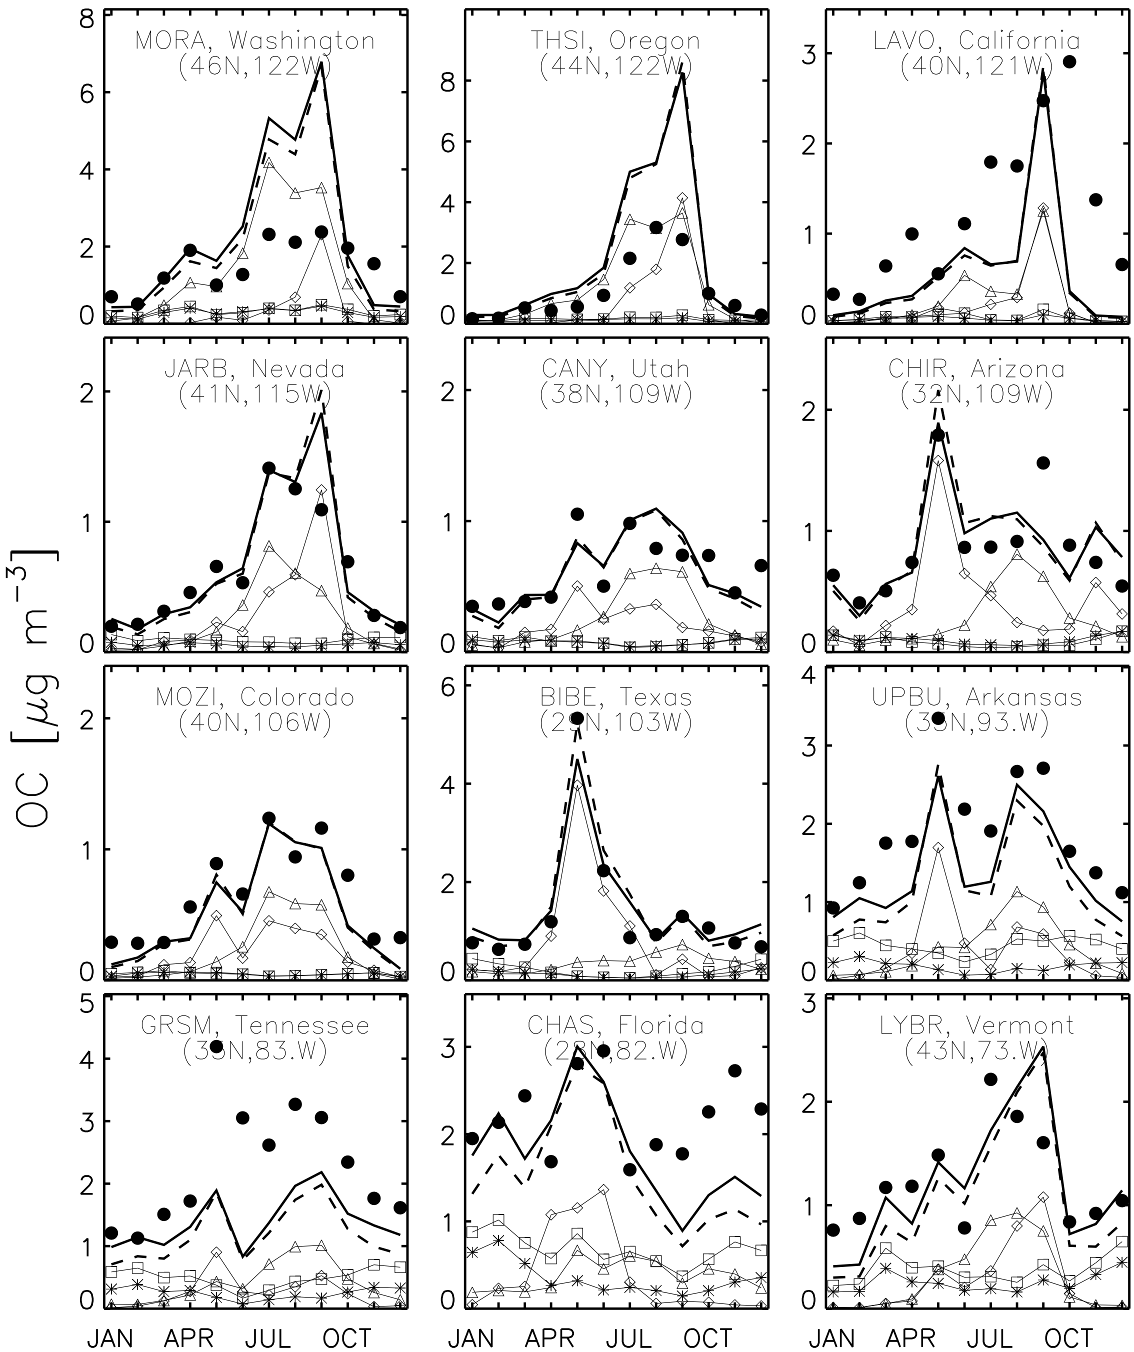

Figure 7. Same as in Figure 6 but for OC. The *a priori* model results by source types are represented as thin solid line with asterisks (fossil fuel), diamonds (biomass burning), squares (biofuel), and triangles (biogenic terpenes).

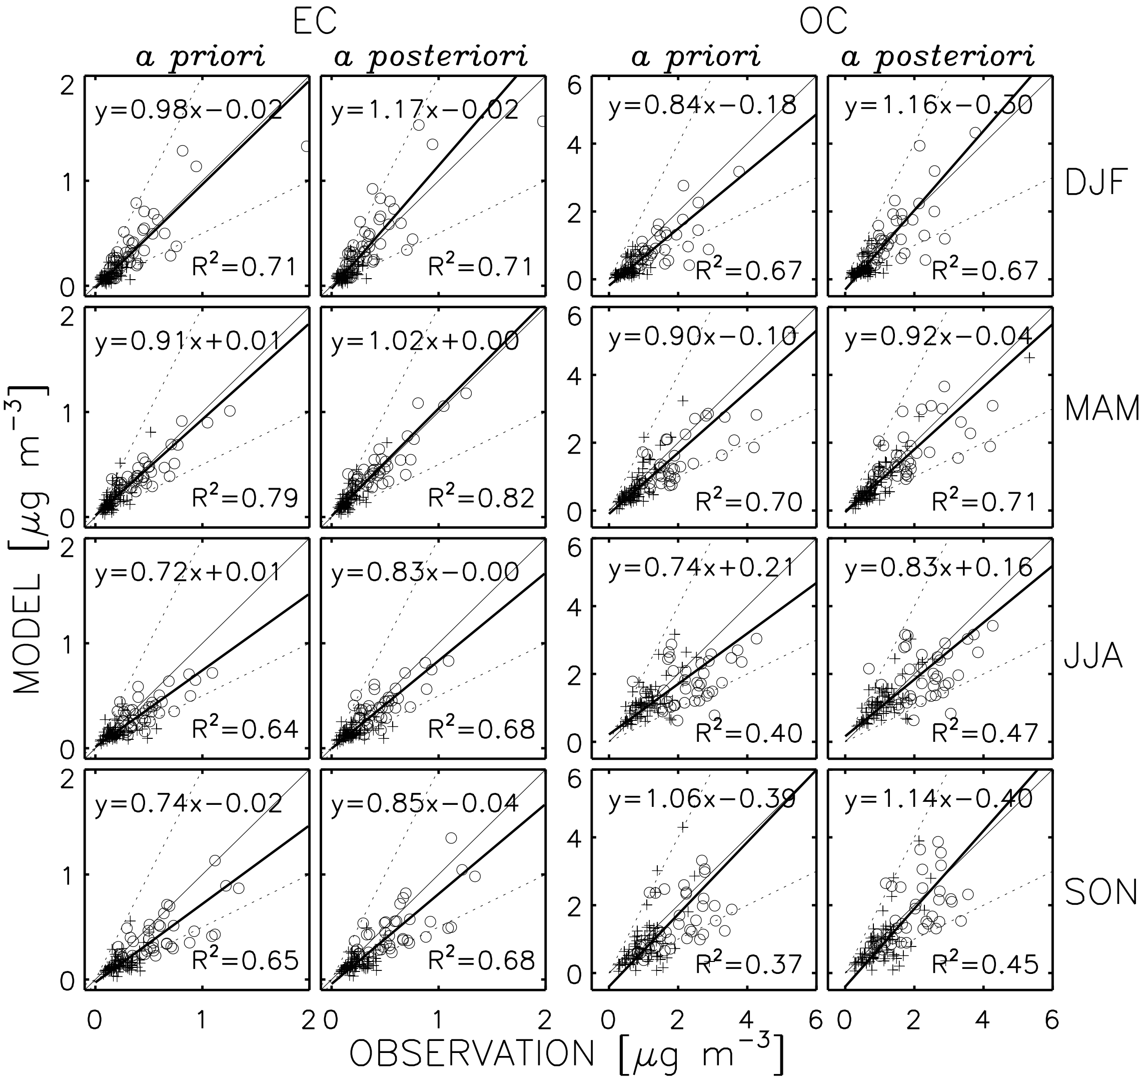

Figure 8. Scatterplots of monthly mean EC (left two columns) and OC (right two columns) simulated vs. observed concentrations with *a priori* (left) and *a posteriori* (right) sources, for the ensemble of IMPROVE sites and for individual seasons in 1998. Sites in the western and eastern United States (separated at 95°W) are shown as pluses and open circles, respectively. Thin solid lines indicate a perfect match of the model results with observations, and dotted lines denote a factor of 2 departure. Thick solid lines represent the reduced major axis regression. The Pearson correlation coefficients R^2 are indicated.

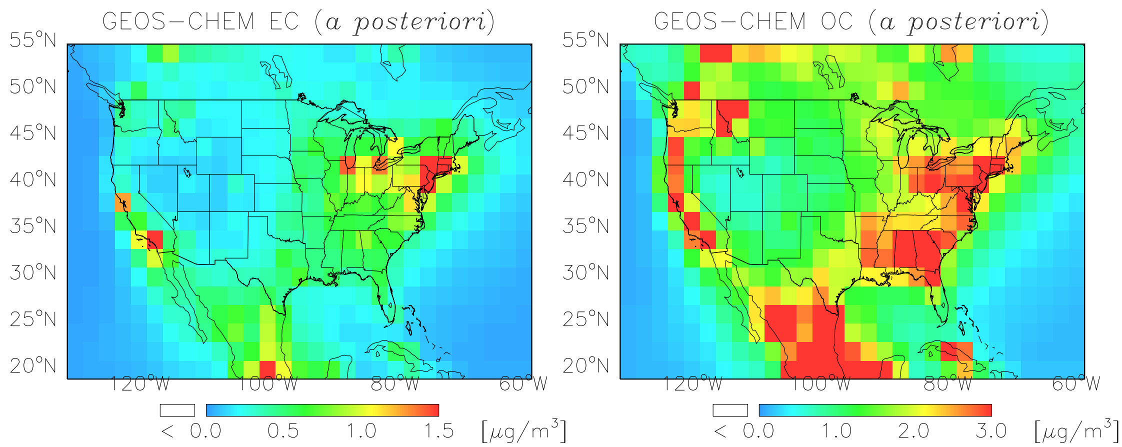

Figure 9. Annual mean concentrations (μg m^{-3}) of EC (left) and OC (right) in surface air over the United States in 1998 from the GEOS-CHEM model using *a posteriori* sources.

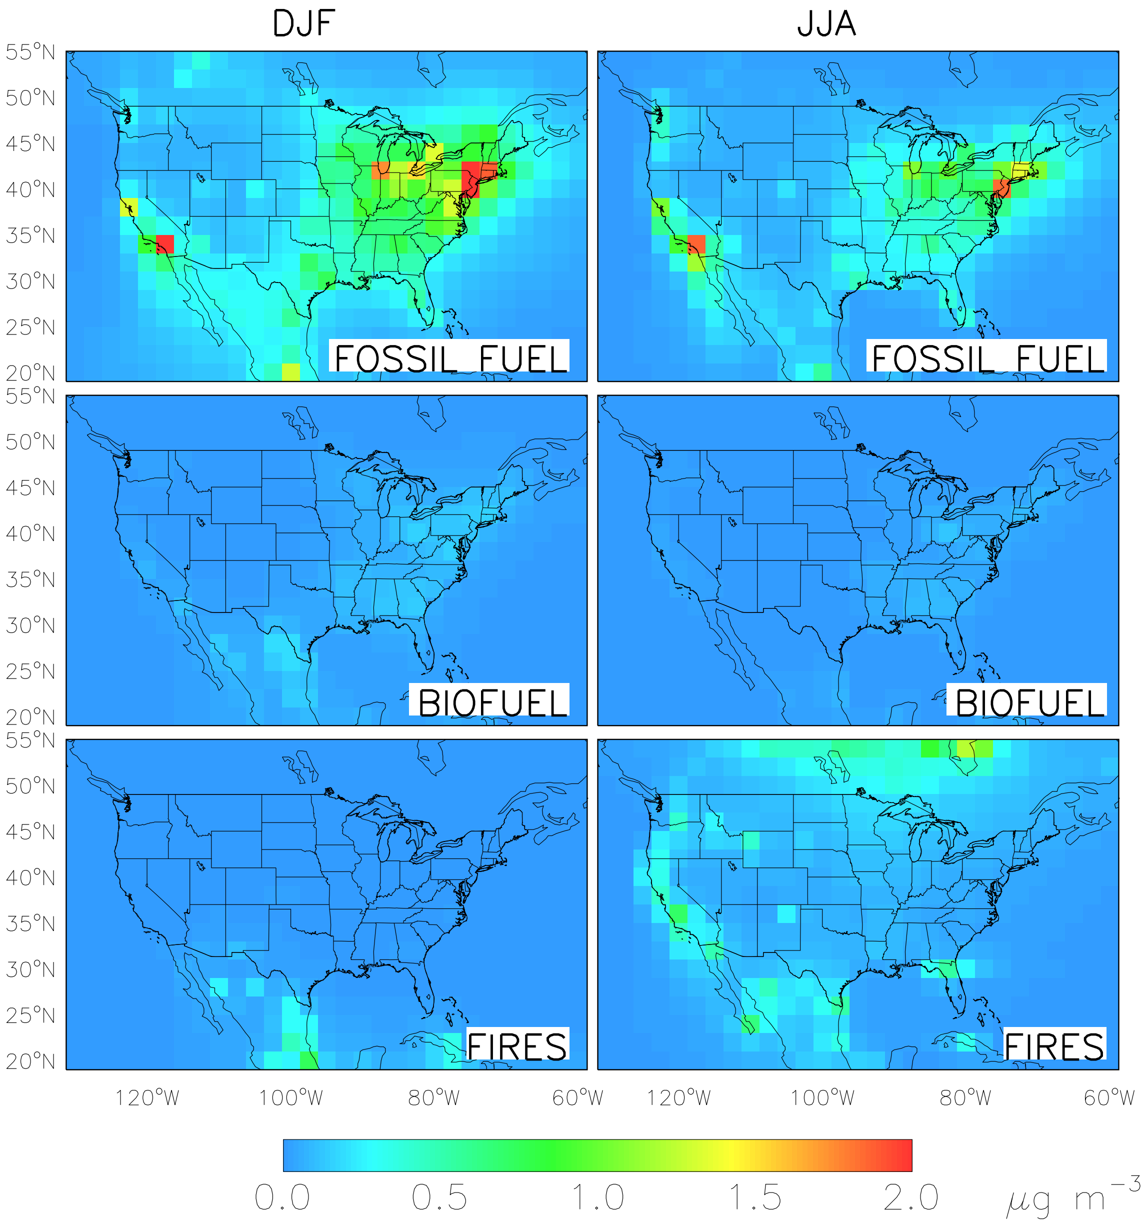

Figure 10. Contribution from different sources types to EC concentrations (μg m^{-3}) in surface air for DJF and JJA. Values are model results for 1998 using a posteriori sources (Table 1).

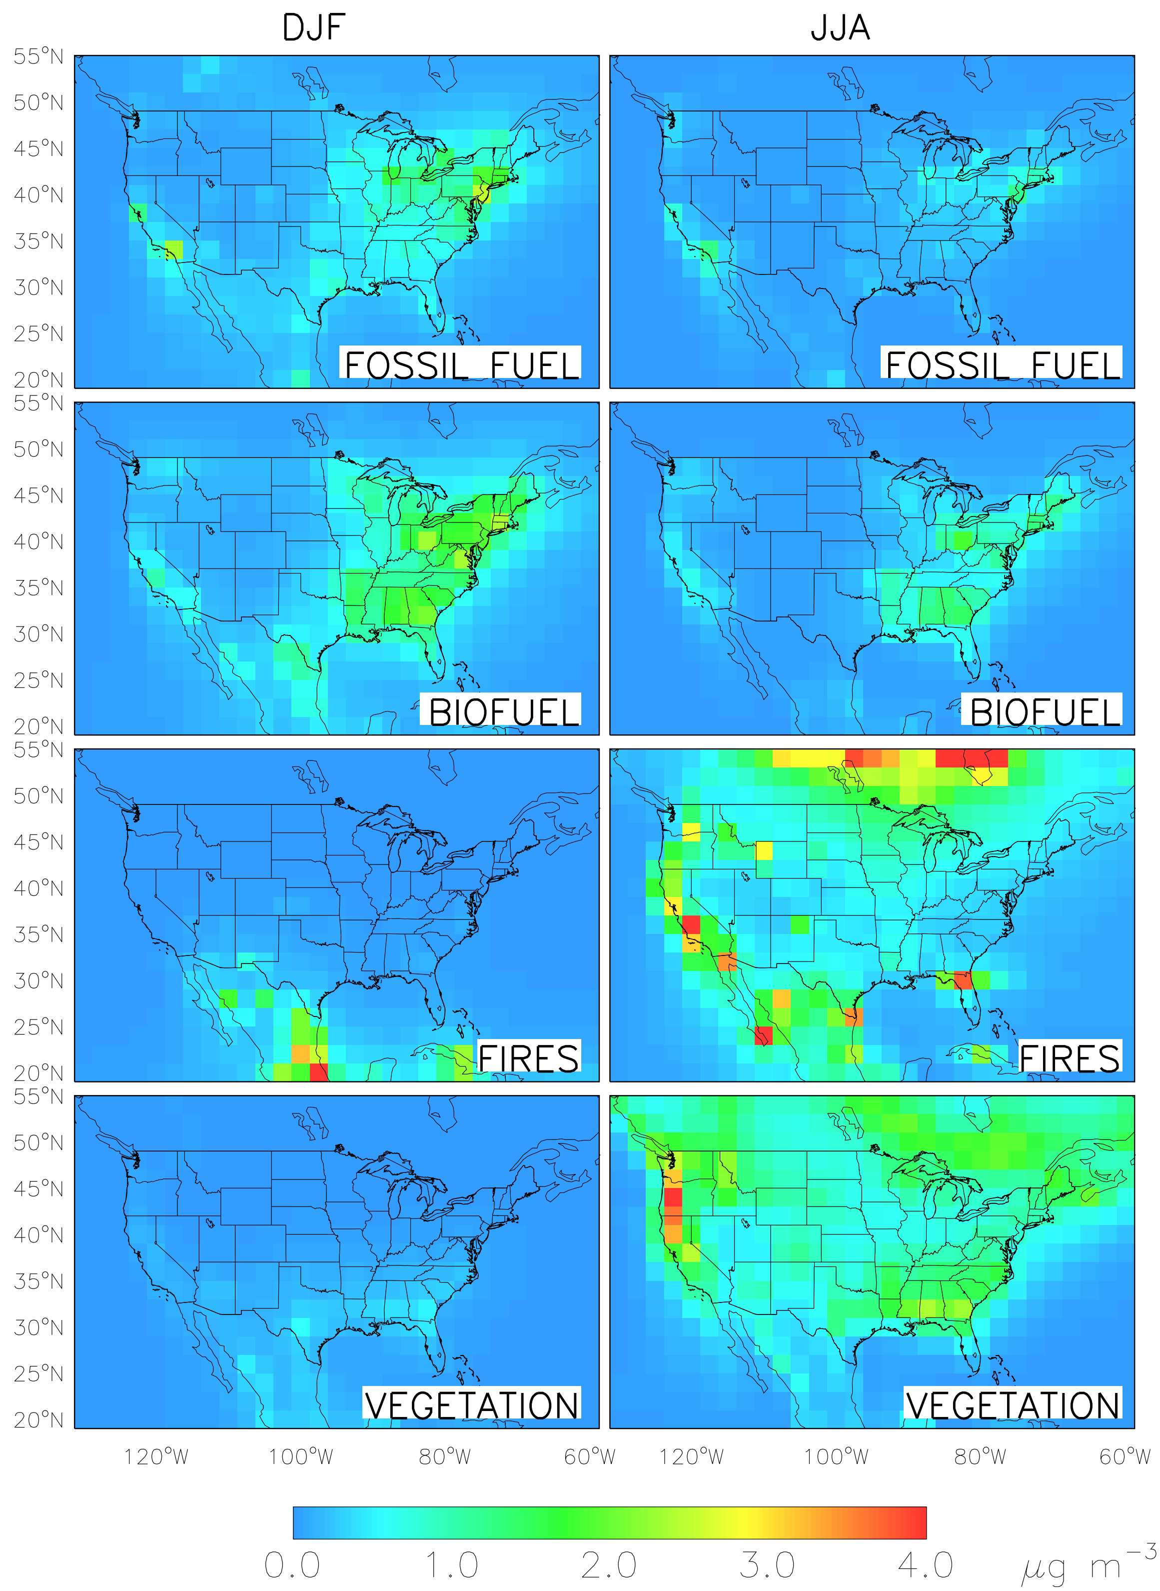

Figure 11. Same as Figure 10 but for OC.

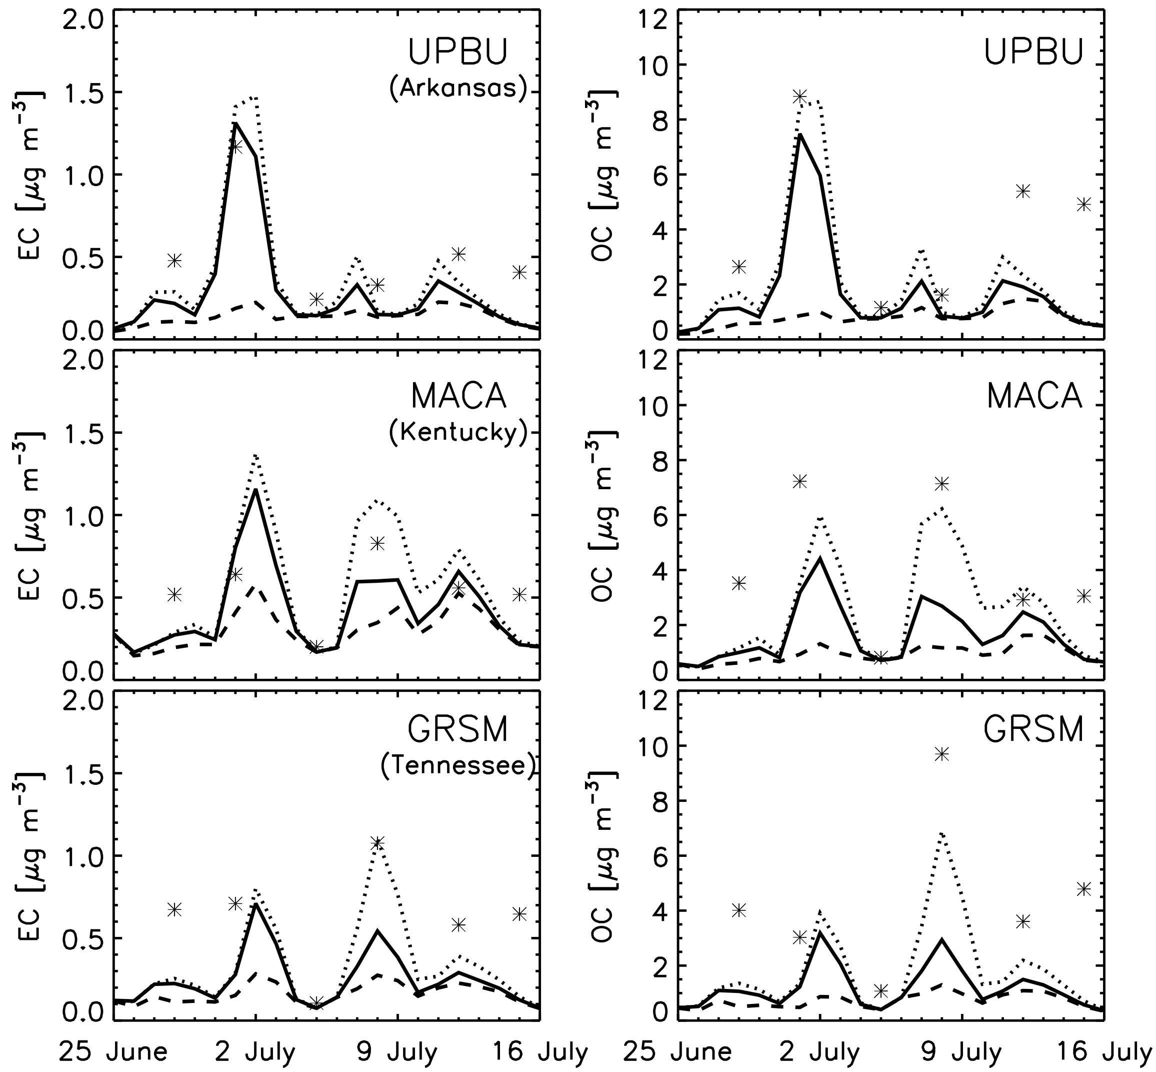

Figure 12. Concentrations of EC and OC at three southeastern U.S. sites (UPBU, MACA, and GRSM) in June-July 1995. Observations (24-h averages, twice a week) are shown as asterisks. The solid line shows results from the standard model simulation. Results from sensitivity simulations without Canadian fire emissions (dashed line) and with fire emissions initially mixed to 600 hPa (dotted line) are also shown.

Appendix B: Rokjin J. Park, Daniel J. Jacob, Brendan D. Field, Robert M. Yantosca, and Mian Chin (2004), Natural and transboundary pollution influences on sulfate-nitrate-ammonium aerosols in the United States: implications for policy, *J. Geophys. Res.*, 109, D15204, doi:10.1029/2003JD004473.

Abstract.

We use a global 3-D coupled oxidant-aerosol model (GEOS-CHEM) to estimate natural and transboundary pollution influences on sulfate-nitrate-ammonium aerosol concentrations in the United States. This work is motivated in part by the Regional Haze Rule of the U.S. Environmental Protection Agency (EPA), which requires immediate action to improve visibility in U.S. wilderness areas along a linear trajectory towards an endpoint of "natural visibility conditions" by 2064. We present full-year simulations for 1998 and 2001 and evaluate them with nationwide networks of observations in the United States and Europe (IMPROVE, CASTNET, NADP, EMEP) and with Asian outflow observations from the NASA TRACE-P aircraft mission. Shutting off U.S. anthropogenic emissions in the model defines "background" aerosol concentrations representing contributions from both natural and transboundary pollution sources. We find that transboundary transport of pollution from Canada, Mexico, and Asia dominates over natural influences for both sulfate and nitrate. Transpacific transport of Asian pollution accounts for 30% of background sulfate in both the western and eastern United States. Our best estimates of natural concentrations for ammonium sulfate and ammonium nitrate in the United States are either consistent with or lower than the default values recommended by EPA for natural visibility calculations. However, the large transboundary pollution influence in our calculation suggests that a natural visibility objective cannot be approached without international emission controls.

1. **Introduction**

Visibility degradation in the United States is mostly due to fine aerosols [*Malm et al.,* 2000] including carbonaceous (elemental and organic), sulfate, nitrate, and soil dust components. These aerosols originate from both anthropogenic and natural sources. The U.S. Environmental Protection Agency Regional Haze Rule [*U.S. EPA*, 2003a] mandates a schedule of increasing emission controls to achieve "natural visibility conditions" in national parks and other wilderness areas of the United States by 2064. Defining this natural visibility endpoint requires better information on natural aerosol concentrations and on the perturbing effects from transboundary transport of anthropogenic pollution. We previously examined this issue in a global 3-D model simulation of carbonaceous aerosols [*Park et al.*, 2003] and found that quantification of wildfire emissions was of critical importance. Transboundary transport of anthropogenic pollution was relatively unimportant for carbonaceous aerosols because of the large natural sources from wildfires and vegetation. We apply here the same analysis to sulfate and nitrate aerosols, which are other important components of visibility degradation and hence prime targets for regulation. As we will see, transboundary transport of pollution including intercontinental transport from Asia emerges in this case as a critical concern.

The main sources of sulfate and nitrate aerosols are atmospheric oxidation of SO_2 and nitrogen oxides ($NO_x \equiv NO + NO_2$) to H_2SO_4 and HNO_3, respectively [*NARSTO*, 2003]. Fossil fuel combustion is the dominant source of SO_2 and NO_x in the United States. Important natural sources include volcanoes and atmospheric oxidation of oceanic dimethylsulfide (DMS) for SO_2; and lightning, soils, and wildfires for NO_x [*NARSTO*, 2003]. The low vapor pressure of H_2SO_4 over H_2SO_4-H_2O solutions implies that all of sulfate is in the aerosol phase. The sulfate aerosols can be partly or totally neutralized by ammonia (NH_3) emitted from livestock, fertilizer use, and other less important sources. If excess ammonia is available beyond that required for sulfate neutralization to ammonium sulfate $(NH_4)_2SO_4$, then ammonium nitrate (NH_4NO_3) aerosol can form; otherwise, and except for cloudy conditions, nitric acid remains in the gas phase. This simple H_2SO_4-HNO_3-NH_3 thermodynamic framework provides a remarkably successful general description of sulfate and nitrate aerosols in the United States [*Seinfeld and Pandis*, 1998; *NARSTO*, 2003]. Sulfate and nitrate can also be incorporated in soil dust or sea salt particles, but these contributions appear to be significant only in desert and coastal areas.

Transboundary transport of pollution could compromise the objective of "natural visibility" in the Regional Haze Rule. We define here an aerosol "background" following *U.S. EPA* [2003b] as the aerosol concentration that would be present over the United States in the absence of domestic anthropogenic emissions. It includes contributions from natural sources but also from transboundary transport of pollution. If the latter are significant, then a "natural visibility" objective can be approached only through international emission controls. Alternatively, one should replace this objective by a "background visibility" objective that allows for uncontrollable emissions outside U.S. borders.

Intercontinental transport of Asian pollution is of particular interest for our study. Previous studies have shown that Asian pollution makes a significant (2-6 ppbv) contribution to background ozone concentrations in surface air in the United States [*Berntsen et al.*, 1999; *Jacob et al.*, 1999; *Fiore et al.*, 2002], principally by enhancing the northern hemispheric ozone background [*Fiore et al.*, 2003b]. Export and transpacific transport of Asian aerosol pollution is expected to be far less efficient than for ozone because the lifting of Asian air to the free troposphere involves wet processes (convection, warm conveyor belts) [*Liu et al.*, 2003] that scavenge aerosols with high efficiency [*Koike et al.*, 2003]. Most previous studies of transpacific transport of aerosols have focused on dust events, where the Asian source is very large and the lifting to the free troposphere takes place by dry processes [*Husar et al.*, 2001; *McKendry et al.*, 2001; *Vaughan et al.*, 2001]. However, *Jaffe et al.* [1999, 2003] and *Bertschi et al.* [2003] also showed significant aerosol enhancements in Asian pollution plumes sampled over the west coast of the United States in spring. As we will see, our model results suggest that transpacific Asian pollution is a major contributor to the sulfate background over the United States on an annual average basis.

2. Model description

2.1 General description

We use the GEOS-CHEM chemical transport model (CTM) [*Bey et al.*, 2001a] to conduct full-year simulations for 1998 and 2001 of the sulfate-nitrate-ammonium inorganic aerosol system coupled to oxidant chemistry. Most of our analysis focuses on the 2001 simulation. The 1998 simulation is used for evaluation with European observations, as 2001 observations were not available in a timely manner. The GEOS-

CHEM model (version 5.03, http://www-as.harvard.edu/chemistry/trop/geos) uses assimilated meteorological data from the NASA Goddard Earth Observing System (GEOS) including winds, convective mass fluxes, mixed layer depths, temperature, clouds, precipitation, and surface properties. Meteorological data for 1998 and 2001 are available with 6-hour temporal resolution (3-hour for surface variables and mixing depths), 1^o latitude by 1^o longitude ($1^o \times 1^o$) horizontal resolution, and 48 sigma vertical layers. We degrade the horizontal resolution to $2^o \times 2.5^o$ for computational expediency. The lowest model levels are centered at approximately 10, 50, 100, 200, 400, 600, 900, 1200, and 1700 m above the local surface.

The GEOS-CHEM simulation of tropospheric oxidant chemistry includes a detailed ozone-NO_x-hydrocarbon chemical mechanism (~80 species, ~300 reactions). Results from this simulation have been reported in a number of papers [*Bey et al.,* 2001ab; *Li et al.,* 2001, 2002ab; *Liu et al.*, 2002; *Martin et al.,* 2002] including focused studies of surface ozone in North America and North American outflow [*Fiore et al.,* 2002, 2003ab; *Li et al.*, 2004]. GEOS-CHEM simulations of aerosols have been reported previously for radionuclides [*Liu et al.,* 2001] and carbonaceous species [*Park et al.,* 2003]. The H_2SO_4-HNO_3-NH_3 aerosol simulation is a new capability for GEOS-CHEM and is described in more detail below. The aerosol and oxidant simulations are coupled through formation of sulfate and nitrate, HNO_3(g)/NO_3^- partitioning of total inorganic nitrate, heterogeneous chemistry [*Jacob*, 2000], and aerosol effects on photolysis rates [*Martin et al.,* 2003]. Partitioning of total ammonia and nitric acid between the gas and aerosol phases is calculated using the MARS-A thermodynamic equilibrium model [*Binkowski and Roselle,* 2003].

The wet deposition scheme for aerosols is described by *Liu et al.* [2001]. It includes contributions from scavenging in convective updrafts, rainout and washout from convective anvils and large-scale precipitation, and it allows for return to the atmosphere following evaporation. We extend it here to soluble gases on the basis of their effective Henry's law partitioning in warm clouds, retention efficiency upon droplet freezing in mixed clouds, and surface coating or co-condensation of ice crystals in cold clouds [*Mari et al.*, 2000]. Scavenging of SO_2 is limited by the local availability of H_2O_2 as a fast aqueous-phase oxidant converting SO_2 to sulfate [*Chin et al.*, 1996, 2000a]. Dry deposition of aerosols and gases uses a standard resistance-in-series model dependent on local surface type and meteorological conditions [*Wesely*, 1989], and implemented as described by *Wang et al.* [1998].

We conducted five different simulations for 2001 including one standard simulation as described above, and four sensitivity simulations excluding anthropogenic emissions (1) globally, (2) in the United States, (3) in North America, and (4) in Asia. From these we quantify the influences of natural, transboundary, and intercontinental pollution sources on sulfate-nitrate-ammonium aerosol concentrations in the United States.

Each simulation was carried out as follows. We first conducted a fully coupled oxidant-aerosol simulation at $4^o \times 5^o$ horizontal resolution for computational expediency. Oxidant concentration fields (OH, O_3, NO_3), H_2O_2 production rates and photolysis frequencies, and total inorganic nitrate concentrations (gas-phase nitric acid plus aerosol nitrate) were archived from this simulation and used to conduct an aerosol-only simulation at finer $2^o \times 2.5^o$ horizontal resolution. The aerosol-only simulation includes 9 prognostic chemical species: dimethylsulfide (DMS), SO_2, sulfate, methane sulfonic acid (MSA), HNO_3(g), NO_3^-, NH_3(g), NH_4^+, and H_2O_2. The 2001 and 1998 simulations were initialized on October 1, 2000 and October 1, 1997, respectively, and conducted for 15 months. The first three months were used to achieve proper initialization, and we focus our attention on the following 12 months.

2.2 Sulfur simulation

The sulfur simulation in GEOS-CHEM is based on the Georgia Tech/Goddard Global Ozone Chemistry Aerosol Radiation and Transport (GOCART) model [*Chin et al.,* 2000a], with a number of modifications described below. Our fossil fuel and industrial emission inventory is for 1999-2000 and is obtained by scaling the gridded, seasonally resolved inventory from the Global Emission Inventory Activity (GEIA) for 1985 [*Benkovitz et al.*, 1996] with updated national emission inventories and fuel use data [*Bey et al.*, 2001a]. The emissions for the United States and Canada are from *U.S. EPA* [2001], and the emissions for European countries are from *EMEP* [2003]. Asian sulfur emission in the model is 20 Tg S yr^{-1}, which can be compared to year 2000 estimates of 17 Tg S yr^{-1} by Streets et al. [2003] and 25 Tg S yr^{-1} by IPCC [2001]. Anthropogenic sulfur is emitted as SO_2 except for a small fraction as sulfate, 5% in Europe and 3% elsewhere [*Chin et al.*, 2000a].

Other anthropogenic sources of SO_2 in the model include gridded monthly aircraft emissions (0.07 Tg S yr^{-1}) taken from *Chin et al.* [2000a] and biofuel use. We use a global biofuel CO emission inventory with $1^o \times 1^o$ spatial resolution from *Yevich and Logan* [2003] and apply an emission factor of 0.0015 moles SO_2 per mole CO [*Andreae and Merlet*, 2001]. Seasonal variations in biofuel emissions are specified from the heating degree-days approach [*Park et al.,* 2003].

Natural sources of sulfur in the model include DMS from oceanic phytoplankton and SO_2 from volcanoes and biomass burning. The oceanic emission of DMS is calculated as the product of local seawater DMS concentration and sea-to-air transfer velocity. The seawater DMS concentrations are gridded monthly averages from *Kettle et al.* [1999], and the transfer velocity of DMS is computed using an empirical formula from *Liss and Merlivat* [1986] as a function of the surface (10m) wind speed. The GEOS surface winds used here assimilate remote sensing data from the Special Sensor Microwave Imager (SSM/I) instrument. Volcanic emissions of SO_2 from continuously active volcanoes are included from the database of *Andres and Kasgnoc* [1998]. Emissions from sporadically erupting volcanoes show large year-to-year variability and are not included in the model. No major volcanic eruptions occurred in 2001. Biomass burning emissions of SO_2 are calculated using a gridded monthly biomass burning inventory of CO constrained from satellite observations in 2001 by *Duncan et al.* [2003] with an emission factor of 0.0026 moles SO_2 per mole CO [*Andreae and Merlet*, 2001].

Table 1a summarizes global and contiguous U.S. (excluding Alaska and Hawaii) sulfur emissions for 2001. The United States contribute 10% of the global source (15% of the global anthropogenic source). Natural sources contribute 27% globally and are negligible within the contiguous United States.

The gas-phase sulfur oxidation chemistry in the model includes DMS oxidation by OH to form SO_2 and MSA, by nitrate radicals (NO_3) to form SO_2, and SO_2 oxidation by OH to form sulfate. Reaction rates are from *DeMore et al.* [1997] and the yields of

SO_2 and MSA from DMS oxidation are from *Chatfield and Crutzen* [1990]. Aqueous-phase oxidation of SO_2 by O_3 and H_2O_2 in clouds to form sulfate is included using kinetic data from *Jacob* [1986] and assuming a pH of 4.5 for the oxidation by O_3. Cloud liquid water content is not available in the GEOS data and we specify it instead in each cloudy grid box by using a temperature-dependent parameterization [*Somerville and Remer*, 1984]. The cloud volume fraction in a given grid box is specified as an empirical function of the relative humidity following *Sundqvist et al.* [1989].

2.3 Ammonia simulation

Ammonia emissions in the model are based on annual data for 1990 from the $1^o \times 1^o$ GEIA inventory of *Bouwman et al.* [1997]. Source categories in that inventory include domesticated animals, fertilizers, human bodies, industry, fossil fuels, oceans, crops, soils, and wild animals. We view the first five as anthropogenic and the last four as natural. Additional emissions from biomass burning and biofuel use are computed using the global inventories of *Duncan et al.* [2003] and *Yevich and Logan* [2003], with an emission factor of 1.3 g NH_3 per kg dry mass burned [*Andreae and Merlet*, 2001]. The resulting total annual source of ammonia for the United States is reduced by 10% to match that derived by *Gilliland et al.* [2003] from an inverse model analysis of monthly precipitation chemistry (NH_4^+) data.

Table 1b shows a summary of global and contiguous U.S. ammonia emissions for 2001. The United States account for 5% of the global source (6% of the global anthropogenic source). Natural sources amount to 37% of global ammonia emissions and 21% of contiguous U.S. emissions.

Several ammonia sources in Table 1b have strong seasonal variations. For the emissions from domesticated animals and soils we use exponential dependences on temperature reported by *Aneja et al.* [2000] and *Roelle and Aneja* [2002], respectively. Ammonia emissions from crops and fertilizers are assumed to vary seasonally with the number of daylight hours [*Adams et al.*, 1999]. Seasonal variations in biomass burning and biofuel emissions are specified from satellite observations [*Duncan et al.*, 2003] and the heating degree-days approach [*Park et al.,* 2003], respectively. Figure 1 shows the resulting seasonal variation of ammonia emission in the United States. The summer maximum is driven mainly by domesticated animals. Compared to the results of the *Gilliland et al.* [2003] inverse model analysis, also shown in Figure 1, our seasonal cycle lags in phase by 1-2 months and emission in October is a factor of 2 higher.

2.4 Nitrate simulation

Production of total inorganic nitrate (gas-phase nitric acid and aerosol nitrate) in the model is computed from the ozone-NO_x-hydrocarbon chemical mechanism (see section 2.1). Table 1c gives a summary of global and contiguous U.S. NO_x emissions; details on these sources are in *Bey et al.* [2001a] and *Martin et al.* [2002]. The United States account for 17% of global emissions (25% of global anthropogenic emissions). Natural sources from lightning, soils, and biomass burning account for 38% of global emissions and 9% in the contiguous United States.

2.5 Global budgets

Tabulated summaries of the global sulfate, nitrate, and ammonium aerosol budgets in GEOS-CHEM are given by *Martin et al.* [2004], who applied the model to an investigation of phase transition effects on aerosol radiative forcing. The global sulfate, nitrate and ammonium burdens for 2001 are 0.40 Tg S, 0.07 Tg N, and 0.32 Tg N, respectively. The lifetimes against deposition are 3.9, 3.2, and 3.8 days, respectively. Wet deposition accounts for 80 - 90% of total deposition.

Our global sulfate burden is lower than those (0.54-1.03 Tg S) from models that participated in the COmparison of large-scale atmospheric Sulfate Aerosol Models (COSAM) [*Barrie et al.,* 2001]. Our anthropogenic emission (57 Tg S yr^{-1}) is lower than that used in COSAM (67 Tg S yr^{-1}) because our emission inventory is for 1999-2000 (vs. 1985 in COSAM) and accounts for emission reductions in Europe (by 61% since 1985) and the United States (by 22% since 1985). The major natural sulfur sources in our model from oceans (15 Tg S yr^{-1}) and volcanoes (5 Tg S yr^{-1}) are also lower than those used in COSAM (29 and 10 Tg S yr^{-1}, respectively). These natural sources contribute disproportionately to the global atmospheric sulfate burden because their sulfur can be delivered efficiently to the free troposphere where precipitation is infrequent [*Chin and Jacob*, 1996]. The lifetime of sulfate in our simulation (3.9 days) is at the low end of the 3.6 – 7.5 days found in COSAM.

Our annual average tropospheric ammonium burden (0.32 Tg N) is consistent with values from previous model studies (0.30 – 0.33 Tg N) [*Dentener and Crutzen*, 1994; *Adams et al.*, 1999] and the lifetime of ammonium is also similar (4.2 – 4.5 days). Our annual average tropospheric nitrate burden (0.07 Tg N) is within the range of 0.03 to 0.09 Tg N found in the previous model study by *Adams et al.* [1999, 2001].

3. **Model evaluation**

We focus our model evaluation on surface networks of sulfate-nitrate-ammonium aerosol observations in the United States and Europe. We also use sulfate wet deposition data in the United States as a test of the sulfur budget, and aircraft observations off the Asian Pacific Rim as a test of Asian export. Previous evaluation with sulfate observations at remote sites has been presented by *Chin et al.* [2000b] using the GOCART model which is similar to ours. Previous evaluations of GEOS-CHEM with aerosol radionuclides globally, and with carbonaceous aerosols in the United States, have been presented by *Liu et al.* [2001] and *Park et al.* [2003], respectively. Other GEOS-CHEM studies have evaluated the simulation of ozone and nitrogen oxides in the United States [*Fiore et al*., 2002, 2003ab; *Li et al.*, 2004] and the transpacific transport of Asian ozone and CO pollution [*Jaeglé et al.*, 2003; *Heald et al.*, 2003].

3.1 United States

We use aerosol observations for the year 2001 at 141 IMPROVE and 79 CASTNET sites, and wet deposition data at 226 NADP sampling sites (Figure 2). The IMPROVE monitoring program was initiated in 1987 in national parks and other protected environments to identify the contributions of different aerosol components to visibility degradation [*Malm et al.*, 1994]. The data for 2001 consist of 24-h sulfate and nitrate concentrations measured every third day by Particle Induced X-ray Emission (PIXE) and ion chromatography (IC), respectively. There are no ammonium data. The CASTNET network of rural sites was initiated in 1990 to monitor regional air pollution

[*Lavery et al.*, 2002]. It provides weekly average concentrations of sulfate, nitrate, and ammonium measured by IC. The NADP network provides weekly chemical precipitation data [*NADP*, 2002]. Sites are predominantly located in rural areas and away from point sources of pollution. Weekly precipitation samples are analyzed for sulfate using IC.

Figure 3 compares simulated and observed annual mean sulfate concentrations at the 141 IMPROVE and 79 CASTNET sites for the year 2001, plotted on the $2^o \times 2.5^o$ model grid. Values are higher in the eastern than the western United States and are highest in the industrial midwest, reflecting the distribution of anthropogenic emissions. Figure 4 shows scatterplots of simulated vs. observed annual and seasonal sulfate concentrations for the ensemble of IMPROVE (left) and CASTNET sites (center). The right column in Figure 4 compares simulated and observed sulfate precipitation data at NADP sites. The correlation between model and observations is high for the annual mean values (R^2 = 0.91-0.94 for the concentration data, 0.75 for the deposition data) and also for the seasonal means (R^2 = 0.79-0.90 for the concentration data, 0.58-0.74 for the deposition data). Western sites in the scatterplots are represented with "+" symbols and should be in general most representative of background conditions. The R^2 coefficients between model and observations for the subset of western sites alone are 0.35-0.39 for the annual mean concentrations at the IMPROVE and CASTNET sites, lower than for the ensemble of U.S. sites, although this could largely reflect the weaker dynamic range. There is no significant bias in the simulation of concentrations at the cleanest western sites.

Regression lines are computed here and elsewhere with the reduced major axis method, which minimizes the area of the right triangle formed by vertical and horizontal lines running from the observed point to the regression line. It is the most appropriate linear regression to characterize a relationship between two data sets with uncertainties [*Hirsch and Gilroy*, 1984]. Results in Figure 4 show no significant model bias in the simulation of annual mean concentrations (slope = 0.91-0.95) but a 30% low bias in summer (slope = 0.71-0.74). Loss of SO_2 in convective updrafts accounts for about 50% of sulfate wet deposition in summer in the model, and much less in other seasons. Our algorithm scavenges SO_2 in convective updrafts as a titration reaction limited solely by the supply of H_2O_2 entrained in the updraft. However, kinetic limitations in the aqueous-phase reaction of SO_2 with H_2O_2, as well as scavenging of H_2O_2, can greatly reduce the SO_2 scavenging efficiency [*Mari et al.,* 2000; *Kreidenweis et al*, 2003]. Accounting for these limitations might correct the model bias but was not attempted here.

Figure 5 compares simulated and observed annual mean concentrations of ammonium at CASTNET sites. Observed concentrations are higher in the east than in the west and are highest in the midwest, reflecting agricultural operations. The model reproduces this spatial distribution but is too high in the midwest. Scatterplots of simulated vs. observed annual and seasonal ammonium concentrations are shown in Figure 6 (left column) for the ensemble of sites. The model reproduces the variability of observed ammonium concentrations, both in an annual mean sense (R^2 = 0.90) and in different seasons (R^2 = 0.82-0.85). It shows a 30% high bias in annual mean concentrations which is mainly driven by the fall (slope = 2.0). Comparison with results from the *Gilliland et al.* [2003] inverse model analysis suggests that our ammonia emissions are excessive in the fall (Figure 1). It appears that a simple exponential temperature dependence of emissions from livestock, as assumed here, does not adequately describe the seasonal variation of this dominant source. For the subset of western sites alone the model has a lower R^2 coefficient (0.53) between the simulated and observed annual mean concentration than that for the ensemble of U.S. sites but no apparent high bias (slope = 1.02).

Figure 7 compares simulated and observed annual mean nitrate concentrations at the 141 IMPROVE and 79 CASTNET sites for 2001. The spatial distribution is similar to that of ammonium concentrations in both the observations and the model, reflecting the limitation of ammonium nitrate formation by the availability of ammonia as discussed further below. The model tends to be too high, by a factor of 2 on an annual basis as shown by the scatterplots of Figure 6. Most of the bias is driven by summer and fall. Nitrate formation is determined by the availability of ammonia beyond that required for sulfate neutralization; we find in a sensitivity analysis that the summer high bias for nitrate can be explained in large part by the low bias of sulfate. High nitrate in fall is likely caused by excessive ammonia emissions. However, the factor of 2 high bias for the simulated annual mean nitrate concentration relative to the observation is not apparent for the subset of western sites alone (slope = 1.09 - 1.34).

Figure 8 shows the simulated Gas Ratio (GR) defined as

$$GR = \frac{[NH_3^T] - 2[SO_4^{2-}]}{[HNO_3^T]}, \quad (1)$$

where concentrations are in molar units, $[NH_3^T]$ is the sum of gas-phase ammonia and aerosol-phase ammonium concentrations, $[HNO_3^T]$ is the total inorganic nitrate concentration (sum of gas-phase nitric acid and aerosol nitrate), and $[SO_4^{2-}]$ is the sulfate concentration. The value of GR diagnoses the limiting reactant (ammonia or nitric acid) for the formation of ammonium nitrate [*Ansari and Pandis*, 1998]. We find that ammonium nitrate formation in most of North America is generally limited by the supply of ammonia (GR < 1). Exceptions are the upper Midwest and Mexico, where GR > 1 indicates that nitrate formation is limited by the supply of nitric acid. Negative GR values, indicating an acidic sulfate aerosol, are mainly confined to the oceans. This neutralization of the aerosol is further illustrated in Figure 9, which compares the simulated (top) vs. observed (bottom) acidity of aerosols at CASTNET sites for different seasons as the regression slopes of the $[NH_4^+]$ vs. $(2[SO_4^{2-}] + [NO_3^-])$ scatterplots. The observations show an annual mean slope of 0.84, i.e., within 16% of neutralization, and varying from 0.79 in summer to 0.93 in winter. The higher acidity in summer reflects the faster sulfate formation. The model is slightly less acidic than the observations on an annual mean basis (slope 0.90) but has the same seasonal trend (0.84 in summer, 0.98 in winter). The weaker apparent model acidity reflects at least in part the association of sulfate and nitrate in the observations with other alkaline cations (e.g., Ca^{2+}) not included in the model.

3.2 Europe

Figure 10 compares model results to annual and seasonal mean observations of sulfate, nitrate, and ammonium at 93 European EMEP sites in 1998. Sulfate in the model reproduces the variability in the observations (R^2 = 0.60 - 0.78) with no systematic bias (the regression slope for the annual mean data is 0.98). There is a slight underestimate in winter (slope = 0.84), possibly caused by seasalt sulfate included in the EMEP observations but not in the model [*Chin et al.*, 2000b; *Gong et al.*, 2002]. Simulated nitrate and ammonium compare less well with observations, with 40-60% overestimates of ammonium in summer and fall, likely due to excessive ammonia emission.

3.3 Asia

We evaluate our simulation of Asian outflow by using sulfate observations from the TRACE-P aircraft mission conducted off the Asian Pacific Rim from bases in Hong Kong and Japan during February-April 2001 [*Jacob et al.*, 2003]. Previous applications of GEOS-CHEM to simulation of TRACE-P observations for ozone, CO, CO_2, CH_4, and nitriles indicate a good simulation of Asian outflow pathways [*Liu et al.*, 2004; *Heald et al.*, 2003; *Palmer et al.*, 2003; *Kiley et al.*, 2003; *Suntharalingam et al.*, 2003; *Xiao et al.*, 2003; *Li et al.*, 2003]. Bulk aerosol measurements from the DC-8 aircraft indicate that 40% of non–seasalt sulfate (nss-SO_4^{2-}) on average was incorporated in dust particles [*Jordan et al.*, 2003]. Figure 11 compares mean vertical profiles of simulated and observed nss-SO_4^{2-} concentrations for the ensemble of DC-8 flights over the NW Pacific west of 177°E and at 30°-45°N latitude [*Liu et al.*, 2003]. Monthly mean concentrations in the model were sampled along the flight tracks. The observations shows strong outflow in the 0-5 km column. The model also shows an enhancement in that column but is lower than observations, by up to a factor of two. Targeted sampling of Asian outflow in the observations [*Jacob et al.*, 2003] could account for part of this discrepancy. In any case, the comparison argues that the model does not overestimate the outflow of sulfate from Asia. This is an important point for our later discussion of transpacific pollution influence.

4. **Background aerosol in the United States: transboundary pollution influence**

We now apply our model simulations to quantify background sulfate-nitrate-ammonium aerosol concentrations in the United States, and to separate the contributions to this background from natural sources and from transboundary pollution. We use for this purpose a sequence of four sensitivity simulations excluding anthropogenic emissions of both oxidant and aerosol precursors (1) globally, (2) in the United States, (3) in North America, and (4) in Asia. The results are summarized in Table 2 as annual averages for the western (west of 95°W) and eastern United States. The EPA Regional Haze Rule document [*EPA*, 2003a] recommends "default average natural concentrations of ammonium sulfate and ammonium nitrate" in these two regions to serve as 2064 endpoints for application of the Rule. For purpose of comparison we present our model results for sulfate and nitrate in Table 2 as those of the corresponding ammonium salts; in the model, almost all of the sulfate and nitrate are indeed associated with ammonium (Figure 9). Model results for the sum of natural and transboundary pollution contributions do not exactly add up to the independently calculated background concentrations because of chemical nonlinearities [*Chin and Jacob*, 1996; *West et al.*, 1999].

Our 2001 base simulation yields annual average concentrations of ammonium sulfate and ammonium nitrate of 1.52 and 1.53 μg m^{-3}, respectively, for the western United States and 4.11 and 3.26 μg m^{-3}, respectively, for the eastern United States. We use the sensitivity simulation with anthropogenic emissions shut off globally to estimate natural concentrations. They are 0.11 μg m^{-3} ammonium sulfate and 0.03 μg m^{-3} ammonium nitrate for both the western and eastern United States. Our estimate of natural concentrations for ammonium sulfate is consistent with the EPA default value (0.12 μg

m^{-3}) in the west but is factor of 2 lower than that (0.23 μg m^{-3}) in the east. Oxidation of DMS is the major natural source of sulfate in the United States in the model. Our estimate of natural ammonium nitrate is three times lower than the EPA default value (0.1 μg m^{-3}); it is not clear how that default value was obtained.

Let us now examine the background concentrations from the sensitivity simulation including anthropogenic emissions only outside of the United States. The mean annual concentrations of background ammonium sulfate and nitrate in surface air over the United States are 0.43 and 0.27 μg m^{-3} for the west and 0.38 and 0.37 μg m^{-3} for the east. These values are several-fold higher than the natural concentrations because of the influence from transboundary pollution. Background sulfate is slightly higher in the west than the east, because of Asian pollution influence as discussed further below, while background nitrate is higher in the east because of Canadian pollution influence.

We thus find that transboundary pollution influence dominates over natural sources in contributing to sulfate and nitrate background concentrations in the United States. Transboundary transport of anthropogenic emissions from Canada and Mexico is most important for nitrate, but for sulfate transpacific transport of Asian pollution is of comparable importance (Table 2). Remarkably, we find that this transpacific pollution source accounts for 30% of the sulfate aerosol background in the United States.

Figure 12a shows the global distribution of Asian pollution influence on sulfate-nitrate-ammonium aerosol concentrations in surface air, as determined by difference between the standard simulation and the sensitivity simulation with anthropogenic Asian emissions shut off. Transpacific transport from Asia to the United States mostly involves lifting of Asian air to the free troposphere by wet processes (convection, warm conveyor belts), followed by rapid advection in the westerlies and subsidence over the United States, generally behind cold fronts. Ammonium aerosol as well as gas-phase ammonia are scavenged in this wet lifting and we see therefore that transpacific transport of ammonium is negligible. In contrast, significant transpacific transport of sulfate can occur as SO_2 partly escapes scavenging during lifting [*Mari et al.*, 2000; *Koike et al.*, 2003; *Tu et al.*, 2003]. Subsidence over the United States takes place mainly in the downwelling regions of the west and east, less in the upwelling region in the center of the country. Ammonium nitrate as we have seen is largely determined by difference between the total ammonium [NH_3^T] and the sulfate concentration, and the preferential export of sulfate relative to ammonium from Asia leads to a slight negative effect of Asian pollution on nitrate concentrations in the United States.

It is of interest to compare the transpacific influence of Asian pollution on North America to the transatlantic influence of North American pollution on Europe. Figure 12b shows the latter as the difference between the standard simulation and the sensitivity simulation with anthropogenic emissions in North America shut off. We find a sulfate enhancement > 0.1 μg m^{-3} in surface air in Western Europe and northern Africa, comparable in magnitude to Asian pollution influence over North America. As in the case of Asian pollution, we find that export of ammonium from North American pollution is far less efficient than for sulfate, resulting in small negative influences on nitrate aerosol concentrations over Europe and Asia.

We show also in Table 2 the natural and background concentrations of elemental carbon (EC) and organic carbon mass (OMC) from our previous work [*Park et al.*, 2003]. In that work we derived optimized estimates of individual EC and OMC sources by fitting model results to observations from the IMPROVE sites. We concluded that the EPA default natural estimates were a factor of 3 too low in the west due to underestimate of wildfire influences. Our values for the east were more consistent with EPA. In contrast to sulfate and nitrate, transboundary transport of anthropogenic carbonaceous aerosols is insignificant relative to the large natural influences from wildfires and vegetation. We further find that transpacific transport of carbonaceous aerosols from Asian pollution is less efficient than for sulfate because of scavenging in the wet lifting processes involved in Asian outflow. The excess of SO_2 over H_2O_2 in the Asian outflow allows part of the sulfur to escape scavenging [*Koike et al.*, 2003; *Tu et al.*, 2003]. This result is consistent with *Jaffe et al.* [2003] who found a larger increase in sulfate concentrations relative to carbonaceous aerosol at three IMPROVE sites in the western United States during a transpacific transport event of Asian pollution.

5. **Policy implications: the Regional Haze Rule**

The U.S. EPA Regional Haze Rule [*U.S. EPA*, 2003a] requires states to develop plans for achieving natural visibility conditions in national parks and other wilderness areas by 2064. Visibility degradation is measured by the deciview index

$$dv = 10 \ln (b_{ext}/10) \, , \qquad (2)$$

where b_{ext} is atmospheric light extinction in units of inverse megameters ($Mm^{-1}=10^{-6}m^{-1}$). In the phase 1 implementation of the Regional Haze Rule, states have to show how they will decrease anthropogenic emissions over the 2004-2018 period in order to achieve a linear trajectory of decreasing deciviews towards the natural visibility endpoint of 2064. A linear decrease in deciviews implies an exponential decrease in aerosol extinction; as a result, and as we will see, the definition of the 2064 endpoint has important implications for determining the level of emission controls required during the 2004-2018 phase 1 implementation.

The EPA Regional Haze Rule document [*U.S. EPA*, 2003a] recommends a simple formula to estimate aerosol extinction by using dry mass concentrations of individual aerosol components (ammonium sulfate, ammonium nitrate, OMC, EC, soil dust, and coarse mass (CM)), as follows:

$$\begin{aligned} b_{ext} &= 3f(RH)[(NH_4)_2SO_4] + 3f(RH)[NH_4NO_3] \\ &+ 4[OMC] + 10[EC] + [soil] + 0.6[CM] + 10 \end{aligned} , \qquad (3)$$

where b_{ext} is in units of Mm^{-1}, aerosol concentrations are in units of $\mu g\ m^{-3}$, and *f(RH)* is a correction factor for hygroscopic growth as a function of relative humidity (RH). The constant of 10 Mm^{-1} describes the scattering by air molecules and is such that an aerosol-free atmosphere would have a deciview index of zero. "Soil" in equation (3) is the fine component of soil dust (diameter < 2.5 μm) and "coarse mass" is the total mass of particles with diameter > 2.5 μm, mostly contributed by dust and sea salt. Recommended values of *f(RH)* for individual wilderness areas are given in the Regional Haze Rule document [*U.S. EPA*, 2003a]. In what follows we use typical *f(RH)* values of 2 and 3 for the west and east, respectively.

Applying equation (3) to aerosol concentrations given in Table 2, and assuming EPA natural default values for fine soil dust (0.5 $\mu g\ m^{-3}$) and coarse mass (3.0 $\mu g\ m^{-3}$), we compute deciview index values for baseline (present-day) conditions and for different definitions of the 2064 natural or background visibility endpoint. We use the results (Table 3) to estimate the implications of our results for phase 1 (2004-2018) implementation of the Regional Haze Rule. Under the EPA Regional Haze Rule, the linear improvement in visibility is to be applied to the 20% most impaired visibility days and at specific locations. Here we use visibility calculated from annual mean aerosol extinctions averaged over the western and eastern United States. Nevertheless, the results serve to illustrate the sensitivity of the required 2004-2018 emission controls to the choice of 2064 endpoint.

Table 3 gives a baseline (current) visibility degradation of 14 and 23 deciviews for the western and the eastern United States, respectively. The natural visibility degradation is 6.3 and 6.2 deciviews, respectively. Organic aerosols are the dominant contributors to natural visibility degradation. Our estimate for natural visibility degradation as expressed in deciviews is 37% higher in the west and 17% lower in the east than the values computed using the natural default aerosol concentrations recommended by EPA (4.6 and 7.5 deciviews). We have previously argued in *Park et al.* [2003] that the EPA natural default concentrations underestimate the influence of wildfires in the west.

Figure 13 shows the trajectories of linear visibility improvement towards a 2064 endpoint of natural visibility defined either from our results (dashed line) or from the EPA defaults (dotted line). Following these trajectories, we find that visibility degradation during the 2004-2018 phase 1 implementation of the Regional Haze Rule should be reduced by 1.8 deciviews (west) and 3.9 deciviews (east) if our estimate of the 2064 natural visibility endpoint is used, and by 2.2 deciviews (west) and 3.6 deciviews (east) if the EPA default endpoint is used. The corresponding reductions in light extinction are 6.7 Mm^{-1} (west) and 32.2 Mm^{-1} (east) if our estimate of the 2064 natural visibility endpoint is used, and 8.1 Mm^{-1} (west) and 30.1 Mm^{-1} (east) if the EPA default endpoint is used.

Let us now estimate the required percentage reductions in U.S. anthropogenic emissions needed to achieve such improvements in light extinction. We assume a linear correspondence between aerosol extinction, aerosol concentrations, and emissions. The current aerosol extinction from U.S. anthropogenic emissions can be calculated from the data in Table 2 by subtracting the background from the baseline aerosol concentrations, and applying equation (3). We obtain values of 18.1 Mm^{-1} in the west and 73 Mm^{-1} in the east. The resulting percentage decreases of U.S. anthropogenic emissions over 2004-2018 are shown in Figure 13. They are 37% and 44% for the western and eastern United States, respectively, using our natural visibility endpoint, and 44% and 41%, respectively, using the EPA natural visibility endpoint.

These differences are significant, but looking beyond the 2018 horizon exposes a more fundamental problem with the Regional Haze Rule. Continued linear decrease towards a 2064 natural visibility endpoint would require total shutdown of U.S. anthropogenic emissions by 2041-2049 (west) or 2053-2058 (east), as shown in Figure 13. Because of transboundary pollution (assumed here to be unchanged in the future), natural visibility cannot be achieved even with total suppression of U.S. anthropogenic emissions. It will be therefore necessary to either impose emission controls on an international level or to amend the 2064 endpoint to allow for uncontrollable transboundary pollution influences. Such an amendment should define the 2064 endpoint as a background rather than natural visibility. One would then have to make estimates of future trends in foreign emissions.

However, amendment of the Regional Haze Rule to target a background visibility endpoint has major implications for phase 1 (2004-2018) emission controls in the west. Using the background deciview values in Table 3 as 2064 endpoint, the required 2004-2018 decrease in visibility degradation is 1.4 deciviews (west) and 3.3 deciviews (east). The corresponding percentage decrease of U.S. anthropogenic emissions in the west is 29%, much lower than 37% if a natural visibility endpoint from our results is used or 44% if the natural visibility endpoint from the EPA defaults is used.

6. **Conclusions**

We used a global 3-D coupled oxidant-aerosol model (GEOS-CHEM) to quantify natural and transboundary pollution influences on sulfate-nitrate-ammonium aerosol concentrations in the United States. The U.S. EPA Regional Haze Rule requires immediate action to improve visibility in U.S. national parks and other wilderness areas along a linear trajectory towards an endpoint of "natural visibility conditions" by 2064. We need to better quantify the natural aerosol concentrations defining this natural visibility, and to determine if transboundary transport of pollution not amenable to domestic emission controls elevates background aerosol concentrations in the United States significantly above the natural values. If they do, then the Regional Haze Rule must either involve international emission controls or be amended to an endpoint of "background" as opposed to "natural" visibility. "Background" is defined here following *EPA* [2003b] as the aerosol concentrations that would be present in the absence of U.S. anthropogenic emissions, but allowing for contributions from transboundary pollution.

We conducted full-year simulations for 1998 and 2001. Results were evaluated with observations from surface networks in the United States and Europe (IMPROVE, CASTNET, NADP, EMEP) and with Asian outflow observations from the NASA TRACE-P aircraft mission over the northwest Pacific. The model reproduces well the spatial pattern and variability of sulfate observations in the United States and Europe across all seasons, with no systematic biases. Comparison with the TRACE-P observations indicates that Asian outflow of sulfate is if anything underestimated. Nitrate and ammonium aerosol concentrations in the model are highly correlated with observations but are too high in summer and fall, a problem that we attribute to seasonal overestimate of ammonia emissions [*Gilliland et al.*, 2003]. We find that the availability of ammonia limits the formation of ammonium nitrate in most of North America. The aerosol is typically 80-100% neutralized, both in the model and in the observations, with maximum acidity in summer.

We used a sequence of sensitivity simulations to quantify background sulfate-nitrate-ammonium aerosol concentrations in the United States, and to separate the contributions to this background from natural sources and from transboundary pollution. Our 2001 base simulation yields annual average concentrations of ammonium sulfate and ammonium nitrate of 1.52 and 1.53 $\mu g\ m^{-3}$, respectively, for the western United States and 4.11 and 3.26 $\mu g\ m^{-3}$, respectively, for the eastern United States. Our best estimates of mean annual natural concentrations are 0.11 $\mu g\ m^{-3}$ ammonium sulfate and 0.03 $\mu g\ m^{-3}$ ammonium nitrate for both the western and eastern United States. Our values are consistent with or lower than the default values recommended by EPA for natural visibility calculations in the context of the Regional Haze Rule.

Our best estimates of background concentrations for ammonium sulfate and ammonium nitrate are 0.43 and 0.27 μg m^{-3} for the west and 0.38 and 0.37 μg m^{-3} for the east. These values are considerably higher than the natural concentrations, pointing to the dominance of transboundary pollution in defining the background. Transpacific transport of Asian pollution is of comparable importance to transport from Canada and Mexico in contributing to the background sulfate enhancement over the United States. A significant enhancement of sulfate relative to other aerosols in the Asian outflow can occur as SO_2 partly escapes scavenging during wet lifting processes. In the case of ammonium nitrate, the transboundary pollution enhancement is mostly from Canada, and transpacific Asian pollution actually causes a slight depression (less than 0.1 μg m^{-3}) due to the added sulfate.

We assessed the implications of our results for implementation of the Regional Haze Rule. For this purpose we used our model to define the linear trend of visibility from present (2004) to natural or background (2064) conditions. We found that transboundary pollution prevents natural visibility from being achieved even with total suppression of U.S. anthropogenic emissions, implying the need for either international emission controls or for amendment of the 2064 endpoint to allow for uncontrollable transboundary pollution influences. The latter would require some estimates of future trends in transboundary pollution influences but these have large uncertainties. Projections by *IPCC* [2001] for 2060 anthropogenic sulfur emissions from Asia range from 30% to 160% of present-day levels depending on the socioeconomic scenario. Consideration of a background rather than natural visibility 2064 endpoint would have immediate implications for phase 1 implementation (2004-2018) of the Regional Haze Rule. It would imply, at least in the west, a significantly slower schedule of U.S. anthropogenic emission reductions.

Our results are only a first attempt to quantify natural and transboundary pollution influences in the United States using a global 3-D model analysis. In future work we plan to examine in more detail the observational constraints on aerosol background concentrations in the United States, including site-by-site analysis and frequency distributions of aerosol concentrations. Specification of natural and background aerosol concentrations for regulatory purposes will require formal uncertainty bounds to be placed on model estimates, and again this will require more extensive evaluation with observations as well as higher-resolution simulations with a nested regional model.

Figures Captions

Figure 1. Monthly ammonia emissions in the contiguous United States. The values used in this work, broken down by source type (left bars), are compared to the values reported by *Gilliland et al.* [2003] (right bars) from inverse modeling of eight months of precipitation NH_4^+ data.

Figure 2. Sampling sites from the I[M]PROVE, [C]ASTNET, and NA[D]P networks in 2001.

Figure 3. Annual mean concentrations of sulfate in surface air over the United States in 2001. The top panel shows results from the GEOS-CHEM model. The middle and bottom panels show the observations from the IMPROVE and CASTNET networks, respectively, averaged over the model $2^o \times 2.5^o$ grid.

Figure 4. Scatterplot of simulated versus observed sulfate concentrations at the IMPROVE and CASTNET sites, and sulfate deposition fluxes at NADP sites (Figure 2). Values are annual means (top panels) and seasonal means for 2001. Sites in the western and eastern United States (separated at 95^oW) are shown as pluses and open circles, respectively. Thick solid lines are reduced major axis regressions for the ensemble of the data; regression equations and R^2 are shown inset. Thin solid lines show the y=x relationship.

Figure 5. Annual mean concentrations of ammonium in surface air over the United States in 2001. The top panel shows results from the GEOS-CHEM model. The bottom panel shows the observations from the CASTNET networks averaged over the model $2^o \times 2.5^o$ grid (ammonium is not measured at the IMPROVE sites).

Figure 6. Scatterplot of simulated versus observed ammonium concentrations at the CASTNET sites (left column), and nitrate concentrations at the CASTNET and IMPROVE sites (right two columns). Values are annual means (top panels) and seasonal means for 2001. Sites in the western and eastern United States (separated at 95^oW) are shown as pluses and open circles, respectively. Thick solid lines are reduced major axis regressions for the ensemble of the data; regression equations and R^2 are shown inset. Thin solid lines show the y=x relationship.

Figure 7. Same as in Figure 3 but for nitrate.

Figure 8. Simulated gas ratio (GR; equation (1)) defined as the available ammonia concentration beyond that required for sulfate neutralization, divided by the total inorganic nitrate concentration (gas + aerosol) [*Ansari and Pandis*, 1998]. Values are computed from annual mean concentrations in surface air. Formation of ammonium nitrate aerosol is limited by the availability of nitric acid if $GR > 1$, by the availability of ammonia if $0 < GR < 1$, and is totally suppressed if $GR < 0$.

Figure 9. Scatterplot of seasonal mean $[NH_4^+]$ vs. $(2[SO_4^{2-}]+[NO_3^-])$ at CASTNET sites in 2001, in the GEOS-CHEM model (top) and in observations (bottom). The reduced-major–axis regression slopes (given on the Figure) indicate the degree of acid neutralization.

Figure 10. Scatterplot of simulated versus observed sulfate (left), nitrate (middle) and ammonium (right) concentrations at 93 European EMEP sites. Values are annual means (top panels) and seasonal means for 1998. Thick solid lines are reduced major axis

regressions for the ensemble of the data; regression equations and R^2 are shown inset. Thin solid lines show the y=x relationship.

Figure 11. Simulated vs. observed mean vertical profiles of non-sea-salt sulfate (nss-SO_4^{2-}) concentrations over the NW Pacific from the TRACE-P aircraft mission in February-April 2001. The observations are binned vertically in 1-km intervals. The solid line shows mean observed values from *Jordan et al.* [2003] for the ensemble of DC-8 flights north of 30^{o}N (30-45^{o}N, 124-177^{o}E), with standard deviations represented by horizontal bars. The dashed line shows the corresponding monthly mean model values along the flight tracks.

Figure 12a. Enhancements of sulfate-nitrate-ammonium aerosol concentrations in surface air due to anthropogenic emissions from Asia. Values are annual means for 2001 and were obtained by difference between the standard model simulation and a sensitivity simulation with Asian anthropogenic sources shut off.

Figure 12b. Same as in Figure 12a but for anthropogenic emissions from North America.

Figure 13. Illustrative example of required visibility improvements (top) and domestic emission reductions (bottom) over the 2004-2064 period for the western and the eastern United States (separated at 95^{o}W) under the EPA Regional Haze Rule [*U.S. EPA*, 2003a]. The visibility endpoints are as given in Table 3. The required percentage decrease in U.S. anthropogenic emissions corresponding to a given visibility improvement is computed by assuming a linear correspondence between aerosol extinction and emissions. Results are shown for different choices for the 2064 endpoint: (1) EPA natural default visibility (dotted lines), (2) our estimate of natural visibility (dashed lines), and (3) our estimate of background visibility (solid lines). Background includes contributions from both natural and transbounary pollution sources. Year 2018 (thin vertical line) is the target date for phase 1 implementation of the Regional Haze Rule.

Biomass burning	6.5	0.05
Natural soil	5.3	0.36
Lightning	4.7	0.25

Table 2. Background aerosol concentrations ($\mu g\ m^{-3}$) in the United States[a].

	Ammonium sulfate		Ammonium nitrate		Elemental carbon		Organic carbon mass	
	West	East	West	East	West	East	West	East
Baseline (2001)	1.52	4.11	1.53	3.26	0.27	0.66	1.77	3.07
Background	0.43	0.38	0.27	0.37	0.08	0.06	1.30	1.22
Natural	0.11	0.11	0.03	0.03	0.06	0.04	1.25	1.17
Transboundary pollution	0.28	0.26	0.18	0.23	0.02	0.02	0.05	0.05
Canada and Mexico	0.15	0.14	0.2	0.25	0.02	0.02	0.04	0.04
Asia	0.13	0.12	-0.02	-0.02	<0.01	<0.01	0.01	<0.01
EPA natural defaults[b]	0.12	0.23	0.1	0.1	0.02	0.02	0.47	1.40

[a]Values are annual and spatial means from the standard 2001 simulation (baseline) and from the sensitivity simulations described in section 2.1. Partitioning between west and east is at 95°W. Background and natural concentrations are obtained from the sensitivity simulations without U.S. and global anthropogenic emissions, respectively. Transboundary pollution influences from Canada and Mexico are determined by difference between two sensitivity simulations with anthropogenic emissions shut off in the United States versus in all of North America. Transpacific pollution influences from Asia are determined by difference between the standard simulation and the sensitivity simulation with anthropogenic sources shut off in Asia. Results for elemental carbon (EC) and organic carbon mass (OMC) are from our previous work [*Park et al.*, 2003] in a simulation using climatological emissions from wildfires.

[b]"Default average natural concentrations" recommended by *U.S. EPA* [2003a] for estimating natural visibility conditions as 2064 endpoint in the application of the EPA Regional Haze Rule.

Table 3. Visibility degradation (deciviews) in the United States[a].

	West	East
Baseline (2001)	14	23
Background[b]	8.1	9.0
Natural		
This work	6.3	6.2
EPA default	4.6	7.5

[a]Visibility degradation in deciviews (equation (2)) calculated from mean annual aerosol extinction as given by equation (3). Aerosol concentrations for use in equation (3) are from Table 2, with in addition EPA default natural values for soil (0.5 $\mu g\ m^{-3}$) and coarse mass (CM) (3.0 $\mu g\ m^{-3}$). Values of *f(RH)* in equation (3) are 2 in the west and 3 in the east.

[b]Including contributions to visibility degradation from both natural and transboundary pollution sources.

Figures

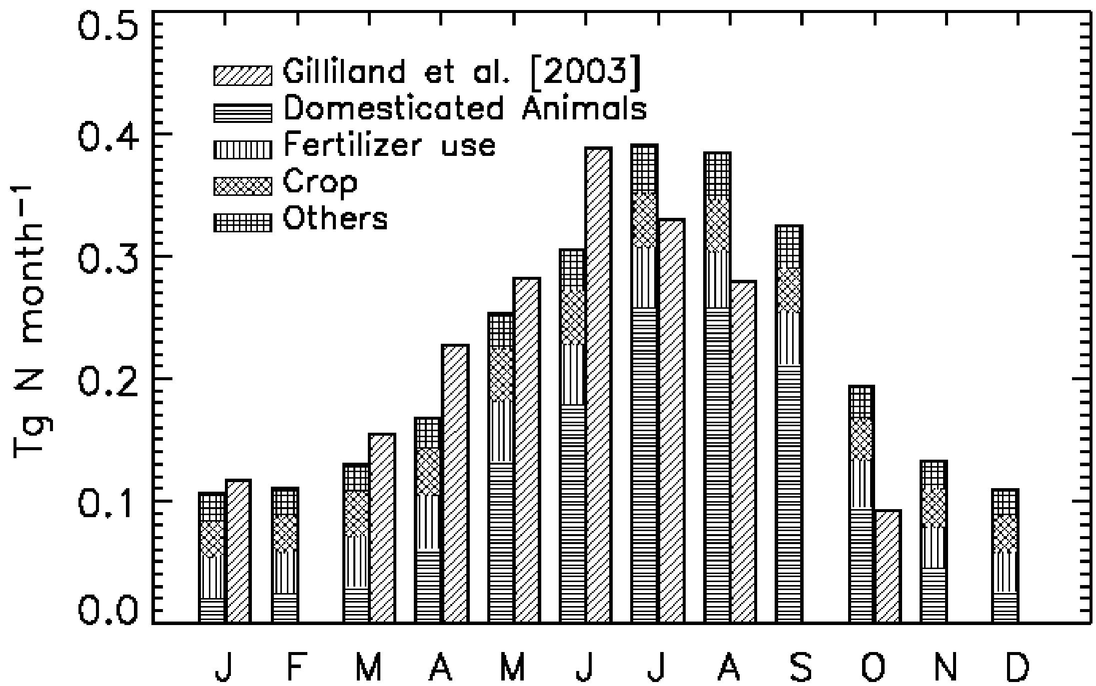

Figure 1. Monthly ammonia emissions in the contiguous United States. The values used in this work, broken down by source type (left bars), are compared to the values reported by *Gilliland et al.* [2003] (right bars) from inverse modeling of eight months of precipitation NH_4^+ data.

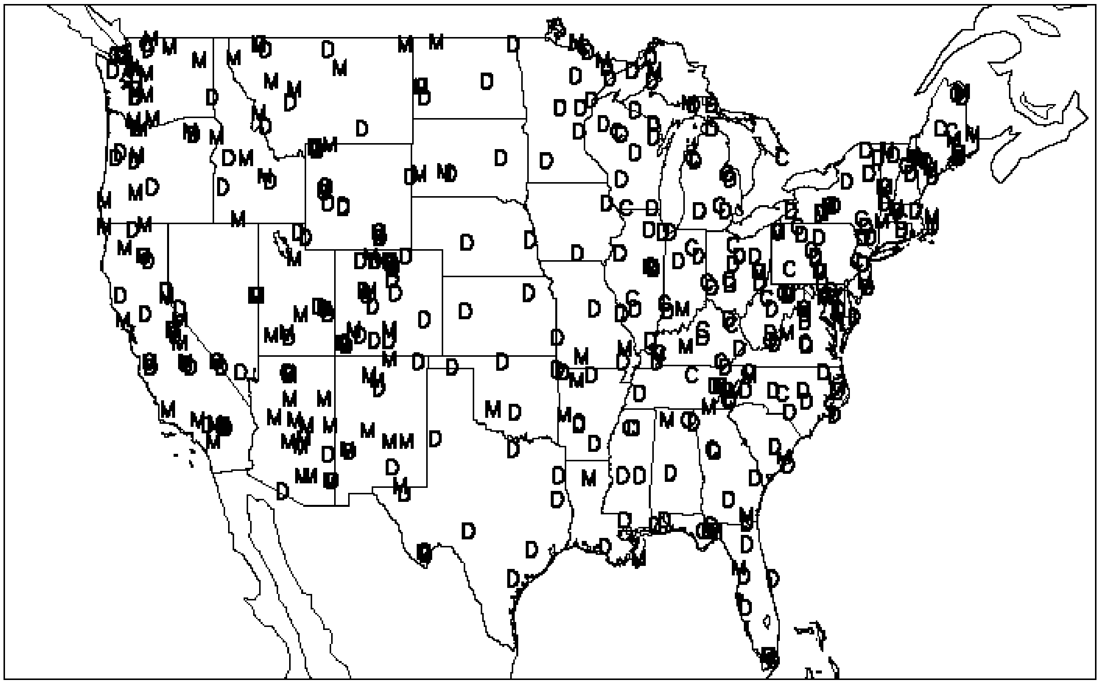

Figure 2. Sampling sites from the I[M]PROVE, [C]ASTNET, and NA[D]P networks in 2001.

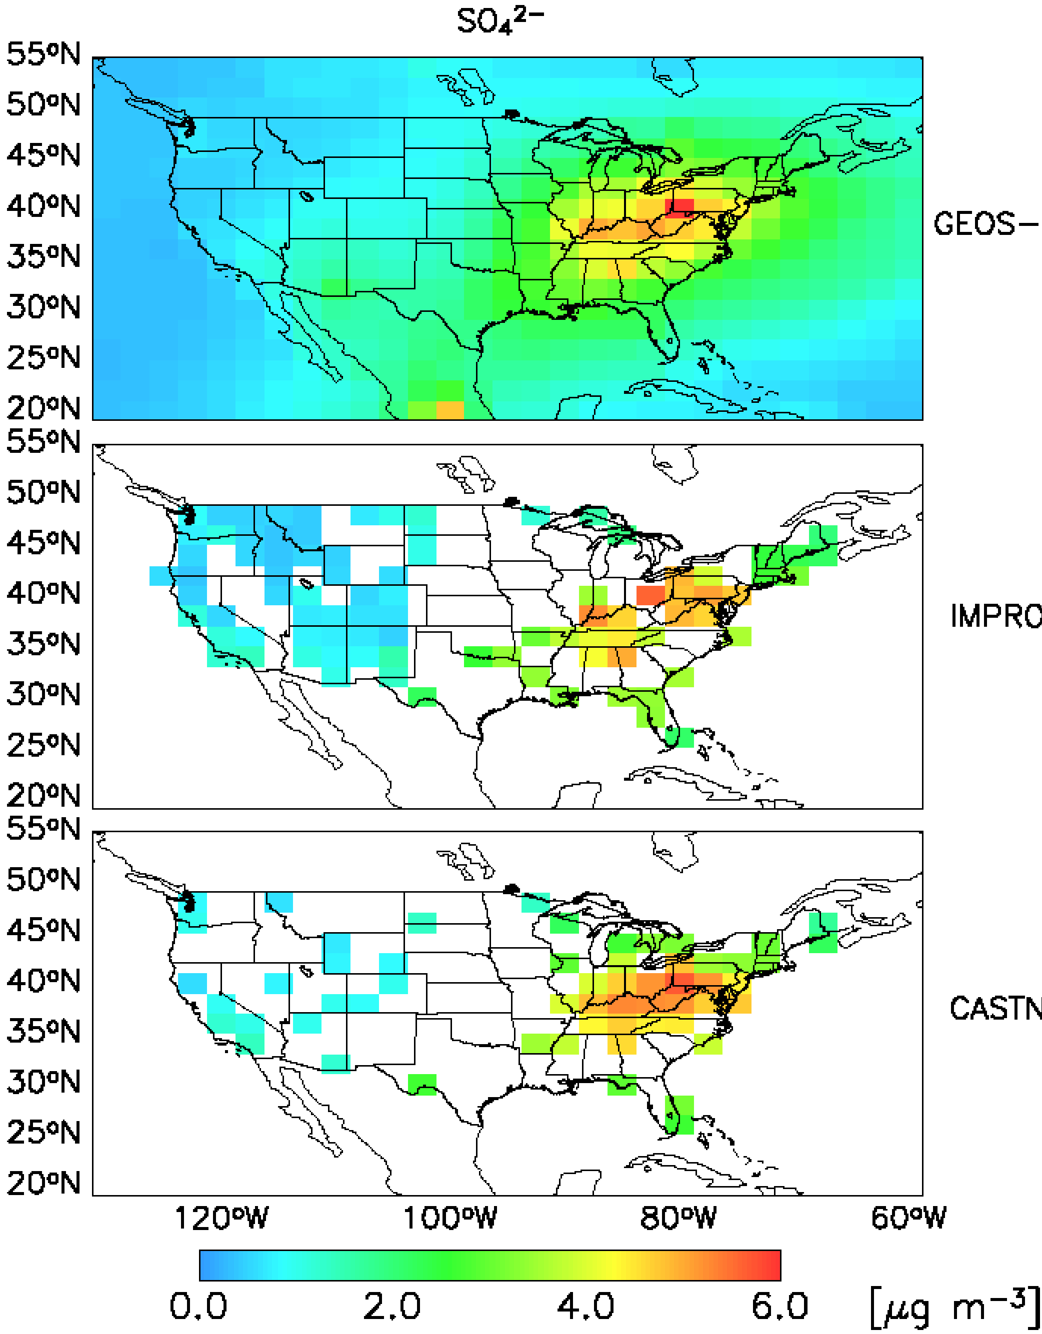

Figure 3. Annual mean concentrations of sulfate in surface air over the United States in 2001. The top panel shows results from the GEOS-CHEM model. The middle and bottom panels show the observations from the IMPROVE and CASTNET networks, respectively, averaged over the model $2^o \times 2.5^o$ grid.

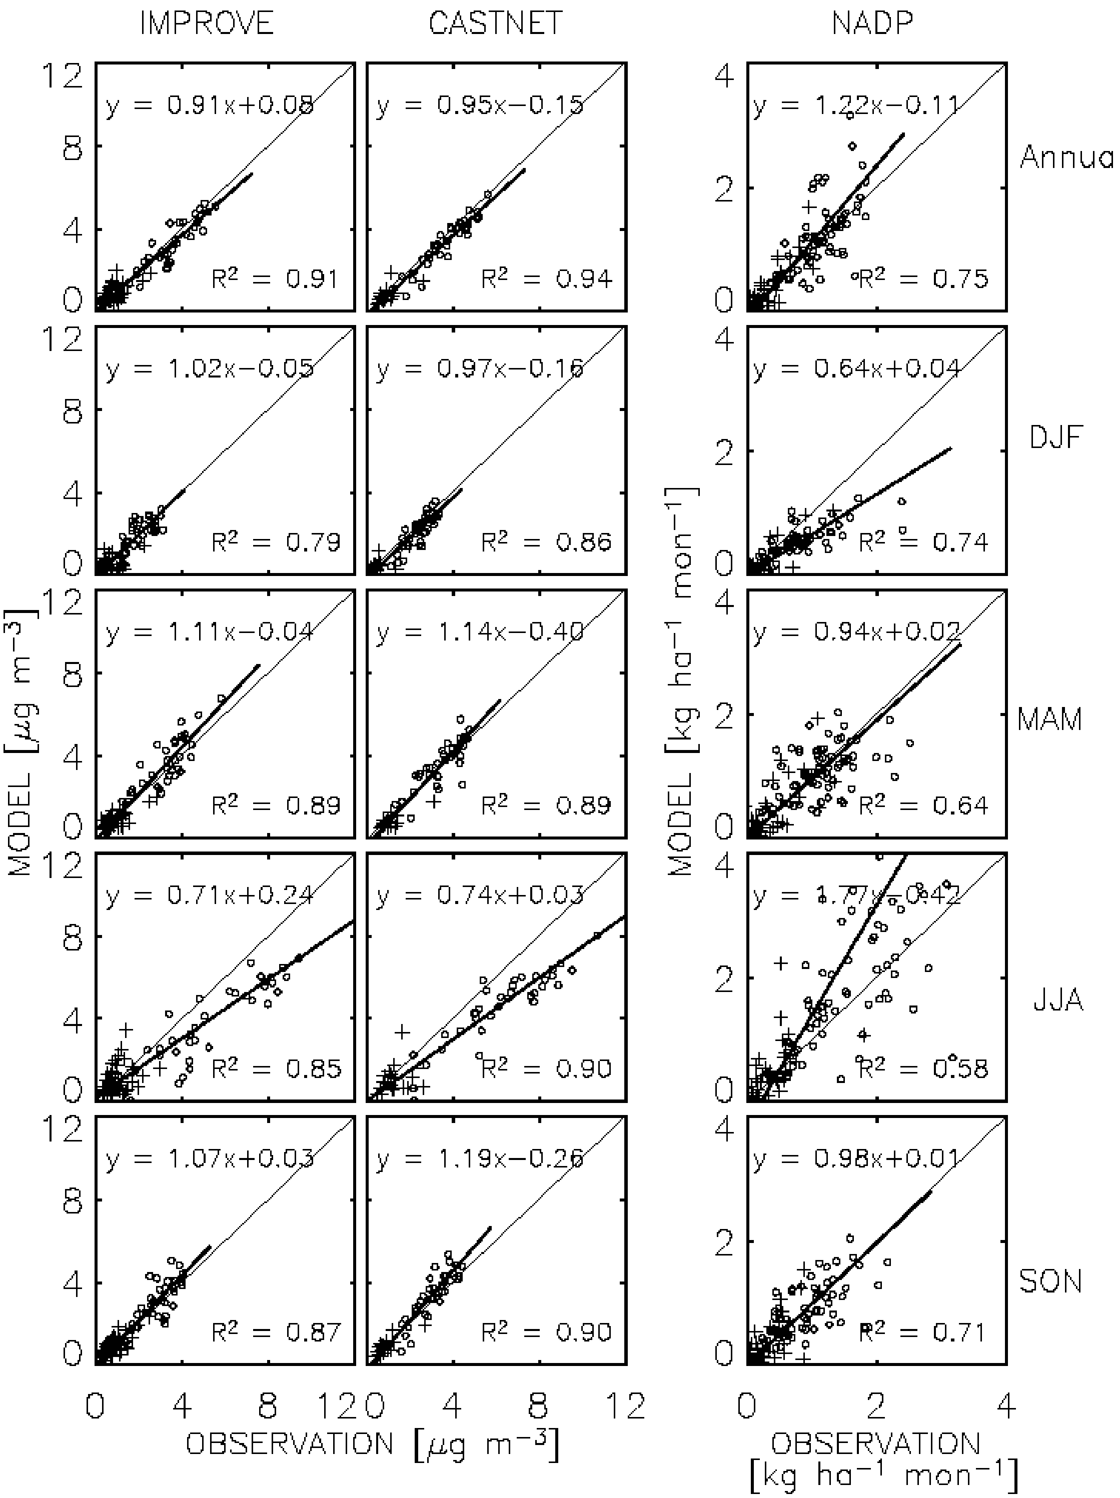

Figure 4. Scatterplot of simulated versus observed sulfate concentrations at the IMPROVE and CASTNET sites, and sulfate deposition fluxes at NADP sites (Figure 2). Values are annual means (top panels) and seasonal means for 2001. Sites in the western and eastern United States (separated at 95°W) are shown as pluses and open circles, respectively. Thick solid lines are reduced major axis regressions for the ensemble of the

data; regression equations and R^2 are shown inset. Thin solid lines show the y=x relationship.

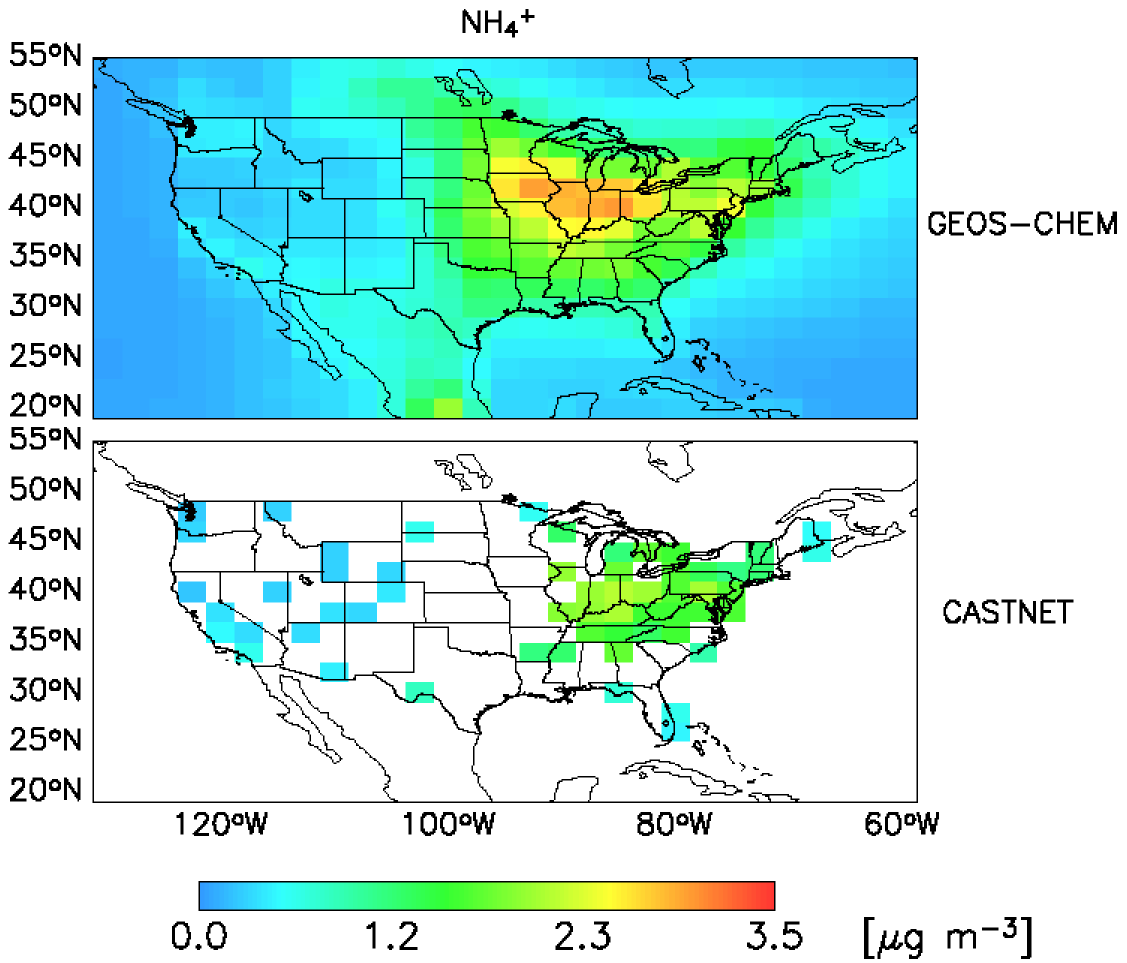

Figure 5. Annual mean concentrations of ammonium in surface air over the United States in 2001. The top panel shows results from the GEOS-CHEM model. The bottom panel shows the observations from the CASTNET networks averaged over the model $2^{o} \times 2.5^{o}$ grid (ammonium is not measured at the IMPROVE sites).

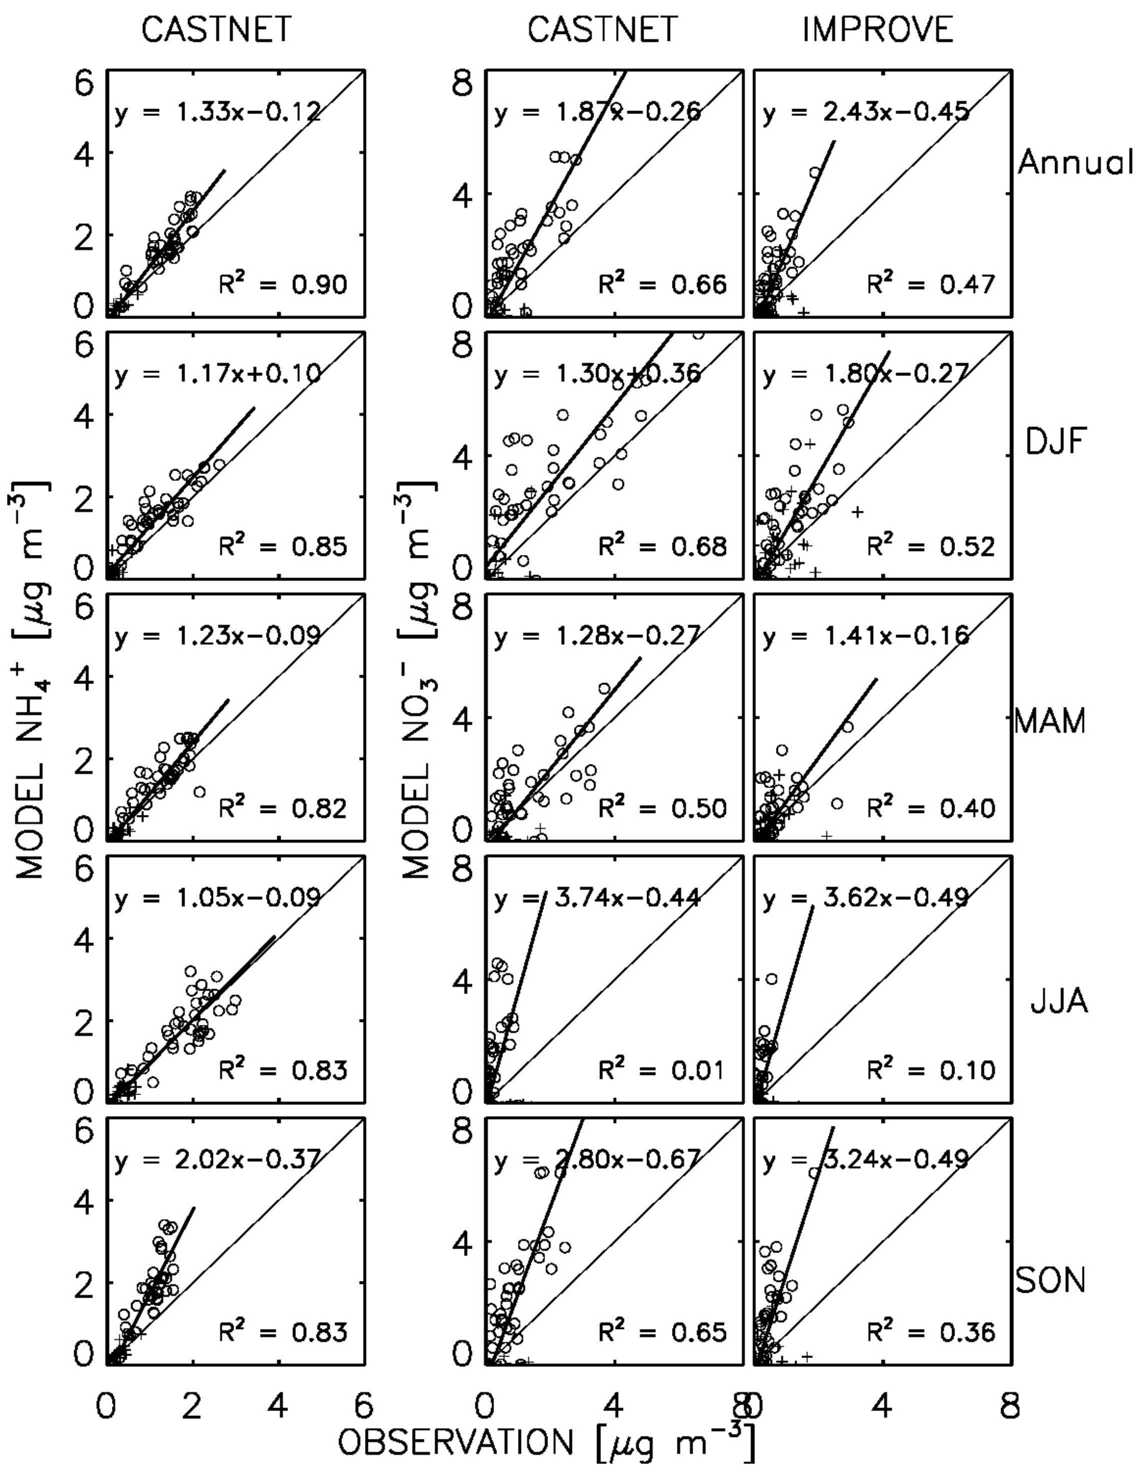

Figure 6. Scatterplot of simulated versus observed ammonium concentrations at the CASTNET sites (left column), and nitrate concentrations at the CASTNET and IMPROVE sites (right two columns). Values are annual means (top panels) and seasonal means for 2001. Sites in the western and eastern United States (separated at 95°W) are shown as pluses and open circles, respectively. Thick solid lines are reduced major axis

regressions for the ensemble of the data; regression equations and R^2 are shown inset. Thin solid lines show the y=x relationship.

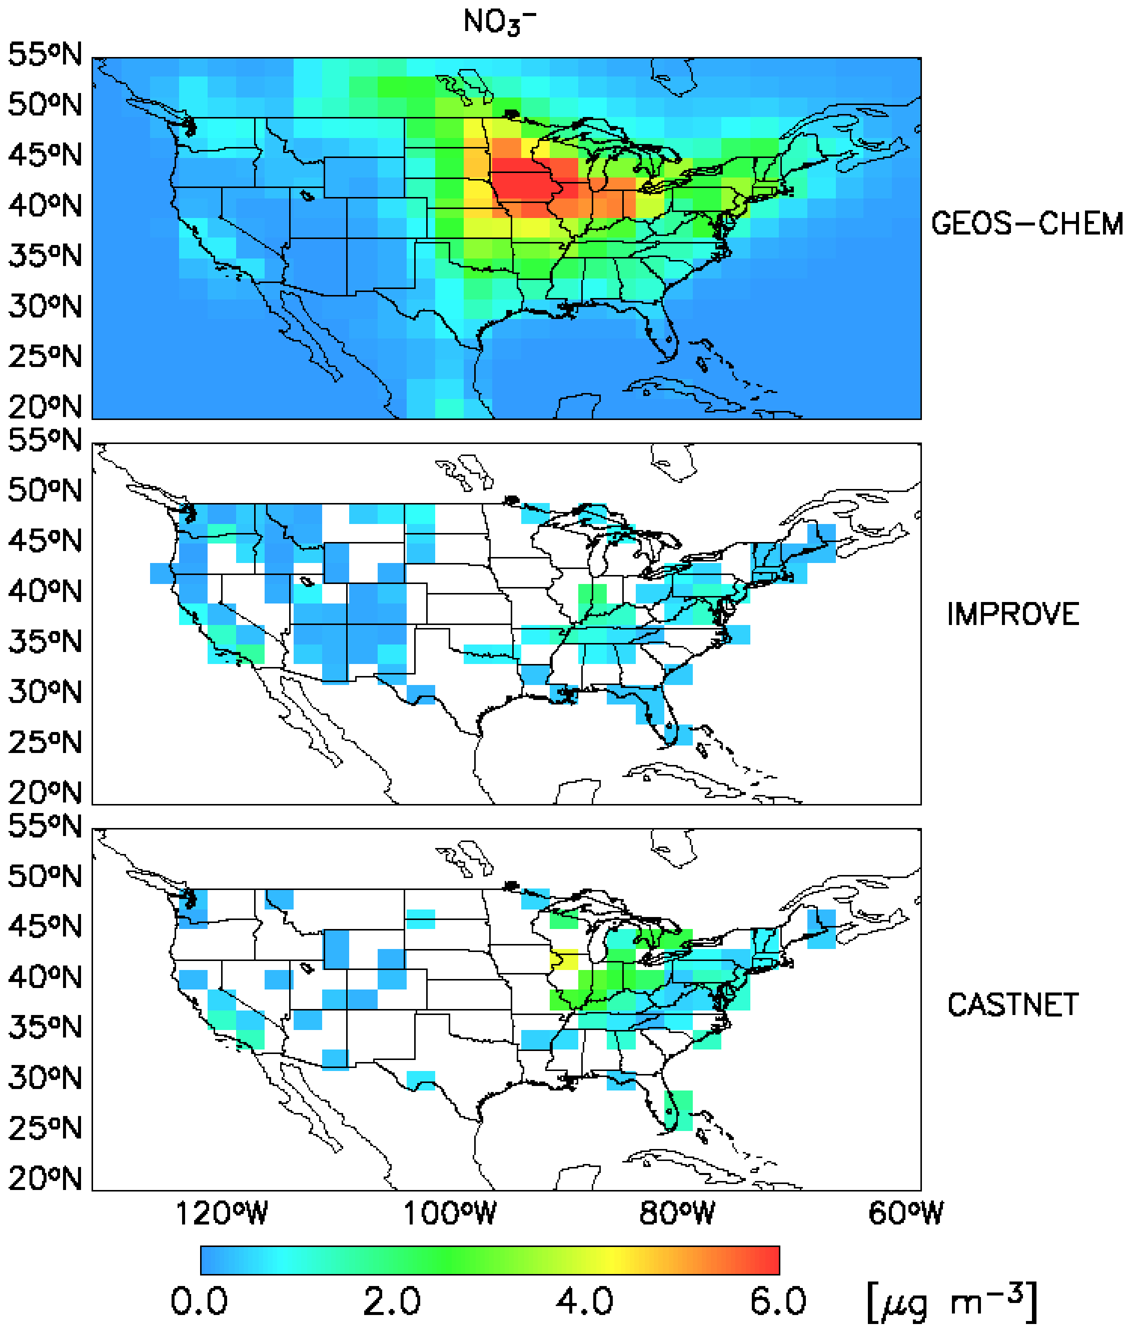

Figure 7. Same as in Figure 3 but for nitrate.

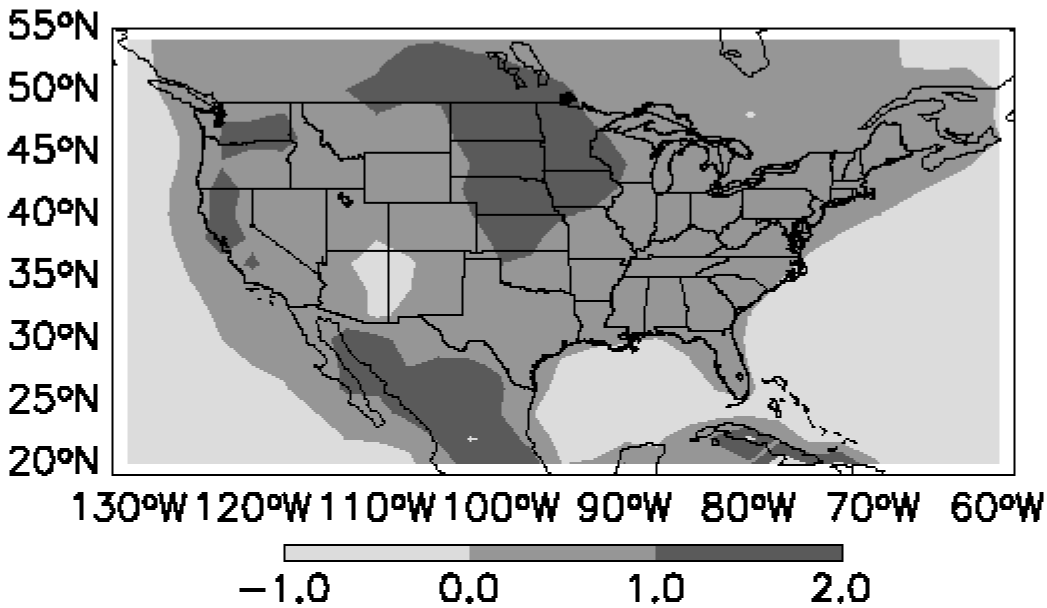

Figure 8. Simulated gas ratio (GR; equation (1)) defined as the available ammonia concentration beyond that required for sulfate neutralization, divided by the total inorganic nitrate concentration (gas + aerosol) [*Ansari and Pandis*, 1998]. Values are computed from annual mean concentrations in surface air. Formation of ammonium nitrate aerosol is limited by the availability of nitric acid if GR > 1, by the availability of ammonia if 0 < GR < 1, and is totally suppressed if GR < 0.

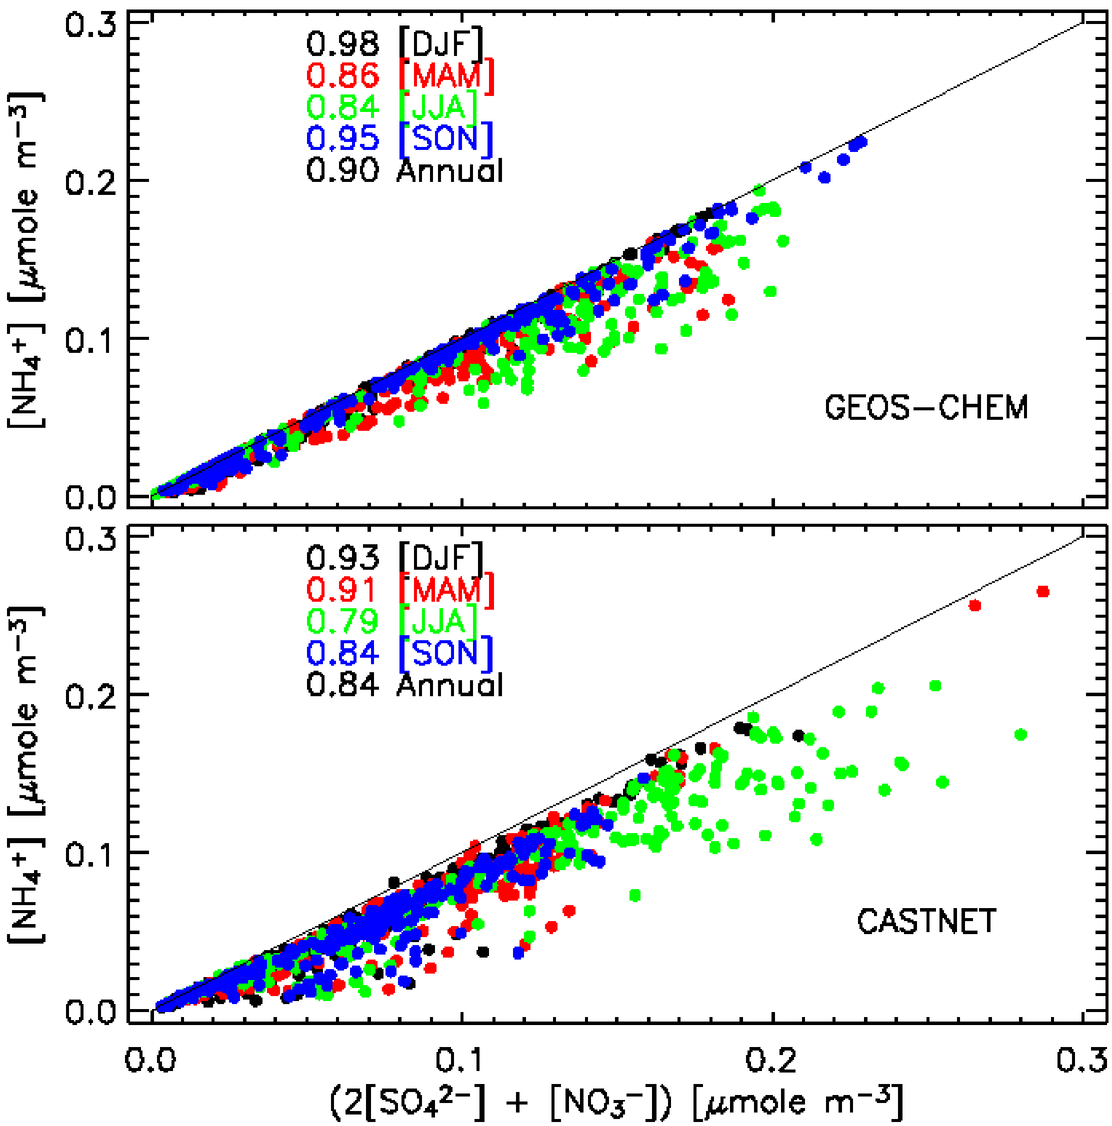

Figure 9. Scatterplot of seasonal mean [NH_4^+] vs. (2[SO_4^{2-}]+[NO_3^-]) at CASTNET sites in 2001, in the GEOS-CHEM model (top) and in observations (bottom). The reduced-major–axis regression slopes (given on the Figure) indicate the degree of acid neutralization.

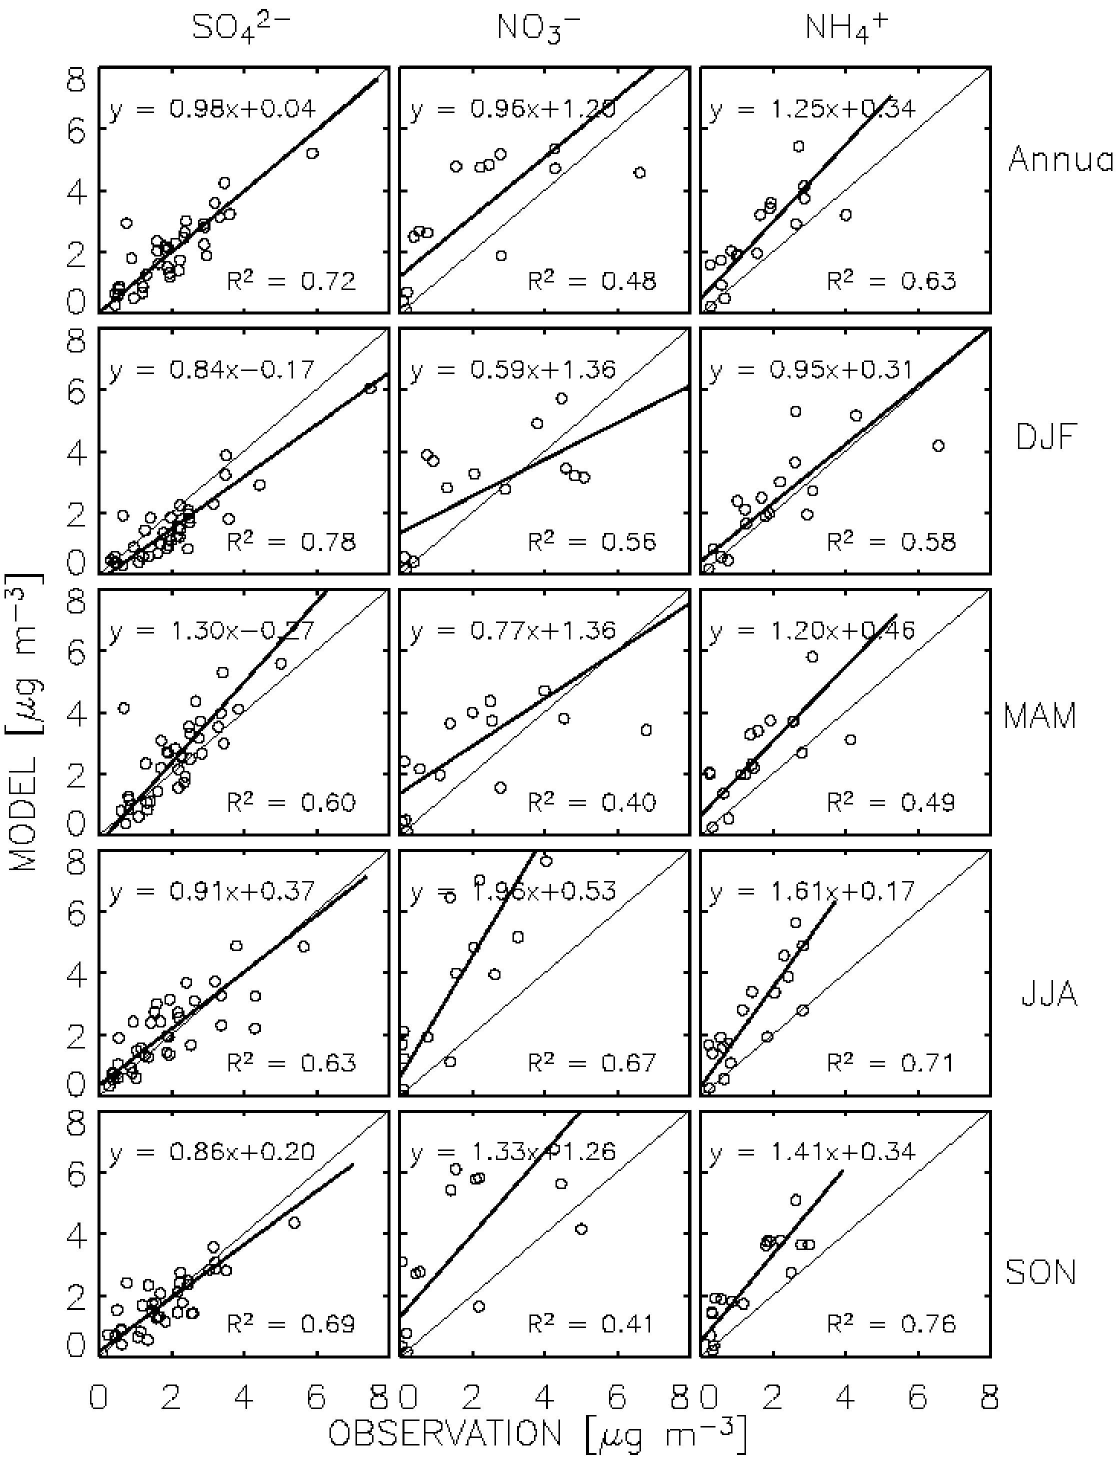

Figure 10. Scatterplot of simulated versus observed sulfate (left), nitrate (middle) and ammonium (right) concentrations at 93 European EMEP sites. Values are annual means (top panels) and seasonal means for 1998. Thick solid lines are reduced major axis regressions for the ensemble of the data; regression equations and R^2 are shown inset. Thin solid lines show the y=x relationship.

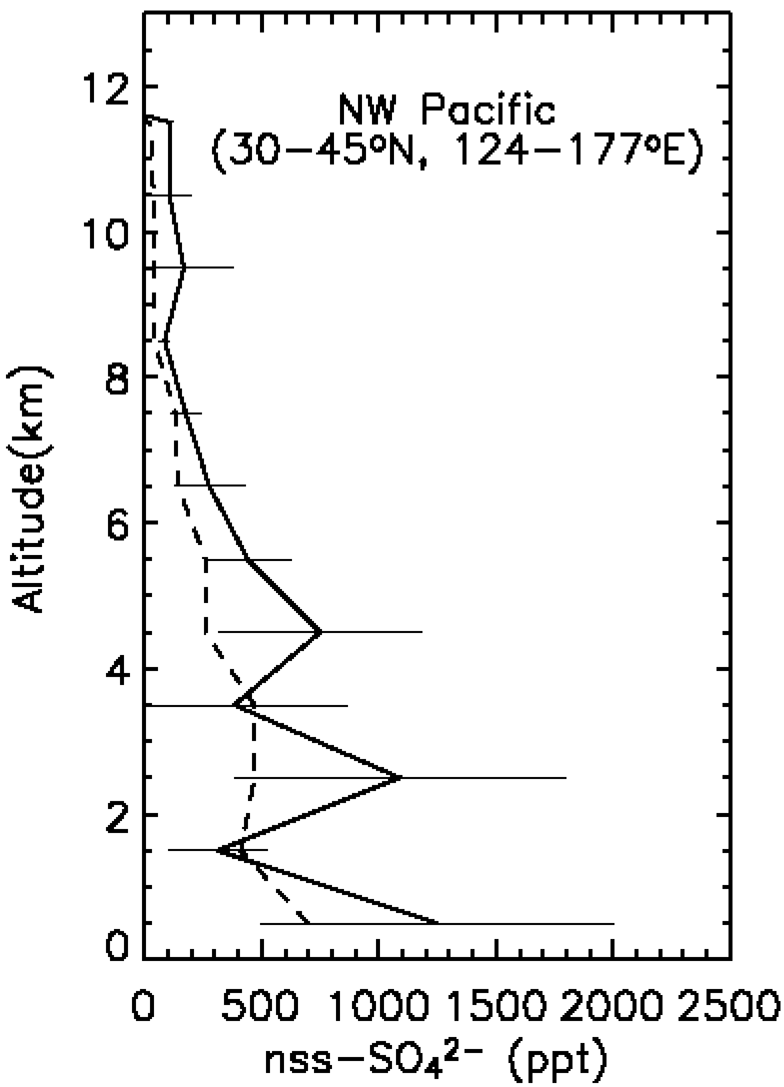

Figure 11. Simulated vs. observed mean vertical profiles of non-sea-salt sulfate (nss-SO_4^{2-}) concentrations over the NW Pacific from the TRACE-P aircraft mission in February-April 2001. The observations are binned vertically in 1-km intervals. The solid line shows mean observed values from *Jordan et al.* [2003] for the ensemble of DC-8 flights north of 30°N (30-45°N, 124-177°E), with standard deviations represented by horizontal bars. The dashed line shows the corresponding monthly mean model values along the flight tracks.

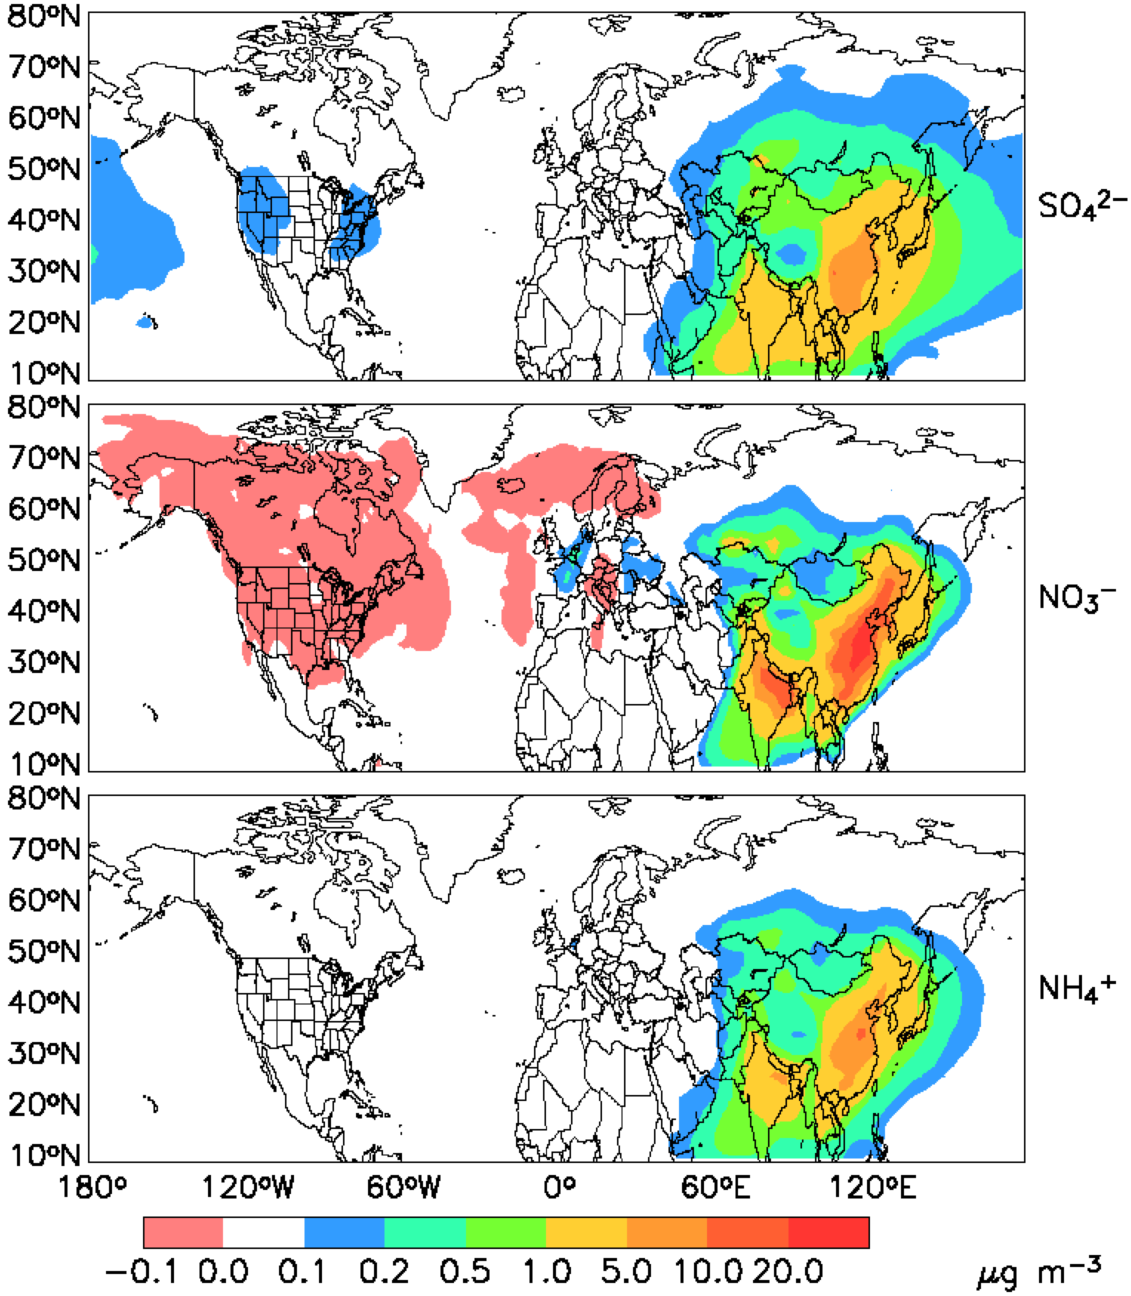

Figure 12a. Enhancements of sulfate-nitrate-ammonium aerosol concentrations in surface air due to anthropogenic emissions from Asia. Values are annual means for 2001 and were obtained by difference between the standard model simulation and a sensitivity simulation with Asian anthropogenic sources shut off.

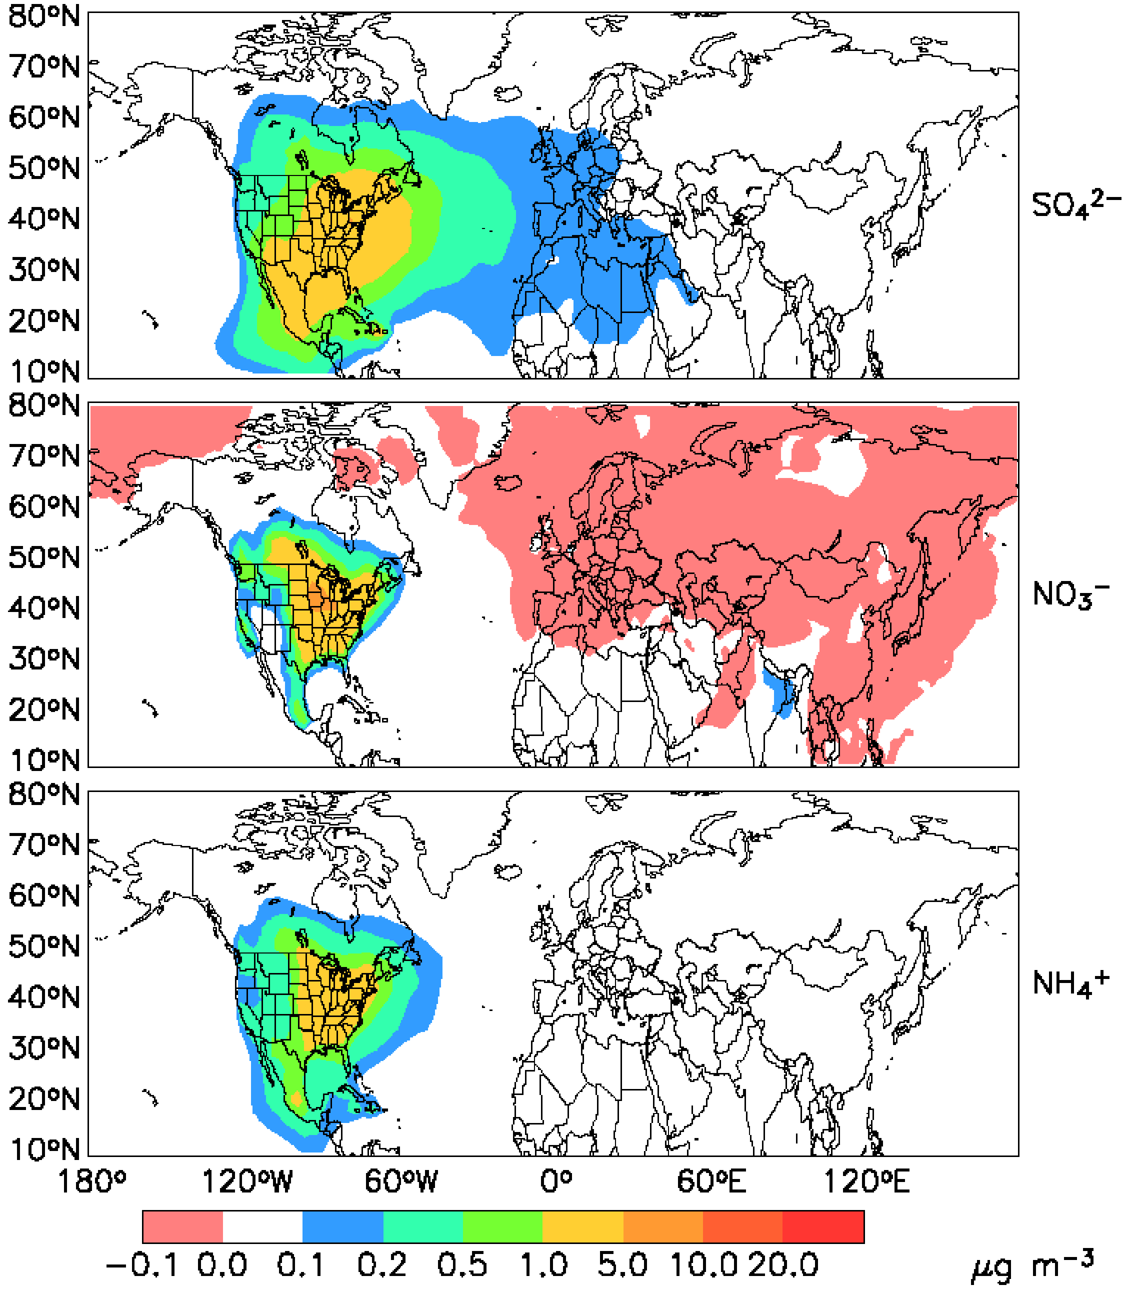

Figure 12b. Same as in Figure 12a but for anthropogenic emissions from North America.

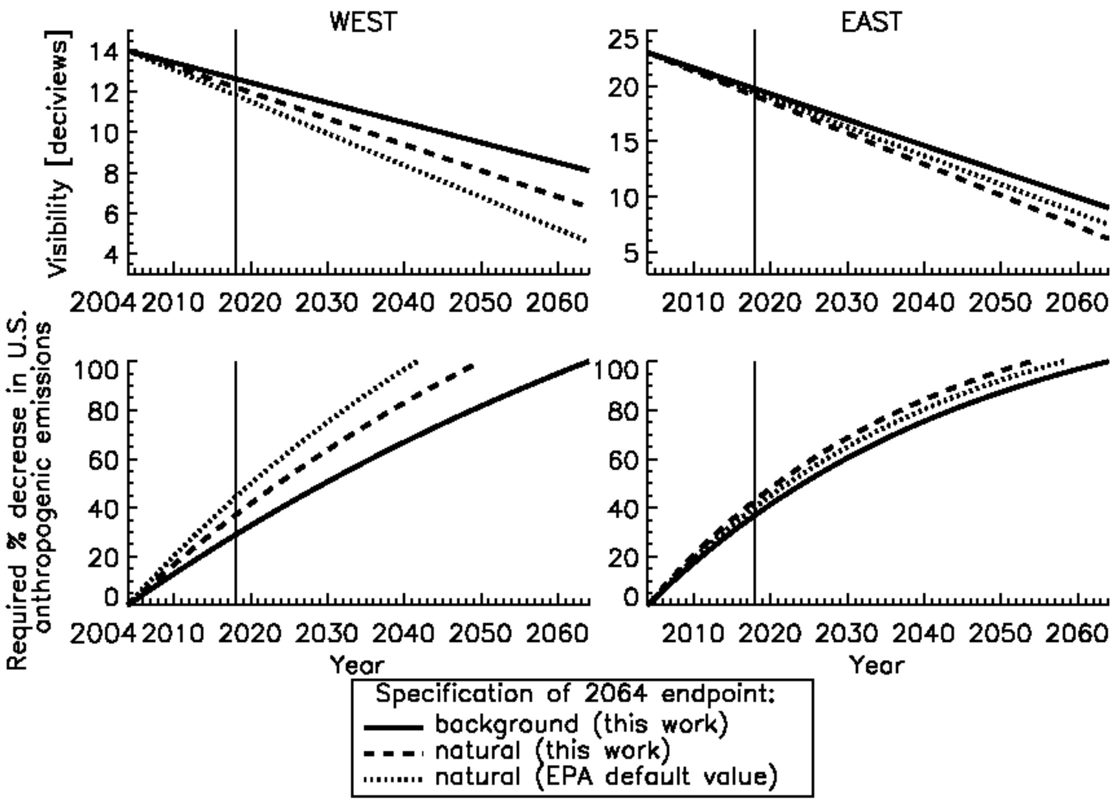

Figure 13. Illustrative example of required visibility improvements (top) and domestic emission reductions (bottom) over the 2004-2064 period for the western and the eastern United States (separated at 95°W) under the EPA Regional Haze Rule [*U.S. EPA*, 2003a]. The visibility endpoints are as given in Table 3. The required percentage decrease in U.S. anthropogenic emissions corresponding to a given visibility improvement is computed by assuming a linear correspondence between aerosol extinction and emissions. Results are shown for different choices for the 2064 endpoint: (1) EPA natural default visibility (dotted lines), (2) our estimate of natural visibility (dashed lines), and (3) our estimate of background visibility (solid lines). Background includes contributions from both natural and transbounary pollution sources. Year 2018 (thin vertical line) is the target date for phase 1 implementation of the Regional Haze Rule.

Public Notice Report
For
The North Carolina Fine Particulate Matter Attainment Demonstration for the Hickory and Greensboro/Winston-Salem/High Point Fine Particulate Matter Nonattainment Areas (Catawba, Davidson, and Guilford Counties)

On April 1, 2009, a draft version of The North Carolina Fine Particulate Matter Attainment Demonstration for the Hickory and Greensboro/Winston-Salem/High Point Fine Particulate Matter Nonattainment Areas for the 1997 $PM_{2.5}$ National Ambient Air Quality Standard (NAAQS) was submitted to the U. S. Environmental Protection Agency (USEPA). A request for public hearing, in accordance with 40 CFR 51.102, and the public comment period were noticed on the North Carolina Division of Air Quality (NCDAQ) web site on April 1, 2009 and in the local newspapers on April 2, 2009. The public comment period was open from April 1, 2009, through May 11, 2009, with a tentative hearing scheduled for May 7, 2009. No requests for public hearing were received and the hearing was cancelled. A hearing cancellation notice was posted on the NCDAQ web site on May 4, 2009. The public comment period elicited comments from only the USEPA. These comments and our response are included later in this Appendix.

Background

The USEPA promulgated a new $PM_{2.5}$ NAAQS (40 CFR 50.7) in 1997, setting the standard at a 15.0 micrograms per cubic meter (µg/m3) annual average and at a 65 µg/m3 daily or 24-hour average. A violation of the annual $PM_{2.5}$ NAAQS occurs when the annual average $PM_{2.5}$ concentration averaged over a three consecutive year period is equal to or greater than 15.1 µg/m3. A violation of the daily $PM_{2.5}$ NAAQS occurs when the annual 98th percentile of daily $PM_{2.5}$ concentration averaged over a three consecutive year period is equal to or greater than 66 µg/m3. The annual or daily $PM_{2.5}$ design value for a nonattainment area is the highest monitor's design value in that area.

The USEPA designated areas as nonattainment for the annual and daily $PM_{2.5}$ NAAQSs based upon air quality monitoring data measured during 2001, 2002 and 2003. The effective date of nonattainment designations was April 5, 2005. In North Carolina, there were two areas designated as nonattainment for violating the annual $PM_{2.5}$ standard. These two areas include the Hickory $PM_{2.5}$ nonattainment area (Catawba County) and Greensboro/Winston-Salem/High Point $PM_{2.5}$ nonattainment area (Davidson and Guilford Counties). All areas of North Carolina met the daily $PM_{2.5}$ standard.

Several control measures already in place or being implemented over the next few years will reduce stationary point, highway mobile, and nonroad mobile sources emissions. The expected Federal and State control measures were modeled for the attainment year of 2009.

The Federal control measures that were modeled included the Tier 2 vehicle standards; the heavy-duty gasoline and diesel highway vehicle standards; low sulfur gasoline and diesel fuels, large nonroad diesel engines standards; the nonroad spark-ignition engines and recreational engines standard; and the Clean Air Interstate Rule.

The State control measures that were modeled included the Clean Air Bill, in which the vehicle emissions inspection and maintenance program was expanded from 9 counties to 48; the NO_x SIP Call Rule, the North Carolina Clean Air Interstate Rule and the Clean Smokestacks Act, which will significantly reduce SO_2 emissions from the large electrical generation units with implementation beginning prior to the 2009 attainment year and well in advance of the Federal Clean Air Interstate Rule. The Clean Smokestacks Act further requires the coal-fired power plants to meet an annual SO_2 emissions cap without an option of emissions trading from outside of North Carolina.

Summary of Public Notice and Comment Period

Please reference page 3 of this Appendix for the full listing of the USEPA's public comments received.

Please reference page 7 of this Appendix for the NCDAQ response letter addressing the USEPA's public comments.

Conclusions

The NCDAQ firmly believes that it has prepared an adequate attainment demonstration package to address and resolve the nonattainment issues in the Hickory and Greensboro/Winston-Salem/ High Point $PM_{2.5}$ nonattainment area and demonstrates that both of these areas will meet the National Ambient Air Quality Standards for fine particulate matter by the April 5, 2010 attainment date. In a testament to the implemented control measures modeled in this attainment demonstration, $PM_{2.5}$ concentrations have already decreased significantly and all the monitoring sites in both nonattainment areas have attained the annual $PM_{2.5}$ NAAQS with the 2006-2008 monitoring data. Furthermore, the NCDAQ has adequately addressed the USEPA public comments received and made all appropriate modifications to the attainment demonstration. As a result, the NCDAQ will be moving forward with the final submittal to the USEPA of The North Carolina Fine Particulate Matter Attainment Demonstration for the Hickory and Greensboro/Winston-Salem/High Point Fine Particulate Matter Nonattainment Areas.

Dear Mr. Overcash:

Thank you for your letter dated April 1, 2009, transmitting a prehearing package regarding the attainment demonstrations for the Hickory and Greensboro-Winston-Salem-High Point (Triad) nonattainment areas for the1997 $PM_{2.5}$ national ambient air quality standard. We have completed our review of your submittals and have included comments in the enclosure.

If you have questions regarding our comments, please contact Lynorae Benjamin at (404) 562-9040 or have your staff contact Nacosta Ward at (404) 562-9140 of the EPA Region 4 office.

Sincerely,

Lynorae Benjamin for

Enclosure

Region 4 EPA Comments for Hickory and Greensboro PM2.5 Attainment Demonstrations
May 19, 2009

Note: Unless otherwise indicated, the sections, tables, and page numbers referenced in these comments are from the narrative portion of the State Implementation Plan (SIP) submittal.

Key Comments

1. On December 23, 2008, the United States Court of Appeals for the District of Columbia Circuit remanded the Clean Air Interstate Rule (CAIR) to EPA without vacatur, directing the Agency to remedy the rule's flaws in accordance with the Court's July 11, 2008, opinion in the case of *North Carolina v. EPA*, 531 F.3d 896, 901 (D.C. Cir. 2008). If the submission relies upon anticipated CAIR reductions, it may need to be revised consistent with EPA's new final action when the Agency responds to the Court's remand.

2. It is unclear how the controls and emissions reductions, from the power plants as part of the Clean Smokestacks Act (CSA) that appear to be needed for attainment are federally enforceable. To the extent that these emission reductions are being relied on for attainment for Hickory and Greensboro for the 1997 $PM_{2.5}$ standard, this discussion will be needed in the SIP submittals to support the demonstrations. Potential options for providing for federal enforceability of CSA emission reductions that may be relied on for attainment in Hickory and/or Greensboro are as follows:

    a. One option is for relevant portions of the North Carolina CSA could be submitted to the EPA as a regulation. We recognize that the entire CSA should not be submitted because it includes actions related to mercury and other parts that are not specifically related to the requirements for emission limitations and permitting conditions.

    b. The other option involves the submittal of the emissions limitations for those power plants that were explicitly modeled and affect the attainment areas as source-specific SIP revisions. The 50 kilometer circle that was used to determine the sources from which contingency measure reductions was obtained could be used to identify the sources that are subject to a source-specific SIP revision.

3. The CSA appears to have a Director's discretion prohibition relating to the North Carolina Commission and revisions to the Title IV permit. The following is from the CSA:

    > "Section 2(c) The Commission shall have the power: (1) To grant and renew a permit with such any conditions attached as that the Commission believes necessary to achieve the purposes of this

2

> section Article or the requirements of the Clean Air Act and implementing regulations adopted by the United States Environmental Protection Agency."

The highlighted portion appears to be in conflict with delegations that might be for the EPA Administration only. We are highlighting this consideration in the event that portions of CSA are submitted for approval in the North Carolina SIP.

4. The contingency measures also need to be federally enforceable. Since the CSA has not been submitted to EPA for incorporation into the SIP you would either need to submit CSA, or submit the individual permits adopted under CSA for incorporation into the SIP, or show that the adopted permit limits are enforceable under CAIR. The incorporation of measures into title V permits does not satisfy the necessity that they originate from a federally enforceable requirement.

Other Comments

1. The SIP narrative states on page 40 that the Clean Air Bill, the Nitrogen Oxide (NOx) SIP Call Rule, the CSA, and the Open Burning Rule were modeled in the attainment demonstration. However, the summary of these regulations that follows in sections 5.2.1 through 5.2.5 includes CAIR. For consistency of paragraph 5.2 State Control Measures, please add "Clean Air Interstate Rule" to sentence two, which will clarify that CAIR was a modeled regulation in the attainment demonstration.

2. In the SIP narrative, air quality data up to 2006 are presented. We recommend that the air quality trend analyses for the annual averages and design values at each monitor also include data from 2007 and 2008. Section 6.3.3 mentions the use of preliminary 2007 data. This data should be officially submitted to EPA and preliminary 2008 data should be available to use in the SIP. It is important to see how air quality is responding to emissions controls in these more recent years, especially since it already is the 2009 attainment year being requested.

3. The SIP narrative does not include a discussion of the changes in emissions and reductions that are associated with air quality improvement in the 2007 to 2009 period. We recommend that a table and/or chart with accompanying discussions of the emissions trends and implementation dates of controls related to the attainment of the areas by the proposed 2009 attainment year be included in the final submittal.

4. EPA guidance requires states to adopt "contingency measures equal to approximately one year's worth of reductions necessary to achieve reasonable further progress for the area." The purpose is to provide a one year of reductions if the area does not attain. Attainment

demonstrations are based on modeling of sulfur dioxide reductions from sources outside the nonattainment area, the inventory based assessment in the guidance does not make sense for this area. We do not believe reliance on the ozone guidance meets the intent of this requirement. Please provide tangible evidence that the emission reductions attributable to CSA will contribute to attainment if these are being relied upon as a contingency measure.

We recommend modeling the facilities with 2009-2010 reductions planned or reviewing existing modeling to develop sensitivity data that demonstrates the impact controlling these units will have on the ambient levels at the monitoring sites. Since the baseline design value for the Triad area is 15.8 ug/m^3, and the baseline design value for the Hickory area is 15.5 ug/m^3, one years' progress would be about 0.1 ug/m^3 ((15.8 – 15.0)/7) for the Triad area and also about 0.1 ug/m^3 ((15.5 – 15.0)/7) for the Hickory area.

5. 110(a)(2) Submittal. For Section 7.7 please clarify that the discussion in this submission is related to the 1997 PM2.5 standard and not the 2006 standard. It is our understanding that North Carolina is in the process of developing a submission for 110(a)(2) infrastructure elements for the 2006 standard and that this submission will be submitted later this year.

6. Page 1970 of the Adobe Acrobat file containing Appendices A-Q appears to be the location of a new document which we believe may be the North Carolina "Clean Smokestacks Act." If this is correct, we recommend adding a title page identifying the document and adding it to the bookmark index.

Subject: Region 4 EPA Comments for Hickory and Greensboro/Winston-Salem/High Point $PM_{2.5}$ Attainment Demonstration

Dear Mr. Schutt:

Thank you for your letter dated May 19, 2009, transmitting the Environmental Protection Agency (EPA) Region 4's comments on the pre-hearing draft of the attainment demonstration for the Greensboro/Winston-Salem/High Point (referred to as the Triad) and Hickory fine particulate matter ($PM_{2.5}$) nonattainment areas. This letter is to provide the North Carolina Division of Air Quality (NCDAQ) response to those comments.

Key Comments:

1. EPA Comment: On December 23, 2008, the United States Court of Appeals for the District of Columbia Circuit remanded the Clean Air Interstate Rule (CAIR) to EPA without vacatur, directing the Agency to remedy the rule's flaws in accordance with the Court's July 11, 2008, opinion in the case of North Carolina v. EPA, 531 F.3d 896, 901 (D.C. Cir. 2008). If the submission relies upon anticipated CAIR reductions, it may need to be revised consistent with EPA's new final action when the Agency responds to the Court's remand.

NCDAQ Response: The $PM_{2.5}$ attainment demonstration relied on emission reductions achieved through the North Carolina Clean Smokestacks Act (CSA) that reduced both nitrogen oxides and sulfur dioxide (SO_2) emissions from the coal-fire utilities in North Carolina. The CAIR Phase I caps for SO_2 do not start until 2010, and since both regions have already attained the standard with the 2006-2008 ambient data, the NCDAQ does not believe our attainment demonstration is reliant upon CAIR.

2. EPA Comment: It is unclear how the controls and emissions reductions, from the power plants as part of the CSA, that appear to be needed for attainment are federally enforceable. To the extent that these emission reductions are being relied on for attainment for Hickory and Greensboro for the 1997 $PM_{2.5}$ standard, this discussion will be needed in the SIP submittals to support the demonstrations.

1641 Mail Service Center, Raleigh, North Carolina 27699-1641
2728 Capital Blvd., Raleigh, NC 27604
Phone: 919-733-3340 \ FAX: 919-715-7175 \ Internet: www.daq.state.nc.us/

NCDAQ Response: As part the final attainment demonstration State Implementation Plan (SIP) submittal, the NCDAQ will request that the portion of the CSA that establishes the system-wide emission caps be incorporated into the North Carolina federally approved SIP.

3. EPA Comment: The CSA appears to have a Director's discretion prohibition relating to the North Carolina Commission and revisions to the Title IV permit. The following is from the CSA:

> *"Section 2(c) The Commission shall have the power: (1) To grant and renew a permit with such any conditions attached as that the Commission believes necessary to achieve the purposes of this section Article or the requirements of the Clean Air Act and implementing regulations adopted by the United States Environmental Protection Agency."*

The highlighted portion appears to be in conflict with delegations that might be for the EPA Administration only. We are highlighting this consideration in the event that portions of CSA are submitted for approval in the North Carolina SIP.

NCDAQ Response: The NCDAQ believes that EPA has misinterpreted the CSA language. It is through the North Carolina Environmental Management Commission (referred to in the CSA as the Commission) that the NCDAQ has the authority to issue Title V permits and to adopt and implement rules. This section of the CSA was added so that the NCDAQ could go beyond the CSA emission reductions if they were required to meet a national ambient air quality standard or meet requirements in regulations promulgated by the EPA. The NCDAQ does not intend to request this section of the CSA be incorporated into the North Carolina federally approved SIP.

4. EPA Comment: The contingency measures also need to be federally enforceable. Since the CSA has not been submitted to EPA for incorporation into the SIP you would either need to submit CSA, or submit the individual permits adopted under CSA for incorporation into the SIP, or show that the adopted permit limits are enforceable under CAIR. The incorporation of measures into title V permits does not satisfy the necessity that they originate from a federally enforceable requirement.

NCDAQ Response: As part of the final attainment demonstration SIP submittal, the NCDAQ will request that the portion of the CSA that establishes the system-wide emission caps be incorporated into the North Carolina federally approved SIP.

Other Comments:

1. EPA Comment: The SIP narrative states on page 40 that the Clean Air Bill, the NOx SIP Call Rule, the CSA, and the Open Burning Rule were modeled in the attainment demonstration. However, the summary of these regulations that follows in sections 5.2.1 through 5.2.5 includes CAIR. For consistency of paragraph 5.2 State Control Measures, please add "Clean Air Interstate Rule".

NCDAQ Response: The appropriate language has been added in the SIP Narrative.

2. EPA Comment: In the SIP narrative, air quality data up to 2006 are presented. We recommend that the air quality trend analyses for the annual averages and design values at each monitor also include data from 2007 and 2008. Section 6.3.3 mentions the use of preliminary 2007 data. This data should be officially submitted to EPA and preliminary 2008 data should be available to use in the SIP. It is important to see how air quality is responding to emissions controls in these more recent years, especially since it already is the 2009 attainment year being requested.

NCDAQ Response: The appropriate tables have been updated in the SIP Narrative and the corresponding appendix.

3. EPA Comment: The SIP narrative does not include a discussion of the changes in emissions and reductions that are associated with air quality improvement in the 2007 to 2009 period. We recommend that a table and/or chart with accompanying discussions of the emissions trends and implementation dates of controls related to the attainment of the areas by the proposed 2009 attainment year be included in the final submittal.

NCDAQ Response: The appropriate language has been added in the SIP Narrative.

4. EPA Comment: EPA guidance requires states to adopt "contingency measures equal to approximately one year's worth of reductions necessary to achieve reasonable further progress for the area." The purpose is to provide a one year of reductions if the area does not attain. Attainment demonstrations are based on modeling of sulfur dioxide reductions from sources outside the nonattainment area, the inventory based assessment in the guidance does not make this requirement. We do not believe reliance on the ozone guidance meets the intent of this requirement. Please provide tangible evidence that the emission reductions attributable to CSA will contribute to attainment if these are being relied upon as a contingency measure.

We recommend modeling the facilities with 2009-2010 reductions planned or reviewing existing modeling to develop sensitivity data that demonstrates the impact controlling these units will have on the ambient levels at the monitoring sites. Since the baseline design value for the Triad area is 15.8 ug/m3, and the baseline design value for the Hickory area is 15.5 ug/m3, one years' progress would be about 0.1 ug/m3 ((15.8 – 15.0)/7) for the Triad area and also about 0.1 ug/m3 ((15.5 – 15.0)/7) for the Hickory area.

NCDAQ Response: The purpose of contingency measures is to provide further reductions in the event that an area does not attain the standard by the prescribed attainment date. Since both nonattainment areas in North Carolina have already attained the 1997 annual $PM_{2.5}$ *standard with the 2006-2008 ambient data, one year earlier than required, the necessity of contingency measures is unlikely. However, for the purposes of this submittal, the NCDAQ has added to the documentation back trajectories and current ambient air quality data to demonstrate that reductions in* SO_2 *emissions from the power plants in North Carolina have an impact on the monitors in the nonattainment areas.*

5. EPA Comment: 110(a)(2) Submittal. For Section 7.7 please clarify that the discussion in this submission is related to the 1997 PM2.5 standard and not the 2006 standard. It is our understanding that North Carolina is in the process of developing a submission for 110(a)(2) infrastructure elements for the 2006 standard and that this submission will be submitted later this year.

NCDAQ Response: The appropriate language has been added in the SIP Narrative.

6. EPA Comment: Page 1970 of the Adobe Acrobat file containing Appendices A-Q appears to be the location of a new document which we believe may be the North Carolina "Clean Smokestacks Act." If this is correct, we recommend adding a title page identifying the document and adding it to the bookmark index.

NCDAQ Response: The Clean Smokestacks Act is part of Appendix M and is properly identified in the Table of Contents for Appendix M. The NCDAQ does not believe that this section of Appendix M requires its own title page.

Thank you for your review of our pre-hearing draft. We look forward to working with EPA Region 4 during your review of our official SIP submittal for this area. If you have questions, please contact Laura Boothe of my staff at (919) 733-1488.

Sincerely,

B. Keith Overcash, P.E.

PUBLIC NOTICE

PURPOSE:	The North Carolina Department of Environment and Natural Resources, Division of Air Quality (NCDAQ) hereby gives notice regarding its Pre-Hearing Draft of The North Carolina Fine Particulate Matter Attainment Demonstration for the Hickory and Triad Fine Particulate Matter Nonattainment Areas. Persons wishing to submit written requests for a public hearing or comments regarding the "PM2.5 Attainment Demonstration Package" are invited to do so.
REQUESTS FOR A PUBLIC HEARING:	Requests for a public hearing must be in writing and include a statement supporting the need for such a hearing, an indication of your interest in the subject, and a brief summary of the information intended to be offered at such hearing. Written requests for a public hearing should be received by no later than Friday, May 1, 2009. If a public hearing is requested, the hearing will be held at 2:00pm on Thursday, May 7, 2009, at the Winston-Salem Region Office of the NCDAQ, located at 585 Waughtown Street, Winston-Salem, NC 27107. If a public hearing is not requested, a cancellation notice will be posted on Monday, May 4, 2009 on the NCDAQ web site by selecting May 7, 2009, on the Events Calendar, http://www.ncair.org/calendar/ or by calling 919-733-1115.
COMMENT PROCEDURES:	Any person wishing to comment may submit a written statement for inclusion in the record of proceedings regarding the PM2.5 Attainment Demonstration Package. Written comments should be received by no later than Monday, May 11, 2009.

INFORMATION: Written requests for a public hearing or comments can be electronically submitted or sent to the following:

Publisher of the
Winston-Salem Journal
Forsyth County

Before the undersigned, a Notary Public of Forsyth County, North Carolina, duly commissioned, qualified, and authorized by law to administer oaths, personally appeared D.H. Stanfield, who by being duly sworn deposes and says: that he is Controller of the Winston-Salem Journal, engaged in the publishing of a newspaper known as Winston-Salem Journal, published, issued and entered as second class mail in the City of Winston-Salem, in said County and State: that he is authorized to make this affidavit and sworn statement: that the notice or other legal advertisement, a true copy of which is attached hereto, was published in the Winston-Salem Journal on the following dates:

04/02/2009

and that the said newspaper in which such notice, paper document, or legal advertisement was published was, at the time of each and every such publication, a newspaper meeting all the requirements and qualifications of Section 1-597 of the General Statutes of North Carolina and was a qualified newspaper within the meaning of Section 1-597 of the General Statutes of North Carolina.

This 2th day of April, 2009

D.H. Stanfield
(signature of person making affidavit)
